MySQL 3.23, 4.0, 4.1 Reference Manual

MySQL 3.23, 4.0, 4.1 Reference Manual

Abstract

This is the MySQL™ Reference Manual. It documents MySQL 3.23 through MySQL 4.1.25.

MySQL 3.23, 4.0, and 4.1 features. This manual describes features that are not included in every edition of MySQL 3.23, MySQL 4.0, and MySQL 4.1; such features may not be included in the edition of MySQL 3.23, MySQL 4.0, or MySQL 4.1; licensed to you. If you have any questions about the features included in your edition of MySQL 3.23, MySQL 4.0, or MySQL 4.1, refer to your MySQL 3.23, MySQL 4.0, or MySQL 4.1 agreement or contact your Oracle sales representative.

For release notes detailing the changes in each release of MySQL 3.23, 4.0, and 4.1, see Appendix C, *MySQL Release Notes*.

Document generated on: 2014-02-17 (revision: 37744)

End of Product Lifecycle. Active development and support for MySQL Database Server versions 3.23, 4.0, and 4.1 has ended. For details, see http://www.mysql.com/about/legal/lifecycle/#calendar. Please consider upgrading to a recent version. Further updates to the content of this manual will be minimal. All formats of this manual will continue to be available until 31 Dec 2010.

Table of Contents

Preface and Legal Notice

This is the Reference Manual for the MySQL Database System, version 4.1, through release 4.1.25. It is also applicable for versions of the MySQL software previous to 4.1 (such as 3.23 or 4.0) because functional changes are indicated with reference to version numbers. For later MySQL releases, see the appropriately numbered edition of this manual. For example, if you are using a version 5.0 release of the MySQL software, please refer to the *MySQL 5.0 Reference Manual*.

If you are using MySQL 5.0, please refer to the *MySQL 5.0 Reference Manual*. If you are using MySQL 5.1, please refer to the *MySQL 5.1 Reference Manual*.

Legal Notices

Oracle Software License and Service Agreement, which has been executed and with which you agree to comply. This document and information contained herein may not be disclosed, copied, reproduced, or distributed to anyone outside Oracle without prior written consent of Oracle or as specifically provided below. This document is not part of your license agreement nor can it be incorporated into any contractual agreement with Oracle or its subsidiaries or affiliates.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

For more information on the terms of this license, or for details on how the MySQL documentation is built and produced, please visit MySQL Contact & Questions.

For additional licensing information, including licenses for third-party libraries used by MySQL products, see Preface and Legal Notice.

For help with using MySQL, please visit either the MySQL Forums or MySQL Mailing Lists where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML and PDF formats, see the MySQL Documentation Library.

Chapter 1 General Information

Table of Contents

End of Product Lifecycle. Active development and support for MySQL Database Server versions 3.23, 4.0, and 4.1 has ended. For details, see http://www.mysql.com/about/legal/lifecycle/#calendar. Please consider upgrading to a recent version. Further updates to the content of this manual will be minimal. All formats of this manual will continue to be available until 31 Dec 2010.

The following list describes some sections of particular interest in this manual:

- For a discussion about the capabilities of the MySQL Database Server, see Section 1.3.2, “The Main Features of MySQL”.
- For installation instructions, see Chapter 2, *Installing and Upgrading MySQL*. For information about upgrading MySQL, see Section 2.11.1, “Upgrading MySQL”, and the change notes at Appendix C, *MySQL Release Notes*.
- For a tutorial introduction to the MySQL Database Server, see Chapter 3, *Tutorial*.
- For information about configuring and administering MySQL Server, see Chapter 5, *MySQL Server Administration*.
- For information about setting up replication servers, see Chapter 14, *Replication*.
- For a list of currently known bugs and misfeatures, see Section B.5.8, “Known Issues in MySQL”.
- For a list of all the contributors to this project, see Section 1.10, “Credits”.
- For a history of new features and bugfixes, see Appendix C, *MySQL Release Notes*.
- For benchmarking information, see the `sql-bench` benchmarking directory in your MySQL distribution.

Important

To report problems or bugs, please use the instructions at Section 1.8, “How to Report Bugs or Problems”. If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to `<secalert_us@oracle.com>`. Exception: Support customers should report all problems, including security bugs, to Oracle Support.

1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 4.1, through release 4.1.25. It is also applicable for versions of the MySQL software previous to 4.1 (such as 3.23 or 4.0) because functional changes are indicated with reference to version numbers. For later MySQL releases, see the appropriately numbered edition of this manual. For example, if you are using a version 5.0 release of the MySQL software, please refer to the *MySQL 5.0 Reference Manual*.

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at http://dev.mysql.com/doc/. Other formats also are available there, including HTML, PDF, and Windows CHM versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see http://docbook.org/

If you have questions about using MySQL, you can ask them using our mailing lists or forums. See Section 1.7.1, “MySQL Mailing Lists”, and Section 1.7.2, “MySQL Community Support at the MySQL Forums”. If you have suggestions concerning additions or corrections to the manual itself, please send them to the http://www.mysql.com/company/contact/.

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Paul DuBois, Stefan Hinz, Philip Olson, Daniel Price, Daniel So, and Jon Stephens.

1.2 Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- `Text in this style` is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- **`Text in this style`** indicates input that you type in examples.
- `Text in this style` indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).
- *`Text in this style`* is used for variable input for which you should substitute a value of your own choosing.
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.
- `Text in this style` is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example*: “The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to”.
- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘`%`’ character.”

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, `root-shell>` is similar but should be executed as `root`, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses *`db_name`*, *`tbl_name`*, and *`col_name`*. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (“`[`” and “`]`”) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (“`|`”). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (“`[`” and “`]`”):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (“`{`” and “`}`”):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (`...`) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple *`reset_option`* values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

1.3 Overview of the MySQL Database Management System

1.3.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL Web site (http://www.mysql.com/) provides the latest information about MySQL software.

- **MySQL is a database management system.**

  A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

  A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

  The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

  SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**

  Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), http://www.fsf.org/licenses/, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (http://www.mysql.com/company/legal/licensing/).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**

  If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

  You can find a performance comparison of MySQL Server with other database managers on our benchmark page. See Section 7.1.3, “The MySQL Benchmark Suite”.

  MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years.

Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**

  The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

  We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**

  MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

1.3.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. See also Section 1.4, “MySQL Development History”. In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 5.6: MySQL 5.6 in a Nutshell
- MySQL 5.5: MySQL 5.5 in a Nutshell
- MySQL 5.1: MySQL 5.1 in a Nutshell
- MySQL 5.0: MySQL 5.0 in a Nutshell

Internals and Portability:

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See `http://www.mysql.com/support/supportedplatforms/database.html`.
- For portability, uses `CMake` in MySQL 5.5 and up. Previous series use GNU Automake, Autoconf, and Libtool.
- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (http://developer.kde.org/~sewardj/).
- Uses multi-layered server design with independent modules.
- Designed to be fully multi-threaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.

- Uses very fast B-tree disk tables (MyISAM) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types:

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, FLOAT, DOUBLE, CHAR, VARCHAR, BINARY, VARBINARY, TEXT, BLOB, DATE, TIME, DATETIME, TIMESTAMP, YEAR, SET, ENUM, and OpenGIS spatial types. See Chapter 10, *Data Types*.
- Fixed-length and variable-length string types.

Statements and Functions:

- Full operator and function support in the SELECT list and WHERE clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
    -> FROM citizen
    -> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL GROUP BY and ORDER BY clauses. Support for group functions (COUNT() [882], AVG() [881], STD() [884], SUM() [884], MAX() [884], MIN() [884], and GROUP_CONCAT() [883]).
- Support for LEFT OUTER JOIN and RIGHT OUTER JOIN with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for DELETE, INSERT, REPLACE, and UPDATE to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.
- Support for MySQL-specific SHOW statements that retrieve information about databases, storage engines, tables, and indexes. MySQL 5.0 adds support for the INFORMATION_SCHEMA database, implemented according to standard SQL.
- An EXPLAIN statement to show how the optimizer resolves a query.
- Independence of function names from table or column names. For example, ABS is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "(" that follows it. See Section 8.3, "Reserved Words".
- You can refer to tables from different databases in the same statement.

Security:

- A privilege and password system that is very flexible and secure, and that enables host-based verification.
- Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits:

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.
- Support for up to 64 indexes per table (32 before MySQL 4.1.2). Each index may consist of 1 to 16 columns or parts of columns. The maximum index width is 767 bytes for `InnoDB` tables, or 1000 for `MyISAM`; before MySQL 4.1.2, the limit is 500 bytes. An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

Connectivity:

- Clients can connect to MySQL Server using several protocols:
  - Clients can connect using TCP/IP sockets on any platform.
  - On Windows systems in the NT family (NT, 2000, XP, 2003, or Vista), clients can connect using named pipes if the server is started with the `--enable-named-pipe` [386] option. In MySQL 4.1 and higher, Windows servers also support shared-memory connections if started with the `--shared-memory` [392] option. Clients can connect through shared memory by using the `--protocol=memory` option.
  - On Unix systems, clients can connect using Unix domain socket files.
- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See Chapter 17, *Connectors and APIs*.
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See MySQL Connector/ODBC Developer Guide.
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See MySQL Connector/J Developer Guide.
- MySQL Connector/Net enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/Net is a fully managed ADO.NET driver written in 100% pure C#. See MySQL Connector/Net Developer Guide.

Localization:

- The server can provide error messages to clients in many languages. See Section 9.3, “Setting the Error Message Language”.

- Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names. Unicode support is available as of MySQL 4.1.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the chosen character set and collation (using `latin1` and Swedish collation by default). It is possible to change this when the MySQL server is started. To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.
- As of MySQL 4.1, the server time zone can be changed dynamically, and individual clients can specify their own time zone. Section 9.7, “MySQL Server Time Zone Support”.

Clients and Tools:

- MySQL includes several client and utility programs. These include both command-line programs such as `mysqldump` and `mysqladmin`, and graphical programs such as MySQL Workbench.
- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on `MyISAM` tables. See Chapter 4, *MySQL Programs*.
- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

1.3.3 History of MySQL

We started out with the intention of using the `mSQL` database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that `mSQL` was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as `mSQL`. This API was designed to enable third-party code that was written for use with `mSQL` to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.4 MySQL Development History

This section describes the general MySQL development history, including major features implemented in or planned for various MySQL releases. The following sections provide information for each release series.

The current production release series is MySQL 5.1, which was declared stable for production use as of MySQL 5.1.30, released in November 2008. The previous production release series was MySQL 5.0, which was declared stable for production use as of MySQL 5.0.15, released in October 2005. “General Availability status” means that future 5.1 and 5.0 development is limited only to bugfixes. For the older MySQL 4.1, 4.0, and 3.23 series, only critical bugfixes are made.

Before upgrading from one release series to the next, please see the notes in Section 2.11.1, “Upgrading MySQL”.

The most requested features and the versions in which they were implemented are summarized in the following table.

Feature	MySQL Series
Unions	4.0
Subqueries	4.1
R-trees	4.1 (for the MyISAM storage engine)
Stored procedures and functions	5.0
Views	5.0
Cursors	5.0
XA transactions	5.0
Triggers	5.0 and 5.1
Event scheduler	5.1
Partitioning	5.1
Pluggable storage engine API	5.1
Plugin API	5.1
InnoDB Plugin	5.1
Row-based replication	5.1
Server log tables	5.1

1.5 MySQL 4.0 in a Nutshell

The following features were added in MySQL 4.0:

- Speed enhancements
  - MySQL 4.0 implemented a query cache that can give a major speed boost to applications with repetitive queries. See Section 7.5.3, “The MySQL Query Cache”.
  - MySQL 4.0 further increased the speed of MySQL Server in a number of areas, such as bulk INSERT statements, searching on packed indexes, full-text searching (using FULLTEXT indexes), and COUNT(DISTINCT) [882].
- InnoDB storage engine as standard
  - The InnoDB storage engine began to be offered as a standard feature of the MySQL server. This provided full support for ACID transactions, foreign keys with cascading UPDATE and DELETE, and row-level locking as standard features. See Section 13.2, “The InnoDB Storage Engine”.
- New functionality
  - The enhanced FULLTEXT search capabilities of MySQL Server 4.0 enabled FULLTEXT indexing of large text masses with both binary and natural-language searching logic. It became possible to customize minimal word length and define your own stop word lists in most human languages, enabling a broader class of applications to be built with MySQL Server. See Section 11.9, “Full-Text Search Functions”.
- Standards compliance, portability, and migration
  - MySQL Server added support for the UNION statement, a standard SQL feature.
  - Starting with version 4.0, MySQL runs natively on Novell NetWare 6.0 and higher. See Section 2.7, “Installing MySQL on NetWare”.

  - Features to simplify migration from other database systems to MySQL Server include `TRUNCATE TABLE` (as in Oracle) and `identity` [414] as a synonym for automatically incremented keys (as in Sybase).

- Internationalization

  - German-speaking users should note that MySQL 4.0 added support for a new character set, `latin1_de`, which ensures that words with umlauts are sorted in the same order as in German telephone books.

- Usability enhancements

  - As of version 4.0, most `mysqld` parameters (startup options) can be set without taking down the server. This is a convenient feature for database administrators. See Section 12.4.4, "`SET` Syntax".

  - Multiple-table `DELETE` and `UPDATE` statements were added.

  - On Windows, symbolic link handling at the database level was enabled by default. On Unix, the `MyISAM` storage engine added support for symbolic linking at the table level (and not just the database level as before).

  - The addition of the `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` [872] functions made it possible to find out the number of rows a `SELECT` query that includes a `LIMIT` clause would have returned without that clause.

- The Embedded MySQL Server

  The embedded server library added in this release can easily be used to create standalone and embedded applications. The embedded server provides an alternative to using MySQL in a client/server environment.

  The `libmysqld` embedded server library made MySQL Server suitable for a wider range of applications. Using this library, developers can embed MySQL Server into various applications and electronics devices, where the end user has no knowledge of there actually being an underlying database. Embedded MySQL Server is ideal for use in Internet appliances, public kiosks, turnkey hardware/software combination units, high performance Internet servers, self-contained databases distributed on CD-ROM, and so on.

  The embedded MySQL library uses the same interface as the normal client library. See Section 17.5, "libmysqld, the Embedded MySQL Server Library". Embedded MySQL is available under the same dual-licensing model as the MySQL Server; see http://www.mysql.com/company/legal/licensing/ for more information.

  On Windows, there are two different libraries, as shown in the following table.

Library Name	Library Type
`libmysqld.lib`	Dynamic library for threaded applications.
`mysqldemb.lib`	Static library for not threaded applications.

The news section of this manual includes a more in-depth list of MySQL 4.0 features. See Section C.2, "Changes in Release 4.0.x (Lifecycle Support Ended)".

1.6 MySQL 4.1 in a Nutshell

The following features were added in MySQL 4.1.

- **Support for subqueries and derived tables**:
  - A “subquery” is a `SELECT` statement nested within another statement. A “derived table” (an unnamed view) is a subquery in the `FROM` clause of another statement. See Section 12.2.8, “Subquery Syntax”.
- **Speed enhancements**:
  - Faster binary client/server protocol with support for prepared statements and parameter binding. See Section 17.6.7, “C API Prepared Statements”.
  - `BTREE` indexing is supported for `HEAP` tables, significantly improving response time for nonexact searches.
- **Added functionality**:
  - `CREATE TABLE tbl_name2 LIKE tbl_name1` enables you to create, with a single statement, a new table with a structure exactly like that of an existing table.
  - The `MyISAM` storage engine added support for OpenGIS spatial types for storing geographical data. See Chapter 16, *Spatial Extensions*.
  - Support was added for replication over SSL connections.
  - Support for a number of additional storage engines was implemented in the MySQL 4.1 release series:
    - The `EXAMPLE` storage engine is a “stub” engine that serves as an example in the MySQL source code for writing new storage engines, and is primarily of interest to developers. See Section 13.6, “The `EXAMPLE` Storage Engine”.
    - `NDBCLUSTER` is the storage engine used by MySQL Cluster to implement tables that are partitioned over many computers. See Chapter 15, *MySQL Cluster*.
    - The `ARCHIVE` storage engine is used for storing large amounts of data without indexes in a very small footprint. See Section 13.7, “The `ARCHIVE` Storage Engine”.
    - The `CSV` storage engine stores data in text files using comma-separated values format. See Section 13.8, “The `CSV` Storage Engine”.
    - The `BLACKHOLE` storage engine accepts but does not store data, and always returns an empty result set. It is for use primarily in replication. See Section 13.9, “The `BLACKHOLE` Storage Engine”.

Note

These engine were implemented at different points in the development of MySQL 4.1. Please see the indicated sections for particulars in each case.

- **Standards compliance, portability, and migration**:
  - The enhanced client/server protocol available beginning with MySQL 4.1.1 provides the ability to pass multiple warnings to the client, rather than only a single result, making it much easier to track problems that occur in operations such as bulk data loading.
  - `SHOW WARNINGS` shows warnings for the last command. See Section 12.4.5.26, “`SHOW WARNINGS` Syntax”.
- **Internationalization and Localization**:

- To support applications that require the use of local languages, the MySQL software added extensive Unicode support through the `utf8` and `ucs2` character sets.
- Definition of character sets by column, table, and database. This enables a high degree of flexibility in application design, particularly for multi-language Web sites. See Section 9.1, “Character Set Support”.
- Per-connection time zones support, enabling individual clients to select their own time zones when necessary.

- **Usability enhancements**:
  - The addition of a server-based `HELP` statement that can be used to get help information for SQL statements. This information is always applicable to the particular server version being used. Because this information is available by issuing an SQL statement, any client can access it. For example, the `help` command of the `mysql` command-line client has been modified to have this capability.
  - The improved client/server protocol permits multiple statements to be issued with a single call, and for returning multiple result sets. See Section 17.6.15, “C API Support for Multiple Statement Execution”.
  - The syntax `INSERT ... ON DUPLICATE KEY UPDATE ...` was implemented. This enables you to update an existing row if the insert would have caused a duplicate value for a primary or unique index. See Section 12.2.4, “`INSERT` Syntax”.
  - The aggregate function `GROUP_CONCAT()` [883], added the capability to concatenate column values from grouped rows into a single result string. See Section 11.15, “Functions and Modifiers for Use with `GROUP BY` Clauses”.

The News section of this manual includes a more in-depth list of MySQL 4.1 features. See Section C.1, “Changes in Release 4.1.x (Lifecycle Support Ended)”.

1.7 MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as the MySQL mailing lists and user forums, and Internet Relay Chat.

1.7.1 MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit http://lists.mysql.com/. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from `lists.mysql.com` to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

To have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the `List-ID:` or `Delivered-To:` headers to identify list messages.

The MySQL mailing lists are as follows:

- `announce`

  The list for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- `mysql`

  The main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- `bugs`

  The list for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See Section 1.8, “How to Report Bugs or Problems”.

- `internals`

  The list for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- `mysqldoc`

  The list for people who work on the MySQL documentation.

- `benchmarks`

  The list for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, file system, disk system, and so on.

- `packagers`

  The list for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- `java`

  The list for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- `win32`

  The list for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- `myodbc`

  The list for all topics concerning connecting to the MySQL server with ODBC.

- `gui-tools`

  The list for all topics concerning MySQL graphical user interface tools such as MySQL Workbench.

- `cluster`

The list for discussion of MySQL Cluster.

- `dotnet`

  The list for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/Net.

- `plusplus`

  The list for all topics concerning programming with the C++ API for MySQL.

- `perl`

  The list for all topics concerning Perl support for MySQL with `DBD::mysql`.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from Oracle. This puts you in direct contact with MySQL developers.

The following MySQL mailing lists are in languages other than English. These lists are not operated by Oracle.

- `<mysql-france-subscribe@yahoogroups.com>`

  A French mailing list.

- `<list@tinc.net>`

  A Korean mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

- `<mysql-de-request@lists.4t2.com>`

  A German mailing list. To subscribe, email `subscribe mysql-de your@email.address` to this list. You can find information about this mailing list at http://www.4t2.com/mysql/.

- `<mysql-br-request@listas.linkway.com.br>`

  A Portuguese mailing list. To subscribe, email `subscribe mysql-br your@email.address` to this list.

- `<mysql-alta@elistas.net>`

  A Spanish mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

1.7.1.1 Guidelines for Using the Mailing Lists

Please do not post mail messages from your browser with HTML mode turned on. Many users do not read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Do not feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

1.7.2 MySQL Community Support at the MySQL Forums

The forums at http://forums.mysql.com are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

1.7.3 MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

freenode (see http://www.freenode.net/ for servers)

- `#mysql` is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.

If you are looking for IRC client software to connect to an IRC network, take a look at `xChat` (http://www.xchat.org/). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at http://www.silverex.org/download/).

1.7.4 MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:

- MySQL Enterprise Server
- MySQL Enterprise Monitor
- Monthly Rapid Updates and Quarterly Service Packs
- MySQL Knowledge Base
- 24x7 Technical and Consultative Support

MySQL Enterprise is available in multiple tiers, giving you the flexibility to choose the level of service that best matches your needs. For more information, see MySQL Enterprise.

1.8 How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at http://dev.mysql.com/doc/. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.
- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

  If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.
- For solutions to some common problems, see Section B.5, “Problems and Common Errors”.
- Search the bugs database at http://bugs.mysql.com/ to see whether the bug has been reported and fixed.
- Search the MySQL mailing list archives at http://lists.mysql.com/. See Section 1.7.1, “MySQL Mailing Lists”.
- You can also use http://www.mysql.com/search/ to search all the Web pages (including the manual) that are located at the MySQL Web site.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at http://bugs.mysql.com/ that are corrected for a given release are noted in the release notes.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to `<secalert_us@oracle.com>`. Exception: Support customers should report all problems, including security bugs, to Oracle Support at http://support.oracle.com/.

To discuss problems with other users, you can use one of the MySQL mailing lists. Section 1.7.1, “MySQL Mailing Lists”.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test < script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See Section 18.4, “Porting to Other Systems”.

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See How to Report Connector/ODBC Problems or Bugs.

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` [265] option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.0.19). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.
- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.

- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See Section 18.4, “Porting to Other Systems”.

- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.

- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` [429] system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` [429] value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

  ```
  SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
  FROM INFORMATION_SCHEMA.ROUTINES;
  ```

  For triggers, you can use this statement:

  ```
  SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
  FROM INFORMATION_SCHEMA.TRIGGERS;
  ```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

  The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

  ```
  mysql> SHOW VARIABLES;
  mysql> SHOW COLUMNS FROM ...\G
         <output from SHOW COLUMNS>
  mysql> EXPLAIN SELECT ...\G
         <output from EXPLAIN>
  mysql> FLUSH STATUS;
  mysql> SELECT ...;
         <A short version of the output from SELECT,
         including the time taken to run the query>
  mysql> SHOW STATUS;
         <output from SHOW STATUS>
  ```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

  If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`.

After you initiate a bug report for our bugs database at http://bugs.mysql.com/, click the Files tab in the bug report for instructions on uploading the archive to the bugs database.

- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.

- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.

- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.

- If your question is related to the privilege system, please include the output of `mysqlaccess`, the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should first run `mysqlaccess`. After this, execute `mysqladmin reload version` and try to connect with the program that gives you trouble. `mysqlaccess` can be found in the `bin` directory under your MySQL installation directory.

- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

  If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.

- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.

- If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:

  - The `InnoDB` crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with `InnoDB` tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` [1069] option enabled so that you can dump the affected tables.

  - For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See Chapter 5, *MySQL Server Administration*.

  If you are running Windows, please verify the value of `lower_case_table_names` [418] using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in Section 8.2.2, “Identifier Case Sensitivity”.

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See Section 5.3.1, “The Error Log”. Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See Section B.5.1, “How to Determine What Is Causing a Problem”.
- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See Section 2.1.2, “Choosing Which MySQL Distribution to Install”.

1.9 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, “SQL:2003” refers to the standard released in 2003, and “SQL:2008” refers to the most recent version of the standard, released in 2008. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See Section 12.2.3, “`HANDLER` Syntax”.

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

Currently, we are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

In MySQL 4.1.2 in later, high-availability database clustering is supported by the `NDBCLUSTER` storage engine. See Chapter 15, *MySQL Cluster*.

XML support is to be implemented in a future version of the database server.

1.9.1 What Standards MySQL Follows

Our aim is to support the full ANSI/ISO SQL standard, but without making concessions to speed and quality of the code.

ODBC levels 0 to 3.51.

1.9.2 Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differentially for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

SQL modes control aspects of server operation such as what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="mode_value"` [394] option. Beginning with MySQL 4.1, you can also change the mode at runtime by setting the `sql_mode` [429] system variable with a `SET [GLOBAL|SESSION] sql_mode='mode_value'` statement.

For more information on setting the SQL mode, see Section 5.1.6, “Server SQL Modes”.

1.9.3 Running MySQL in ANSI Mode

You can tell `mysqld` to run in ANSI mode with the `--ansi` [384] startup option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

As of MySQL 4.1.1, you can achieve the same effect at runtime by executing these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` [429] system variable to `'ANSI'` enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@global.sql_mode;
        -> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` [384] is not quite the same as setting the SQL mode to `'ANSI'`. The `--ansi` [384] option affects the SQL mode and also sets the transaction isolation level. Setting the SQL mode to `'ANSI'` has no effect on the isolation level.

See Section 5.1.2, “Server Command Options”, and Section 1.9.2, “Selecting SQL Modes”.

1.9.4 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably won't find in other SQL DBMSs. Be warned that if you use them, your code won't be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the "`!`" character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

  MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:

  - Database and table names are case sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See Section 8.2.2, "Identifier Case Sensitivity".
  - You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the `MyISAM` or `ISAM` storage engines. For example, it is possible to rename a `MyISAM` table by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

  Database and table names cannot contain path name separator characters ("`/`", "`\`").

- General language syntax
  - By default, strings can be enclosed by either "`"`" or "`'`", not just by "`'`". (If the `ANSI_QUOTES` [458] SQL mode is enabled, strings can be enclosed only by "`'`" and the server interprets strings enclosed by "`"`" as identifiers.)
  - "`\`" is the escape character in strings.
  - In SQL statements, you can access tables from different databases with the *`db_name.tbl_name`* syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.
- SQL statement syntax
  - The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
  - The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See Section 12.1.3, "`CREATE DATABASE` Syntax", Section 12.1.6, "`DROP DATABASE` Syntax", and Section 12.1.1, "`ALTER DATABASE` Syntax".
  - The `DO` statement.
  - `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
  - The `FLUSH` and `RESET` statements.

- The `SET` statement. See Section 12.4.4, “`SET` Syntax”.
- The `SHOW` statement. See Section 12.4.5, “`SHOW` Syntax”.
- Use of `LOAD DATA INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD DATA INFILE`. See Section 12.2.5, “`LOAD DATA INFILE` Syntax”.
- Use of `RENAME TABLE`. See Section 12.1.9, “`RENAME TABLE` Syntax”.
- Use of `REPLACE` instead of `DELETE` plus `INSERT`. See Section 12.2.6, “`REPLACE` Syntax”.
- Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See Section 12.1.2, “`ALTER TABLE` Syntax”.
- Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See Section 12.1.5, “`CREATE TABLE` Syntax”.
- Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.
- Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.
- The capability of dropping multiple tables with a single `DROP TABLE` statement.
- The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.
- `INSERT INTO tbl_name SET col_name = ...` syntax.
- The `DELAYED` clause of the `INSERT` and `REPLACE` statements.
- The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.
- Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See Section 12.2.7, “`SELECT` Syntax”.
- Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.
- You don't need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See Section 11.15, “Functions and Modifiers for Use with `GROUP BY` Clauses”.
- You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.
- The ability to set variables in a statement with the `:=` assignment operator:

```
mysql> SELECT @a:=SUM(total),@b:=COUNT(*),@a/@b AS avg
    -> FROM test_table;
mysql> SELECT @t1:=(@t2:=1)+@t3:=4,@t1,@t2,@t3;
```

- Data types
  - The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.
  - The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.
- Functions and operators

- To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
- MySQL Server understands the || [787] and && [787] operators to mean logical OR and AND, as in the C programming language. In MySQL Server, || [787] and OR [787] are synonyms, as are && [787] and AND [787]. Because of this nice syntax, MySQL Server doesn't support the standard SQL || [787] operator for string concatenation; use CONCAT() [795] instead. Because CONCAT() [795] takes any number of arguments, it is easy to convert use of the || [787] operator to MySQL Server.
- Use of COUNT(DISTINCT *value_list*) [882] where *value_list* has more than one element.
- String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is latin1 (cp1252 West European) by default. If you don't like this, you should declare your columns with the BINARY attribute or use the BINARY cast, which causes comparisons to be done using the underlying character code values rather then a lexical ordering.
- The % [821] operator is a synonym for MOD() [821]. That is, *N* % *M* is equivalent to MOD(*N*,*M*) [821]. % [821] is supported for C programmers and for compatibility with PostgreSQL.
- The = [782], <> [782], <= [782], < [782], >= [782], > [783], << [863], >> [863], <=> [782], AND [787], OR [787], or LIKE [804] operators may be used in expressions in the output column list (to the left of the FROM) in SELECT statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```

- The LAST_INSERT_ID() [874] function returns the most recent AUTO_INCREMENT value. See Section 11.13, “Information Functions”.
- LIKE [804] is permitted on numeric values.
- The REGEXP [808] and NOT REGEXP [808] extended regular expression operators.
- CONCAT() [795] or CHAR() [794] with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)
- The BIT_COUNT() [863], CASE [790], ELT() [795], FROM_DAYS() [834], FORMAT() [796], IF() [790], PASSWORD() [868], ENCRYPT() [867], MD5() [868], ENCODE() [867], DECODE() [866], PERIOD_ADD() [837], PERIOD_DIFF() [838], TO_DAYS() [841], and WEEKDAY() [844] functions.
- Use of TRIM() [803] to trim substrings. Standard SQL supports removal of single characters only.
- The GROUP BY functions STD() [884], BIT_OR() [882], BIT_AND() [882], BIT_XOR() [882], and GROUP_CONCAT() [883]. See Section 11.15, “Functions and Modifiers for Use with GROUP BY Clauses”.

1.9.5 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- For VARCHAR columns, trailing spaces are removed when the value is stored. See Section B.5.8, “Known Issues in MySQL”.

- In some cases, `CHAR` columns are silently converted to `VARCHAR` columns when you define a table or alter its structure. See Section 12.1.5.2, “Silent Column Specification Changes”.
- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see Section 12.4.1.3, “`REVOKE` Syntax”.
- The `CAST()` [859] function does not support cast to `REAL` or `BIGINT`. See Section 11.10, “Cast Functions and Operators”.

1.9.5.1 Subquery Support

MySQL 4.1 and up supports subqueries and derived tables. A “subquery” is a `SELECT` statement nested within another statement. A “derived table” (an unnamed view) is a subquery in the `FROM` clause of another statement. See Section 12.2.8, “Subquery Syntax”.

For MySQL versions older than 4.1, most subqueries can be rewritten using joins or other methods. See Section 12.2.8.11, “Rewriting Subqueries as Joins for Earlier MySQL Versions”, for examples that show how to do this.

1.9.5.2 `SELECT INTO TABLE`

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See Section 12.2.4.1, “`INSERT ... SELECT` Syntax”. For example:

```
INSERT INTO tbl_temp2 (fld_id)
    SELECT tbl_temp1.fld_order_id
    FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

1.9.5.3 `UPDATE`

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

1.9.5.4 Transactions and Atomic Operations

MySQL Server (version 3.23-max and all versions 4.0 and above) supports transactions with the `InnoDB` and `BDB` transactional storage engines. `InnoDB` provides *full* ACID compliance. MySQL Cluster is also a transaction-safe storage engine. See Chapter 13, *Storage Engines*. For information about `InnoDB` differences from standard SQL with regard to treatment of transaction errors, see Section 13.2.13, “`InnoDB` Error Handling”.

The other nontransactional storage engines in MySQL Server (such as `MyISAM`) follow a different paradigm for data integrity called “atomic operations.” In transactional terms, `MyISAM` tables effectively always operate in `autocommit = 1` [406] mode. Atomic operations often offer comparable integrity with higher performance.

Because MySQL Server supports both paradigms, you can decide whether your applications are best served by the speed of atomic operations or the use of transactional features. This choice can be made on a per-table basis.

As noted, the tradeoff for transactional versus nontransactional storage engines lies mostly in performance. Transactional tables have significantly higher memory and disk space requirements, and more CPU overhead. On the other hand, transactional storage engines such as `InnoDB` also offer many significant features. MySQL Server's modular design enables the concurrent use of different storage engines to suit different requirements and deliver optimum performance in all situations.

But how do you use the features of MySQL Server to maintain rigorous integrity even with the nontransactional `MyISAM` tables, and how do these features compare with the transactional storage engines?

- If your applications are written in a way that is dependent on being able to call `ROLLBACK` rather than `COMMIT` in critical situations, transactions are more convenient. Transactions also ensure that unfinished updates or corrupting activities are not committed to the database; the server is given the opportunity to do an automatic rollback and your database is saved.

  If you use nontransactional tables, MySQL Server in almost all cases enables you to resolve potential problems by including simple checks before updates and by running simple scripts that check the databases for inconsistencies and automatically repair or warn if such an inconsistency occurs. You can normally fix tables perfectly with no data integrity loss just by using the MySQL log or even adding one extra log.

- More often than not, critical transactional updates can be rewritten to be atomic. Generally speaking, all integrity problems that transactions solve can be done with `LOCK TABLES` or atomic updates, ensuring that there are no automatic aborts from the server, which is a common problem with transactional database systems.

- To be safe with MySQL Server, regardless of whether you use transactional tables, you only need to have backups and have binary logging turned on. When that is true, you can recover from any situation that you could with any other transactional database system. It is always good to have backups, regardless of which database system you use.

The transactional paradigm has its advantages and disadvantages. Many users and application developers depend on the ease with which they can code around problems where an abort appears to be necessary, or is necessary. However, even if you are new to the atomic operations paradigm, or more familiar with transactions, do consider the speed benefit that nontransactional tables can offer on the order of three to five times the speed of the fastest and most optimally tuned transactional tables.

In situations where integrity is of highest importance, MySQL Server offers transaction-level reliability and integrity even for nontransactional tables. If you lock tables with `LOCK TABLES`, all updates stall until integrity checks are made. If you obtain a `READ LOCAL` lock (as opposed to a write lock) for a table that enables concurrent inserts at the end of the table, reads are permitted, as are inserts by other clients. The newly inserted records are not be seen by the client that has the read lock until it releases the lock. With `INSERT DELAYED`, you can write inserts that go into a local queue until the locks are released, without having the client wait for the insert to complete. See Section 7.6.3, “Concurrent Inserts”, and Section 12.2.4.2, “`INSERT DELAYED` Syntax”.

“Atomic,” in the sense that we mean it, is nothing magical. It only means that you can be sure that while each specific update is running, no other user can interfere with it, and there can never be an automatic rollback (which can happen with transactional tables if you are not very careful). MySQL Server also guarantees that there are no dirty reads.

Following are some techniques for working with nontransactional tables:

- Loops that need transactions normally can be coded with the help of `LOCK TABLES`, and you don't need cursors to update records on the fly.
- To avoid using `ROLLBACK`, you can employ the following strategy:

  1. Use `LOCK TABLES` to lock all the tables you want to access.
  2. Test the conditions that must be true before performing the update.
  3. Update if the conditions are satisfied.
  4. Use `UNLOCK TABLES` to release your locks.

  This is usually a much faster method than using transactions with possible rollbacks, although not always. The only situation this solution doesn't handle is when someone kills the threads in the middle of an update. In that case, all locks are released but some of the updates may not have been executed.
- You can also use functions to update records in a single operation. You can get a very efficient application by using the following techniques:

  - Modify columns relative to their current value.
  - Update only those columns that actually have changed.

  For example, when we are updating customer information, we update only the customer data that has changed and test only that none of the changed data, or data that depends on the changed data, has changed compared to the original row. The test for changed data is done with the `WHERE` clause in the `UPDATE` statement. If the record wasn't updated, we give the client a message: “Some of the data you have changed has been changed by another user.” Then we show the old row versus the new row in a window so that the user can decide which version of the customer record to use.

  This gives us something that is similar to column locking but is actually even better because we only update some of the columns, using values that are relative to their current values. This means that typical `UPDATE` statements look something like these:

  ```
  UPDATE tablename SET pay_back=pay_back+125;

  UPDATE customer
    SET
      customer_date='current_date',
      address='new address',
      phone='new phone',
      money_owed_to_us=money_owed_to_us-125
    WHERE
      customer_id=id AND address='old address' AND phone='old phone';
  ```

  This is very efficient and works even if another client has changed the values in the `pay_back` or `money_owed_to_us` columns.
- In many cases, users have wanted `LOCK TABLES` or `ROLLBACK` for the purpose of managing unique identifiers. This can be handled much more efficiently without locking or rolling back by using an `AUTO_INCREMENT` column and either the `LAST_INSERT_ID()` [874] SQL function or the `mysql_insert_id()` C API function. See Section 11.13, “Information Functions”, and Section 17.6.6.35, “`mysql_insert_id()`”.

  You can generally code around the need for row-level locking. Some situations really do need it, and `InnoDB` tables support row-level locking. Otherwise, with `MyISAM` tables, you can use a flag column in the table and do something like the following:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID;
```

MySQL returns `1` for the number of affected rows if the row was found and `row_flag` wasn't `1` in the original row. You can think of this as though MySQL Server changed the preceding statement to:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID AND row_flag <> 1;
```

1.9.5.5 Stored Routines and Triggers

Stored procedures and functions are implemented beginning with MySQL 5.0.

Basic trigger functionality is implemented beginning with MySQL 5.0.2, with further development planned for MySQL 5.1.

1.9.5.6 Foreign Keys

The `InnoDB` storage engine supports checking of foreign key constraints, including `CASCADE`, `ON DELETE`, and `ON UPDATE`. See Section 13.2.5.4, “`FOREIGN KEY` Constraints”.

For storage engines other than `InnoDB`, MySQL Server parses the `FOREIGN KEY` syntax in `CREATE TABLE` statements, but does not use or store it. In the future, the implementation will be extended to store this information in the table specification file so that it may be retrieved by `mysqldump` and ODBC. At a later stage, foreign key constraints will be implemented for `MyISAM` tables as well.

Foreign key enforcement offers several benefits to database developers:

- Assuming proper design of the relationships, foreign key constraints make it more difficult for a programmer to introduce an inconsistency into the database.
- Centralized checking of constraints by the database server makes it unnecessary to perform these checks on the application side. This eliminates the possibility that different applications may not all check the constraints in the same way.
- Using cascading updates and deletes can simplify the application code.
- Properly designed foreign key rules aid in documenting relationships between tables.

Do keep in mind that these benefits come at the cost of additional overhead for the database server to perform the necessary checks. Additional checking by the server affects performance, which for some applications may be sufficiently undesirable as to be avoided if possible. (Some major commercial applications have coded the foreign key logic at the application level for this reason.)

MySQL gives database developers the choice of which approach to use. If you don't need foreign keys and want to avoid the overhead associated with enforcing referential integrity, you can choose another storage engine instead, such as `MyISAM`. (For example, the `MyISAM` storage engine offers very fast performance for applications that perform only `INSERT` and `SELECT` operations. In this case, the table has no holes in the middle and the inserts can be performed concurrently with retrievals. See Section 7.6.3, “Concurrent Inserts”.)

If you choose not to take advantage of referential integrity checks, keep the following considerations in mind:

- In the absence of server-side foreign key relationship checking, the application itself must handle relationship issues. For example, it must take care to insert rows into tables in the proper order, and to avoid creating orphaned child records. It must also be able to recover from errors that occur in the middle of multiple-record insert operations.

- If `ON DELETE` is the only referential integrity capability an application needs, you can achieve a similar effect as of MySQL Server 4.0 by using multiple-table `DELETE` statements to delete rows from many tables with a single statement. See Section 12.2.1, “`DELETE` Syntax”.
- A workaround for the lack of `ON DELETE` is to add the appropriate `DELETE` statements to your application when you delete records from a table that has a foreign key. In practice, this is often as quick as using foreign keys and is more portable.

Be aware that the use of foreign keys can sometimes lead to problems:

- Foreign key support addresses many referential integrity issues, but it is still necessary to design key relationships carefully to avoid circular rules or incorrect combinations of cascading deletes.
- It is not uncommon for a DBA to create a topology of relationships that makes it difficult to restore individual tables from a backup. (MySQL alleviates this difficulty by enabling you to temporarily disable foreign key checks when reloading a table that depends on other tables. See Section 13.2.5.4, “`FOREIGN KEY` Constraints”. As of MySQL 4.1.1, `mysqldump` generates dump files that take advantage of this capability automatically when they are reloaded.)

Foreign keys in SQL are used to check and enforce referential integrity, not to join tables. If you want to get results from multiple tables from a `SELECT` statement, you do this by performing a join between them:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.id;
```

See Section 12.2.7.1, “`JOIN` Syntax”, and Section 3.6.6, “Using Foreign Keys”.

The `FOREIGN KEY` syntax without `ON DELETE ...` is often used by ODBC applications to produce automatic `WHERE` clauses.

1.9.5.7 Views

Views (including updatable views) are implemented beginning with MySQL Server 5.0.1.

Views are useful for enabling users to access a set of relations (tables) as if it were a single table, and limiting their access to just that. Views can also be used to restrict access to rows (a subset of a particular table). For access control to columns, you can also use the sophisticated privilege system in MySQL Server. See Section 5.5, “The MySQL Access Privilege System”.

In designing an implementation of views, our ambitious goal, as much as is possible within the confines of SQL, has been full compliance with “Codd's Rule #6” for relational database systems: “All views that are theoretically updatable, should in practice also be updatable.”

1.9.5.8 '`--`' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in Section 8.6, “Comment Syntax”.

Standard SQL uses “`--`” as a start-comment sequence. MySQL Server uses “`#`” as the start comment character. MySQL Server 3.23.3 and up also supports a variant of the “`--`” comment style. That is, the “`--`” start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a legal expression in SQL, but "`--`" is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with "`--`" can have serious consequences.

Using our implementation requires a space following the "`--`" for it to be recognized as a start-comment sequence in MySQL Server 3.23.3 and newer. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with "`--`".

The following information is relevant only if you are running a MySQL version earlier than 3.23.3:

If you have an SQL script in a text file that contains "`--`" comments, you should use the `replace` utility as follows to convert the comments to use "`#`" characters before executing the script:

```
shell> replace " --" " #" < text-file-with-funny-comments.sql \
        | mysql db_name
```

That is safer than executing the script in the usual way:

```
shell> mysql db_name < text-file-with-funny-comments.sql
```

You can also edit the script file "in place" to change the "`--`" comments to "`#`" comments:

```
shell> replace " --" " #" -- text-file-with-funny-comments.sql
```

Change them back with this command:

```
shell> replace " #" " --" -- text-file-with-funny-comments.sql
```

See Section 4.8.2, "`replace` — A String-Replacement Utility".

1.9.6 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce illegal values to the closest legal values.

The following sections describe how MySQL Server handles different types of constraints.

1.9.6.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occurs for data-change statements (such as INSERT or UPDATE) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as InnoDB, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an IGNORE keyword for INSERT, UPDATE, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using (Section 12.2.4, “INSERT Syntax”, Section 12.2.9, “UPDATE Syntax”, and so forth).

You can get information about the number of rows actually inserted or updated with the mysql_info() C API function. In MySQL 4.1 and up, you also can use the SHOW WARNINGS statement. See Section 17.6.6.33, “mysql_info()”, and Section 12.4.5.26, “SHOW WARNINGS Syntax”.

Currently, only InnoDB tables support foreign keys. See Section 13.2.5.4, “FOREIGN KEY Constraints”.

1.9.6.2 Constraints on Invalid Data

Through version 4.1, MySQL is forgiving of illegal or improper data values and coerces them to legal values for data entry. When you insert an “incorrect” value into a column, such as a NULL into a NOT NULL column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error. The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.
- If you try to store a string that doesn't start with a number into a numeric column, MySQL Server stores 0.
- Invalid values for ENUM and SET columns are handled as described in Section 1.9.6.3, “ENUM and SET Constraints”.
- MySQL enables you to store certain incorrect date values into DATE and DATETIME columns (such as '2000-02-31' or '2000-02-00'). The idea is that it is not the job of the SQL server to validate dates. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value '0000-00-00' is stored in the column instead.
- If you try to store NULL into a column that doesn't take NULL values, an error occurs for single-row INSERT statements. For multiple-row INSERT statements or for INSERT INTO ... SELECT statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string ('') for string types, and the “zero” value for date and time types. Implicit default values are discussed in Section 10.1.4, “Data Type Default Values”.
- If an INSERT statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit DEFAULT clause. If the definition has no such DEFAULT clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in

this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

1.9.6.3 `ENUM` and `SET` Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See Section 10.4.4, “The `ENUM` Type”, and Section 10.4.5, “The `SET` Type”. However, in MySQL 4.1 and earlier, `ENUM` and `SET` columns do not provide true constraints on entry of invalid data:

- `ENUM` columns always have a default value. If you specify no default value, then it is `NULL` for columns that can have `NULL`, otherwise it is the first enumeration value in the column definition.
- If you insert an incorrect value into an `ENUM` column or if you force a value into an `ENUM` column with `IGNORE`, it is set to the reserved enumeration value of `0`, which is displayed as an empty string in string context.
- If you insert an incorrect value into a `SET` column, the incorrect value is ignored. For example, if the column can contain the values `'a'`, `'b'`, and `'c'`, an attempt to assign `'a,x,b,y'` results in a value of `'a,b'`.

1.10 Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

1.10.1 Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize those who have made contributions of one kind or another to the `MySQL distribution`. Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola `<qwerg@mbox.vol.it>` or `<qwerg@tin.it>`

  The initial port to Win32/NT.

- Per Eric Olsson

  For constructive criticism and real testing of the dynamic record format.

- Irena Pancirov `<irena@mail.yacc.it>`

  Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`.

- David J. Hughes

  For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with `mSQL`, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. `mysqladmin` and `mysql` client are programs that were largely influenced by their `mSQL` counterparts. We have put a lot of effort into making the MySQL syntax a superset of `mSQL`. Many of the API's ideas are borrowed from `mSQL` to make it easy to port free `mSQL` programs to the MySQL API. The MySQL software doesn't contain any code from `mSQL`. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based on the corresponding (noncopyrighted) files in the `mSQL` distribution, but are modified as examples showing the changes necessary to convert code from `mSQL` to MySQL Server. (`mSQL` is copyrighted David J. Hughes.)

- Patrick Lynch

For helping us acquire http://www.mysql.com/.

- Fred Lindberg

  For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko <igor@frog.kiev.ua>

  mysqldump (previously msqldump, but ported and enhanced by Monty).

- Yuri Dario

  For keeping up and extending the MySQL OS/2 port.

- Tim Bunce

  Author of mysqlhotcopy.

- Zarko Mocnik <zarko.mocnik@dem.si>

  Sorting for Slovenian language.

- "TAMITO" <tommy@valley.ne.jp>

  The _MB character set macros and the ujis and sjis character sets.

- Joshua Chamas <joshua@chamas.com>

  Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.

- Yves Carlier <Yves.Carlier@rug.ac.be>

  mysqlaccess, a program to show the access rights for a user.

- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)

  For one of the early JDBC drivers.

- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>

  Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <pixel@organic.com>

  For setting up a searchable mailing list archive at his site.

- Rick Mehalick <Rick_Mehalick@i-o.com>

  For xmysql, a graphical X client for MySQL Server.

- Doug Sisk <sisk@wix.com>

  For providing RPM packages of MySQL for Red Hat Linux.

- Diemand Alexander V. <axeld@vial.ethz.ch>

  For providing RPM packages of MySQL for Red Hat Linux-Alpha.

- Antoni Pamies Olive <toni@readysoft.es>

  For providing RPM versions of a lot of MySQL clients for Intel and SPARC.

- Jay Bloodworth <jay@pathways.sde.state.sc.us>

  For providing RPM versions for MySQL 3.21.

- David Sacerdote <davids@secnet.com>

  Ideas for secure checking of DNS host names.

- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>

  Some support for Chinese(BIG5) characters.

- Wei He <hewei@mail.ied.ac.cn>

  A lot of functionality for the Chinese(GBK) character set.

- Jan Pazdziora <adelton@fi.muni.cz>

  Czech sorting order.

- Zeev Suraski <bourbon@netvision.net.il>

  `FROM_UNIXTIME()` [834] time formatting, `ENCRYPT()` [867] functions, and `bison` advisor. Active mailing list member.

- Luuk de Boer <luuk@wxs.nl>

  Ported (and extended) the benchmark suite to `DBI`/`DBD`. Have been of great help with `crash-me` and running benchmarks. Some new date functions. The `mysql_setpermission` script.

- Alexis Mikhailov <root@medinf.chuvashia.su>

  User-defined functions (UDFs); `CREATE FUNCTION` and `DROP FUNCTION`.

- Andreas F. Bobak <bobak@relog.ch>

  The `AGGREGATE` extension to user-defined functions.

- Ross Wakelin <R.Wakelin@march.co.uk>

  Help to set up InstallShield for MySQL-Win32.

- Jethro Wright III <jetman@li.net>

  The `libmysql.dll` library.

- James Pereria <jpereira@iafrica.com>

  Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.

- Curt Sampson <cjs@portal.ca>

  Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.

- Martin Ramsch <m.ramsch@computer.org>

Examples in the MySQL Tutorial.

- Steve Harvey

  For making `mysqlaccess` more secure.

- Konark IA-64 Centre of Persistent Systems Private Limited

  http://www.pspl.co.in/konark/. Help with the Win64 port of the MySQL server.

- Albert Chin-A-Young.

  Configure updates for Tru64, large file support and better TCP wrappers support.

- John Birrell

  Emulation of `pthread_mutex()` for OS/2.

- Benjamin Pflugmann

  Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.

- Jocelyn Fournier

  Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

- Marc Liyanage

  Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X packages.

- Robert Rutherford

  Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

  Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

- Google Inc.

  We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, `<jehamby@lightside>`, `<psmith@BayNetworks.com>`, `<duane@connect.com.au>`, Ted Deppner `<ted@psyber.com>`, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <dkoch@amcity.com>

  Irix setup.

- Luuk de Boer <luuk@wxs.nl>

  Benchmark questions.

- Tim Sailer <tps@users.buoy.com>

  DBD::mysql questions.

- Boyd Lynn Gerber <gerberb@zenez.com>

  SCO-related questions.

- Richard Mehalick <RM186061@shellus.com>

  xmysql-related questions and basic installation questions.

- Zeev Suraski <bourbon@netvision.net.il>

  Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

- Francesc Guasch <frankie@citel.upc.es>

  General questions.

- Jonathan J Smith <jsmith@wtp.net>

  Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.

- David Sklar <sklar@student.net>

  Using MySQL from PHP and Perl.

- Alistair MacDonald <A.MacDonald@uel.ac.uk>

  Is flexible and can handle Linux and perhaps HP-UX.

- John Lyon <jlyon@imag.net>

  Questions about installing MySQL on Linux systems, using either .rpm files or compiling from source.

- Lorvid Ltd. <lorvid@WOLFENET.com>

  Simple billing/license/support/copyright issues.

- Patrick Sherrill <patrick@coconet.com>

  ODBC and VisualC++ interface questions.

- Randy Harmon <rjharmon@uptimecomputers.com>

  DBD, Linux, some SQL syntax questions.

1.10.2 Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois

  Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.

- Kim Aldale

  Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <mke@terrapin.turbolift.com>

  For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

  First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded (http://mysql.hitstar.com/) versions were based. Personal home page at linuxdb.yeah.net.

- Jay Flaherty <fty@mediapulse.com>

  Big parts of the Perl DBI/DBD section in the manual.

- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

  Proof-reading of the Reference Manual.

- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>

  French error messages.

- Petr Snajdr, <snajdr@pvt.net>

  Czech error messages.

- Jaroslaw Lewandowski <jotel@itnet.com.pl>

  Polish error messages.

- Miguel Angel Fernandez Roiz

  Spanish error messages.

- Roy-Magne Mo <rmo@www.hivolda.no>

  Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev <root@timur.tatarstan.ru>

  Russian error messages.

- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>

  Italian error messages.

- Dirk Munzinger <dirk@trinity.saar.de>

German error messages.

- Billik Stefan <billik@sun.uniag.sk>

  Slovak error messages.

- Stefan Saroiu <tzoompy@cs.washington.edu>

  Romanian error messages.

- Peter Feher

  Hungarian error messages.

- Roberto M. Serqueira

  Portuguese error messages.

- Carsten H. Pedersen

  Danish error messages.

- Arjen Lentz

  Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

1.10.3 Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at http://solutions.mysql.com/software/.

- Tim Bunce, Alligator Descartes

  For the `DBD` (Perl) interface.

- Andreas Koenig <a.koenig@mind.de>

  For the Perl interface for MySQL Server.

- Jochen Wiedmann <wiedmann@neckar-alb.de>

  For maintaining the Perl `DBD::mysql` module.

- Eugene Chan <eugene@acenet.com.sg>

  For porting PHP for MySQL Server.

- Georg Richter

  MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.

- Giovanni Maruzzelli <maruzz@matrice.it>

  For porting iODBC (Unix ODBC).

- Xavier Leroy <Xavier.Leroy@inria.fr>

  The author of LinuxThreads (used by the MySQL Server on Linux).

1.10.4 Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

  From whom we got an excellent compiler (`gcc`), an excellent debugger (`gdb` and the `libc` library (from which we have borrowed `strto.c` to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

  For a really great editor/environment.

- Julian Seward

  Author of `valgrind`, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

  For `DDD` (The Data Display Debugger) which is an excellent graphical front end to `gdb`).

1.10.5 Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize the following companies, which helped us finance the development of the `MySQL server`, such as by paying us for developing a new feature or giving us hardware for development of the `MySQL server`.

- VA Linux / Andover.net

  Funded replication.

- NuSphere

  Editing of the MySQL manual.

- Stork Design studio

  The MySQL Web site in use between 1998-2000.

- Intel

  Contributed to development on Windows and Linux platforms.

- Compaq

  Contributed to Development on Linux/Alpha.

- SWSoft

  Development on the embedded `mysqld` version.

- FutureQuest

  The `--skip-show-database` [394] option.

Chapter 2 Installing and Upgrading MySQL

Table of Contents

End of Product Lifecycle. Active development and support for MySQL Database Server versions 3.23, 4.0, and 4.1 has ended. For details, see http://www.mysql.com/about/legal/lifecycle/#calendar. Please consider upgrading to a recent version. Further updates to the content of this manual will be minimal. All formats of this manual will continue to be available until 31 Dec 2010.

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see Section 2.11.1, “Upgrading MySQL”, for information about upgrade procedures and about issues that you should consider before upgrading.

1. **Determine whether MySQL runs and is supported on your platform.** Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation. See Section 2.1.1, “Operating Systems On Which MySQL Is Known To Run”, for details.

2. **Choose which distribution to install.** Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. We also provide public access to our current source tree for those who want to see our most recent developments and help us test new code. To determine which version and type of distribution you should use, see Section 2.1.2, “Choosing Which MySQL Distribution to Install”.

3. **Download the distribution that you want to install.** For instructions, see Section 2.1.3, “How to Get MySQL”. To verify the integrity of the distribution, use the instructions in Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.

4. **Install the distribution.** To install MySQL from a binary distribution, use the instructions in Section 2.2, “Standard MySQL Installation from a Binary Distribution”. To install MySQL from a source distribution or from the current development source tree, use the instructions in Section 2.9, “Installing MySQL from Source”.

   If you encounter installation difficulties, see Section 2.12, “Operating System-Specific Notes”, for information on solving problems for particular platforms.

5. **Perform any necessary postinstallation setup.** After installing MySQL, read Section 2.10, “Postinstallation Setup and Testing”. This section contains important information about making sure the MySQL server is working properly. It also describes how to secure the initial MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See Section 2.14, “Perl Installation Notes”.

2.1 General Installation Guidance

Before installing MySQL, you should do the following:

1. Determine whether MySQL runs on your platform.
2. Choose a distribution to install.
3. Download the distribution and verify its integrity.

This section contains the information necessary to carry out these steps. After doing so, you can use the instructions in later sections of the chapter to install the distribution that you choose.

2.1.1 Operating Systems On Which MySQL Is Known To Run

This section lists the operating systems on which MySQL is known to run.

Important

Oracle Corporation does not necessarily provide official support for all the platforms listed in this section. For information about those platforms that are officially supported, see http://www.mysql.com/support/supportedplatforms/database.html on the MySQL Web site.

We use GNU Autoconf, so it is possible to port MySQL to all modern systems that have a C++ compiler and a working implementation of POSIX threads. (Thread support is needed for the server. To compile only the client code, the only requirement is a C++ compiler.)

MySQL has been reported to compile successfully on the following combinations of operating system and thread package.

- AIX 4.x, 5.x with native threads. See Section 2.12.5.3, “IBM-AIX notes”.
- Amiga.
- FreeBSD 5.x and up with native threads.
- HP-UX 11.x with the native threads. See Section 2.12.5.2, “HP-UX Version 11.x Notes”.
- Linux, builds on all fairly recent Linux distributions with `glibc` 2.3. See Section 2.12.1, “Linux Notes”.
- Mac OS X. See Section 2.5, “Installing MySQL on Mac OS X”.
- NetBSD 1.3/1.4 Intel and NetBSD 1.3 Alpha. See Section 2.12.4.2, “NetBSD Notes”.
- Novell NetWare 6.0 and 6.5. See Section 2.7, “Installing MySQL on NetWare”.
- OpenBSD 2.5 and with native threads. OpenBSD earlier than 2.5 with the MIT-pthreads package. See Section 2.12.4.3, “OpenBSD 2.5 Notes”.
- SCO OpenServer 5.0.X with a recent port of the FSU Pthreads package. See Section 2.12.5.8, “SCO UNIX and OpenServer 5.0.x Notes”.
- SCO Openserver 6.0.x. See Section 2.12.5.9, “SCO OpenServer 6.0.x Notes”.
- SCO UnixWare 7.1.x. See Section 2.12.5.10, “SCO UnixWare 7.1.x and OpenUNIX 8.0.0 Notes”.
- SGI Irix 6.x with native threads. See Section 2.12.5.7, “SGI Irix Notes”.
- Solaris 2.5 and above with native threads on SPARC and x86. See Section 2.12.3, “Solaris Notes”.

- Tru64 Unix. See Section 2.12.5.5, “Alpha-DEC-UNIX Notes (Tru64)”.
- Windows 9x, Me, NT, 2000, XP, and Windows Server 2003. See Section 2.3, “Installing MySQL on Microsoft Windows”.

MySQL has also been known to run on other systems in the past. See Section 2.12, “Operating System-Specific Notes”. Some porting effort might be required for current versions of MySQL on these systems.

Not all platforms are equally well-suited for running MySQL. How well a certain platform is suited for a high-load mission-critical MySQL server is determined by the following factors:

- General stability of the thread library. A platform may have an excellent reputation otherwise, but MySQL is only as stable as the thread library it calls, even if everything else is perfect.
- The capability of the kernel and the thread library to take advantage of symmetric multi-processor (SMP) systems. In other words, when a process creates a thread, it should be possible for that thread to run on a CPU different from the original process.
- The capability of the kernel and the thread library to run many threads that acquire and release a mutex over a short critical region frequently without excessive context switches. If the implementation of `pthread_mutex_lock()` is too anxious to yield CPU time, this hurts MySQL tremendously. If this issue is not taken care of, adding extra CPUs actually makes MySQL slower.
- General file system stability and performance.
- Table size. If your tables are large, performance is affected by the ability of the file system to deal with large files at all and to deal with them efficiently.
- Our level of expertise here at Oracle Corporation with the platform. If we know a platform well, we enable platform-specific optimizations and fixes at compile time. We can also provide advice on configuring your system optimally for MySQL.
- The amount of testing we have done internally for similar configurations.
- The number of users that have run MySQL successfully on the platform in similar configurations. If this number is high, the likelihood of encountering platform-specific surprises is much smaller.

2.1.2 Choosing Which MySQL Distribution to Install

When preparing to install MySQL, you should decide which version to use. MySQL development occurs in several release series, and you can pick the one that best fits your needs. After deciding which version to install, you can choose a distribution format. Releases are available in binary or source format.

2.1.2.1 Choosing Which Version of MySQL to Install

The first decision to make is whether you want to use a production (stable) release or a development release. In the MySQL development process, multiple release series co-exist, each at a different stage of maturity.

Production Releases

- MySQL 5.6: Latest General Availability (Production) release
- MySQL 5.5: Previous General Availability (Production) release
- MySQL 5.1: Older General Availability (Production) release
- MySQL 5.0: Older Production release nearing the end of the product lifecycle

MySQL 4.1, 4.0, and 3.23 are old releases that are no longer supported.

See http://www.mysql.com/about/legal/lifecycle/ for information about support policies and schedules.

Normally, if you are beginning to use MySQL for the first time or trying to port it to some system for which there is no binary distribution, use the most recent General Availability series listed in the preceding descriptions. All MySQL releases, even those from development series, are checked with the MySQL benchmarks and an extensive test suite before being issued.

If you are running an older system and want to upgrade, but do not want to take the chance of having a nonseamless upgrade, you should upgrade to the latest version in the same release series you are using (where only the last part of the version number is newer than yours). We have tried to fix only fatal bugs and make only small, relatively “safe” changes to that version.

If you want to use new features not present in the production release series, you can use a version from a development series. Be aware that development releases are not as stable as production releases.

We do not use a complete code freeze because this prevents us from making bugfixes and other fixes that must be done. We may add small things that should not affect anything that currently works in a production release. Naturally, relevant bugfixes from an earlier series propagate to later series.

If you want to use the very latest sources containing all current patches and bugfixes, you can use one of our source code repositories (see Section 2.9.2, “Installing MySQL from a Development Source Tree”). These are not “releases” as such, but are available as previews of the code on which future releases are to be based.

The naming scheme in MySQL 4.1 uses release names that consist of three numbers and a suffix; for example, `mysql-4.1.2-alpha`. The numbers within the release name are interpreted like this:

- The first number (4) is the major version and also describes the file format. All version 4 releases have the same file format.
- The second number (1) is the release level. Taken together, the major version and release level constitute the release series number.
- The third number (2) is the version number within the release series. This is incremented for each new release. Usually you want the latest version for the series you have chosen.

For each minor update, the last number in the version string is incremented. When there are major new features or minor incompatibilities with previous versions, the second number in the version string is incremented. When the file format changes, the first number is increased.

Release names also include a suffix to indicates the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **alpha** indicates that the release is for preview purposes only. Known bugs should be documented in the News section (see Appendix C, *MySQL Release Notes*). Most alpha releases implement new commands and extensions. Active development that may involve major code changes can occur in an alpha release. However, we do conduct testing before issuing a release.
- **beta** indicates that the release is appropriate for use with new development. Within beta releases, the features and compatibility should remain consistent. However, beta releases may contain numerous and major unaddressed bugs.

  All APIs, externally visible structures, and columns for SQL statements will not change during future beta, release candidate, or production releases.
- **rc** indicates a Release Candidate. Release candidates are believed to be stable, having passed all of MySQL's internal testing, and with all known fatal runtime bugs fixed. However, the release has not been

in widespread use long enough to know for sure that all bugs have been identified. Only minor fixes are added. (A release candidate is what formerly was known as a gamma release.)

- If there is no suffix, it indicates that the release is a General Availability (GA) or Production release. GA releases are stable, having successfully passed through all earlier release stages and are believed to be reliable, free of serious bugs, and suitable for use in production systems. Only critical bugfixes are applied to the release.

All releases of MySQL are run through our standard tests and benchmarks to ensure that they are relatively safe to use. Because the standard tests are extended over time to check for all previously found bugs, the test suite keeps getting better.

All releases have been tested at least with these tools:

- **An internal test suite.** The `mysql-test` directory contains an extensive set of test cases. We run these tests for every server binary. See Section 18.1.2, “The MySQL Test Suite”, for more information about this test suite.
- **The MySQL benchmark suite.** This suite runs a range of common queries. It is also a test to determine whether the latest batch of optimizations actually made the code faster. See Section 7.1.3, “The MySQL Benchmark Suite”.
- **The `crash-me` test.** This test tries to determine what features the database supports and what its capabilities and limitations are. See Section 7.1.3, “The MySQL Benchmark Suite”.

2.1.2.2 Choosing a Distribution Format

After choosing which version of MySQL to install, you should decide whether to use a binary distribution or a source distribution. In most cases, you should probably use a binary distribution, if one exists for your platform. Binary distributions are available in native format for many platforms, such as RPM packages for Linux, DMG packages for Mac OS X, and PKG packages for Solaris. Distributions are also available in more generic formats such as Zip archives or compressed `tar` files.

Reasons to choose a binary distribution include the following:

- Binary distributions generally are easier to install than source distributions.
- To satisfy different user requirements, we provide two different binary versions. One is compiled with the core feature set. The other (MySQL-Max) is compiled with an extended feature set. Both versions are compiled from the same source distribution. All native MySQL clients can connect to servers from either MySQL version.

  The extended MySQL binary distribution is identified by the `-max` suffix and is configured with the same options as `mysqld-max`. See Section 5.2, “The `mysqld-max` Extended MySQL Server”.

  For RPM distributions, if you want to use the `MySQL-Max` RPM, you must first install the standard `MySQL-server` RPM.

Under some circumstances, you may be better off installing MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` to ensure that features are available that might not be included in the standard binary distributions. Here is a list of the most common extra options that you may want to use to ensure feature availability:

- `--with-berkeley-db` (not available on all platforms)
- `--with-raid`
- `--with-libwrap`
- `--with-named-z-libs` (this is done for some of the binaries)
- `--with-debug[=full]` [98]

- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.
- You want to use the latest sources from one of the Bazaar repositories to have access to all current bugfixes. For example, if you have found a bug and reported it to the MySQL development team, the bugfix is committed to the source repository and you can access it there. The bugfix does not appear in a release until a release actually is issued.
- You want to read (or modify) the C and C++ code that makes up MySQL. For this purpose, you should get a source distribution, because the source code is always the ultimate manual.
- Source distributions contain more tests and examples than binary distributions.

2.1.2.3 How and When Updates Are Released

MySQL is evolving quite rapidly and we want to share new developments with other MySQL users. We try to produce a new release whenever we have new and useful features that others also seem to have a need for.

We also try to help users who request features that are easy to implement. We take note of what our licensed users want, and we especially take note of what our support customers want and try to help them in this regard.

No one is *required* to download a new release. The News section helps you determine whether the new release has something you really want. See Appendix C, *MySQL Release Notes*.

We use the following policy when updating MySQL:

- Releases are issued within each series. For each release, the last number in the version is one more than the previous release within the same series.
- Production (stable) releases are meant to appear about 1-2 times a year. However, if small bugs are found, a release with only bugfixes is issued.
- Working releases/bugfixes to old releases are meant to appear about every 4-8 weeks.
- Binary distributions for some platforms are made by us for major releases. Other people may make binary distributions for other systems, but probably less frequently.
- We make fixes available as soon as we have identified and corrected small or noncritical but annoying bugs. The fixes are available immediately from our public Bazaar repositories, and are included in the next release.
- If by any chance a fatal bug is found in a release, our policy is to fix it in a new release as soon as possible. (We would like other companies to do this, too!)

2.1.2.4 MySQL Binaries Compiled by Oracle Corporation

Oracle Corporation provides a set of binary distributions of MySQL. In addition to binaries provided in platform-specific package formats, we offer binary distributions for a number of platforms in the form of compressed `tar` files (`.tar.gz` files). See Section 2.2, “Standard MySQL Installation from a Binary Distribution”. For Windows distributions, see Section 2.3, “Installing MySQL on Microsoft Windows”.

If you want to compile MySQL from a source distribution, see Section 2.9, “Installing MySQL from Source”. To compile a debug version of MySQL, see Section 2.9.3, “MySQL Source-Configuration Options” for options that enable debugging.

2.1.3 How to Get MySQL

Check our downloads page at http://dev.mysql.com/downloads/ for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see http://dev.mysql.com/downloads/mirrors.html. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

To obtain the latest development source, see Section 2.9.2, “Installing MySQL from a Development Source Tree”.

2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG

After you have downloaded the MySQL package that suits your needs and before you attempt to install it, you should make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using `GnuPG`, the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site. If you repeatedly cannot successfully verify the integrity of the package, please notify us about such incidents, including the full package name and the download site you have been using, at `<webmaster@mysql.com>` or `<build@mysql.com>`. Do not report downloading problems using the bug-reporting system.

2.1.4.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify with the following command, where *`package_name`* is the name of the package you downloaded:

```
shell> md5sum package_name
```

Example:

```
shell> md5sum mysql-standard-4.0.17-pc-linux-i686.tar.gz
60f5fe969d61c8f82e4f7f62657e1f06  mysql-standard-4.0.17-pc-linux-i686.tar.gz
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

Note

Make sure to verify the checksum of the *archive file* (for example, the `.zip` or `.tar.gz` file) and not of the files that are contained inside of the archive.

Note that not all operating systems support the `md5sum` command. On some, it is simply called `md5`, and others do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can download the source code from http://www.gnu.org/software/textutils/ as well. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the `md5` command line utility is available from http://www.fourmilab.ch/md5/. `winMd5Sum` is a graphical MD5 checking tool that can be obtained from http://www.nullriver.com/index/products/winmd5sum.

2.1.4.2 Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

Beginning with MySQL 4.0.10 (February 2003), we started signing downloadable packages with `GnuPG` (`GNU Privacy Guard`). `GnuPG` is an Open Source alternative to the very well-known `Pretty Good Privacy` (`PGP`) by Phil Zimmermann. See http://www.gnupg.org/ for more information about `GnuPG` and how to obtain and install it on your system. Most Linux distributions ship with `GnuPG` installed by default. For more information about `OpenPGP`, see http://www.openpgp.org/.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from http://keyserver.pgp.com/. The key that you want to obtain is named `build@mysql.com`. Alternatively, you can cut and paste the key directly from the following text:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.4.5 (GNU/Linux)

=Mski
```

```
-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
gpg: key 5072E1F5: public key "MySQL Package signing key (www.mysql.com) <build@mysql.com>" imported
gpg: Total number processed: 1
gpg:               imported: 1
gpg: no ultimately trusted keys found
```

You can also download the key from the public keyserver using the public key id, `5072E1F5`:

```
shell> gpg --recv-keys 5072E1F5
gpg: requesting key 5072E1F5 from hkp server subkeys.pgp.net
gpg: key 5072E1F5: "MySQL Package signing key (www.mysql.com) <build@mysql.com>" 2 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg:         new signatures: 2
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> rpm --import mysql_pubkey.asc
```

If you experience problems, try exporting the key from `gpg` and importing:

```
shell> gpg --export -a 5072e1f5 > 5072e1f5.asc
shell> rpm --import 5072e1f5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you cas use this manual page:

```
shell> rpm --import http://dev.mysql.com/doc/refman/4.1/en/checking-gpg-signature.html
```

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension. For example:

File Type	File Name
Distribution file	`mysql-standard-4.0.17-pc-linux-i686.tar.gz`
Signature file	`mysql-standard-4.0.17-pc-linux-i686.tar.gz.asc`

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

Example:

```
shell> gpg --verify mysql-standard-4.0.17-pc-linux-i686.tar.gz.asc
gpg: Warning: using insecure memory!
gpg: Signature made Mon 03 Feb 2003 08:50:39 PM MET
using DSA key ID 5072E1F5
gpg: Good signature from
     "MySQL Package signing key (www.mysql.com) <build@mysql.com>"
```

The `Good signature` message indicates that everything is all right. You can ignore any `insecure memory` warning you might obtain.

See the GPG documentation for more information on how to work with public keys.

2.1.4.3 Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-4.1.25-0.glibc23.i386.rpm
MySQL-server-4.1.25-0.glibc23.i386.rpm: md5 gpg OK
```

Note

If you are using RPM 4.1 and it complains about `(GPG) NOT OK (MISSING KEYS: GPG#5072e1f5)`, even though you have imported the MySQL public build key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, it maintains its own keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key as described in Section 2.1.4.2, “Signature Checking Using GnuPG”. Then use `rpm --import` to import the key. For example, if you have saved the public key in a file named `mysql_pubkey.asc`, import it using this command:

```
shell> rpm --import mysql_pubkey.asc
```

If you need to obtain the MySQL public key, see Section 2.1.4.2, “Signature Checking Using GnuPG”.

2.1.5 Installation Layouts

This section describes the default layout of the directories created by installing binary or source distributions provided by Oracle Corporation. A distribution provided by another vendor might use a layout different from those shown here.

On Windows, the default installation directory is `C:\mysql`. With MySQL version 4.1.5 and higher, this has changed to `C:\Program Files\MySQL\MySQL Server 4.1`, where 4.1 is the major version of the installation. The folder has the following subdirectories:

Table 2.1 MySQL Installation Layout for Windows

Directory	Contents of Directory
`bin`	Client programs and the `mysqld` server
`data`	Log files, databases
`examples`	Example programs and scripts
`include`	Include (header) files
`lib`	Libraries
`scripts`	Utility scripts
`share`	Error message and character set files

Installations created from our Linux RPM distributions result in files under the following system directories:

Table 2.2 MySQL Installation Layout for Linux RPM

Directory	Contents of Directory
`/usr/bin`	Client programs and scripts
`/usr/sbin`	The `mysqld` server
`/var/lib/mysql`	Log files, databases
`/usr/share/info`	Manual in Info format
`/usr/share/man`	Unix manual pages
`/usr/include/mysql`	Include (header) files
`/usr/lib/mysql`	Libraries
`/usr/share/mysql`	Error message and character set files
`/usr/share/sql-bench`	Benchmarks

On Unix, a `tar` file binary distribution is installed by unpacking it at the installation location you choose (typically `/usr/local/mysql`) and creates the following directories in that location:

Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package

Directory	Contents of Directory
`bin`	Client programs and the `mysqld` server
`data`	Log files, databases
`docs`	Manual in Info format
`man`	Unix manual pages
`include`	Include (header) files
`lib`	Libraries
`scripts`	`mysql_install_db`
`share/mysql`	Error message and character set files
`sql-bench`	Benchmarks

By default, when you install MySQL after compiling it from a source distribution, the installation step installs files under `/usr/local`. Components are installed in the directories shown in the following table. To configure particular installation locations, use the options described at Section 2.9.3, “MySQL Source-Configuration Options”.

Table 2.4 MySQL Layout for Installation from Source

Directory	Contents of Directory
`bin`	Client programs and scripts
`include/mysql`	Include (header) files
`Docs`	Manual in Info format
`man`	Unix manual pages
`lib/mysql`	Libraries
`libexec`	The `mysqld` server
`share/mysql`	Error message and character set files
`sql-bench`	Benchmarks
`var`	Log files, databases

Within its installation directory, the layout of a source installation differs from that of a binary installation in the following ways:

- The `mysqld` server is installed in the `libexec` directory rather than in the `bin` directory.
- The data directory is `var` rather than `data`.
- `mysql_install_db` is installed in the `bin` directory rather than in the `scripts` directory.
- The header file and library directories are `include/mysql` and `lib/mysql` rather than `include` and `lib`.

To create your own binary installation from a compiled source distribution, execute the `scripts/make_binary_distribution` script from the top directory of the source distribution.

2.1.6 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

`icc` (Intel C++ Compiler) Builds

A server built with `icc` has these characteristics:

- SSL support is not included.

2.2 Standard MySQL Installation from a Binary Distribution

The next several sections cover the installation of MySQL on platforms where we offer packages using the native packaging format of the respective platform. (This is also known as performing a “binary install.”) However, binary distributions of MySQL are available for many other platforms as well. See Section 2.8, “Installing MySQL from Generic Binaries on Other Unix-Like Systems”, for generic installation instructions for these packages that apply to all platforms.

See Section 2.1, “General Installation Guidance”, for more information on what other binary distributions are available and how to obtain them.

2.3 Installing MySQL on Microsoft Windows

A native Windows distribution of MySQL has been available since version 3.21 and represents a sizable percentage of the daily downloads of MySQL. This section describes the process for installing MySQL on Windows.

MySQL 4.1.5 introduced a new installer for the Windows version of MySQL, combined with a new GUI Configuration Wizard. This combination automatically installs MySQL, creates an option file, starts the server, and secures the default user accounts.

Note

If you are upgrading MySQL from an existing installation older than MySQL 4.1.5, you must first perform the procedure described in Section 2.3.14, “Upgrading MySQL on Windows”.

To run MySQL on Windows, you need the following:

- A 32-bit Windows operating system such as 9x, Me, NT, 2000, XP, Vista, or Windows Server 2003.

  A Windows NT-based operating system (NT, 2000, XP, Vista, 2003) permits you to run the MySQL server as a service. The use of a Windows NT-based operating system is strongly recommended. See Section 2.3.11, “Starting MySQL as a Windows Service”.

  Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the `Service Control Manager`.

- TCP/IP protocol support.

- Enough space on the hard drive to unpack, install, and create the databases in accordance with your requirements (generally a minimum of 200 megabytes is recommended.)

For a list of limitations within the Windows version of MySQL, see Section D.3.3, “Windows Platform Limitations”.

There may also be other requirements, depending on how you plan to use MySQL:

- If you plan to connect to the MySQL server using ODBC, you need a Connector/ODBC driver. See Chapter 17, *Connectors and APIs*.

- If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See Section 12.1.5, “`CREATE TABLE` Syntax”.

MySQL for Windows is available in several distribution formats:

- Binary distributions are available that contain a setup program that installs everything you need so that you can start the server immediately. Another binary distribution format contains an archive that you simply unpack in the installation location and then configure yourself. For details, see Section 2.3.1, “Choosing An Installation Package”.

- The source distribution contains all the code and support files for building the executables using the Visual Studio 7.1 compiler system.

Generally speaking, you should use a binary distribution that includes an installer. It is simpler to use than the others, and you need no additional tools to get MySQL up and running. The installer for the Windows version of MySQL, combined with a GUI Configuration Wizard, automatically installs MySQL, creates an option file, starts the server, and secures the default user accounts.

The following section describes how to install MySQL on Windows using a binary distribution. To use an installation package that does not include an installer, follow the procedure described in Section 2.3.5, “Installing MySQL from a Noinstall Zip Archive”. To install using a source distribution, see Section 2.9.7, “Installing MySQL from Source on Windows”.

MySQL distributions for Windows can be downloaded from http://dev.mysql.com/downloads/. See Section 2.1.3, “How to Get MySQL”.

2.3.1 Choosing An Installation Package

Starting with MySQL version 4.1.5, there are three install packages to choose from when installing MySQL on Windows. The Packages are as follows:

- **The Essentials Package**: This package has a file name similar to `mysql-essential-4.1.13a-win32.msi` and contains the minimum set of files needed to install MySQL on Windows, including the

Configuration Wizard. This package does not include optional components such as the embedded server and benchmark suite.

- **The Complete Package**: This package has a file name similar to `mysql-4.1.13a-win32.zip` and contains all files needed for a complete Windows installation, including the Configuration Wizard. This package includes optional components such as the embedded server and benchmark suite.
- **The Noinstall Archive**: This package has a file name similar to `mysql-noinstall-4.1.13a-win32.zip` and contains all the files found in the Complete install package, with the exception of the Configuration Wizard. This package does not include an automated installer, and must be manually installed and configured.

The Essentials package is recommended for most users. It is provided as an `.msi` file for use with the Windows Installer. The Complete and Noinstall distributions are packaged as Zip archives. To use them, you must have a tool that can unpack `.zip` files.

Your choice of install package affects the installation process you must follow. If you choose to install either the Essentials or Complete install packages, see Section 2.3.2, “Installing MySQL with the Automated Installer”. If you choose to install MySQL from the Noinstall archive, see Section 2.3.5, “Installing MySQL from a Noinstall Zip Archive”.

2.3.2 Installing MySQL with the Automated Installer

Starting with MySQL 4.1.5, users can use the new MySQL Installation Wizard and MySQL Configuration Wizard to install MySQL on Windows. The MySQL Installation Wizard and MySQL Configuration Wizard are designed to install and configure MySQL in such a way that new users can immediately get started using MySQL.

The MySQL Installation Wizard and MySQL Configuration Wizard are available in the Essentials and Complete install packages. They are recommended for most standard MySQL installations. Exceptions include users who need to install multiple instances of MySQL on a single server host and advanced users who want complete control of server configuration.

If you are installing a version of MySQL prior to MySQL 4.1.5, please follow the instructions for installing MySQL from the Noinstall installation package. See Section 2.3.5, “Installing MySQL from a Noinstall Zip Archive”.

2.3.3 Using the MySQL Installation Wizard

2.3.3.1 Introduction to the Installation Wizard

MySQL Installation Wizard is an installer for the MySQL server that uses the latest installer technologies for Microsoft Windows. The MySQL Installation Wizard, in combination with the MySQL Configuration Wizard, enables a user to install and configure a MySQL server that is ready for use immediately after installation.

The MySQL Installation Wizard is the standard installer for all MySQL server distributions, version 4.1.5 and higher. Users of previous versions of MySQL need to shut down and remove their existing MySQL installations manually before installing MySQL with the MySQL Installation Wizard. See Section 2.3.3.7, “Upgrading MySQL with the Installation Wizard”, for more information on upgrading from a previous version.

Microsoft has included an improved version of their Microsoft Windows Installer (MSI) in the recent versions of Windows. MSI has become the de-facto standard for application installations on Windows 2000, Windows XP, and Windows Server 2003. The MySQL Installation Wizard makes use of this technology to provide a smoother and more flexible installation process.

The Microsoft Windows Installer Engine was updated with the release of Windows XP; those using a previous version of Windows can reference this Microsoft Knowledge Base article for information on upgrading to the latest version of the Windows Installer Engine.

In addition, Microsoft has introduced the WiX (Windows Installer XML) toolkit recently. This is the first highly acknowledged Open Source project from Microsoft. We have switched to WiX because it is an Open Source project and it enables us to handle the complete Windows installation process in a flexible manner using scripts.

Improving the MySQL Installation Wizard depends on the support and feedback of users like you. If you find that the MySQL Installation Wizard is lacking some feature important to you, or if you discover a bug, please report it in our bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”.

2.3.3.2 Downloading and Starting the MySQL Installation Wizard

The MySQL installation packages can be downloaded from http://dev.mysql.com/downloads/. If the package you download is contained within a Zip archive, you need to extract the archive first.

Note

If you are installing on Windows Vista it is best to open a port before beginning the installation. To do this first ensure that you are logged in as an administrator, go to the `Control Panel`, and double-click the `Windows Firewall` icon. Choose the `Allow a program through Windows Firewall` option and click the Add port button. Enter `MySQL` into the **Name** text box and `3306` (or the port of your choice) into the **Port number** text box. Also ensure that the **TCP** protocol radio button is selected. If you wish, you can also limit access to the MySQL server by choosing the **Change scope** button. Confirm your choices by clicking the OK button. If you do not open a port prior to installation, you cannot configure the MySQL server immediately after installation. Additionally, when running the MySQL Installation Wizard on Windows Vista, ensure that you are logged in as a user with administrative rights.

The process for starting the wizard depends on the contents of the installation package you download. If there is a `setup.exe` file present, double-click it to start the installation process. If there is an `.msi` file present, double-click it to start the installation process.

2.3.3.3 Choosing an Install Type

There are three installation types available: **Typical**, **Complete**, and **Custom**.

The **Typical** installation type installs the MySQL server, the `mysql` command-line client, and the command-line utilities. The command-line clients and utilities include `mysqldump`, `myisamchk`, and several other tools to help you manage the MySQL server.

The **Complete** installation type installs all components included in the installation package. The full installation package includes components such as the embedded server library, the benchmark suite, support scripts, and documentation.

The **Custom** installation type gives you complete control over which packages you wish to install and the installation path that is used. See Section 2.3.3.4, “The Custom Install Dialog”, for more information on performing a custom install.

If you choose the **Typical** or **Complete** installation types and click the Next button, you advance to the confirmation screen to verify your choices and begin the installation. If you choose the **Custom** installation

type and click the Next button, you advance to the custom installation dialog, described in Section 2.3.3.4, “The Custom Install Dialog”.

2.3.3.4 The Custom Install Dialog

If you wish to change the installation path or the specific components that are installed by the MySQL Installation Wizard, choose the **Custom** installation type.

A tree view on the left side of the custom install dialog lists all available components. Components that are not installed have a red X icon; components that are installed have a gray icon. To change whether a component is installed, click that component's icon and choose a new option from the drop-down list that appears.

You can change the default installation path by clicking the Change... button to the right of the displayed installation path.

After choosing your installation components and installation path, click the Next button to advance to the confirmation dialog.

2.3.3.5 The Confirmation Dialog

Once you choose an installation type and optionally choose your installation components, you advance to the confirmation dialog. Your installation type and installation path are displayed for you to review.

To install MySQL if you are satisfied with your settings, click the Install button. To change your settings, click the Back button. To exit the MySQL Installation Wizard without installing MySQL, click the Cancel button.

After installation is complete, you have the option of registering with the MySQL Web site. Registration gives you access to post in the MySQL forums at forums.mysql.com, along with the ability to report bugs at bugs.mysql.com and to subscribe to our newsletter. The final screen of the installer provides a summary of the installation and gives you the option to launch the MySQL Configuration Wizard, which you can use to create a configuration file, install the MySQL service, and configure security settings.

2.3.3.6 Changes Made by MySQL Installation Wizard

Once you click the Install button, the MySQL Installation Wizard begins the installation process and makes certain changes to your system which are described in the sections that follow.

Changes to the Registry

The MySQL Installation Wizard creates one Windows registry key in a typical install situation, located in `HKEY_LOCAL_MACHINE\SOFTWARE\MySQL AB`.

The MySQL Installation Wizard creates a key named after the major version of the server that is being installed, such as `MySQL Server 4.1`. It contains two string values, `Location` and `Version`. The `Location` string contains the path to the installation directory. In a default installation it contains `C:\Program Files\MySQL\MySQL Server 4.1\`. The `Version` string contains the release number. For example, for an installation of MySQL Server 4.1.5, the key contains a value of `4.1.5`.

These registry keys are used to help external tools identify the installed location of the MySQL server, preventing a complete scan of the hard-disk to determine the installation path of the MySQL server. The registry keys are not required to run the server, and if you install MySQL using the `noinstall` Zip archive, the registry keys are not created.

Changes to the Start Menu

The MySQL Installation Wizard creates a new entry in the Windows Start menu under a common MySQL menu heading named after the major version of MySQL that you have installed. For example, if you install MySQL 4.1, the MySQL Installation Wizard creates a MySQL Server 4.1 section in the start menu.

The following entries are created within the new Start menu section:

- MySQL Command Line Client: This is a shortcut to the `mysql` command-line client and is configured to connect as the `root` user. The shortcut prompts for a `root` user password when you connect.
- MySQL Server Instance Config Wizard: This is a shortcut to the MySQL Configuration Wizard. Use this shortcut to configure a newly installed server, or to reconfigure an existing server.
- MySQL Documentation: This is a link to the MySQL server documentation that is stored locally in the MySQL server installation directory. This option is not available when the MySQL server is installed from the Essentials installation package.

Changes to the File System

The MySQL Installation Wizard by default installs the MySQL server to `C:\Program Files\MySQL\MySQL Server 4.1`, where `Program Files` is the default location for applications in your system, and `4.1` is the major version of your MySQL server. This is the new location for the MySQL server, replacing the former default location of `c:\mysql`.

By default, all MySQL applications are stored in a common directory at `C:\Program Files\MySQL`, where `Program Files` is the default location for applications in your Windows installation. A typical MySQL installation on a developer machine might look like this:

```
C:\Program Files\MySQL\MySQL Server 4.1
C:\Program Files\MySQL\MySQL Workbench 5.1 OSS
```

This approach makes it easier to manage and maintain all MySQL applications installed on a particular system.

2.3.3.7 Upgrading MySQL with the Installation Wizard

From MySQL version 4.1.5, the new MySQL Installation Wizard can perform server upgrades automatically using the upgrade capabilities of MSI. That means you do not need to remove a previous installation manually before installing a new release. The installer automatically shuts down and removes the previous MySQL service before installing the new version.

Automatic upgrades are available only when upgrading between installations that have the same major and minor version numbers. For example, you can upgrade automatically from MySQL 4.1.5 to MySQL 4.1.6, but not from MySQL 4.1 to MySQL 5.0.

If you are upgrading MySQL version 4.1.4 or earlier to version 4.1.5 or later, you must first manually shut down and remove the older installation before upgrading. Be sure to back up your databases before performing such an upgrade, so that you can restore the databases after the upgrade is completed. It is always recommended that you back up your data before performing any upgrades.

See Section 2.3.14, “Upgrading MySQL on Windows”.

2.3.4 Using the Configuration Wizard

2.3.4.1 Introduction to the Configuration Wizard

The MySQL Configuration Wizard helps automate the process of configuring your server under Windows. The MySQL Configuration Wizard creates a custom `my.ini` file by asking you a series of questions and then applying your responses to a template to generate a `my.ini` file that is tuned to your installation.

The MySQL Configuration Wizard is included with the MySQL server starting with MySQL version 4.1.5, but is designed to work with MySQL servers versions 4.1 and higher. The MySQL Configuration Wizard is currently available for Windows users only.

The MySQL Configuration Wizard is to a large extent the result of feedback that we have received from many users over a period of several years. However, if you find that it lacks some feature important to you, please report it in our bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”.

2.3.4.2 Starting the MySQL Configuration Wizard

The MySQL Configuration Wizard is typically launched from the MySQL Installation Wizard, as the MySQL Installation Wizard exits. You can also launch the MySQL Configuration Wizard by clicking the MySQL Server Instance Config Wizard entry in the MySQL section of the Windows Start menu.

Alternatively, you can navigate to the `bin` directory of your MySQL installation and launch the `MySQLInstanceConfig.exe` file directly.

Note

If you chose not to open a port prior to installing MySQL on Windows Vista, you can choose to use the MySQL Server Configuration Wizard after installation. However, you must open a port in the Windows Firewall. To do this see the instructions given in Section 2.3.3.2, “Downloading and Starting the MySQL Installation Wizard”. Rather than opening a port, you also have the option of adding MySQL as a program that bypasses the Windows Firewall. One or the other option is sufficient—you need not do both. Additionally, when running the MySQL Server Configuration Wizard on Windows Vista ensure that you are logged in as a user with administrative rights.

2.3.4.3 Choosing a Maintenance Option

If the MySQL Configuration Wizard detects an existing `my.ini` file, you have the option of either reconfiguring your existing server, or removing the server instance by deleting the `my.ini` file and stopping and removing the MySQL service.

To reconfigure an existing server, choose the Re-configure Instance option and click the Next button. Your existing `my.ini` file is renamed to `my`*`timestamp`*`.ini.bak`, where *`timestamp`* is the date and time at which the existing `my.ini` file was created. To remove the existing server instance, choose the Remove Instance option and click the Next button.

If you choose the Remove Instance option, you advance to a confirmation window. Click the Execute button. The MySQL Configuration Wizard stops and removes the MySQL service, and then deletes the `my.ini` file. The server installation and its `data` folder are not removed.

If you choose the Re-configure Instance option, you advance to the Configuration Type dialog where you can choose the type of installation that you wish to configure.

2.3.4.4 Choosing a Configuration Type

When you start the MySQL Configuration Wizard for a new MySQL installation, or choose the Re-configure Instance option for an existing installation, you advance to the Configuration Type dialog.

There are two configuration types available: Detailed Configuration and Standard Configuration. The Standard Configuration option is intended for new users who want to get started with MySQL quickly without having to make a lot of decisions about server configuration. The `Detailed Configuration` option is intended for advanced users who want more fine-grained control of server configuration.

If you are new to MySQL and need a server configured as a single-user developer machine, the Standard Configuration should suit your needs. Choosing the Standard Configuration option causes the MySQL Configuration Wizard to automatically set all configuration options with the exception of the `Service Options` and `Security Options`.

The `Standard Configuration` sets options that may be incompatible with systems where there are existing MySQL installations. If you have an existing MySQL installation on your system in addition to the installation you wish to configure, the `Detailed Configuration` option is recommended.

To complete the Standard Configuration, please refer to the sections on Service Options and Security Options in Section 2.3.4.11, “The Service Options Dialog”, and Section 2.3.4.12, “The Security Options Dialog”, respectively.

2.3.4.5 The Server Type Dialog

There are three different server types available to choose from. The server type that you choose affects the decisions that the MySQL Configuration Wizard makes with regard to memory, disk, and processor usage.

- Developer Machine: Choose this option for a typical desktop workstation where MySQL is intended only for personal use. It is assumed that many other desktop applications are running. The MySQL server is configured to use minimal system resources.
- Server Machine: Choose this option for a server machine where the MySQL server is running alongside other server applications such as FTP, email, and Web servers. The MySQL server is configured to use a medium portion of the system resources.
- Dedicated MySQL Server Machine: Choose this option for a server machine that is intended to run only the MySQL server. It is assumed that no other applications are running. The MySQL server is configured to use all available system resources.

Note

By selecting one of the preconfigured configurations, the values and settings of various options in your `my.cnf` or `my.ini` will be altered accordingly. The default values and options as described in the reference manual may therefore be different to the options and values that were created during the execution of the configuration wizard.

2.3.4.6 The Database Usage Dialog

The Database Usage dialog enables you to indicate the storage engines that you expect to use when creating MySQL tables. The option you choose determines whether the `InnoDB` storage engine is available and what percentage of the server resources are available to `InnoDB`.

- Multifunctional Database: This option enables both the `InnoDB` and `MyISAM` storage engines, and divides resources evenly between the two. This option is recommended for users who use both table handlers on a regular basis.
- Transactional Database Only: This option enables both the `InnoDB` and `MyISAM` storage engines but dedicates most server resources to the `InnoDB` storage engine. This option is recommended for users who use `InnoDB` almost exclusively and make only minimal use of `MyISAM`.
- Non-Transactional Database Only: This option disables the `InnoDB` storage engine completely, and dedicates all server resources to the `MyISAM` storage engine. This option is recommended for users who do not use `InnoDB`.

The Configuration Wizard uses a template to generate the server configuration file. The Database Usage dialog sets one of the following option strings:

```
Multifunctional Database:        MIXED
Transactional Database Only:     INNODB
Non-Transactional Database Only: MYISAM
```

When these options are processed through the default template (my-template.ini) the result is:

```
Multifunctional Database:
default-storage-engine=InnoDB
_myisam_pct=50

Transactional Database Only:
default-storage-engine=InnoDB
_myisam_pct=5

Non-Transactional Database Only:
default-storage-engine=MyISAM
_myisam_pct=100
skip-innodb
```

The `_myisam_pct` value is used to calculate the percentage of resources dedicated to `MyISAM`. The remaining resources are allocated to `InnoDB`.

2.3.4.7 The InnoDB Tablespace Dialog

Some users may want to locate the `InnoDB` tablespace files in a location other than the MySQL server data directory. Placing the tablespace files in a separate location can be desirable if your system has available a storage device availablehas with higher capacity or higher performance, such as a RAID storage system.

To change the default location for the `InnoDB` tablespace files, choose a new drive from the drop-down list of drive letters and choose a new path from the drop-down list of paths. To create a custom path, click the ... button.

If you are modifying the configuration of an existing server, you must click the Modify button before you change the path. In this situation you must move existing tablespace files to the new location manually before starting the server.

2.3.4.8 The Concurrent Connections Dialog

To prevent the server from running out of resources, it is important to limit the number of concurrent connections to the MySQL server that can be established. The Concurrent Connections dialog enables you to choose the expected usage of your server, and sets the limit for concurrent connections accordingly. It is also possible to manually set the concurrent connection limit.

- Decision Support (DSS)/OLAP: Choose this option if the server does not require a large number of concurrent connections. The maximum number of connections is set at 100, with an average of 20 concurrent connections assumed.
- Online Transaction Processing (OLTP): Choose this option if the server requires a large number of concurrent connections. The maximum number of connections is set at 500.
- Manual Setting: Choose this option to set the maximum number of concurrent connections to the server manually. Choose the number of concurrent connections from the drop-down box provided, or type the maximum number of connections into the drop-down box if the number you desire is not listed.

2.3.4.9 The Networking and Strict Mode Options Dialog

Use the Networking Options dialog to enable or disable TCP/IP networking and to configure the port number that is used to connect to the MySQL server.

TCP/IP networking is enabled by default. To disable TCP/IP networking, uncheck the box next to the Enable TCP/IP Networking option.

Port 3306 is used by default. To change the port used to access MySQL, choose a new port number from the drop-down box or type a new port number directly into the drop-down box. If the port number you choose is in use, you are prompted to confirm your choice of port number.

Set the Server SQL Mode to either enable or disable strict mode. Enabling strict mode (default) makes MySQL behave more like other database management systems. *If you run applications that rely on MySQL's old "forgiving" behavior, make sure to either adapt those applications or to disable strict mode.* For more information about strict mode, see Section 5.1.6, "Server SQL Modes".

2.3.4.10 The Character Set Dialog

The MySQL server supports multiple character sets and it is possible to set a default server character set that is applied to all tables, columns, and databases unless overridden. Use the Character Set dialog to change the default character set of the MySQL server.

- Standard Character Set: Choose this option if you want to use `latin1` as the default server character set. `latin1` is used for English and many Western European languages.
- Best Support For Multilingualism: Choose this option if you want to use `utf8` as the default server character set. This is a Unicode character set that can store characters from many different languages.
- Manually Selected Default Character Set / Collation: Choose this option if you want to pick the server's default character set manually. Choose the desired character set from the provided drop-down list.

2.3.4.11 The Service Options Dialog

On Windows NT-based platforms, the MySQL server can be installed as a Windows service. When installed this way, the MySQL server can be started automatically during system startup, and even restarted automatically by Windows in the event of a service failure.

The MySQL Configuration Wizard installs the MySQL server as a service by default, using the service name `MySQL`. If you do not wish to install the service, un-check the box next to the Install As Windows Service option. You can change the service name by picking a new service name from the drop-down box provided or by typing a new service name into the drop-down box.

To install the MySQL server as a service but not have it started automatically at startup, un-check the box next to the Launch the MySQL Server automatically option.

2.3.4.12 The Security Options Dialog

It is strongly recommended that you set a `root` password for your MySQL server, and the MySQL Configuration Wizard requires by default that you do so. If you do not wish to set a `root` password, uncheck the box next to the Modify Security Settings option.

To set the `root` password, enter the desired password into both the New root password and Confirm boxes. If you are reconfiguring an existing server, you need to enter the existing `root` password into the Current root password box.

To prevent `root` logins from across the network, check the box next to the Root may only connect from localhost option. This increases the security of your `root` account.

To create an anonymous user account, check the box next to the Create An Anonymous Account option. Creating an anonymous account can decrease server security and cause login and permission difficulties and is not recommended.

2.3.4.13 The Confirmation Dialog

The final dialog in the MySQL Configuration Wizard is the Confirmation Dialog. To start the configuration process, click the Execute button. To return to a previous dialog, click the Back button. To exit the MySQL Configuration Wizard without configuring the server, click the Cancel button.

After you click the Execute button, the MySQL Configuration Wizard performs a series of tasks and displays the progress onscreen as the tasks are performed.

The MySQL Configuration Wizard firsts determines various configuration file options based on your choices using a template prepared by MySQL developers and engineers. This template is named `my-template.ini` and is located in your server installation directory.

The MySQL Configuration Wizard then writes these options to a `my.ini` file. The final location of the `my.ini` file is displayed next to the **Write configuration file** task.

If you chose to create a service for the MySQL server, the MySQL Configuration Wizard creates and starts the service. If you are reconfiguring an existing service, the MySQL Configuration Wizard restarts the service to apply your configuration changes.

If you chose to set a `root` password, the MySQL Configuration Wizard connects to the server, sets your new `root` password and applies any other security settings you may have selected.

After the MySQL Configuration Wizard has completed its tasks, it displays a summary. Click the Finish button to exit the MySQL Configuration Wizard.

2.3.4.14 The Location of the my.ini File

In MySQL installations prior to version 4.1.5 it was customary to name the server configuration file `my.cnf` or `my.ini` and locate the file either at `c:\my.cnf` or `c:\Windows\my.ini`.

The new MySQL Configuration Wizard places the `my.ini` file in the installation directory of the MySQL server. This helps associate configuration files with particular server instances.

To ensure that the MySQL server knows where to look for the `my.ini` file, an argument similar to this is passed to the MySQL server as part of the service installation:

```
--defaults-file="C:\Program Files\MySQL\MySQL Server 4.1\my.ini"
```

Here, *`C:\Program Files\MySQL\MySQL Server 4.1`* is replaced with the installation path to the MySQL Server. The `--defaults-file` [235] option instructs the MySQL server to read the specified file for configuration options when it starts.

2.3.4.15 Editing the my.ini File

To modify the `my.ini` file, open it with a text editor and make any necessary changes. You can also modify the server configuration with the http://www.mysql.com/products/administrator/ utility.

MySQL clients and utilities such as the `mysql` and `mysqldump` command-line clients are not able to locate the `my.ini` file located in the server installation directory. To configure the client and utility applications, create a new `my.ini` file in the `C:\WINDOWS` or `C:\WINNT` directory (whichever is applicable to your Windows version).

2.3.5 Installing MySQL from a Noinstall Zip Archive

Users who are installing from the Noinstall package, or who are installing a version of MySQL prior to 4.1.5 can use the instructions in this section to manually install MySQL. If you are installing a version prior

to 4.1.5 with an install package that includes a Setup program, substitute running the Setup program for extracting the archive.

The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory
2. Create an option file
3. Choose a MySQL server type
4. Start the MySQL server
5. Secure the default user accounts

This process is described in the sections that follow.

2.3.6 Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to Section 2.3.14, “Upgrading MySQL on Windows”, before beginning the upgrade process.
2. If you are using a Windows NT-based operating system such as Windows NT, Windows 2000, Windows XP, or Windows Server 2003, make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server has been installed at `C:\mysql`. The MySQL Installation Wizard installs MySQL under `C:\Program Files\MySQL`. If you do not install MySQL in `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See Section 2.3.7, “Creating an Option File”.
4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.7 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations differ from the default locations (`C:\mysql` and `C:\mysql\data`).
- You need to tune the server settings. For example, to use the `InnoDB` transactional tables in MySQL 3.23, you must manually add some extra lines to the option file, as described in Section 13.2.3, “`InnoDB` Configuration”. (As of MySQL 4.0, `InnoDB` creates its data files and log files in the data directory by default. This means you need not configure `InnoDB` explicitly. You may still do so if you wish, and an option file is also useful in this case.)

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see Section 4.2.3.3, “Using Option Files”). The Windows directory typically is named something like `C:\WINDOWS` or `C:\WINNT`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
shell> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where the `C:` drive is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

You can also make use of the example option files included with your MySQL distribution; see Preconfigured Option Files.

An option file can be created and modified with any text editor, such as the `Notepad` program. For example, if MySQL is installed in `E:\mysql` and the data directory is `E:\mydata\data`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=E:/mydata/data
```

Note that Windows path names are specified in option files using forward slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

The rules for use of backslash in option file values are given in Section 4.2.3.3, “Using Option Files”.

On Windows, the MySQL installer places the data directory directly under the directory where you install MySQL. If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, by default, the installer places MySQL in `C:\mysql`, and the data directory in `C:\mysql\data`. If you want to use `E:\mydata` as the data directory, you must do two things:

- Move the data directory from `C:\mysql\data` to `E:\mydata`.
- Use a `--datadir` [385] option to specify the new data directory location each time you start the server.

2.3.8 Selecting a MySQL Server Type

Starting with MySQL 3.23.38, the Windows distribution includes both the normal and the MySQL-Max server binaries.

Up through the early releases of MySQL 4.1, the servers included in Windows distributions are named like this:

Binary	Description
`mysqld`	Compiled with full debugging and automatic memory allocation checking, and `InnoDB` and `BDB` tables.
`mysqld-opt`	Optimized binary. From version 4.0 on, `InnoDB` is enabled. Before 4.0, this server includes no transactional table support.

Binary	Description
mysqld-nt	Optimized binary for Windows NT, 2000, and XP with named-pipe support.
mysqld-max	Optimized binary with InnoDB and BDB support.
mysqld-max-nt	Like mysqld-max, but compiled with named-pipe support.

We have found that the server with the most generic name (mysqld) is the one that many users are likely to choose by default. However, that is also the server that results in the highest memory and CPU use due to the inclusion of full debugging support. The server named mysqld-opt is a better general-use server choice to make instead if you do not need debugging support and do not want the maximal feature set offered by the -max servers or named pipe support offered by the -nt servers.

To make it less likely that the debugging server would be chosen inadvertently, some name changes were made from MySQL 4.1.2 to 4.1.4: mysqld has been renamed to mysqld-debug and mysqld-opt has been renamed to mysqld. Thus, the server that includes debugging support indicates that in its name, and the server named mysqld is an efficient default choice. The other servers still have their same names. The resulting servers are named like this:

Binary	Description
mysqld-debug	Compiled with full debugging and automatic memory allocation checking, and InnoDB and BDB tables.
mysqld	Optimized binary with InnoDB support.
mysqld-nt	Optimized binary for Windows NT, 2000, and XP with support for named pipes.
mysqld-max	Optimized binary with support for InnoDB and BDB tables.
mysqld-max-nt	Like mysqld-max, but compiled with support for named pipes.

The name changes were not both instituted at the same time. If you have MySQL 4.1.2 or 4.1.3, it might be that you have a server named mysqld-debug but not one named mysqld. In this case, you should have a server mysqld-opt, which you should choose as your default server unless you need maximal features, named pipes, or debugging support.

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

As of MySQL 4.0, all Windows servers have support for symbolic linking of database directories. Before MySQL 4.0, only the debugging and Max server versions include this feature.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows support named pipes as indicated in the following list. However, the default is to use TCP/IP regardless of platform. (Named pipes are slower than TCP/IP in many Windows configurations.)

Use of named pipes is subject to these conditions:

- Starting from MySQL 3.23.50, named pipes are enabled only if you start the server with the --enable-named-pipe [386] option. It is necessary to use this option explicitly because some users have experienced problems shutting down the MySQL server when named pipes were used.
- Named-pipe connections are permitted only by the mysqld-nt or mysqld-max-nt servers, and only if the server is run on a version of Windows that supports named pipes (NT, 2000, XP, 2003).
- These servers can be run on Windows 98 or Me, but only if TCP/IP is installed; named-pipe connections cannot be used.
- These servers cannot be run on Windows 95.

Note

Most of the examples in this manual use `mysqld` as the server name. If you choose to use a different server, such as `mysqld-nt`, make the appropriate substitutions in the commands that are shown in the examples.

2.3.9 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `Noinstall` version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

On Windows 95, 98, or Me, MySQL clients always connect to the server using TCP/IP. (This enables any machine on your network to connect to your MySQL server.) Because of this, you must make sure that TCP/IP support is installed on your machine before starting MySQL. You can find TCP/IP on your Windows CD-ROM.

Note that if you are using an old Windows 95 release (for example, OSR2), it is likely that you have an old Winsock package; MySQL requires Winsock 2. You can get the newest Winsock from http://www.microsoft.com/. Windows 98 has the new Winsock 2 library, so it is unnecessary to update the library.

On NT-based systems such as Windows NT, 2000, XP, or 2003, clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections. For MySQL to work with TCP/IP on Windows NT 4, you must install service pack 3 (or newer).

In MySQL versions 4.1 and higher, Windows servers also support shared-memory connections if the server is started with the `--shared-memory` [392] option. Clients can connect through shared memory by using the `--protocol=MEMORY` [226] option.

For information about which server binary to run, see Section 2.3.8, “Selecting a MySQL Server Type”.

The examples in these sections assume that MySQL is installed under the default location of `C:\mysql`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Testing is best done from a command prompt in a console window (a “DOS window”). This way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
shell> C:\mysql\bin\mysqld --console
```

For a server that includes `InnoDB` support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
```

```
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25  InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '4.0.14-log'  socket: ''  port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` [385] option, the server writes diagnostic output to the error log in the data directory (`C:\mysql\data` by default). The error log is the file with the `.err` extension.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

2.3.10 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (a “DOS window”) and enter this command:

```
shell> "C:\Program Files\MySQL\MySQL Server 4.1\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

On non-NT versions of Windows, this command starts `mysqld` in the background. That is, after the server starts, you should see another command prompt. If you start the server this way on Windows NT, 2000, XP, or 2003, the server runs in the foreground and no command prompt appears until the server exits. Because of this, you should open another console window to run client programs while the server is running.

You can stop the MySQL server by executing this command:

```
shell> "C:\Program Files\MySQL\MySQL Server 4.1\bin\mysqladmin" -u root shutdown
```

Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the `C:\mysql\data` directory. It is the file with a suffix of `.err`. You can also try to start the server as `mysqld --console`; in this case, you may get some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with the `--standalone` [393] and `--debug` [385] options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See Section 18.4, “Porting to Other Systems”.

Use `mysqld --verbose --help` to display all the options that `mysqld` supports. (Prior to MySQL 4.1, omit the `--verbose` [395] option.)

2.3.11 Starting MySQL as a Windows Service

On the NT family (Windows NT, 2000, XP, 2003), the recommended way to run MySQL is to install it as a Windows service. With the MySQL server installed as a service, Windows starts and stops it server automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The `Services` utility (the Windows `Service Control Manager`) can be found in the Windows Control Panel (under Administrative Tools on Windows 2000, XP, Vista and Server 2003). To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
shell> C:\mysql\bin\mysqladmin -u root shutdown
```

Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
shell> C:\mysql\bin\mysqld --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

Before MySQL 4.0.2, no command-line arguments can be given following the `--install` option. MySQL 4.0.2 and up offers limited support for additional arguments:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.
- As of MySQL 4.0.3, if a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=`*`file_name`* [235] to specify the name of an option file from which the server should read options when it starts.

  The use of a single option other than `--defaults-file` [235] is possible but discouraged. `--defaults-file` [235] is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the a service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.
- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the group that has the same name as the service, and reads options from the standard option files.

  As of MySQL 4.0.17, the server also reads options from the `[mysqld]` group from the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the same name as a service for use by the server installed with that service name.
- If the service-installation command specifies a `--defaults-file` [235] option after the service name, the server reads options only from the `[mysqld]` group of the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
shell> C:\mysql\bin\mysqld --install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (`MySQL`) is given after the `--install` option. If no `--defaults-file` [235] option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` [235] option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

You can also specify options in Start parameters in the Windows `Services` utility before you start the MySQL service.

Note

Prior to MySQL 4.0.17, a server installed as a Windows service has problems starting if its path name or the service name contains spaces. For this reason, with older versions, avoid installing MySQL in a directory such as `C:\Program Files` or using a service name containing spaces.

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the `Services` utility, or by using a `NET START MySQL` command. The `NET` command is not case sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\mysql\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the `Services` utility, the `NET STOP MySQL` command, or the `mysqladmin shutdown` command.

From MySQL 3.23.44 on, you have the choice of installing the server as a **Manual** service if you do not wish the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
shell> C:\mysql\bin\mysqld --install-manual
```

To remove a server that is installed as a service, first stop it if it is running by executing `NET STOP MySQL`. Then use the `--remove` option to remove it:

```
shell> C:\mysql\bin\mysqld --remove
```

For MySQL versions older than 3.23.49, one problem with automatic MySQL service shutdown is that Windows waited only for a few seconds for the shutdown to complete, and then killed the database server process if the time limit was exceeded. This had the potential to cause problems. (For example, the `InnoDB` storage engine would have to perform crash recovery at the next startup.) Starting from MySQL 3.23.49, Windows waits longer for the MySQL server shutdown to complete. If you notice this still is not enough for your installation, it is safest not to run the MySQL server as a service. Instead, start it from the command-line prompt, and stop it with `mysqladmin shutdown`.

This change to tell Windows to wait longer when stopping the MySQL server works for Windows 2000 and XP. It does not work for Windows NT, where Windows waits only 20 seconds for a service to shut down, and after that kills the service process. You can increase this default by opening the `Registry Editor` (`\winnt\system32\regedt32.exe`) and editing the value of `WaitToKillServiceTimeout` at `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control` in the Registry tree. Specify the new larger value in milliseconds. For example, the value `120000` tells Windows NT to wait up to 120 seconds.

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see Section 2.3.10, “Starting MySQL from the Windows Command Line”.

Please see Section 2.3.13, “Troubleshooting a MySQL Installation Under Windows”, if you encounter difficulties during installation.

2.3.12 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
shell> C:\mysql\bin\mysqlshow
shell> C:\mysql\bin\mysqlshow -u root mysql
shell> C:\mysql\bin\mysqladmin version status proc
shell> C:\mysql\bin\mysql test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs on Windows 9x/Me, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` [393] option and use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables.

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` [226] option or by specifying `.` (period) as the host name. Use the `--socket` [227] option to specify the name of the pipe if you do not want to use the default pipe name. As of MySQL 4.1, you can use the `--protocol=PIPE` [226] option instead.

Note that if you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then you must use the appropriate `-u` and `-p` options with the commands shown above to connect with the MySQL Server. See Section 4.2.2, “Connecting to the MySQL Server”.

There are two versions of the MySQL command-line tool on Windows:

Binary	Description
`mysql`	Compiled on native Windows, offering limited text editing capabilities.
`mysqlc`	Compiled with the Cygnus GNU compiler and libraries, which offers `readline` editing. `mysqlc` was intended for use primarily with Windows 9x/Me. It does not support the updated authentication protocol used beginning with MySQL 4.1, and is not supported in

Binary	Description
	MySQL 4.1 and above. Beginning with MySQL 4.1.8, it is no longer included in MySQL Windows distributions.

To use `mysqlc`, you must have a copy of the `cygwinb19.dll` library installed somewhere that `mysqlc` can find it. If your distribution does not have the `cygwinb19.dll` library in the `bin` directory under the base directory of your MySQL installation, look for it in the `lib` directory and copy it to your Windows system directory (`\Windows\system` or a similar place).

For more information about `mysqlshow`, see Section 4.5.6, “`mysqlshow` — Display Database, Table, and Column Information”.

2.3.13 Troubleshooting a MySQL Installation Under Windows

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. The purpose of this section is to help you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the error log. The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the data directory specified in your `my.ini` file. The default data directory location is `C:\mysql\data`. See Section 5.3.1, “The Error Log”.

Another source of information regarding possible errors is the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See Section 2.3.11, “Starting MySQL as a Windows Service”.

The following examples show other common error messages you may encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, you may see these messages:

```
System error 1067 has occurred.
Fatal error: Can't open privilege tables: Table 'mysql.host' does not exist
```

  These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\mysql` and `C:\mysql\data`, respectively).

  This situation may occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, there may be old and new configuration files that conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

  If you have installed MySQL to a directory other than `C:\mysql`, you need to ensure that the MySQL server is aware of this through the use of a configuration (`my.ini`) file. The `my.ini` file needs to be located in your Windows directory, typically `C:\WINDOWS` or `C:\WINNT`. You can determine its exact location from the value of the `WINDIR` environment variable by issuing the following command from the command prompt:

```
shell> echo %WINDIR%
```

  An option file can be created and modified with any text editor, such as the `Notepad` program. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Note that Windows path names are specified in option files using forward slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\mysql
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

The rules for use of backslash in option file values are given in Section 4.2.3.3, “Using Option Files”.

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See Section 2.3.7, “Creating an Option File”.

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Configuration Wizard, you may see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command-line:

```
shell> sc delete mysql
[SC] DeleteService SUCCESS
```

If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp and use the `delsrv mysql` syntax.

2.3.14 Upgrading MySQL on Windows

This section lists some of the steps you should take when upgrading MySQL on Windows.

1. Review Section 2.11.1, “Upgrading MySQL”, for additional information on upgrading MySQL that is not specific to Windows.
2. You should always back up your current MySQL installation before performing an upgrade. See Section 6.2, “Database Backup Methods”.
3. Download the latest Windows distribution of MySQL from http://dev.mysql.com.

4. Before upgrading MySQL, you must stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

   ```
   shell> NET STOP MySQL
   ```

   If you are not running the MySQL server as a service, use the following command to stop it:

   ```
   shell> C:\mysql\bin\mysqladmin -u root shutdown
   ```

   

   Note

   If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

5. Before upgrading to MySQL 4.1.5 or higher from a previous version, or from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must first manually remove the previous installation and MySQL service (if the server is installed as a service).

   To remove the MySQL service, use the following command:

   ```
   shell> C:\mysql\bin\mysqld --remove
   ```

   If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.

6. If you are using the MySQL Installation Wizard, start the wizard as described in Section 2.3.3, “Using the MySQL Installation Wizard”.

7. If you are installing MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql5`. Overwriting the existing installation is recommended.

8. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See Section 2.3.11, “Starting MySQL as a Windows Service”.)

9. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.

10. If you encounter errors, see Section 2.3.13, “Troubleshooting a MySQL Installation Under Windows”.

2.4 Installing MySQL from RPM Packages on Linux

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages. The RPMs that we provide to the community should work on all versions of Linux that support RPM packages and use `glibc` 2.3. We also provide RPMs with binaries that are statically linked to a patched version of `glibc` 2.2, but only for the x86 (32-bit) architecture. To obtain RPM packages, see Section 2.1.3, “How to Get MySQL”.

For non-RPM Linux distributions, you can install MySQL using a `.tar.gz` package. See Section 2.8, “Installing MySQL from Generic Binaries on Other Unix-Like Systems”.

We do provide some platform-specific RPMs; the difference between a platform-specific RPM and a generic RPM is that a platform-specific RPM is built on the targeted platform and is linked dynamically whereas a generic RPM is linked statically with LinuxThreads.

Note

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by us in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

If you have problems with an RPM file (for example, if you receive the error `Sorry, the host 'xxxx' could not be looked up`), see Section 2.12.1.2, “Linux Binary Distribution Notes”.

In most cases, you need to install only the `MySQL-server` and `MySQL-client` packages to get a functional MySQL installation. The other packages are not required for a standard installation. If you want to run a MySQL-Max server that has additional capabilities, you should also install the `MySQL-Max` RPM. However, you should do so only *after* installing the `MySQL-server` RPM. See Section 5.2, “The `mysqld-max` Extended MySQL Server”.

For upgrades, if your installation was originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

If you get a dependency failure when trying to install the MySQL 4.0 packages (for example, `error: removing these packages would break dependencies: libmysqlclient.so.10 is needed by ...`), you should also install the `MySQL-shared-compat` package, which includes both the shared libraries for backward compatibility (`libmysqlclient.so.12` for MySQL 4.0 and `libmysqlclient.so.10` for MySQL 3.23).

Some Linux distributions still ship with MySQL 3.23 and they usually link applications dynamically to save disk space. If these shared libraries are in a separate package (for example, `MySQL-shared`), it is sufficient to simply leave this package installed and just upgrade the MySQL server and client packages (which are statically linked and do not depend on the shared libraries). For distributions that include the shared libraries in the same package as the MySQL server (for example, Red Hat Linux), you could either install our 3.23 `MySQL-shared` RPM, or use the `MySQL-shared-compat` package instead. (Do not install both.)

The RPM packages shown in the following list are available. The names shown here use a suffix of `.glibc23.i386.rpm`, but particular packages can have different suffixes, as described later.

- `MySQL-server-`*`VERSION`*`.glibc23.i386.rpm`

  The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine.

  Note: Server RPM files were called `MySQL-`*`VERSION`*`.i386.rpm` before MySQL 4.0.10. That is, they did not have `-server` in the name.

- `MySQL-Max-`*`VERSION`*`.i386.rpm`

  The MySQL-Max server. This server has additional capabilities that the one provided in the `MySQL-server` RPM does not. You must install the `MySQL-server` RPM first, because the `MySQL-Max` RPM depends on it.

- `MySQL-client-`*`VERSION`*`.glibc23.i386.rpm`

  The standard MySQL client programs. You probably always want to install this package.

- `MySQL-bench-`*`VERSION`*`.glibc23.i386.rpm`

  Tests and benchmarks. Requires Perl and the `DBI` and `DBD::mysql` modules.

- `MySQL-devel-VERSION.glibc23.i386.rpm`

  The libraries and include files that are needed if you want to compile other MySQL clients, such as the Perl modules.

- `MySQL-debuginfo-VERSION.glibc23.i386.rpm`

  This package contains debugging information. `debuginfo` RPMs are never needed to use MySQL software; this is true both for the server and for client programs. However, they contain additional information that might be needed by a debugger to analyze a crash.

- `MySQL-shared-VERSION.glibc23.i386.rpm`

  This package contains the shared libraries (`libmysqlclient.so*`) that certain languages and applications need to dynamically load and use MySQL. It contains single-threaded and thread-safe libraries. If you install this package, do not install the `MySQL-shared-compat` package.

- `MySQL-shared-compat-VERSION.glibc23.i386.rpm`

  This package includes the shared libraries for MySQL 3.23, 4.0, and so on, up to the current release. It contains single-threaded and thread-safe libraries. Install this package instead of `MySQL-shared` if you have applications installed that are dynamically linked against older versions of MySQL but you want to upgrade to the current version without breaking the library dependencies. This package has been available since MySQL 4.0.13.

- `MySQL-embedded-VERSION.glibc23.i386.rpm`

  The embedded MySQL server library (available as of MySQL 4.0).

- `MySQL-ndb-management-VERSION.glibc23.i386.rpm`, `MySQL-ndb-storage-VERSION.glibc23.i386.rpm`, `MySQL-ndb-tools-VERSION.glibc23.i386.rpm`, `MySQL-ndb-extra-VERSION.glibc23.i386.rpm`

  Packages that contain additional files for MySQL Cluster installations.

  

  Note

  The `MySQL-clustertools` RPM requires a working installation of perl and the `DBI` and `HTML::Template` packages. See Section 2.14, “Perl Installation Notes”, and Section 15.4.18, “`ndb_size.pl` — NDBCLUSTER Size Requirement Estimator”, for more information.

- `MySQL-VERSION.src.rpm`

  This contains the source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, Alpha or SPARC).

The suffix of RPM package names (following the *`VERSION`* value) has the following syntax:

```
[.PLATFORM].CPU.rpm
```

The *`PLATFORM`* and *`CPU`* values indicate the type of system for which the package is built. *`PLATFORM`*, if present, indicates the platform, and *`CPU`* indicates the processor type or family.

If the *`PLATFORM`* value is missing (for example, `MySQL-server-VERSION.i386.rpm`), the package is statically linked against a version of `glibc` 2.2 that has been patched to handle larger numbers of threads with larger stack sizes than the stock library. (The exception is that MySQL-Max RPMs are always dynamically linked.)

If *PLATFORM* is present, the package is dynamically linked against glibc 2.3 and the *PLATFORM* value indicates whether the package is platform independent or intended for a specific platform, as shown in the following table.

***PLATFORM* Value**	**Intended Use**
glibc23	Platform independent, should run on any Linux distribution that supports glibc 2.3
rhel3, rhel4	Red Hat Enterprise Linux 3 or 4
sles9, sles10	SuSE Linux Enterprise Server 9 or 10

The *CPU* value indicates the processor type or family for which the package is built.

***CPU* Value**	**Intended Processor Type or Family**
i386	x86 processor, 386 and up
i586	x86 processor, Pentium and up
x86_64	64-bit x86 processor
ia64	Itanium (IA-64) processor

To see all files in an RPM package (for example, a MySQL-server RPM), run a command like this:

```
shell> rpm -qpl MySQL-server-VERSION.glibc23.i386.rpm
```

To perform a standard minimal installation, install the server and client RPMs:

```
shell> rpm -i MySQL-server-VERSION.glibc23.i386.rpm
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

To install only the client programs, install just the client RPM:

```
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. If you would like to learn more about this feature, see Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.

The server RPM places data under the /var/lib/mysql directory. The RPM also creates a login account for a user named mysql (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in /etc/init.d/ to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you do not lose it when you install a newer RPM.) See Section 2.10.2.2, “Starting and Stopping MySQL Automatically”, for more information on how MySQL can be started automatically on system startup.

If the RPM files that you install include MySQL-server, the mysqld server should be up and running after installation. You should be able to start using MySQL.

If something goes wrong, you can find more information in the binary installation section. See Section 2.8, “Installing MySQL from Generic Binaries on Other Unix-Like Systems”.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

During RPM installation, a user named `mysql` and a group named `mysql` are created on the system. This is done using the `useradd`, `groupadd`, and `usermod` commands. Those commands require appropriate administrative privileges, which is ensured for locally managed users and groups (as listed in the `/etc/passwd` and `/etc/group` files) by the RPM installation process being run by `root`.

If you log in as the `mysql` user, you may find that MySQL displays “Invalid (old?) table or database name” errors that mention `.mysqlgui`, `lost+found`, `.mysqlgui`, `.bash_history`, `.fonts.cache-1`, `.lesshst`, `.mysql_history`, `.profile`, `.viminfo`, and similar files created by MySQL or operating system utilities. You can safely ignore these error messages or remove the files or directories that cause them if you do not need them.

For nonlocal user management (LDAP, NIS, and so forth), the administrative tools may require additional authentication (such as a password), and will fail if the installing user does not provide this authentication. Even if they fail, the RPM installation will not abort but succeed, and this is intentional. If they failed, some of the intended transfer of ownership may be missing, and it is recommended that the system administrator then manually ensures some appropriate user andgroup exists and manually transfers ownership following the actions in the RPM spec file.

2.5 Installing MySQL on Mac OS X

Beginning with MySQL 4.0.11, you can install MySQL on Mac OS X 10.3.x (“Panther”) or newer using a Mac OS X binary package in DMG format instead of the binary tarball distribution. Please note that older versions of Mac OS X (for example, 10.1.x or 10.2.x) are not supported by this package.

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

To obtain MySQL, see Section 2.1.3, “How to Get MySQL”.

Note

Before proceeding with the installation, be sure to shut down all running MySQL server instances by using either the MySQL Manager Application (on Mac OS X Server) or `mysqladmin shutdown` on the command line.

To install the MySQL DMG file, double-click the package icon. This launches the Mac OS X Package Installer, which guides you through the installation of MySQL.

Due to a bug in the Mac OS X package installer, you may see this error message in the destination disk selection dialog:

```
You cannot install this software on this disk. (null)
```

If this error occurs, simply click the Go Back button once to return to the previous screen. Then click Continue to advance to the destination disk selection again, and you should be able to choose the destination disk correctly. We have reported this bug to Apple and it is investigating this problem.

The Mac OS X DMG of MySQL installs itself into `/usr/local/mysql-`*`VERSION`* and also installs a symbolic link, `/usr/local/mysql`, that points to the new location. If a directory named `/usr/local/mysql` exists, it is renamed to `/usr/local/mysql.bak` first. In addition, the installer creates the grant tables in the `mysql` database by executing `mysql_install_db`.

The installation layout is similar to that of a `tar` file binary distribution; all MySQL binaries are located in the directory `/usr/local/mysql/bin`. The MySQL socket file is created as `/tmp/mysql.sock` by default. See Section 2.1.5, “Installation Layouts”.

MySQL installation requires a Mac OS X user account named `mysql`. A user account with this name should exist by default on Mac OS X 10.2 and up.

If you are running Mac OS X Server, a version of MySQL should already be installed. The following table shows the versions of MySQL that ship with Mac OS X Server versions.

Mac OS X Server Version	MySQL Version
10.2-10.2.2	3.23.51
10.2.3-10.2.6	3.23.53
10.3	4.0.14
10.3.2	4.0.16
10.4.0	4.1.10a

This manual section covers the installation of the official MySQL Mac OS X DMG only. Make sure to read Apple's help information about installing MySQL: Run the `Help View` application, select Mac OS X Server help, search for “MySQL”, and read the item entitled “Installing MySQL”.

For preinstalled versions of MySQL on Mac OS X Server, note especially that you should start `mysqld` with `safe_mysqld` instead of `mysqld_safe` if MySQL is older than version 4.0.

If you previously used Marc Liyanage's MySQL packages for Mac OS X from http://www.entropy.ch, you can simply follow the update instructions for packages using the binary installation layout as given on his pages.

If you are upgrading from Marc's 3.23.x versions or from the Mac OS X Server version of MySQL to the official MySQL DMG, you also need to convert the existing MySQL privilege tables to the current format, because some new security privileges have been added. See Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

If you want MySQL to start automatically during system startup, you also need to install the MySQL Startup Item. Starting with MySQL 4.0.15, it is part of the Mac OS X installation disk images as a separate installation package. Simply double-click the MySQLStartupItem.pkg icon and follow the instructions to install it. The Startup Item need be installed only once. There is no need to install it each time you upgrade the MySQL package later.

The Startup Item for MySQL is installed into `/Library/StartupItems/MySQLCOM`. (Before MySQL 4.1.2, the location was `/Library/StartupItems/MySQL`, but that collided with the MySQL Startup Item installed by Mac OS X Server.) Startup Item installation adds a variable `MYSQLCOM=-YES-` to the system configuration file `/etc/hostconfig`. If you want to disable the automatic startup of MySQL, simply change this variable to `MYSQLCOM=-NO-`.

On Mac OS X Server, the default MySQL installation uses the variable `MYSQL` in the `/etc/hostconfig` file. The MySQL Startup Item installer disables this variable by setting it to `MYSQL=-NO-`. This avoids boot time conflicts with the `MYSQLCOM` variable used by the MySQL Startup Item. However, it does not shut down a running MySQL server. You should do that yourself.

After the installation, you can start up MySQL by running the following commands in a terminal window. You must have administrator privileges to perform this task.

If you have installed the Startup Item, use this command:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM start
(Enter your password, if necessary)
(Press Control-D or enter "exit" to exit the shell)
```

For versions of MySQL older than 4.1.3, substitute `/Library/StartupItems/MySQLCOM/MySQLCOM` with `/Library/StartupItems/MySQL/MySQL` above.

If you do not use the Startup Item, enter the following command sequence:

```
shell> cd /usr/local/mysql
shell> sudo ./bin/mysqld_safe
(Enter your password, if necessary)
(Press Control-Z)
shell> bg
(Press Control-D or enter "exit" to exit the shell)
```

You should be able to connect to the MySQL server, for example, by running `/usr/local/mysql/bin/mysql`.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see Section 4.2.1, “Invoking MySQL Programs”.

If you are upgrading an existing installation, note that installing a new MySQL DMG does not remove the directory of an older installation. Unfortunately, the Mac OS X Installer does not yet offer the functionality required to properly upgrade previously installed packages.

To use your existing databases with the new installation, you will need to copy the contents of the old data directory to the new data directory. Make sure that neither the old server nor the new one is running when you do this. After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

2.6 Installing MySQL on Solaris

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, http://dev.mysql.com/downloads/mysql/4.1.html.

If you install MySQL using a binary tarball distribution on Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

You can install MySQL on Solaris using a binary package in PKG format instead of the binary tarball distribution. Some basic PKG-handling commands follow:

- To add a package:

```
pkgadd -d package_name.pkg
```

- To remove a package:

```
pkgrm package_name
```

- To get a full list of installed packages:

```
pkginfo
```

- To get detailed information for a package:

```
pkginfo -l package_name
```

- To list the files belonging to a package:

```
pkgchk -v package_name
```

- To get packaging information for an arbitrary file:

```
pkgchk -l -p file_name
```

For additional information about installing MySQL on Solaris, see Section 2.12.3, “Solaris Notes”.

2.7 Installing MySQL on NetWare

Porting MySQL to NetWare was an effort spearheaded by Novell. Novell customers should be pleased to note that NetWare 6.5 ships with bundled MySQL binaries, complete with an automatic commercial use license for all servers running that version of NetWare.

MySQL for NetWare is compiled using a combination of `Metrowerks CodeWarrior for NetWare` and special cross-compilation versions of the GNU autotools.

The latest binary packages for NetWare can be obtained at http://dev.mysql.com/downloads/. See Section 2.1.3, “How to Get MySQL”.

To host MySQL, the NetWare server must meet these requirements:

- The latest Support Pack of NetWare 6.5 must be installed.
- The system must meet Novell's minimum requirements to run the respective version of NetWare.
- MySQL data and the program binaries must be installed on an NSS volume; traditional volumes are not supported.

To install MySQL for NetWare, use the following procedure:

1. If you are upgrading from a prior installation, stop the MySQL server. This is done from the server console, using the following command:

```
SERVER:  mysqladmin -u root shutdown
```

Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

2. Log on to the target server from a client machine with access to the location where you are installing MySQL.

3. Extract the binary package Zip file onto the server. Be sure to allow the paths in the Zip file to be used. It is safe to simply extract the file to `SYS:\`.

   If you are upgrading from a prior installation, you may need to copy the data directory (for example, `SYS:MYSQL\DATA`), as well as `my.cnf`, if you have customized it. You can then delete the old copy of MySQL.

4. You might want to rename the directory to something more consistent and easy to use. The examples in this manual use `SYS:MYSQL` to refer to the installation directory.

   Note that MySQL installation on NetWare does not detect if a version of MySQL is already installed outside the NetWare release. Therefore, if you have installed the latest MySQL version from the Web (for example, MySQL 4.1 or later) in `SYS:\MYSQL`, you must rename the folder before upgrading the NetWare server; otherwise, files in `SYS:\MySQL` are overwritten by the MySQL version present in NetWare Support Pack.

5. At the server console, add a search path for the directory containing the MySQL NLMs. For example:

   ```
   SERVER:  SEARCH ADD SYS:MYSQL\BIN
   ```

6. Initialize the data directory and the grant tables, if necessary, by executing `mysql_install_db` at the server console.

7. Start the MySQL server using `mysqld_safe` at the server console.

8. To finish the installation, you should also add the following commands to `autoexec.ncf`. For example, if your MySQL installation is in `SYS:MYSQL` and you want MySQL to start automatically, you could add these lines:

   ```
   #Starts the MySQL 4.0.x database server
   SEARCH ADD SYS:MYSQL\BIN
   MYSQLD_SAFE
   ```

   If you are running MySQL on NetWare 6.0, we strongly suggest that you use the `--skip-external-locking` [392] option on the command line:

   ```
   #Starts the MySQL 4.0.x database server
   SEARCH ADD SYS:MYSQL\BIN
   MYSQLD_SAFE --skip-external-locking
   ```

   It is also necessary to use `CHECK TABLE` and `REPAIR TABLE` instead of `myisamchk`, because `myisamchk` makes use of external locking. External locking is known to have problems on NetWare 6.0; the problem has been eliminated in NetWare 6.5. Note that the use of MySQL on Netware 6.0 is not officially supported.

   `mysqld_safe` on NetWare provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not go away by default. Instead, it prompts for user input:

```
*<NLM has terminated; Press any key to close the screen>*
```

If you want NetWare to close the screen automatically instead, use the `--autoclose` [243] option to `mysqld_safe`. For example:

```
#Starts the MySQL 4.0.x database server
SEARCH ADD SYS:MYSQL\BIN
MYSQLD_SAFE --autoclose
```

The behavior of `mysqld_safe` on NetWare is described further in Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

9. When installing MySQL version 4.1.x or later, either for the first time or upgrading the 4.0.x version to 4.1.x or later, download and install the latest and appropriate Perl module and PHP extension for NetWare:
   - Perl: http://forge.novell.com/modules/xfcontent/downloads.php/perl/Modules/
   - PHP: http://forge.novell.com/modules/xfcontent/downloads.php/php/Modules/

If there was an existing installation of MySQL on the NetWare server, be sure to check for existing MySQL startup commands in `autoexec.ncf`, and edit or delete them as necessary.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

2.8 Installing MySQL from Generic Binaries on Other Unix-Like Systems

Oracle provides a set of binary distributions of MySQL. These include binary distributions in the form of compressed `tar` files (files with a `.tar.gz` extension) for a number of platforms, as well as binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed `tar` file binary distribution. For other platform-specific package formats, see the other platform-specific sections. For example, for Windows distributions, see Section 2.3, “Installing MySQL on Microsoft Windows”.

To obtain MySQL, see Section 2.1.3, “How to Get MySQL”.

MySQL compressed `tar` file binary distributions have names of the form `mysql-`*`VERSION`*`-`*`OS`*`.tar.gz`, where *`VERSION`* is a number (for example, `4.1.25`), and *`OS`* indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

To install MySQL from a compressed `tar` file binary distribution, your system must have GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU tar. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from http://www.gnu.org/software/tar/.

If you run into problems and need to file a bug report, please use the instructions in Section 1.8, “How to Report Bugs or Problems”.

To install and use a MySQL binary distribution, the basic command sequence looks like this:

```
shell> groupadd mysql
shell> useradd -r -g mysql mysql
shell> cd /usr/local
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
shell> cp /usr/local/mysql/support-files/my-small/etc/my.cnf # Optional
shell> bin/mysqld_safe --user=mysql &
shell> cp /usr/local/mysql/support-files/mysql.server /etc/init.d/mysql.server # Optional
```

For versions of MySQL older than 4.0, substitute `bin/safe_mysqld` for `bin/mysqld_safe`.

A more detailed version of the preceding description for installing a binary distribution follows.

Note

This procedure assumes that you have `root` (administrator) access to your system. Alternatively, you can prefix each command using the `sudo` (Linux) or `pfexec` (OpenSolaris) command.

The procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, “Postinstallation Setup and Testing”.

Create a `mysql` User and Group

If your system does not already have a user and group for `mysqld` to run as, you may need to create one. The following commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

```
shell> groupadd mysql
shell> useradd -r -g mysql mysql
```

Note

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` option to create a user that does not have login permissions to your server. Omit this option to permit logins for the user (or if your `useradd` does not support the option).

You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the preceding commands and in the following steps.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have

permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```
shell> cd /usr/local
```

Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”. For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. Then create a symbolic link to that directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `tar` command creates a directory named `mysql-VERSION-OS`. The `ln` command makes a symbolic link to that directory. This enables you to refer more easily to the installation directory as `/usr/local/mysql`.

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it. Replace the preceding `tar` command with the following alternative command to uncompress and extract the distribution:

```
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
```

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see Section 2.10, “Postinstallation Setup and Testing”.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

2.9 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see Section 2.1.1, “Operating Systems On Which MySQL Is Known To Run”.

Before you proceed with an installation from source, check whether we produce a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in Section 2.8, “Installing MySQL from Generic Binaries on Other Unix-Like Systems”.

To obtain a source distribution for MySQL, see Section 2.1.3, “How to Get MySQL”. MySQL source distributions are available as compressed `tar` files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or `mysql-VERSION.rpm`, where `VERSION` is a number like `4.1.25`.

To perform a MySQL installation using the source code:

- To build MySQL from source on Unix-like systems, including Linux, commercial Unix, BSD, Mac OS X and others using a `.tar.gz` or RPM-based source code distribution, see Section 2.9.1, “Installing MySQL from a Standard Source Distribution”.
- To build MySQL from source on Windows (Windows XP or newer required), see Section 2.9.7, “Installing MySQL from Source on Windows”.
- For information on building from one of our development trees, see Section 2.9.2, “Installing MySQL from a Development Source Tree”.
- For information on using the `configure` command to specify the source build parameters, including links to platform specific parameters that you might need, see Section 2.9.3, “MySQL Source-Configuration Options”.

To install MySQL from source, your system must have the following tools:

- GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it (if you use a `.tar.gz` distribution), or `WinZip` or another tool that can read `.zip` files (if you use a `.zip` distribution).

  GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU tar. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from http://www.gnu.org/software/tar/.
- A working ANSI C++ compiler. GCC 3.2 or later, Sun Studio 10 or later, Visual Studio 2005 or later, and many current vendor-supplied compilers are known to work.
- A good `make` program. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make` 3.75 or newer. It may already be available on your system as `gmake`. GNU `make` is available from http://www.gnu.org/software/make/.
- `libtool` 1.5, available from http://www.gnu.org/software/libtool/. 1.5.24 or later is recommended.

If you are using a version of `gcc` recent enough to understand the `-fno-exceptions` option, it is *very important* that you use this option. Otherwise, you may compile a binary that crashes randomly. Also use `-felide-constructors` and `-fno-rtti` as well. When in doubt, do the following:

```
CFLAGS="-O3" CXX=gcc CXXFLAGS="-O3 -felide-constructors \
       -fno-exceptions -fno-rtti" ./configure \
       --prefix=/usr/local/mysql --enable-assembler \
       --with-mysqld-ldflags=-all-static
```

On most systems, this gives you a fast and stable binary.

If you run into problems and need to file a bug report, please use the instructions in Section 1.8, “How to Report Bugs or Problems”.

2.9.1 Installing MySQL from a Standard Source Distribution

To install MySQL from source, first configure, build, and install from a source package. Then follow the same postinstallation setup sequence as for a binary installation.

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```
```

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in Section 2.4, “Installing MySQL from RPM Packages on Linux”.

The sequence for installation from a compressed `tar` file source distribution is similar to the process for installing from a generic binary distribution that is detailed in Section 2.8, “Installing MySQL from Generic Binaries on Other Unix-Like Systems”. For a MySQL `.tar.gz` source distribution, the basic installation command sequence looks like this:

```
# Preconfiguration setup
shell> groupadd mysql
shell> useradd -g mysql mysql
# Beginning of source-build specific instructions
shell> tar zxvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> ./configure --prefix=/usr/local/mysql
shell> make
shell> make install
# End of source-build specific instructions
# Postinstallation setup
shell> cp support-files/my-medium.cnf /etc/my.cnf
shell> cd /usr/local/mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> bin/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql var
shell> bin/mysqld_safe --user=mysql &
```

For versions of MySQL older than 4.0, substitute `bin/safe_mysqld` for `bin/mysqld_safe` in the final command.

Note

This procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, “Postinstallation Setup and Testing”, for postinstallation setup and testing.

A more detailed version of the preceding description for installing MySQL from a source distribution follows:

1. Add a login user and group for `mysqld` to run as:

   ```
   shell> groupadd mysql
   shell> useradd -g mysql mysql
   ```

   These commands add the `mysql` group and the `mysql` user. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

   You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following steps.

2. Perform the following steps as the `mysql` user, except as noted.

3. Pick the directory under which you want to unpack the distribution and change location into it.

4. Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”.

5. Unpack the distribution into the current directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

   ```
   shell> tar zxvf /path/to/mysql-VERSION.tar.gz
   ```

   This command creates a directory named `mysql-VERSION`.

   If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it:

   ```
   shell> gunzip < /path/to/mysql-VERSION.tar.gz | tar xvf -
   ```

6. Change location into the top-level directory of the unpacked distribution:

   ```
   shell> cd mysql-VERSION
   ```

   Note that currently you must configure and build MySQL from this top-level directory. You cannot build it in a different directory.

7. Configure the release and compile everything:

   ```
   shell> ./configure --prefix=/usr/local/mysql
   shell> make
   ```

   When you run `configure`, you might want to specify other options. For example, if you need to debug `mysqld` or a MySQL client, run `configure` with the `--with-debug` [98] option, and then recompile and link your clients with the new client library. See Section 18.4, “Porting to Other Systems”.

   Run `./configure --help` for a list of options. Section 2.9.3, “MySQL Source-Configuration Options”, discusses some of the more useful options.

   If `configure` fails and you are going to send mail to a MySQL mailing list to ask for assistance, please include any lines from `config.log` that you think can help solve the problem. Also include the last couple of lines of output from `configure`. To file a bug report, please use the instructions in Section 1.8, “How to Report Bugs or Problems”.

   If the compile fails, see Section 2.9.4, “Dealing with Problems Compiling MySQL”, for help.

8. Install the distribution:

   ```
   shell> make install
   ```

   You might need to run this command as `root`.

   If you want to set up an option file, use one of those present in the `support-files` directory as a template. For example:

   ```
   shell> cp support-files/my-medium.cnf /etc/my.cnf
   ```

   You might need to run this command as `root`.

   If you want to configure support for `InnoDB` tables, you should edit the `/etc/my.cnf` file, removing the `#` character before the option lines that start with `innodb_...`, and modify the option values to be what you want. See Section 4.2.3.3, “Using Option Files”, and Section 13.2.3, “`InnoDB` Configuration”.

9. Change location into the installation directory:

```
shell> cd /usr/local/mysql
```

10. If you ran the `make install` command as `root`, the installed files will be owned by `root`. Ensure that the installation is accessible to `mysql` by executing the following commands as `root` in the installation directory:

```
shell> chown -R mysql .
shell> chgrp -R mysql .
```

    The first command changes the owner attribute of the files to the `mysql` user. The second changes the group attribute to the `mysql` group.

11. If you have not installed MySQL before, you must create the MySQL data directory and initialize the grant tables:

```
shell> bin/mysql_install_db --user=mysql
```

    If you run the command as `root`, include the `--user` option as shown. If you run the command while logged in as `mysql`, you can omit the `--user` option.

    The command should create the data directory and its contents with `mysql` as the owner.

    Note that for MySQL versions older than 3.22.10, `mysql_install_db` left the server running after creating the grant tables. This is no longer true; you need to restart the server after performing the remaining steps in this procedure.

12. Most of the MySQL installation can be owned by `root` if you like. The exception is that the data directory must be owned by `mysql`. To accomplish this, run the following commands as `root` in the installation directory:

```
shell> chown -R root .
shell> chown -R mysql var
```

13. If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` [423] read only to the server.

14. If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the script itself, and in Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

15. You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl modules. See Section 4.6.15, “`mysql_setpermission` — Interactively Set Permissions in Grant Tables”. For Perl module installation instructions, see Section 2.14, “Perl Installation Notes”.

After everything has been installed, test the distribution. To start the MySQL server, use the following command:

```
shell> /usr/local/mysql/bin/mysqld_safe --user=mysql &
```

For versions of MySQL older than 4.0, substitute `safe_mysqld` for `mysqld_safe` in the command.

If you run the command as `root`, you should use the `--user` option as shown. The option value is the name of the login account that you created in the first step to use for running the server. If you run the `mysqld_safe` command while logged in as that user, you can omit the `--user` option.

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the *`host_name`*`.err` file in the data directory).

More information about `mysqld_safe` is given in Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

To make it more convenient to invoke programs installed in `/usr/local/mysql/bin`, you can add that directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. See Section 4.2.4, “Setting Environment Variables”.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

2.9.2 Installing MySQL from a Development Source Tree

This section discusses how to install MySQL from the latest development source code. Development trees have not necessarily received the same level of testing as standard release distributions, so this installation method is usually required only if you need the most recent code changes. Do not use a development tree for production systems. If your goal is simply to get MySQL up and running on your system, you should use a standard release distribution (either a binary or source distribution). See Section 2.1.3, “How to Get MySQL”.

To obtain the source tree, you must have Bazaar installed. The Bazaar VCS Web site has instructions for downloading and installing Bazaar on different platforms. Bazaar is supported on any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows, or Mac OS X host.

MySQL development projects are hosted on Launchpad. MySQL projects, including MySQL Server, MySQL Workbench, and others are available from the Oracle/MySQL Engineering page. For the repositories related only to MySQL Server, see the MySQL Server page.

To build under Unix/Linux, you must have the following tools installed:

- A good `make` program. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make` 3.75 or newer. It may already be available on your system as `gmake`. GNU `make` is available from http://www.gnu.org/software/make/.
- `autoconf` 2.58 (or newer), available from http://www.gnu.org/software/autoconf/.
- `automake` 1.8.1, available from http://www.gnu.org/software/automake/.
- `libtool` 1.5, available from http://www.gnu.org/software/libtool/. 1.5.24 or later is recommended.
- `m4`, available from http://www.gnu.org/software/m4/.
- `bison`, available from http://www.gnu.org/software/bison/. You should use the latest version of `bison` where possible. Versions 1.75 and 2.1 are known to work. There have been reported problems with `bison` 1.875. If you experience problems, upgrade to a later, rather than earlier, version. Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

To build under Windows you must have Microsoft Visual C++ 2005 Express Edition, Visual Studio .Net 2003 (7.1), or Visual Studio 2005 (8.0) compiler system.

Once the necessary tools are installed, create a local branch of the MySQL development tree on your machine using this procedure:

1. To obtain a copy of the MySQL source code, you must create a new Bazaar branch. If you do not already have a Bazaar repository directory set up, you must initialize a new directory:

   ```
   shell> mkdir mysql-server
   shell> bzr init-repo --trees mysql-server
   ```

   This is a one-time operation.

2. Assuming that you have an initialized repository directory, you can branch from the public MySQL server repositories to create a local source tree. To create a branch of a specific version:

   ```
   shell> cd mysql-server
   shell> bzr branch lp:mysql-server/4.1 mysql-4.1
   ```

   This is a one-time operation per source tree. You can branch the source trees for several versions of MySQL under the `mysql-server` directory.

3. The initial download will take some time to complete, depending on the speed of your connection. Please be patient. Once you have downloaded the first tree, additional trees should take significantly less time to download.

4. When building from the Bazaar branch, you may want to create a copy of your active branch so that you can make configuration and other changes without affecting the original branch contents. You can achieve this by branching from the original branch:

   ```
   shell> bzr branch mysql-4.1 mysql-4.1-build
   ```

5. To obtain changes made after you have set up the branch initially, update it using the `pull` option periodically. Use this command in the top-level directory of the local copy:

   ```
   shell> bzr pull
   ```

   You can examine the changeset comments for the tree by using the `log` option to `bzr`:

   ```
   shell> bzr log
   ```

   You can also browse changesets, comments, and source code online at the Launchpad MySQL Server page.

   If you see diffs (changes) or code that you have a question about, do not hesitate to send email to the MySQL `internals` mailing list. See Section 1.7.1, “MySQL Mailing Lists”. If you think you have a better idea on how to do something, send an email message to the list with a patch.

After you have the local branch, you can build MySQL server from the source code. On Windows, the build process is different from Unix/Linux: see Section 2.9.7, “Installing MySQL from Source on Windows”.

On Unix/Linux, use the `autoconf` system to create the `configure` script so that you can configure the build environment before building. The following example shows the typical commands required to build MySQL from a source tree.

1. Change location to the top-level directory of the source tree; replace `mysql-4.1` with the appropriate directory name.

   ```
   shell> cd mysql-4.1
   ```

2. Prepare the source tree for configuration.

   You must separately configure the `BDB` and `InnoDB` storage engines. Run the following commands from the main source directory:

   ```
   shell> (cd bdb/dist; sh s_all)
   shell> (cd innobase; autoreconf --force --install)
   ```

   You can omit the previous commands if you do not require `BDB` or `InnoDB` support.

   Prepare the remainder of the source tree:

   ```
   shell> autoreconf --force --install
   ```

   As an alternative to the preceding `autoreconf` command, you can use `BUILD/autorun.sh`, which acts as a shortcut for the following sequence of commands:

   ```
   shell> aclocal; autoheader
   shell> libtoolize --automake --force
   shell> automake --force --add-missing; autoconf
   shell> (cd bdb/dist; sh s_all)
   shell> (cd innobase; aclocal; autoheader; autoconf; automake)
   ```

   If you get some strange errors during this stage, verify that you have the correct version of `libtool` installed.

3. Configure the source tree and compile MySQL:

   ```
   shell> ./configure  # Add your favorite options here
   shell> make
   ```

   For a description of some `configure` options, see Section 2.9.3, “MySQL Source-Configuration Options”.

   A collection of configuration scripts is located in the `BUILD/` subdirectory. For example, you may find it more convenient to use the `BUILD/compile-pentium-debug` script than the preceding set of shell commands. To compile on a different architecture, modify the script by removing flags that are Pentium-specific, or use another script that may be more appropriate. These scripts are provided on an “as-is” basis. They are not supported and their contents may change from release to release.

4. When the build is done, run `make install`. Be careful with this on a production machine; the installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run `./configure` with values for the `--prefix` [95], `--with-tcp-port` [96], and `--with-unix-socket-path` [96] options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see Section 5.7, “Running Multiple MySQL Servers on the Same Machine”.

5. Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See Section 18.1.2, “The MySQL Test Suite”.

6. If you have gotten to the `make` stage, but the distribution does not compile, please enter the problem into our bugs database using the instructions given in Section 1.8, “How to Report Bugs or Problems”. If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a `command not found` error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

2.9.3 MySQL Source-Configuration Options

The `configure` script provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the `configure` command line. For a full list of options supported by `configure`, run this command:

```
shell> ./configure --help
```

You can also affect `configure` using certain environment variables. See Section 2.13, “Environment Variables”.

Some of the `configure` options available are described here. For options that may be of use if you have difficulties building MySQL, see Section 2.9.4, “Dealing with Problems Compiling MySQL”.

Many options configure compile-time defaults that can be overridden at server startup. For example, the `--prefix` [95], `--with-tcp-port` [96], and `with-unix-socket-path` [96] options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the `--basedir` [384], `--port` [391], and `--socket` [394] options for `mysqld`.

- To compile just the MySQL client libraries and client programs and not the server, use the `--without-server` [95] option:

  ```
  shell> ./configure --without-server
  ```

  If you have no C++ compiler, some client programs such as `mysql` cannot be compiled because they require C++. In this case, you can remove the code in `configure` that tests for the C++ compiler and then run `./configure` with the `--without-server` [95] option. The compile step should still try to build all clients, but you can ignore any warnings about files such as `mysql.cc`. (If `make` stops, try `make -k` to tell it to continue with the rest of the build even if errors occur.)

- To build the embedded MySQL library (`libmysqld.a`), use the `--with-embedded-server` [95] option.

- To place your log files and database directories elsewhere than under `/usr/local/var`, use a `configure` command something like one of these:

  ```
  shell> ./configure --prefix=/usr/local/mysql
  shell> ./configure --prefix=/usr/local \
             --localstatedir=/usr/local/mysql/data
  ```

  The first command changes the installation prefix so that everything is installed under `/usr/local/mysql` rather than the default of `/usr/local`. The second command preserves the default installation prefix, but overrides the default location for database directories (normally `/usr/local/var`) and changes it to `/usr/local/mysql/data`.

You can also specify the installation directory and data directory locations at server startup time by using the `--basedir` [384] and `--datadir` [385] options. These can be given on the command line or in an MySQL option file, although it is more common to use an option file. See Section 4.2.3.3, "Using Option Files".

- The `--with-tcp-port` [96] option specifies the port number on which the server listens for TCP/IP connections. The default is port 3306. To listen on a different port, use a `configure` command like this:

```
shell> ./configure --with-tcp-port=3307
```

- On Unix, if you want the MySQL socket file location to be somewhere other than the default location (normally in the directory `/tmp` or `/var/run`), use a `configure` command like this:

```
shell> ./configure \
          --with-unix-socket-path=/usr/local/mysql/tmp/mysql.sock
```

The socket file name must be an absolute path name. You can also change the location of `mysql.sock` at server startup by using a MySQL option file. See Section B.5.4.5, "How to Protect or Change the MySQL Unix Socket File".

- To compile statically linked programs (for example, to make a binary distribution, to get better performance, or to work around problems with some Red Hat Linux distributions), run `configure` like this:

```
shell> ./configure --with-client-ldflags=-all-static \
          --with-mysqld-ldflags=-all-static
```

- If you are using `gcc` and do not have `libg++` or `libstdc++` installed, you can tell `configure` to use `gcc` as your C++ compiler:

```
shell> CC=gcc CXX=gcc ./configure
```

When you use `gcc` as your C++ compiler, it does not attempt to link in `libg++` or `libstdc++`. This may be a good thing to do even if you have those libraries installed. Some versions of them have caused strange problems for MySQL users in the past.

The following list indicates some compilers and environment variable settings that are commonly used with each one.

- `gcc` 2.7.2:

```
CC=gcc CXX=gcc CXXFLAGS="-O3 -felide-constructors"
```

- `gcc` 2.95.2:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
-felide-constructors -fno-exceptions -fno-rtti"
```

In most cases, you can get a reasonably optimized MySQL binary by using the options from the preceding list and adding the following options to the `configure` line:

```
--prefix=/usr/local/mysql --enable-assembler \
```

```
--with-mysqld-ldflags=-all-static
```

The full `configure` line would, in other words, be something like the following for all recent `gcc` versions:

```
CFLAGS="-O3 -mpentiumpro" CXX=gcc CXXFLAGS="-O3 -mpentiumpro \
-felide-constructors -fno-exceptions -fno-rtti" ./configure \
--prefix=/usr/local/mysql --enable-assembler \
--with-mysqld-ldflags=-all-static
```

The binaries we provide on the MySQL Web site at http://dev.mysql.com/downloads/ are all compiled with full optimization and should work well for most users. See Section 2.8, “Installing MySQL from Generic Binaries on Other Unix-Like Systems”.

- If the build fails and produces errors about your compiler or linker not being able to create the shared library `libmysqlclient.so.N` (where `N` is a version number), you can work around this problem by giving the `--disable-shared` option to `configure`. In this case, `configure` does not build a shared `libmysqlclient.so.N` library.

- By default, MySQL uses the `latin1` (cp1252 West European) character set. To change the default set, use the `--with-charset` [97] option:

```
shell> ./configure --with-charset=CHARSET
```

`CHARSET` may be one of `big5`, `cp1251`, `cp1257`, `czech`, `danish`, `dec8`, `dos`, `euc_kr`, `gb2312`, `gbk`, `german1`, `hebrew`, `hp8`, `hungarian`, `koi8_ru`, `koi8_ukr`, `latin1`, `latin2`, `sjis`, `swe7`, `tis620`, `ujis`, `usa7`, or `win1251ukr`. (Additional character sets might be available. Check the output from `./configure --help` for the current list.)

As of MySQL 4.1.1, the default collation may also be specified. MySQL uses the `latin1_swedish_ci` collation. To change this, use the `--with-collation` [97] option:

```
shell> ./configure --with-collation=COLLATION
```

To change both the character set and the collation, use both the `--with-charset` [97] and `--with-collation` [97] options. The collation must be a legal collation for the character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.)

Warning

Before MySQL 4.1, if you change character sets after having created any tables, you have to run `myisamchk -r -q --set-character-set=charset_name` on every `MyISAM` table. Your indexes may be sorted incorrectly otherwise. This can happen if you install MySQL, create some tables, and then reconfigure MySQL to use a different character set and reinstall it.

With the `configure` option `--with-extra-charsets=LIST` [97], you can define which additional character sets should be compiled into the server. *`LIST`* is one of the following:

- A list of character set names separated by spaces
- `complex` to include all character sets that can't be dynamically loaded
- `all` to include all character sets into the binaries

Clients that want to convert characters between the server and the client should use the `SET NAMES` statement. See Section 9.1.4, “Connection Character Sets and Collations”.

- To configure MySQL with debugging code, use the `--with-debug` [98] option:

```
shell> ./configure --with-debug
```

This causes a safe memory allocator to be included that can find some errors and that provides output about what is happening. See Section 18.4, “Porting to Other Systems”.

- If your client programs are using threads, you must compile a thread-safe version of the MySQL client library with the `--enable-thread-safe-client` [98] configure option. This creates a `libmysqlclient_r` library with which you should link your threaded applications. See Section 17.6.3.2, “Writing C API Threaded Client Programs”.

- Some features require that the server be built with compression library support, such as the `COMPRESS()` [866] and `UNCOMPRESS()` [869] functions, and compression of the client/server protocol. The `--with-zlib-dir=no|bundled|`*`DIR`* [98] option provides control over compression library support. The value `no` explicitly disables compression support. `bundled` causes the `zlib` library bundled in the MySQL sources to be used. A *`DIR`* path name specifies the directory in which to find the compression library sources.

- It is possible to build MySQL with big table support using the `--with-big-tables` [98] option, beginning with the following MySQL versions:

  - **4.0 series**: 4.0.25
  - **4.1 series**: 4.1.11

  This option causes the variables that store table row counts to be declared as `unsigned long long` rather than `unsigned long`. This enables tables to hold up to approximately 1.844E+19 ($(2^{32})^2$) rows rather than 2^{32} (~4.295E+09) rows. Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable this feature.

- See Section 2.12, “Operating System-Specific Notes”, for options that pertain to particular operating systems.

- See Section 5.6.6.2, “Using SSL Connections”, for options that pertain to configuring MySQL to support secure (encrypted) connections.

2.9.4 Dealing with Problems Compiling MySQL

All MySQL programs compile cleanly for us with no warnings on Solaris or Linux using `gcc`. On other systems, warnings may occur due to differences in system include files. See Section 2.9.6, “MIT-pthreads Notes”, for warnings that may occur when using MIT-pthreads. For other problems, check the following list.

The solution to many problems involves reconfiguring. If you do need to reconfigure, take note of the following:

- If `configure` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `config.cache`. When `configure` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run `configure`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old configuration information or object files from being used, run these commands before re-running `configure`:

```
shell> rm config.cache
shell> make clean
```

Alternatively, you can run `make distclean`.

The following list describes some of the problems that have been found to occur most often when compiling MySQL:

- If you get errors such as the ones shown here when compiling `sql_yacc.cc`, you probably have run out of memory or swap space:

  ```
  Internal compiler error: program cc1plus got fatal signal 11
  Out of virtual memory
  Virtual memory exhausted
  ```

  The problem is that `gcc` requires a huge amount of memory to compile `sql_yacc.cc` with inline functions. Try running `configure` with the `--with-low-memory` [99] option:

  ```
  shell> ./configure --with-low-memory
  ```

  This option causes `-fno-inline` to be added to the compile line if you are using `gcc` and `-O0` if you are using something else. You should try the `--with-low-memory` [99] option even if you have so much memory and swap space that you think you can't possibly have run out. This problem has been observed to occur even on systems with generous hardware configurations, and the `--with-low-memory` [99] option usually fixes it.

- By default, `configure` picks `c++` as the compiler name and GNU `c++` links with `-lg++`. If you are using `gcc`, that behavior can cause problems during configuration such as this:

  ```
  configure: error: installation or configuration problem:
  C++ compiler cannot create executables.
  ```

  You might also observe problems during compilation related to `g++`, `libg++`, or `libstdc++`.

  One cause of these problems is that you may not have `g++`, or you may have `g++` but not `libg++`, or `libstdc++`. Take a look at the `config.log` file. It should contain the exact reason why your C++ compiler did not work. To work around these problems, you can use `gcc` as your C++ compiler. Try setting the environment variable `CXX` to `"gcc -O3"`. For example:

  ```
  shell> CXX="gcc -O3" ./configure
  ```

  This works because `gcc` compiles C++ source files as well as `g++` does, but does not link in `libg++` or `libstdc++` by default.

  Another way to fix these problems is to install `g++`, `libg++`, and `libstdc++`. However, do not use `libg++` or `libstdc++` with MySQL because this only increases the binary size of `mysqld` without

providing any benefits. Some versions of these libraries have also caused strange problems for MySQL users in the past.

Using `gcc` as the C++ compiler is also required if you want to compile MySQL with RAID functionality (see Section 12.1.5, “CREATE TABLE Syntax”, for more info on RAID table type) and you are using GNU `gcc` version 3 and above. If you get errors like those following during the linking stage when you configure MySQL to compile with the option `--with-raid`, try to use `gcc` as your C++ compiler by defining the `CXX` environment variable:

```
gcc -O3 -DDBUG_OFF -rdynamic -o isamchk isamchk.o sort.o  libnisam.a
../mysys/libmysys.a ../dbug/libdbug.a ../strings/libmystrings.a
 -lpthread -lz -lcrypt -lnsl -lm -lpthread
../mysys/libmysys.a(raid.o)(.text+0x79): In function
`my_raid_create':: undefined reference to `operator new(unsigned)'
../mysys/libmysys.a(raid.o)(.text+0xdd): In function
`my_raid_create':: undefined reference to `operator delete(void*)'
../mysys/libmysys.a(raid.o)(.text+0x129): In function
`my_raid_open':: undefined reference to `operator new(unsigned)'
../mysys/libmysys.a(raid.o)(.text+0x189): In function
`my_raid_open':: undefined reference to `operator delete(void*)'
../mysys/libmysys.a(raid.o)(.text+0x64b): In function
`my_raid_close':: undefined reference to `operator delete(void*)'
collect2: ld returned 1 exit status
```

- To define flags to be used by your C or C++ compilers, specify them using the `CFLAGS` and `CXXFLAGS` environment variables. You can also specify the compiler names this way using `CC` and `CXX`. For example:

```
shell> CC=gcc
shell> CFLAGS=-O3
shell> CXX=gcc
shell> CXXFLAGS=-O3
shell> export CC CFLAGS CXX CXXFLAGS
```

- If you get errors such as those shown here when compiling `mysqld`, `configure` did not correctly detect the type of the last argument to `accept()`, `getsockname()`, or `getpeername()`:

```
cxx: Error: mysqld.cc, line 645: In this statement, the referenced
     type of the pointer value ''length'' is ''unsigned long'',
     which is not compatible with ''int''.
new_sock = accept(sock, (struct sockaddr *)&cAddr, &length);
```

To fix this, edit the `config.h` file (which is generated by `configure`). Look for these lines:

```
/* Define as the base type of the last arg to accept */
#define SOCKET_SIZE_TYPE XXX
```

Change `XXX` to `size_t` or `int`, depending on your operating system. (You must do this each time you run `configure` because `configure` regenerates `config.h`.)

- If your compile fails with errors such as any of the following, you must upgrade your version of `make` to GNU `make`:

```
making all in mit-pthreads
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome make programs.

GNU make 3.75 is known to work.

- The sql_yacc.cc file is generated from sql_yacc.yy. Normally, the build process does not need to create sql_yacc.cc because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

  ```
  "sql_yacc.yy", line xxx fatal: default action causes potential...
  ```

  This is a sign that your version of yacc is deficient. You probably need to install bison (the GNU version of yacc) and use that instead.

- On Debian Linux 3.0, you need to install gawk instead of the default mawk if you want to compile MySQL 4.1 or higher with Berkeley DB support.

- If you get a compilation error on Linux (for example, SuSE Linux 8.1 or Red Hat Linux 7.3) similar to the following one, you probably do not have g++ installed:

  ```
  libmysql.c:1329: warning: passing arg 5 of `gethostbyname_r' from
  incompatible pointer type
  libmysql.c:1329: too few arguments to function `gethostbyname_r'
  libmysql.c:1329: warning: assignment makes pointer from integer
  without a cast
  make[2]: *** [libmysql.lo] Error 1
  ```

  By default, the configure script attempts to determine the correct number of arguments by using g++ (the GNU C++ compiler). This test yields incorrect results if g++ is not installed. There are two ways to work around this problem:

  - Make sure that the GNU C++ g++ is installed. On some Linux distributions, the required package is called gpp; on others, it is named gcc-c++.

  - Use gcc as your C++ compiler by setting the CXX environment variable to gcc:

    ```
    export CXX="gcc"
    ```

  You must run configure again after making either of those changes.

For information about acquiring or updating tools, see the system requirements in Section 2.9, “Installing MySQL from Source”.

2.9.5 Compiling and Linking an Optimized mysqld Server

Most of the following tests were performed on Linux with the MySQL benchmarks, but they should give some indication for other operating systems and workloads.

You obtain the fastest executables when you link with -static.

By using better compiler and compilation options, you can obtain a 10% to 30% speed increase in applications. This is particularly important if you compile the MySQL server yourself.

When we tested both the Cygnus CodeFusion and Fujitsu compilers, neither was sufficiently bug-free to enable MySQL to be compiled with optimizations enabled.

The standard MySQL binary distributions are compiled with support for all character sets. When you compile MySQL yourself, you should include support only for the character sets that you are going to use. This is controlled by the `--with-charset` [97] option to `configure`.

Here is a list of some measurements that we have made:

- If you link dynamically (without `-static`), the result is 13% slower on Linux. Note that you still can use a dynamically linked MySQL library for your client applications. It is the server that is most critical for performance.
- For a connection from a client to a server running on the same host, if you connect using TCP/IP rather than a Unix socket file, performance is 7.5% slower. (On Unix, if you connect to the host name `localhost`, MySQL uses a socket file by default.)
- For TCP/IP connections from a client to a server, connecting to a remote server on another host is 8% to 11% slower than connecting to a server on the same host, even for connections faster than 100Mb/s Ethernet.
- When running our benchmark tests using secure connections (all data encrypted with internal SSL support) performance was 55% slower than with unencrypted connections.
- If you compile with `--with-debug=full` [98], most queries are 20% slower. Some queries may take substantially longer; for example, the MySQL benchmarks run 35% slower. If you use `--with-debug` [98] (without `=full`), the speed decrease is only 15%. For a version of `mysqld` that has been compiled with `--with-debug=full` [98], you can disable memory checking at runtime by starting it with the `--skip-safemalloc` [394] option. The execution speed should then be close to that obtained when configuring with `--with-debug` [98].
- On a Sun UltraSPARC-IIe, a server compiled with Forte 5.0 is 4% faster than one compiled with `gcc` 3.2.
- On a Sun UltraSPARC-IIe, a server compiled with Forte 5.0 is 4% faster in 32-bit mode than in 64-bit mode.
- Compiling with `gcc` 2.95.2 for UltraSPARC with the `-mcpu=v8 -Wa,-xarch=v8plusa` options gives 4% more performance.
- On Solaris 2.5.1, MIT-pthreads is 8% to 12% slower than Solaris native threads on a single processor. With greater loads or more CPUs, the difference should be larger.
- Compiling on Linux-x86 using `gcc` without frame pointers (`-fomit-frame-pointer` or `-fomit-frame-pointer -ffixed-ebp`) makes `mysqld` 1% to 4% faster.

2.9.6 MIT-pthreads Notes

This section describes some of the issues involved in using MIT-pthreads.

On Linux, you should *not* use MIT-pthreads. Use the installed LinuxThreads implementation instead. See Section 2.12.1, “Linux Notes”.

If your system does not provide native thread support, you should build MySQL using the MIT-pthreads package. This includes older FreeBSD systems, SunOS 4.x, Solaris 2.4 and earlier, and some others. See Section 2.1.1, “Operating Systems On Which MySQL Is Known To Run”.

Beginning with MySQL 4.0.2, MIT-pthreads is no longer part of the source distribution. If you require this package, you need to download it separately from http://dev.mysql.com/Downloads/Contrib/pthreads-1_60_beta6-mysql.tar.gz

After downloading, extract this source archive into the top level of the MySQL source directory. It creates a new subdirectory named `mit-pthreads`.

- On most systems, you can force MIT-pthreads to be used by running `configure` with the `--with-mit-threads` option:

```
shell> ./configure --with-mit-threads
```

  Building in a nonsource directory is not supported when using MIT-pthreads because we want to minimize our changes to this code.

- The checks that determine whether to use MIT-pthreads occur only during the part of the configuration process that deals with the server code. If you have configured the distribution using `--without-server` [95] to build only the client code, clients do not know whether MIT-pthreads is being used and use Unix socket file connections by default. Because Unix socket files do not work under MIT-pthreads on some platforms, this means you need to use `-h` or `--host` with a value other than `localhost` when you run client programs.

- When MySQL is compiled using MIT-pthreads, system locking is disabled by default for performance reasons. You can tell the server to use system locking with the `--external-locking` [387] option. This is needed only if you want to be able to run two MySQL servers against the same data files, but that is not recommended, anyway.

- Sometimes the pthread `bind()` command fails to bind to a socket without any error message (at least on Solaris). The result is that all connections to the server fail. For example:

```
shell> mysqladmin version
mysqladmin: connect to server at '' failed;
error: 'Can't connect to mysql server on localhost (146)'
```

  The solution to this problem is to kill the `mysqld` server and restart it. This has happened to us only when we forced the server to shut down and then restarted it immediately.

- With MIT-pthreads, the `sleep()` system call isn't interruptible with `SIGINT` (break). This is noticeable only when you run `mysqladmin --sleep`. You must wait for the `sleep()` call to terminate before the interrupt is served and the process stops.

- When linking, you might receive warning messages like these (at least on Solaris); they can be ignored:

```
ld: warning: symbol `_iob' has differing sizes:
    (file /my/local/pthreads/lib/libpthread.a(findfp.o) value=0x4;
file /usr/lib/libc.so value=0x140);
    /my/local/pthreads/lib/libpthread.a(findfp.o) definition taken
ld: warning: symbol `__iob' has differing sizes:
    (file /my/local/pthreads/lib/libpthread.a(findfp.o) value=0x4;
file /usr/lib/libc.so value=0x140);
    /my/local/pthreads/lib/libpthread.a(findfp.o) definition taken
```

- Some other warnings also can be ignored:

```
implicit declaration of function `int strtoll(...)'
implicit declaration of function `int strtoul(...)'
```

- We have not gotten `readline` to work with MIT-pthreads. (This is not needed, but may be interesting for someone.)

2.9.7 Installing MySQL from Source on Windows

These instructions describe how to build binaries from source for MySQL 4.1 on Windows. Instructions are provided building binaries from a standard source distribution or from the Bazaar tree that contains the latest development source.

Note

The instructions here are strictly for users who want to test MySQL on Microsoft Windows from the latest source distribution or from the Bazaar tree. For production use, we do not advise using a MySQL server built by yourself from source. Normally, it is best to use precompiled binary distributions of MySQL that are built specifically for optimal performance on Windows by Oracle Corporation. Instructions for installing binary distributions are available in Section 2.3, “Installing MySQL on Microsoft Windows”.

To build MySQL on Windows from source, you must satisfy the following system, compiler, and resource requirements:

- Windows XP, Windows 2000, or newer version
- Visual Studio .Net 2003 (7.1) compiler system
- 3GB to 5GB of disk space

You also need a MySQL source distribution for Windows, which can be obtained two ways:

- Obtain a Windows source distribution packaged for the particular version of MySQL in which you are interested. These are available from http://dev.mysql.com/downloads/.
- Package a source distribution yourself from the latest Bazaar developer source tree. If you plan to do this, you must create the package on a Unix system and then transfer it to your Windows system. (Some of the configuration and build steps require tools that work only on Unix.) The Bazaar approach thus requires:
  - A system running Unix, or a Unix-like system such as Linux.
  - Bazaar installed on that system. See Section 2.9.2, “Installing MySQL from a Development Source Tree”, for instructions how to download and install Bazaar.

If you are using a Windows source distribution, you can go directly to Section 2.9.7.1, “Building MySQL from Source Using VC++”. To build from the Bazaar tree, proceed to Section 2.9.7.2, “Creating a Windows Source Package from the Latest Development Source”.

If you find something not working as expected, or you have suggestions about ways to improve the current build process on Windows, please send a message to the `win32` mailing list. See Section 1.7.1, “MySQL Mailing Lists”.

2.9.7.1 Building MySQL from Source Using VC++

Note

VC++ workspace files for MySQL 4.1 and above are compatible with Microsoft Visual Studio 7.1 and tested by us before each release.

Follow this procedure to build MySQL:

1. Create a work directory (for example, `C:\workdir`).
2. Unpack the source distribution in the aforementioned directory using `WinZip` or other Windows tool that can read `.zip` files.
3. Start Visual Studio .Net 2003 (7.1).
4. From the File menu, select Open Solution....
5. Open the `mysql.sln` solution you find in the work directory.
6. From the Build menu, select Configuration Manager....
7. In the Active Solution Configuration pop-up menu, select the configuration to use. You likely want to use one of nt (normal server, not for Windows 98/ME), Max nt (more engines and features, not for 98/ME) or Debug configuration.
8. From the Build menu, select Build Solution.
9. Debug versions of the programs and libraries are placed in the `client_debug` and `lib_debug` directories. Release versions of the programs and libraries are placed in the `client_release` and `lib_release` directories.
10. Test the server. The server built using the preceding instructions expects that the MySQL base directory and data directory are `C:\mysql` and `C:\mysql\data` by default. If you want to test your server using the source tree root directory and its data directory as the base directory and data directory, you need to tell the server their path names. You can either do this on the command line with the `--basedir` [384] and `--datadir` [385] options, or by placing appropriate options in an option file. (See Section 4.2.3.3, “Using Option Files”.) If you have an existing data directory elsewhere that you want to use, you can specify its path name instead.
11. Start your server from the `client_release` or `client_debug` directory, depending on which server you built or want to use. The general server startup instructions are in Section 2.3, “Installing MySQL on Microsoft Windows”. You must adapt the instructions appropriately if you want to use a different base directory or data directory.
12. When the server is running in standalone fashion or as a service based on your configuration, try to connect to it from the `mysql` interactive command-line utility that exists in your `client_release` or `client_debug` directory.

When you are satisfied that the programs you have built are working correctly, stop the server. Then install MySQL as follows:

1. Create the directories where you want to install MySQL. For example, to install into `C:\mysql`, use these commands:

```
shell> mkdir C:\mysql
shell> mkdir C:\mysql\bin
shell> mkdir C:\mysql\data
shell> mkdir C:\mysql\share
shell> mkdir C:\mysql\scripts
```

   If you want to compile other clients and link them to MySQL, you should also create several additional directories:

```
shell> mkdir C:\mysql\include
```

```
shell> mkdir C:\mysql\lib
shell> mkdir C:\mysql\lib\debug
shell> mkdir C:\mysql\lib\opt
```

If you want to benchmark MySQL, create this directory:

```
shell> mkdir C:\mysql\sql-bench
```

Benchmarking requires Perl support. See Section 2.14, “Perl Installation Notes”.

2. From the `workdir` directory, copy into the `C:\mysql` directory the following directories:

```
shell> cd \workdir
C:\workdir> copy client_release\*.exe C:\mysql\bin
C:\workdir> copy client_debug\mysqld.exe C:\mysql\bin\mysqld-debug.exe
C:\workdir> xcopy scripts\*.* C:\mysql\scripts /E
C:\workdir> xcopy share\*.* C:\mysql\share /E
```

If you want to compile other clients and link them to MySQL, you should also copy several libraries and header files:

```
C:\workdir> copy lib_debug\mysqlclient.lib C:\mysql\lib\debug
C:\workdir> copy lib_debug\libmysql.* C:\mysql\lib\debug
C:\workdir> copy lib_debug\zlib.* C:\mysql\lib\debug
C:\workdir> copy lib_release\mysqlclient.lib C:\mysql\lib\opt
C:\workdir> copy lib_release\libmysql.* C:\mysql\lib\opt
C:\workdir> copy lib_release\zlib.* C:\mysql\lib\opt
C:\workdir> copy include\*.h C:\mysql\include
C:\workdir> copy libmysql\libmysql.def C:\mysql\include
```

If you want to benchmark MySQL, you should also do this:

```
C:\workdir> xcopy sql-bench\*.* C:\mysql\bench /E
```

After installation, set up and start the server in the same way as for binary Windows distributions. See Section 2.3, “Installing MySQL on Microsoft Windows”.

2.9.7.2 Creating a Windows Source Package from the Latest Development Source

To create a Windows source package from the current Bazaar source tree, use the instructions here. This procedure must be performed on a system running a Unix or Unix-like operating system because some of the configuration and build steps require tools that work only on Unix. For example, the following procedure is known to work well on Linux.

1. Copy the Bazaar source tree for MySQL 4.1. For instructions on how to do this, see Section 2.9.2, “Installing MySQL from a Development Source Tree”.

2. Configure and build the distribution so that you have a server binary to work with. One way to do this is to run the following command in the top-level directory of your source tree:

```
shell> ./BUILD/compile-pentium-max
```

3. After making sure that the build process completed successfully, run the following utility script from top-level directory of your source tree:

```
shell> ./scripts/make_win_src_distribution
```

This script creates a Windows source package to be used on your Windows system. You can supply different options to the script based on your needs. See Section 4.4.2, "`make_win_src_distribution` — Create Source Distribution for Windows", for a list of permissible options.

By default, `make_win_src_distribution` creates a Zip-format archive with the name `mysql-VERSION-win-src.zip`, where *`VERSION`* represents the version of your MySQL source tree.

4. Copy or upload the Windows source package that you have just created to your Windows machine. To compile it, use the instructions in Section 2.9.7.1, "Building MySQL from Source Using VC++".

2.10 Postinstallation Setup and Testing

After installing MySQL, there are some issues that you should address. For example, on Unix, you should initialize the data directory and create the MySQL grant tables. On all platforms, an important security concern is that the initial accounts in the grant tables have no passwords. You should assign passwords to prevent unauthorized access to the MySQL server. Optionally, for MySQL 4.1.3 and up, you can create time zone tables to enable recognition of named time zones.

The following sections include postinstallation procedures that are specific to Windows systems and to Unix systems. Another section, Section 2.10.2.3, "Starting and Troubleshooting the MySQL Server", applies to all platforms; it describes what to do if you have trouble getting the server to start. Section 2.10.3, "Securing the Initial MySQL Accounts", also applies to all platforms. You should follow its instructions to make sure that you have properly protected your MySQL accounts by assigning passwords to them.

When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in Section 5.5, "The MySQL Access Privilege System", and Section 5.6, "MySQL User Account Management".

2.10.1 Windows Postinstallation Procedures

On Windows, you need not create the data directory and the grant tables. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory. It is unnecessary to run the `mysql_install_db` script that is used on Unix. Regarding passwords, if you installed MySQL using the Windows Installation Wizard, you may have already assigned passwords to the accounts. (See Section 2.3.3, "Using the MySQL Installation Wizard".) Otherwise, use the password-assignment procedure given in Section 2.10.3, "Securing the Initial MySQL Accounts".

Before setting up passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see Section 2.3.9, "Starting the Server for the First Time"), and then issue the following commands to verify that you can retrieve information from the server. You may need to specify directory different from `C:\mysql\bin` on the command line. If you used the Windows Installation Wizard, the default directory is `C:\Program Files\MySQL\MySQL Server 4.1`, and the `mysql` and `mysqlshow` client programs are in `C:\Program Files\MySQL\MySQL Server 4.1\bin`. See Section 2.3.3, "Using the MySQL Installation Wizard", for more information.

Use `mysqlshow` to see what databases exist:

```
C:\> C:\mysql\bin\mysqlshow
+-----------+
| Databases |
+-----------+
| mysql     |
```

```
| test      |
+-----------+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`. In most cases, the `test` database will also be installed automatically.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you installed using the MSI packages and used the MySQL Server Instance Config Wizard, then the `root` user will have been created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You will also need to use the `-u root` and `-p` options if you have already secured the initial MySQL accounts.) With `-p`, you will be prompted for the `root` password. For example:

```
C:\> C:\mysql\bin\mysqlshow -u root -p
Enter password: (enter root password here)
+-----------+
| Databases |
+-----------+
| mysql     |
| test      |
+-----------+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> C:\mysql\bin\mysqlshow mysql
Database: mysql
+---------------------------+
|          Tables           |
+---------------------------+
| columns_priv              |
| db                        |
| func                      |
| help_category             |
| help_keyword              |
| help_relation             |
| help_topic                |
| host                      |
| tables_priv               |
| time_zone                 |
| time_zone_leap_second     |
| time_zone_name            |
| time_zone_transition      |
| time_zone_transition_type |
| user                      |
+---------------------------+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> C:\mysql\bin\mysql -e "SELECT Host,Db,User FROM db" mysql
+------+-------+------+
| host | db    | user |
+------+-------+------+
| %    | test% |      |
+------+-------+------+
```

For more information about `mysqlshow` and `mysql`, see Section 4.5.6, “`mysqlshow` — Display Database, Table, and Column Information”, and Section 4.5.1, “`mysql` — The MySQL Command-Line Tool”.

If you are running a version of Windows that supports services, you can set up the MySQL server to run automatically when Windows starts. See Section 2.3.11, “Starting MySQL as a Windows Service”.

2.10.2 Unix Postinstallation Procedures

After installing MySQL on Unix, you must initialize the grant tables, start the server, and make sure that the server works satisfactorily. You may also wish to arrange for the server to be started and stopped automatically when your system starts and stops. You should also assign passwords to the accounts in the grant tables.

On Unix, the grant tables are set up by the `mysql_install_db` program. For some installation methods, this program is run for you automatically if an existing database cannot be found.

- If you install MySQL on Linux using RPM distributions, the server RPM runs `mysql_install_db`.
- If you install MySQL on Mac OS X using a DMG distribution, the installer runs `mysql_install_db`.

For other platforms and installation types, including generic binary and source installs, you will need to run `mysql_install_db` yourself.

The following procedure describes how to initialize the grant tables (if that has not previously been done) and start the server. It also suggests some commands that you can use to test whether the server is accessible and working properly. For information about starting and stopping the server automatically, see Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

After you complete the procedure and have the server running, you should assign passwords to the accounts created by `mysql_install_db` and perhaps tighten access to test databases. For instructions, see Section 2.10.3, “Securing the Initial MySQL Accounts”.

In the examples shown here, the server runs under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location into the top-level directory of your MySQL installation, represented here by *`BASEDIR`*:

   ```
   shell> cd BASEDIR
   ```

   `BASEDIR` is the installation directory for your MySQL instance. It is likely to be something like `/usr/local/mysql` or `/usr/local`. The following steps assume that you have changed location to this directory.

   You will find several files and subdirectories in the *`BASEDIR`* directory. The most important for installation purposes are the `bin` and `scripts` subdirectories:

   - The `bin` directory contains client programs and the server. You should add the full path name of this directory to your `PATH` environment variable so that your shell finds the MySQL programs properly. See Section 2.13, “Environment Variables”.

     For some distribution types, `mysqld` is in the `libexec` directory.

   - The `scripts` directory contains the `mysql_install_db` script used to initialize the `mysql` database containing the grant tables that store the server access permissions.

     For some distribution types, `mysql_install_db` is in the `bin` directory.

2. If necessary, ensure that the distribution contents are accessible to `mysql`. If you unpacked the distribution as `mysql`, no further action is required. If you unpacked the distribution as `root`, its contents will be owned by `root`. Change its ownership to `mysql` by executing the following commands as `root` in the installation directory:

```
shell> chown -R mysql .
shell> chgrp -R mysql .
```

The first command changes the owner attribute of the files to the `mysql` user. The second changes the group attribute to the `mysql` group.

3. If necessary, run the `mysql_install_db` program to set up the initial MySQL grant tables containing the privileges that determine how users are permitted to connect to the server. You will need to do this if you used a distribution type for which the installation procedure does not run the program for you.

   Typically, `mysql_install_db` needs to be run only the first time you install MySQL, so you can skip this step if you are upgrading an existing installation, However, `mysql_install_db` does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

   The exact location of `mysql_install_db` will depends on the layout for your given installation. To initialize the grant tables, use one of the following commands, depending on whether `mysql_install_db` is located in the `bin` or `scripts` directory:

   ```
   shell> bin/mysql_install_db --user=mysql
   shell> scripts/mysql_install_db --user=mysql
   ```

   It might be necessary to specify other options such as `--basedir` [254] or `--datadir` [254] if `mysql_install_db` does not identify the correct locations for the installation directory or data directory. For example:

   ```
   shell> bin/mysql_install_db --user=mysql \
            --basedir=/opt/mysql/mysql \
            --datadir=/opt/mysql/mysql/data
   ```

   The `mysql_install_db` script creates the server's data directory with `mysql` as the owner. Under the data directory, it creates directories for the `mysql` database that holds the grant tables and the `test` database that you can use to test MySQL. The script also creates privilege table entries for `root` and anonymous-user accounts. The accounts have no passwords initially. Section 2.10.3, “Securing the Initial MySQL Accounts”, describes the initial privileges. Briefly, these privileges permit the MySQL `root` user to do anything, and permit anybody to create or use databases with a name of `test` or starting with `test_`.

   It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this, the `--user` [255] option should be used as shown if you run `mysql_install_db` as `root`. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` [255] option from the command.

   `mysql_install_db` creates several tables in the `mysql` database, including `user`, `db`, `host`, `tables_priv`, `columns_priv`, `func`, and others. See Section 5.5, “The MySQL Access Privilege System”, for a complete listing and description of these tables.

   If you do not want to have the `test` database, you can remove it after starting the server, using the instructions in Section 2.10.3, “Securing the Initial MySQL Accounts”.

   If you have trouble with `mysql_install_db` at this point, see Section 2.10.2.1, “Problems Running `mysql_install_db`”.

For MySQL versions older than 3.22.10, `mysql_install_db` left the server running after creating the grant tables. This is no longer true; you need to restart the server after performing the remaining steps in this procedure.

4. Most of the MySQL installation can be owned by `root` if you like. The exception is that the data directory must be owned by `mysql`. To accomplish this, run the following commands as `root` in the installation directory. For some distribution types, the data directory might be named `var` rather than `data`; adjust the second command accordingly.

```
shell> chown -R root .
shell> chown -R mysql data
```

5. If the plugin directory (the directory named by the `plugin_dir` [423] system variable) is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` [423] read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

6. If you installed MySQL using a source distribution, you may want to optionally copy one of the provided configuration files from the `support-files` directory into your `/etc` directory. There are different sample configuration files for different use cases, server types, and CPU and RAM configurations. If you want to use one of these standard files, you should copy it to `/etc/my.cnf`, or `/etc/mysql/my.cnf` and edit and check the configuration before starting your MySQL server for the first time.

   If you do not copy one of the standard configuration files, the MySQL server will be started with the default settings.

   If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `mysql.server` script itself, and in Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

7. Start the MySQL server:

```
shell> bin/mysqld_safe --user=mysql &
```

   For versions of MySQL older than 4.0, substitute `bin/safe_mysqld` for `bin/mysqld_safe`.

   It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this, the `--user` option should be used as shown if you run `mysqld_safe` as `root`. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

   Further instructions for running MySQL as an unprivileged user are given in Section 5.4.6, “How to Run MySQL as a Normal User”.

   If the command fails immediately and prints `mysqld ended`, you can find some information in the *`host_name`*`.err` file in the data directory.

   If you neglected to create the grant tables by running `mysql_install_db` before proceeding to this step, the following message appears in the error log file when you start the server:

```
mysqld: Can't find file: 'host.frm'
```

This error also occurs if you run `mysql_install_db` as `root` without the `--user` [255] option. Remove the `data` directory and run `mysql_install_db` with the `--user` [255] option as described previously.

If you have other problems starting the server, see Section 2.10.2.3, “Starting and Troubleshooting the MySQL Server”. For more information about `mysqld_safe`, see Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

8. Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin  Ver 14.7 Distrib 4.1.19, for linux on i586
...

Server version          4.1.19-max
Protocol version        10
Connection              Localhost via Unix socket
TCP port                3306
UNIX socket             var/lib/mysql/mysql.sock
Uptime:                 5 days 19 hours 19 min 0 sec

Threads: 1  Questions: 163  Slow queries: 0
Opens: 11  Flush tables:1  Open tables: 0  Queries per second avg: 0.007
Threads: 1  Questions: 9  Slow queries: 0
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` [280] option.

9. Verify that you can shut down the server:

```
shell> bin/mysqladmin -u root shutdown
```

10. Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql --log &
```

If `mysqld_safe` fails, see Section 2.10.2.3, “Starting and Troubleshooting the MySQL Server”.

11. Run some simple tests to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
shell> bin/mysqlshow
+-----------+
| Databases |
+-----------+
| mysql     |
| test      |
+-----------+

shell> bin/mysqlshow mysql
```

```
Database: mysql
+--------------+
|    Tables    |
+--------------+
| columns_priv |
| db           |
| func         |
| host         |
| tables_priv  |
| user         |
+--------------+

shell> bin/mysql -e "SELECT Host,Db,User FROM db" mysql
+------+--------+------+
| host | db     | user |
+------+--------+------+
| %    | test   |      |
| %    | test_% |      |
+------+--------+------+
```

12. There is a benchmark suite in the `sql-bench` directory (under the MySQL installation directory) that you can use to compare how MySQL performs on different platforms. The benchmark suite is written in Perl. It requires the Perl DBI module that provides a database-independent interface to the various databases, and some other additional Perl modules:

    ```
    DBI
    DBD::mysql
    Data::Dumper
    Data::ShowTable
    ```

    These modules can be obtained from CPAN (http://www.cpan.org/). See also Section 2.14.1, “Installing Perl on Unix”.

    The `sql-bench/Results` directory contains the results from many runs against different databases and platforms. To run all tests, execute these commands:

    ```
    shell> cd sql-bench
    shell> perl run-all-tests
    ```

    If you do not have the `sql-bench` directory, you probably installed MySQL using RPM files other than the source RPM. (The source RPM includes the `sql-bench` benchmark directory.) In this case, you must first install the benchmark suite before you can use it. Beginning with MySQL 3.22, there are separate benchmark RPM files named `mysql-bench-`*`VERSION`*`.i386.rpm` that contain benchmark code and data.

    If you have a source distribution, there are also tests in its `tests` subdirectory that you can run. For example, to run `auto_increment.tst`, execute this command from the top-level directory of your source distribution:

    ```
    shell> mysql -vvf test < ./tests/auto_increment.tst
    ```

    The expected result of the test can be found in the `./tests/auto_increment.res` file.

13. At this point, you should have the server running. However, none of the initial MySQL accounts have a password, and the server permits permissive access to test databases. To tighten security, follow the instructions in Section 2.10.3, “Securing the Initial MySQL Accounts”.

As of MySQL 4.1.3, the installation procedure creates time zone tables in the `mysql` database but does not populate them. To do so, use the instructions in Section 9.7, “MySQL Server Time Zone Support”.

You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl modules. See Section 4.6.15, “`mysql_setpermission` — Interactively Set Permissions in Grant Tables”. For Perl module installation instructions, see Section 2.14, “Perl Installation Notes”.

If you would like to use `mysqlaccess` and have the MySQL distribution in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `bin/mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL     = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

Note

On Windows, you can also perform the process described in this section using the Configuration Wizard (see Section 2.3.4.12, “The Security Options Dialog”). On other platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation.

2.10.2.1 Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` script is to generate new MySQL privilege tables. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

If you want to re-create your privilege tables, first stop the `mysqld` server if it is running. Then rename the `mysql` directory under the data directory to save it, and then run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
shell> mv data/mysql data/mysql.old
shell> bin/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

  You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

  ```
  Starting mysqld daemon with databases from XXXXXX
  mysqld ended
  ```

  In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message and should indicate why `mysqld` did not start. If you do not understand what happened, include the log when you post a bug report. See Section 1.8, “How to Report Bugs or Problems”.

- **There is a `mysqld` process running**

  This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once (when you install MySQL the first time).

- **Installing a second `mysqld` server does not work when one server is running**

  This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

  ```
  Can't start server: Bind on TCP/IP port:
  Address already in use
  Can't start server: Bind on unix socket...
  ```

  For instructions on setting up multiple servers, see Section 5.7, “Running Multiple MySQL Servers on the Same Machine”.

- **You do not have write access to the `/tmp` directory**

  If you do not have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory), an error occurs when you run `mysql_install_db` or the `mysqld` server.

  You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where *`some_tmp_dir`* is the full path name to some directory for which you have write permission:

  ```
  shell> TMPDIR=/some_tmp_dir/
  shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
  shell> export TMPDIR MYSQL_UNIX_PORT
  ```

  Then you should be able to run `mysql_install_db` and start the server with these commands:

  ```
  shell> bin/mysql_install_db --user=mysql
  shell> bin/mysqld_safe --user=mysql &
  ```

  If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

  See Section B.5.4.5, “How to Protect or Change the MySQL Unix Socket File”, and Section 2.13, “Environment Variables”.

There are some alternatives to running the `mysql_install_db` script provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, you can modify `mysql_install_db` before you run it. However, it is preferable to use `GRANT` and `REVOKE` to change the privileges *after* the grant tables have been set up. In other words, you can run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the necessary `GRANT` and `REVOKE` statements.

  If you want to install MySQL on several machines with the same privileges, you can put the `GRANT` and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

  ```
  shell> bin/mysql_install_db --user=mysql
  shell> bin/mysql -u root < your_script_file
  ```

  By doing this, you can avoid having to issue the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you are just learning how to use `GRANT` and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

  To re-create the grant tables, remove all the `.frm`, `.MYI`, and `.MYD` files in the `mysql` database directory. Then run the `mysql_install_db` script again.

  

  Note

  For MySQL versions older than 3.22.10, you should not delete the `.frm` files. If you accidentally do this, you should copy them back into the `mysql` directory from your MySQL distribution before running `mysql_install_db`.

- You can start `mysqld` manually using the `--skip-grant-tables` [392] option and add the privilege information yourself using `mysql`:

```
shell> bin/mysqld_safe --user=mysql --skip-grant-tables &
shell> bin/mysql mysql
```

  From `mysql`, manually execute the SQL commands contained in `mysql_install_db`. Make sure that you run `mysqladmin flush-privileges` or `mysqladmin reload` afterward to tell the server to reload the grant tables.

  Note that by not using `mysql_install_db`, you not only have to populate the grant tables manually, you also have to create them first.

2.10.2.2 Starting and Stopping MySQL Automatically

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.
- Run the MySQL server as a Windows service. This can be done on versions of Windows that support services (such as NT, 2000, XP, and 2003). The service can be set to start the server automatically when Windows starts, or as a manual service that you start on request. For instructions, see Section 2.3.11, “Starting MySQL as a Windows Service”.
- Invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. This script is used on Unix and Unix-like systems. See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.
- Invoke `mysql.server`. This script is used primarily at system startup and shutdown on systems that use System V-style run directories (that is, `/etc/init.d` and run-level specific directories), where it usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See Section 4.3.3, “`mysql.server` — MySQL Server Startup Script”.
- On Mac OS X, install a separate MySQL Startup Item package to enable the automatic startup of MySQL on system startup. The Startup Item starts the server by invoking `mysql.server`. See Section 2.5, “Installing MySQL on Mac OS X”, for details.

The `mysqld_safe` and `mysql.server` scripts and the Mac OS X Startup Item can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

To start or stop the server manually using the `mysql.server` script, invoke it with `start` or `stop` arguments:

```
shell> mysql.server start
shell> mysql.server stop
```

Before `mysql.server` starts the server, it changes location to the MySQL installation directory, and then invokes `mysqld_safe`. If you want the server to run as some specific user, add an appropriate `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file, as shown later in this section. (It is possible that you will need to edit `mysql.server` if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you need to add start and stop commands to the appropriate places in your `/etc/rc*` files.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), the `mysql.server` script is installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See Section 2.4, “Installing MySQL from RPM Packages on Linux”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. The script can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree.

To install `mysql.server` manually, copy it to the `/etc/init.d` directory with the name `mysql`, and then make it executable. Do this by changing location into the appropriate directory where `mysql.server` is located and executing these commands:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

Note

Older Red Hat systems use the `/etc/rc.d/init.d` directory rather than `/etc/init.d`. Adjust the preceding commands accordingly. Alternatively, first create `/etc/init.d` as a symbolic link that points to `/etc/rc.d/init.d`:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. The `rc(8)` manual page states that scripts in this directory are executed only if their basename matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored. In other words, on

FreeBSD, you should install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, you could append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `/etc/my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the following options: `basedir`, `datadir`, and `pid-file`. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

The following table shows which option groups the server and each startup script read from option files.

Table 2.5 MySQL Startup scripts and supported server option groups

Script	Option Groups
`mysqld`	`[mysqld]`, `[server]`, `[mysqld-major_version]`
`mysqld_safe`	`[mysqld]`, `[server]`, `[mysqld_safe]`
`mysql.server`	`[mysqld]`, `[mysql.server]`, and as of MySQL 4.1.1, `[server]`

`[mysqld-major_version]` means that groups with names like `[mysqld-4.0]`, `[mysqld-4.1]`, and `[mysqld-5.0]` are read by servers having versions 4.0.x, 4.1.x, 5.0.x, and so forth. This feature was added in MySQL 4.0.14. It can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead when you begin using MySQL 4.0 or later.

For more information on MySQL configuration files and their structure and contents, see Section 4.2.3.3, “Using Option Files”.

2.10.2.3 Starting and Troubleshooting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server on Unix. If you are using Windows, see Section 2.3.13, “Troubleshooting a MySQL Installation Under Windows”.

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start.
- Specify any special options needed by the storage engines you are using.

- Make sure that the server knows where to find the data directory.
- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must be set such that the server can read and modify them.
- Verify that the network interfaces the server wants to use are available.

Some storage engines have options that control their behavior. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (`InnoDB`, `BDB`, `NDB`), be sure that you have them configured the way you want before starting the server:

- If you are using `InnoDB` tables, refer to the `InnoDB`-specific startup options. In MySQL 3.23, you must configure `InnoDB` explicitly or the server fails to start. From MySQL 4.0 on, `InnoDB` uses default values for its configuration options if you specify none. See Section 13.2.3, “`InnoDB` Configuration”.
- If you are using `BDB` (Berkeley DB) tables, see Section 13.5.3, “`BDB` Startup Options”.
- If you are using MySQL Cluster, see Section 15.3, “MySQL Cluster Configuration”.

Storage engines will use default option values if you specify none, but it is recommended that you review the available options and specify explicit values for those for which the defaults are not appropriate for your installation.

When the `mysqld` server starts, it changes location to the data directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The data directory location is hardwired in when the server is compiled. This is where the server looks for the data directory by default. If the data directory is located somewhere else on your system, the server will not work properly. You can determine what the default path settings are by invoking `mysqld` with the `--verbose` [395] and `--help` [384] options. (Prior to MySQL 4.1, omit the `--verbose` [395] option.)

If the default locations do not match the MySQL installation layout on your system, you can override them by specifying options to `mysqld` or `mysqld_safe` on the command line or in an option file.

To specify the location of the data directory explicitly, use the `--datadir` [385] option. However, normally you can tell `mysqld` the location of the base directory under which MySQL is installed and it looks for the data directory there. You can do this with the `--basedir` [384] option.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` [395] and `--help` [384] options. For example, if you change location into the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` [385] as well, but `--verbose` [395] and `--help` [384] must be the last options. (Prior to MySQL 4.1, omit the `--verbose` [395] option.)

Once you determine the path settings you want, start the server without `--verbose` [395] and `--help` [384].

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

host_name is the name of the MySQL server host.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

On Unix, change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

If it possible that even with correct ownership, MySQL may fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, you may need to reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

If the server fails to start up correctly, check the error log. Log files are located in the data directory (typically `C:\mysql\data` on Windows, `/usr/local/mysql/data` for a Unix binary distribution, and `/usr/local/var` for a Unix source distribution). Look in the data directory for files with names of the form *host_name*`.err` and *host_name*`.log`, where *host_name* is the name of your server host. (Older servers on Windows use `mysql.err` as the error log name.) Then check the last few lines of these files. On Unix, you can use `tail` to display the last few lines:

```
shell> tail host_name.err
shell> tail host_name.log
```

The error log should contain information that indicates why the server could not start. For example, you might see something like this in the log:

```
000729 14:50:10  bdb:  Recovery function for LSN 1 27595 failed
000729 14:50:10  bdb:  warning: ./test/t1.db: No such file or directory
000729 14:50:10  Can't init databases
```

This means that you did not start `mysqld` with the `--bdb-no-recover` [1138] option and Berkeley DB found something wrong with its own log files when it tried to recover your databases. To be able to continue, you should move the old Berkeley DB log files from the database directory to some other place, where you can later examine them. The `BDB` log files are named in sequence beginning with `log.0000000001`, where the number increases over time.

If you are running `mysqld` with `BDB` table support and `mysqld` dumps core at startup, this could be due to problems with the `BDB` recovery log. In this case, you can try starting `mysqld` with `--bdb-no-recover` [1138]. If that helps, you should remove all `BDB` log files from the data directory and try starting `mysqld` again without the `--bdb-no-recover` [1138] option.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in Section 5.7, “Running Multiple MySQL Servers on the Same Machine”.)

If no other server is running, try to execute the command `telnet *your_host_name tcp_ip_port_number*`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. You will need to track down what program this is and disable it, or else tell `mysqld` to listen to a different port with the `--port` [391] option. In this case, you will also need to specify the port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, you should make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1       localhost
```

This problem occurs only on systems that do not have a working thread library and for which MySQL must be configured to use MIT-pthreads.

If you cannot get `mysqld` to start, you can try to make a trace file to find the problem by using the `--debug` [385] option. See Section 18.4.3, “The DBUG Package”.

2.10.3 Securing the Initial MySQL Accounts

Part of the MySQL installation process is to set up the `mysql` database that contains the grant tables:

- Windows distributions contain preinitialized grant tables.
- On Unix, the `mysql_install_db` program populates the grant tables. Some installation methods run this program for you. Others require that you execute it manually. For details, see Section 2.10.2, “Unix Postinstallation Procedures”.

The `mysql.user` grant table defines the initial MySQL user accounts and their access privileges:

- Some accounts have the user name `root`. These are superuser accounts that have all privileges and can do anything. The initial `root` account passwords are empty, so anyone can connect to the MySQL server as `root` *without a password* and be granted all privileges.
  - On Windows, prior to MySQL 4.1.10, two `root` accounts are created; one of these is for connections from the local host and the other permits connections from any host. Beginning with MySQL 4.1.10, the Windows installer creates only one `root` account by default, which permits connections only from the local host. If the user selects the **Enable root access from remote machines** option during installation, the Windows installer creates another `root` account that permits connections from any host.
  - On Unix, each `root` account permits connections from the local host. Connections can be made by specifying a host name of `localhost` or the actual host name or IP address.

- Some accounts are for anonymous users. These have an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.
  - On Windows, one anonymous account permits connections from the local host. It has all privileges, just like the `root` accounts. The other permits connections from any host.
  - On Unix, each anonymous account permits connections from the local host. Connections can be made by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP address for the other.

To display which accounts exist in the `mysql.user` table and check whether their passwords are empty, use the following statement:

```
mysql> SELECT User, Host, Password FROM mysql.user;
+------+-------------------+----------+
| User | Host              | Password |
+------+-------------------+----------+
| root | localhost         |          |
| root | myhost.example.com |          |
|      | localhost         |          |
|      | myhost.example.com |          |
+------+-------------------+----------+
```

This output indicates that there are several `root` and anonymous-user accounts, none of which have passwords. The output might differ on your system, but the presence of accounts with empty passwords means that your MySQL installation is unprotected until you do something about it:

- You should assign a password to each MySQL `root` account.
- If you want to prevent clients from connecting as anonymous users without a password, you should either assign a password to each anonymous account or else remove the accounts.

In addition, the `mysql.db` table contains rows that permit all accounts to access the `test` database and other databases with names that start with `test` (on Windows) or that start with `test_` (on Unix). Access to test databases is permitted even for accounts that otherwise have no special privileges such as the default anonymous accounts. This is convenient for testing but inadvisable on production servers. Administrators who want database access restricted only to accounts that have permissions granted explicitly for that purpose should remove these `mysql.db` table rows.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the `root` accounts, then for the anonymous accounts. The instructions also cover how to remove the anonymous accounts, should you prefer not to permit anonymous access at all, and describe how to remove permissive access to test databases. Replace *`newpwd`* in the examples with the password that you want to use. Replace *`host_name`* with the name of the server host. You can determine this name from the output of the preceding `SELECT` statement. For the output shown, *`host_name`* is `myhost.example.com`.

Note

For additional information about setting passwords, see Section 5.6.5, “Assigning Account Passwords”. If you forget your `root` password after setting it, see Section B.5.4.1, “How to Reset the Root Password”.

You might want to defer setting the passwords until later, to avoid the need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

To set up additional accounts, see Section 5.6.2, “Adding User Accounts”.

Assigning `root` Account Passwords

The `root` account passwords can be set several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement
- Use the `UPDATE` statement
- Use the `mysqladmin` command-line client program

To assign passwords using `SET PASSWORD`, connect to the server as `root` and issue a `SET PASSWORD` statement for each `root` account listed in the `mysql.user` table. Be sure to encrypt the password using the `PASSWORD()` [868] function.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('newpwd');
```

The last statement is unnecessary if the `mysql.user` table has no `root` account with a host value of `%`.

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

You can also use a single statement that assigns a password to all `root` accounts by using `UPDATE` to modify the `mysql.user` table directly. This method works on any platform:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
    ->     WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```
shell> mysqladmin -u root password "newpwd"
shell> mysqladmin -u root -h host_name password "newpwd"
```

Those commands apply both to Windows and to Unix. The double quotation marks around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

If you are using a server from a *very* old version of MySQL, the `mysqladmin` commands to set the password fail with the message `parse error near 'SET password'`. The solution to this problem is to upgrade the server to a newer version of MySQL.

After the `root` passwords have been set, you must supply the appropriate password whenever you connect as `root` to the server. For example, to shut down the server with `mysqladmin`, use this command:

```
shell> mysqladmin -u root -p shutdown
```

```
Enter password: (enter root password here)
```

Assigning Anonymous Account Passwords

The `mysql` commands in the following instructions include a `-p` option based on the assumption that you have set the `root` account passwords using the preceding instructions and must specify that password when connecting to the server.

To assign passwords to the anonymous accounts, connect to the server as `root`, then use either `SET PASSWORD` or `UPDATE`. Be sure to encrypt the password using the `PASSWORD()` [868] function.

To use `SET PASSWORD` on Windows, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'%' = PASSWORD('newpwd');
```

To use `SET PASSWORD` on Unix, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('newpwd');
```

To set the anonymous-user account passwords with `UPDATE`, do this (on any platform):

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
    ->     WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

Removing Anonymous Accounts

If you prefer to remove any anonymous accounts rather than assigning them passwords, do so as follows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.user WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The `DELETE` statement applies both to Windows and to Unix. On Windows, if you want to remove only the anonymous account that has the same privileges as `root`, do this instead:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.user WHERE Host='localhost' AND User='';
mysql> FLUSH PRIVILEGES;
```

That account permits anonymous access but has full privileges, so removing it improves security.

Securing Test Databases

By default, the `mysql.db` table contains rows that permit access by any user to the `test` database and other databases with names that start with `test_`. (These rows have an empty `User` column value, which

for access-checking purposes matches any user name.) This means that such databases can be used even by accounts that otherwise possess no privileges. If you want to remove any-user access to test databases, do so as follows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.db WHERE Db LIKE 'test%';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the privilege change remains unnoticed by the server until you restart it.

With the preceding change, only users who have global database privileges or privileges granted explicitly for the `test` database can use it. However, if you do not want the database to exist at all, drop it:

```
mysql> DROP DATABASE test;
```

2.11 Upgrading or Downgrading MySQL

2.11.1 Upgrading MySQL

As a general rule, to upgrade from one release series to another, you should go to the next series rather than skipping a series. For example, if you currently are running MySQL 3.23 and wish to upgrade to a newer series, upgrade to MySQL 4.0 rather than to 4.1 or 5.0.

Whenever you perform an upgrade, use the items in the following checklist as a guide:

- Before any upgrade, back up your databases, including the `mysql` database that contains the grant tables.
- Read *all* the notes the upgrading section for the release series to which you are upgrading. Read the change notes as well. These provide information about new features you can use.
- Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. After you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.
- If you run MySQL Server on Windows, see Section 2.3.14, “Upgrading MySQL on Windows”.
- If you use replication, see Section 14.6, “Upgrading a Replication Setup”, for information on upgrading your replication setup.
- If you upgrade an installation originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.
- If you previously installed a MySQL-Max distribution that includes a server named `mysqld-max`, and then upgrade later to a non-Max version of MySQL, `mysqld_safe` still attempts to run the old `mysqld-max` server. If you perform such an upgrade, you should remove the old `mysqld-max` server manually to ensure that `mysqld_safe` runs the new `mysqld` server.
- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF

with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See Section 8.2.3, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

You can always move the MySQL format files and data files between different versions on the same architecture as long as you stay within versions for the same release series of MySQL. Before MySQL 4.1, if you change the character set when running MySQL, you must run `myisamchk -r -q --set-character-set=charset_name` on all `MyISAM` tables. Otherwise, your indexes may not be ordered correctly, because changing the character set may also change the sort order. As of MySQL 4.1, to convert tables created before 4.1 to the format that includes character set and collation information, use the instructions in Section 9.1.11.2, “Converting 4.0 Character Columns to 4.1 Format”.

Normally, you can upgrade MySQL to a newer MySQL version without having to do any changes to your tables. Please confirm whether the upgrade notes to the particular version you are upgrading to tell you anything about this. If there would be any incompatibilities you can use `mysqldump` to dump your tables before upgrading. After upgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables.

If you are cautious about using new versions, you can always rename your old `mysqld` before installing a newer one. For example, if you are using a version of MySQL 4.0 and want to upgrade to 4.1, rename your current server from `mysqld` to `mysqld-4.0`. If your new `mysqld` then does something unexpected, you can simply shut it down and restart with your old `mysqld`.

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, you should check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example from `libmysqlclient.so.15` to `libmysqlclient.so.16`.

If problems occur, such as that the new `mysqld` server does not want to start or that you cannot connect without a password, verify that you do not have some old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` [235] option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

It is a good idea to rebuild and reinstall the Perl `DBD::mysql` module whenever you install a new release of MySQL. The same applies to other MySQL interfaces as well, such as PHP `mysql` and extensions or the Python `MySQLdb` module.

2.11.1.1 Upgrading from MySQL 4.0 to 4.1

Note

It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, you should protect your data by making a backup.

> To upgrade to 4.1 from any previous version, MySQL recommends that you dump your tables with `mysqldump` before upgrading and reload the dump file after upgrading.

In general, you should do the following when upgrading from MySQL 4.0 to 4.1.

- Read *all* the items in the following sections to see whether any of them might affect your applications:
  - Section 2.11.1, “Upgrading MySQL”, has general update information.
  - The items in the change lists found later in this section enable you to identify upgrade issues that apply to your current MySQL installation.
  - The MySQL 4.1 change history describes significant new features you can use in 4.1 or that differ from those found in MySQL 4.0. Some of these changes may result in incompatibilities. See Section C.1, “Changes in Release 4.1.x (Lifecycle Support Ended)”.

  Note particularly any changes that are marked **Known issue** or **Incompatible change**. These incompatibilities with earlier versions of MySQL may require your attention *before you upgrade*. Note particularly the items under “Server Changes” that related to changes in character set support.
- After upgrading, update the grant tables to obtain the new longer `Password` column that is needed for more secure handling of passwords. The procedure uses `mysql_fix_privilege_tables` and is described in Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”. If you do not do this, MySQL does not use the new more secure protocol to authenticate. Implications of the password-handling change for applications are given later in this section.
- If you run MySQL Server on Windows, see Section 2.3.14, “Upgrading MySQL on Windows”. You should also be aware that two of the Windows MySQL servers were renamed in MySQL 4.1. See Section 2.3.8, “Selecting a MySQL Server Type”.
- If you use replication, see Section 14.6, “Upgrading a Replication Setup”, for information on upgrading your replication setup.
- The Berkeley DB table handler is updated to DB 4.1 (from 3.2) which has a new log format. If you have to downgrade back to 4.0 you must use `mysqldump` to dump your `BDB` tables in text format and delete all `log.XXXXXXXXXX` files before you start MySQL 4.0 and reload the data.
- MySQL 4.1.3 introduces support for per-connection time zones. See Section 9.7, “MySQL Server Time Zone Support”. To enable recognition of named time zones, you should create the time zone tables in the `mysql` database. For instructions, see Section 2.10, “Postinstallation Setup and Testing”.
- If you are using an old `DBD-mysql` module (`Msql-MySQL-modules`) you must upgrade to the newer `DBD-mysql` module. Anything above `DBD-mysql` 2.xx should be satisfactory.

  If you do not upgrade, some methods (such as `DBI->do()`) do not notice error conditions correctly.
- The `--defaults-file=`*`option_file_name`* [235] option gives an error if the option file does not exist.
- Some notes about upgrading from MySQL 4.0 to MySQL 4.1 on Netware: Make sure to upgrade Perl and PHP versions. Download Perl 5 for Netware from http://forge.novell.com/modules/xfmod/project/?perl5 and PHP from http://forge.novell.com/modules/xfmod/project/?php. Download and install the Perl module for MySQL 4.1 from http://forge.novell.com/modules/xfmod/project/showfiles.php?group_id=1126 and the PHP Extension for MySQL 4.1 from http://forge.novell.com/modules/xfmod/project/showfiles.php?group_id=1078.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

Several visible behaviors have changed between MySQL 4.0 and MySQL 4.1 to fix some critical bugs and make MySQL more compatible with standard SQL. These changes may affect your applications.

Some of the 4.1 behaviors can be tested in 4.0 before performing a full upgrade to 4.1. We have added to later MySQL 4.0 releases (from 4.0.12 on) a `--new` startup option for `mysqld`. See Section 5.1.2, “Server Command Options”.

This option gives you the 4.1 behavior for the most critical changes. You can also enable these behaviors for a given client connection with the `SET @@new=1` command, or turn them off if they are on with `SET @@new=0`.

If you believe that some of the 4.1 changes affect you, we recommend that before upgrading to 4.1, you download the latest MySQL 4.0 version and run it with the `--new` option by adding the following to your config file:

```
[mysqld-4.0]
new
```

That way you can test the new behaviors in 4.0 to make sure that your applications work with them. This helps you have a smooth, painless transition when you perform a full upgrade to 4.1 later. Putting the `--new` option in the `[mysqld-4.0]` option group ensures that you do not accidentally later run the 4.1 version with the `--new` option.

The following lists describe changes that may affect applications and that you should watch out for when upgrading from MySQL 4.0 to 4.1.

Server Changes

The most notable change is that character set support has been improved. The server supports multiple character sets, and all tables and nonbinary string columns (`CHAR`, `VARCHAR`, and `TEXT`) have a character set. See Section 9.1, “Character Set Support”. Binary string columns (`BINARY`, `VARBINARY`, and `BLOB`) contain strings of bytes and do not have a character set.

Note

This change in character set support results in the potential for table damage if you do not upgrade properly, so consider carefully the incompatibilities noted here.

- **Incompatible change**: There are conditions under which you should rebuild tables. In general, to rebuild a table, dump it with `mysqldump` and reload the dump file. Some items in the following list indicate alternatives means for rebuilding.

  - If you have created or used `InnoDB` tables with `TIMESTAMP` columns in MySQL versions 4.1.0 to 4.1.3, you must rebuild those tables when you upgrade to MySQL 4.1.4 or later. The storage format in those MySQL versions for `TIMESTAMP` columns was incorrect. If you upgrade from MySQL 4.0 to 4.1.4 or later, no rebuild of tables with `TIMESTAMP` columns is needed.

  - Starting from MySQL 4.1.3, `InnoDB` uses the same character set comparison functions as MySQL for non-`latin1_swedish_ci` character strings that are not `BINARY`. This changes the sorting order

of space and characters with a code < ASCII(32) in those character sets. For `latin1_swedish_ci` character strings and `BINARY` strings, `InnoDB` uses its own pad-spaces-at-end comparison method, which stays unchanged. Note that `latin1_swedish_ci` is the default collation order for `latin1` in 4.0. If you have an `InnoDB` table created with MySQL 4.1.2 or earlier, with an index on a non-`latin1_swedish_ci` character set and collation order column that is not `BINARY` (in the case of 4.1.0 and 4.1.1, with any character set and collation), and that column may contain characters with a code < ASCII(32), you should do `ALTER TABLE` or `OPTIMIZE TABLE` on it to regenerate the index, after upgrading to MySQL 4.1.3 or later. You can also rebuild the table from a dump.

`MyISAM` tables also have to be rebuilt or repaired in these cases. You can use `mysqldump` to dump them in 4.0 and then reload them in 4.1. An alternative is to use `OPTIMIZE TABLE` after upgrading, but this *must* be done before any updates are made in 4.1.

- As of MySQL 4.1.2, string comparison works according to the SQL standard: Instead of stripping end spaces before comparison, we now extend the shorter string with spaces. The problem with this is that now `'a' > 'a\t'`, which it was not before. If you have any tables where you have indexes on `CHAR`, `VARCHAR` or `TEXT` column in which the last character in index values may be less than `ASCII(32)`, you should rebuild those indexes to ensure that the table is correct.
- If you have used column prefix indexes on UTF-8 columns or other multi-byte character set columns in MySQL 4.1.0 to 4.1.5, you must rebuild the tables when you upgrade to MySQL 4.1.6 or later.
- If you have used accent characters (characters with byte values of 128 to 255) in database names, table names, constraint names, or column names in versions of MySQL earlier than 4.1, you cannot upgrade to MySQL 4.1 directly, because 4.1 uses UTF-8 to store metadata. Use `RENAME TABLE` to overcome this if the accent character is in the table name or the database name, or rebuild the table.
- `MyISAM` tables now use an improved checksum algorithm in MySQL 4.1. If you have `MyISAM` tables with live checksum enabled (you used `CHECKSUM=1` in `CREATE TABLE` or `ALTER TABLE`), these tables appear to be corrupted following an upgrade. Use `REPAIR TABLE` to recalculate the checksum for each such table.

- **Incompatible change**: MySQL interprets length specifications in character column definitions in characters. (Earlier versions interpret them in bytes.) For example, `CHAR(N)` means *`N`* characters, not *`N`* bytes.

  For single-byte character sets, this change makes no difference. However, if you upgrade to MySQL 4.1 and configure the server to use a multi-byte character set, the apparent length of character columns changes. Suppose that a 4.0 table contains a `CHAR(8)` column used to store `ujis` characters. Eight bytes can store from two to four `ujis` characters. If you upgrade to 4.1 and configure the server to use `ujis` as its default character set, the server interprets character column lengths based on the maximum size of a `ujis` character, which is three bytes. The number of three-byte characters that fit in eight bytes is two. Consequently, if you use `SHOW CREATE TABLE` to view the table definition, MySQL displays `CHAR(2)`. You can retrieve existing data from the table, but you can only store new values containing up to two characters. To correct this issue, use `ALTER TABLE` to change the column definition. For example:

  ```
  ALTER TABLE tbl_name MODIFY col_name CHAR(8);
  ```

- **Incompatible change:** As of MySQL 4.1.2, handling of the `FLOAT` and `DOUBLE` floating-point data types is more strict to follow standard SQL. For example, a data type of `FLOAT(3,1)` stores a maximum value of 99.9. Before 4.1.2, the server permitted larger numbers to be stored. That is, it stored a value such as 100.0 as 100.0. As of 4.1.2, the server clips 100.0 to the maximum permissible value of 99.9. If you have tables that were created before MySQL 4.1.2 and that contain floating-point data not strictly legal for the data type, you should alter the data types of those columns. For example:

```
ALTER TABLE tbl_name MODIFY col_name FLOAT(4,1);
```

- **Incompatible change**: In connection with the support for per-connection time zones in MySQL 4.1.3, the `timezone` [432] system variable was renamed to `system_time_zone` [430].

- **Incompatible change**: For `ENUM` columns that had enumeration values containing commas, the commas were mapped to 0xff internally. However, this rendered the commas indistinguishable from true 0xff characters in the values. This no longer occurs. However, the fix requires that you dump and reload any tables that have `ENUM` columns containing true 0xff in their values: Dump the tables using `mysqldump` with the current server before upgrading from a version of MySQL 4.1 older than 4.1.23 to version 4.1.23 or newer.

- **Incompatible change**: The interface to aggregate user-defined functions changed as of MySQL 4.1.1. You must declare a `xxx_clear()` function for each aggregate function `XXX()`. `xxx_clear()` is used instead of `xxx_reset()`. See Section 18.2.2.2, “UDF Calling Sequences for Aggregate Functions”.

- **Incompatible change:** MySQL 4.1 stores table names and column names in `utf8`. If you have table names or column names that use characters outside of the standard 7-bit US-ASCII range, you may have to do a `mysqldump` of your tables in MySQL 4.0 and restore them after upgrading to MySQL 4.1. The symptom for this problem is that you get a `table not found` error when trying to access your tables. In this case, you should be able to downgrade back to MySQL 4.0 and access your data.

- **Important note:** If you upgrade to MySQL 4.1.1 or higher, it is difficult to downgrade back to 4.0 or 4.1.0. That is because, for earlier versions, `InnoDB` is not aware of multiple tablespaces.

- All tables and nonbinary string columns (`CHAR`, `VARCHAR`, and `TEXT`) have a character set. See Section 9.1, “Character Set Support”. Binary string columns (`BINARY`, `VARBINARY`, and `BLOB`) contain strings of bytes and do not have a character set.

  Character set information is displayed by `SHOW CREATE TABLE` and `mysqldump`. (MySQL versions 4.0.6 and above can read the new dump files; older versions cannot.) This change should not affect applications that use only one character set.

- If you were using columns with the `CHAR BINARY` or `VARCHAR BINARY` data types in MySQL 4.0, these were treated as binary strings. To have them treated as binary strings in MySQL 4.1, you should convert them to the `BINARY` and `VARBINARY` data types, respectively.

- If you have table columns that store character data represented in a character set that the 4.1 server supports directly, you can convert the columns to the proper character set using the instructions in Section 9.1.11.2, “Converting 4.0 Character Columns to 4.1 Format”. Also, database, table, and column identifiers are stored internally using Unicode (UTF-8) regardless of the default character set. See Section 8.2, “Database, Table, Index, Column, and Alias Names”.

- The table definition format used in `.frm` files has changed slightly in 4.1. MySQL 4.0 versions from 4.0.11 on can read the new `.frm` format directly, but older versions cannot. If you need to move tables from 4.1 to a version earlier than 4.0.11, you should use `mysqldump`.

- Windows servers support connections from local clients using shared memory if run with the `--shared-memory` [392] option. If you are running multiple servers this way on the same Windows machine, you should use a different `--shared-memory-base-name` option for each server.

- As of MySQL 4.1.21, the `lc_time_names` [417] system variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()` [832], `DAYNAME()` [833] and `MONTHNAME()` [837] functions. See Section 9.8, “MySQL Server Locale Support”.

- As of MySQL 4.1.10a, the server by default no longer loads user-defined functions (UDFs) unless they have at least one auxiliary symbol defined in addition to the main function symbol. This behavior can be overridden with the `--allow-suspicious-udfs` [384] option. See Section 18.2.2.6, "User-Defined Function Security Precautions".

Client Changes

- As of MySQL 4.1, `mysqldump` has the `--opt` [297] and `--quote-names` [298] options enabled by default. You can turn these off using `--skip-opt` [299] and `--skip-quote-names`.

SQL Changes

- **Incompatible change**: `TIMESTAMP` is returned in MySQL 4.1 as a string in `'YYYY-MM-DD HH:MM:SS'` format. (See Section 10.3.1.2, "`TIMESTAMP` Properties as of MySQL 4.1".) From 4.0.12 on, the `--new` option can be used to make a 4.0 server behave as 4.1 in this respect. The effect of this option is described in Section 10.3.1.1, "`TIMESTAMP` Properties Prior to MySQL 4.1".

  When running the server with `--new`, if you want to have a `TIMESTAMP` column returned as a number (as MySQL 4.0 does by default), you should add `+0` when you retrieve it:

```
mysql> SELECT ts_col + 0 FROM tbl_name;
```

  Display widths for `TIMESTAMP` columns are no longer supported in MySQL 4.1. For example, if you declare a column as `TIMESTAMP(10)`, the `(10)` is ignored.

- **Incompatible change**: Binary values such as `0xFFDF` are assumed to be strings instead of numbers. This fixes some problems with character sets where it is convenient to input a string as a binary value. With this change, you should use `CAST()` [859] if you want to compare binary values numerically as integers:

```
mysql> SELECT CAST(0xFEFF AS UNSIGNED INTEGER)
    ->        < CAST(0xFF AS UNSIGNED INTEGER);
        -> 0
```

  If you do not use `CAST()` [859], a lexical string comparison is made instead:

```
mysql> SELECT 0xFEFF < 0xFF;
        -> 1
```

  Using binary items in a numeric context or comparing them using the `=` operator should work as before. (The `--new` option can be used from 4.0.13 on to make a 4.0 server behave as 4.1 in this respect.)

- **Incompatible change:** Before MySQL 4.1.13, conversion of `DATETIME` values to numeric form by adding zero produced a result in `YYYYMMDDHHMMSS` format. The result of `DATETIME+0` is now in `YYYYMMDDHHMMSS.000000` format.

- **Incompatible change:** In MySQL 4.1.12, the behavior of `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` has changed when the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values both are empty. Formerly, a column was read or written using the display width of the column. For example, `INT(4)` was read or written using a field with a width of 4. Now columns are read and written using a field width wide enough to hold all values in the field. However, data files written before this change was made might not be reloaded correctly with `LOAD DATA INFILE` for MySQL 4.1.12 and up. This change also affects data files read by `mysqlimport` and written by `mysqldump --tab`, which use `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`. For more information, see Section 12.2.5, "`LOAD DATA INFILE` Syntax".

- **Incompatible change**: Before MySQL 4.1.1, the statement parser was less strict and its string-to-date conversion would ignore everything up to the first digit. As a result, invalid statements such as the following were accepted:

```
INSERT INTO t (datetime_col) VALUES ('stuff 2005-02-11 10:17:01');
```

  As of MySQL 4.1.1, the parser is stricter and treats the string as an invalid date, so the preceding statement results in a warning.

- **Incompatible change**: In MySQL 4.1.2, the `Type` column in the output from `SHOW TABLE STATUS` was renamed to `Engine`. This affects applications that identify output columns by name rather than by position.

- **Incompatible change**: The syntax for multiple-table `DELETE` statements that use table aliases changed between MySQL 4.0 and 4.1. In MySQL 4.0, you should use the true table name to refer to any table from which rows should be deleted:

```
DELETE test FROM test AS t1, test2 WHERE ...
```

  In MySQL 4.1, you must use the alias:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

  We did not make this change in 4.0 to avoid breaking any old 4.0 applications that were using the old syntax. However, if you use such `DELETE` statements and are using replication, the change in syntax means that a 4.0 master cannot replicate to 4.1 (or higher) slaves.

- Some keywords are reserved in MySQL 4.1 that were not reserved in MySQL 4.0. See Section 8.3, “Reserved Words”.

- The `LOAD DATA FROM MASTER` and `LOAD TABLE FROM MASTER` statements are deprecated. See Section 12.5.2.2, “`LOAD DATA FROM MASTER` Syntax”, for recommended alternatives.

- For functions that produce a `DATE`, `DATETIME`, or `TIME` value, the result returned to the client is fixed up to have a temporal type. For example, in MySQL 4.1, you obtain the following:

```
mysql> SELECT CAST('2001-1-1' AS DATETIME);
       -> '2001-01-01 00:00:00'
```

  In MySQL 4.0, the result of the stement is different:

```
mysql> SELECT CAST('2001-1-1' AS DATETIME);
       -> '2001-01-01'
```

- `DEFAULT` values no longer can be specified for `AUTO_INCREMENT` columns. (In 4.0, a `DEFAULT` value is silently ignored; in 4.1, an error occurs.)

- `LIMIT` no longer accepts negative arguments. Use some large number (maximum 18446744073709551615) instead of -1.

- `SERIALIZE` is no longer a valid mode value for the `sql_mode` [429] variable. You should use `SET TRANSACTION ISOLATION LEVEL SERIALIZABLE` instead. `SERIALIZE` is no longer valid for the `--sql-mode` [394] option for `mysqld`, either. Use `--transaction-isolation=SERIALIZABLE` instead.

- A new startup option named `innodb_table_locks` was added that causes `LOCK TABLE` to also acquire `InnoDB` table locks. This option is enabled by default. This can cause deadlocks in applications that use `autocommit = 1` [406] and `LOCK TABLES`. If you application encounters deadlocks after upgrading, you may need to add `innodb_table_locks = 0` to your `my.cnf` file.

C API Changes

- **Incompatible change**: The `mysql_shutdown()` C API function has an extra parameter as of MySQL 4.1.3: `SHUTDOWN`-level. You should convert any `mysql_shutdown(X)` call you have in your application to `mysql_shutdown(X,SHUTDOWN_DEFAULT)`. Any third-party API that links against the C API library must be modified to account for this change or it will not compile.

- Some C API calls such as `mysql_real_query()` return `1` on error, not `-1`. You may have to change some old applications if they use constructs like this:

```
if (mysql_real_query(mysql_object, query, query_length) == -1)
{
  printf("Got error");
}
```

  Change the call to test for a nonzero value instead:

```
if (mysql_real_query(mysql_object, query, query_length) != 0)
{
  printf("Got error");
}
```

Password-Handling Changes

The password hashing mechanism changed in 4.1 to provide better security; this may cause compatibility problems if you have clients using the client library from 4.0 or earlier. (It is very likely that you have 4.0 clients in situations where clients connect from remote hosts that have not yet upgraded to 4.1.) The following list indicates some possible upgrade strategies. They represent various tradeoffs between the goals of compatibility with old clients and security.

- Only upgrade the client to use 4.1 client libraries (not the server). No behavior changes (except the return value of some API calls), but you cannot use any of the new features provided by the 4.1 client/server protocol, either. (MySQL 4.1 has an extended client/server protocol that offers such features as prepared statements and multiple result sets.) See Section 17.6.7, “C API Prepared Statements”.

- Upgrade to 4.1 and run the `mysql_fix_privilege_tables` script to widen the `Password` column in the `user` table so that it can hold long password hashes. However—to provide backward compatibility enabling pre-4.1 clients to continue connecting to their short-hash accounts—run the server with the `--old-passwords` [391] option. Eventually, when all your clients are upgraded to 4.1, you can stop using the `--old-passwords` [391] server option. You can also change the passwords for your MySQL accounts to use the new more secure format. A 4.1 installation using only the improved authentication protocol is the most secure one.

Further background on password hashing with respect to client authentication and password-changing operations may be found in Section 5.4.2.3, “Password Hashing in MySQL”, and Section B.5.2.4, “`Client does not support authentication protocol`”.

2.11.1.2 Upgrading from MySQL 3.23 to 4.0

In general, you should do the following when upgrading from MySQL 3.23 to 4.0:

- Read all the items in Section 2.11.1, “Upgrading MySQL”, to see whether any of them might affect your applications.
- Read all the items in the change list found later in this section to see whether any of them might affect your applications. Note particularly any that are marked **Known issue** or **Incompatible change**; these result in incompatibilities with earlier versions of MySQL.
- Read the 4.0 changelog to see what significant new features you can use in 4.0. See Section C.2, “Changes in Release 4.0.x (Lifecycle Support Ended)”.
- If you run MySQL Server on Windows, see Section 2.3.14, “Upgrading MySQL on Windows”.
- After upgrading, update the grant tables to add new privileges and features. This procedure uses the `mysql_fix_privilege_tables` script and is described in Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.
- If you use replication, see Section 14.6, “Upgrading a Replication Setup”, for information on upgrading your replication setup.
- Edit any MySQL startup scripts or option files so that they do not use any of the options described as deprecated later in this section.
- Convert your old `ISAM` tables to `MyISAM` format. One way to do this is with the `mysql_convert_table_format` script. (This is a Perl script; it requires that `DBI` be installed.) To convert all of the tables in a given database, use this command:

  ```
  shell> mysql_convert_table_format database db_name
  ```

  Note that the above command should be used only if *all* tables in the database are `ISAM` or `MyISAM` tables. To avoid converting tables of other types to `MyISAM`, you can explicitly list the names of the `ISAM` tables following the database name on the command line.

  Individual tables can be changed to `MyISAM` by using the following `ALTER TABLE` statement for each table to be converted:

  ```
  mysql> ALTER TABLE tbl_name TYPE=MyISAM;
  ```

  If you are not sure of the storage engine for a given table, use this statement:

  ```
  mysql> SHOW TABLE STATUS LIKE 'tbl_name';
  ```

- Ensure that you do not have any MySQL clients that use shared libraries (like the Perl `DBD::mysql` module). If you do, you should recompile them, because the data structures used in `libmysqlclient.so` have changed. The same applies to other MySQL interfaces such as the Python `MySQLdb` module.

MySQL 4.0 works even if you do not perform the preceding actions, but you cannot use the new security privileges in MySQL 4.0 and you may run into problems when upgrading later to MySQL 4.1 or newer. The `ISAM` file format still works in MySQL 4.0, but is deprecated and is not compiled in by default as of MySQL 4.1. `MyISAM` tables should be used instead.

Old clients should work with a MySQL 4.0 server without any problems.

Even if you perform the preceding actions, you can still downgrade to MySQL 3.23.52 or newer if you run into problems with the MySQL 4.0 series. In this case, you must use `mysqldump` to dump any tables that

use full-text indexes and reload the dump file into the 3.23 server. This is necessary because 4.0 uses an improved format for full-text indexing that is not backward-compatible.

The following lists describe changes that may affect applications and that you should watch out for when upgrading from MySQL 3.23 to 4.0.

Server Changes

- As of MySQL 4.0.24, the server by default no longer loads user-defined functions unless they have at least one auxiliary symbol defined in addition to the main function symbol. This behavior can be overridden with the `--allow-suspicious-udfs` [384] option. See Section 18.2.2.6, "User-Defined Function Security Precautions".

- MySQL 4.0 has many new privileges in the `mysql.user` table. See Section 5.5.1, "Privileges Provided by MySQL".

  For these new privileges to work, you must update the grant tables. The procedure for this is described in Section 4.4.5, "`mysql_fix_privilege_tables` — Upgrade MySQL System Tables". Until you do this, all accounts have the `SHOW DATABASES` [492], `CREATE TEMPORARY TABLES` [491], and `LOCK TABLES` [492] privileges. `SUPER` [493] and `EXECUTE` [491] privileges take their value from `PROCESS` [492]. `REPLICATION SLAVE` [492] and `REPLICATION CLIENT` [492] take their values from `FILE` [491].

  If you have any scripts that create new MySQL user accounts, you may want to change them to use the new privileges. If you are not using `GRANT` commands in the scripts, this is a good time to change your scripts to use `GRANT` instead of modifying the grant tables directly.

  From version 4.0.2 on, the option `--safe-show-database` [391] is deprecated (and no longer does anything). See Section 5.4.4, "Security-Related `mysqld` Options".

  If you get `Access denied` errors for new users in version 4.0.2 and up, you should check whether you need some of the new grants that you did not need before. In particular, you need `REPLICATION SLAVE` [492] (instead of `FILE` [491]) for new slave servers.

- `safe_mysqld` has been renamed to `mysqld_safe`. For backward compatibility, binary distributions will for some time include `safe_mysqld` as a symlink to `mysqld_safe`.

- `InnoDB` support is included by default in binary distributions. If you build MySQL from source, `InnoDB` is configured in by default. If you do not use `InnoDB` and want to save memory when running a server that has `InnoDB` support enabled, use the `--skip-innodb` [1066] server startup option. To compile MySQL without `InnoDB` support, run `configure` with the `--without-innodb` option.

- Values for the startup parameters `myisam_max_extra_sort_file_size` [421] and `myisam_max_extra_sort_file_size` [421] are given in bytes (prior to 4.0.3,they were given in megabytes).

- `mysqld` has the option `--temp-pool` [394] enabled by default because this gives better performance with some operating systems (most notably Linux).

- The `mysqld` startup options `--skip-locking` and `--enable-locking` were renamed to `--skip-external-locking` [392] and `--external-locking` [387]. `--skip-locking` and `--enable-locking` are deprecated.

- External system locking of `MyISAM`/`ISAM` files is turned off by default. You can turn this on with `--external-locking` [387]. (However, this is never needed for most users.)

- The following startup variables and options were renamed:

Name in 3.23	Name in 4.0 (and above)
myisam_bulk_insert_tree_size	bulk_insert_buffer_size [408]
query_cache_startup_type	query_cache_type [424]
record_buffer	read_buffer_size [425]
record_rnd_buffer	read_rnd_buffer_size [426]
sort_buffer	sort_buffer_size [427]
--warnings	--log-warnings [389]
--err-log	--log-error [388] (for mysqld_safe)

The startup options record_buffer, sort_buffer, and warnings still work in MySQL 4.0 but are deprecated.

SQL Changes

- Some keywords are reserved in MySQL 4.0 that were not reserved in MySQL 3.23. See Section 8.3, “Reserved Words”.
- The following SQL variables have been renamed:

Name in 3.23	Name in 4.0 and above
sql_big_tables	big_tables [407]
sql_low_priority_updates	low_priority_updates [418]
sql_max_join_size	max_join_size [419]
sql_query_cache_type	query_cache_type [424]

The older names still work in MySQL 4.0 but are deprecated.

- You must use SET GLOBAL SQL_SLAVE_SKIP_COUNTER=skip_count instead of SET SQL_SLAVE_SKIP_COUNTER=skip_count.
- SHOW MASTER STATUS returns an empty set if binary logging is not enabled.
- SHOW SLAVE STATUS returns an empty set if the slave is not initialized.
- SHOW INDEX has two more columns in 4.0 than in 3.23 (Null and Index_type).
- The format of SHOW OPEN TABLES changed.
- As of MySQL 4.0.11, ORDER BY col_name DESC sorts NULL values last. In 3.23 and in earlier 4.0 versions, this was not always consistent.
- CHECK, LOCALTIME, and LOCALTIMESTAMP are reserved words.
- DOUBLE and FLOAT columns honor the UNSIGNED flag on storage (previously, UNSIGNED was ignored for these columns).
- The result of all bitwise operators (|, &, <<, >>, and ~) is unsigned. This may cause problems if you are using them in a context where you want a signed result. See Section 11.10, “Cast Functions and Operators”.

Note

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned. In other words, before upgrading to MySQL 4.0, you should check your application for cases in which you are subtracting a value from an unsigned entity and want a negative answer or subtracting an unsigned value from an integer column. You can disable this behavior by using the `--sql-mode=NO_UNSIGNED_SUBTRACTION` [394] option when starting `mysqld`. See Section 5.1.6, “Server SQL Modes”.

- You should use integers to store values in `BIGINT` columns (instead of using strings as in MySQL 3.23). Using strings still works, but using integers is more efficient.
- In MySQL 3.23, `INSERT INTO ... SELECT` always had `IGNORE` enabled. As of 4.0.1, MySQL stops (and possibly rolls back) by default in case of an error unless you specify `IGNORE`.
- You should use `TRUNCATE TABLE` when you want to delete all rows from a table and you do not need to obtain a count of the number of rows that were deleted. (`DELETE FROM` *`tbl_name`* returns a row count in 4.0 and does not reset the `AUTO_INCREMENT` counter, and `TRUNCATE TABLE` is faster.)
- You get an error if you have an active transaction or `LOCK TABLES` statement when trying to execute `TRUNCATE TABLE` or `DROP DATABASE`.
- To use `MATCH ... AGAINST (... IN BOOLEAN MODE)` full-text searches, you must rebuild existing table indexes using `REPAIR TABLE` *`tbl_name`* `USE_FRM`. If you attempt a boolean full-text search without rebuilding the indexes in this manner, the search returns incorrect results. See Section 11.9.6, “Fine-Tuning MySQL Full-Text Search”.
- `LOCATE()` [798] and `INSTR()` [797] are case sensitive if one of the arguments is a binary string. Otherwise they are case insensitive.
- `STRCMP()` [807] uses the current character set when performing comparisons. This makes the default comparison behavior not case sensitive unless one or both of the operands are binary strings.
- `HEX(`*`str`*`)` [796] returns the characters in *`str`* converted to hexadecimal. If you want to convert a number to hexadecimal, you should ensure that you call `HEX()` [796] with a numeric argument.
- `RAND(seed)` [822] returns a different random number series in 4.0 than in 3.23; this was done to further differentiate `RAND(seed)` [822] and `RAND(seed+1)` [822].
- The default type returned by `IFNULL(A,B)` [791] is set to be the more “general” of the types of `A` and `B`. (The general-to-specific order is string, `REAL`, `INTEGER`).

C API Changes

- The old C API functions `mysql_drop_db()`, `mysql_create_db()`, and `mysql_connect()` are no longer supported in MySQL 4.0 unless MySQL is compiled with `CFLAGS=-DUSE_OLD_FUNCTIONS`. It is preferable to change client programs to use the new 4.0 API instead.
- In the `MYSQL_FIELD` structure, `length` and `max_length` have changed from `unsigned int` to `unsigned long`. This should not cause any problems, except that they may generate warning messages when used as arguments in the `printf()` class of functions.
- Multi-threaded clients should use `mysql_thread_init()` and `mysql_thread_end()`. See Section 17.6.3.2, “Writing C API Threaded Client Programs”.

Other Changes

- If you want to recompile the Perl `DBD::mysql` module, use a recent version. Version 2.9003 is recommended. Versions older than 1.2218 should not be used because they use the deprecated `mysql_drop_db()` call.

2.11.2 Downgrading MySQL

This section describes what you should do to downgrade to an older MySQL version in the unlikely case that the previous version worked better than the new one.

If you are downgrading within the same release series (for example, from 4.0.20 to 4.0.19) the general rule is that you merely need to install the new binaries on top of the old ones. There is no need to do anything with the databases. As always, however, it is always a good idea to make a backup.

The following items form a checklist of things you should do whenever you perform a downgrade:

- Read the upgrading section for the release series from which you are downgrading to be sure that it does not have any features you really need. See Section 2.11.1, “Upgrading MySQL”.
- If there is a downgrading section for that version, please read it, too!
- To see which new features were added between the version to which you are downgrading and your current version, see the change logs (Appendix C, *MySQL Release Notes*).
- Check Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”, to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are downgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to downgrade the affected tables using the instructions in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

You can always move the MySQL format files and data files between different versions on the same architecture as long as you stay within versions for the same release series of MySQL.

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use `mysqldump` to dump your tables before downgrading. After downgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables. For examples, ee Section 2.11.5, “Copying MySQL Databases to Another Machine”.

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.
4. Stop the newer MySQL server and restart the older one.
5. Reload the dump file into the older server. Your tables should be accessible.

It might also be the case that the structure of the system tables in the `mysql` database has changed and that downgrading introduces some loss of functionality or requires some adjustments. Here are some examples:

- Trigger creation requires the `TRIGGER` privilege as of MySQL 5.1. In MySQL 5.0, there is no `TRIGGER` privilege and `SUPER` is required instead. If you downgrade from MySQL 5.1 to 5.0, you will need to give the `SUPER` privilege to those accounts that had the `TRIGGER` privilege in 5.1.

- Triggers were added in MySQL 5.0, so if you downgrade from 5.0 to 4.1, you cannot use triggers at all.

2.11.2.1 Downgrading to MySQL 4.0

The table format in 4.1 changed to include more and new character set information. Because of this, you must use `mysqldump` to dump any tables you have created with the newer MySQL server. For example, if all the tables in a particular database need to be dumped to be reverted back to MySQL 4.0 format, use this command:

```
shell> mysqldump --create-options --compatible=mysql40 db_name > dump_file
```

Then stop the newer server, restart the older server, and read in the dump file:

```
shell> mysql db_name < dump_file
```

In the special case that you are downgrading `MyISAM` tables, no special treatment is necessary if all columns in the tables contain only numeric columns or string columns (`CHAR`, `VARCHAR`, `TEXT`, and so forth) that contain only `latin1` data. Your 4.1 tables should be directly usable with a 4.0 server.

If you used the `mysql_fix_privilege_tables` script to upgrade the grant tables, you can either use the preceding method to convert them to back to MySQL 4.0 or do the following in MySQL 4.1 (or above):

```
ALTER TABLE mysql.user
  CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_ci;
ALTER TABLE mysql.db
  CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_ci;
ALTER TABLE mysql.host
  CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_ci;
ALTER TABLE mysql.tables_priv
  CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_ci;
ALTER TABLE mysql.columns_priv
  CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_ci;
ALTER TABLE mysql.func
  CONVERT TO CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

2.11.3 Checking Whether Tables or Indexes Must Be Rebuilt

A binary upgrade or downgrade is one that installs one version of MySQL “in place” over an existing version, without dumping and reloading tables:

1. Stop the server for the existing version if it is running.
2. Install a different version of MySQL. This is an upgrade if the new version is higher than the original version, a downgrade if the version is lower.
3. Start the server for the new version.

In many cases, the tables from the previous version of MySQL can be used without problem by the new version. However, sometimes changes occur that require tables or table indexes to be rebuilt, as described in this section. If you have tables that are affected by any of the issues described here, rebuild the tables or indexes as necessary using the instructions given in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

Index Incompatibilities

If you perform a binary upgrade without dumping and reloading tables, you cannot upgrade directly from MySQL 4.1 to 5.1 or higher. This occurs due to an incompatible change in the `MyISAM` table index format

in MySQL 5.0. Upgrade from MySQL 4.1 to 5.0 and repair all `MyISAM` tables. Then upgrade from MySQL 5.0 to 5.1 and check and repair your tables.

Modifications to the handling of character sets or collations might change the character sort order, which causes the ordering of entries in any index that uses an affected character set or collation to be incorrect. Such changes result in several possible problems:

- Comparison results that differ from previous results
- Inability to find some index values due to misordered index entries
- Misordered `ORDER BY` results
- Tables that `CHECK TABLE` reports as being in need of repair

The solution to these problems is to rebuild any indexes that use an affected character set or collation, either by dropping and re-creating the indexes, or by dumping and reloading the entire table. For information about rebuilding indexes, see Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

To check whether a table has indexes that must be rebuilt, consult the following list. It indicates which versions of MySQL introduced character set or collation changes that require indexes to be rebuilt. Each entry indicates the version in which the change occurred and the character sets or collations that the change affects. If the change is associated with a particular bug report, the bug number is given.

The list applies both for binary upgrades and downgrades. For example, Bug #27877 was fixed in MySQL 5.1.24 and 5.4.0, so it applies to upgrades from versions older than 5.1.24 to 5.1.24 or newer, and to downgrades from 5.1.24 or newer to versions older than 5.1.24.

Changes that cause index rebuilding to be necessary:

- MySQL 4.1.2 (Bug #3152)

  String comparison works according to the SQL standard: Instead of stripping end spaces before comparison, we now extend the shorter string with spaces. The problem with this is that now `'a' > 'a\t'`, which it was not before. If you have any tables where you have indexes on `CHAR`, `VARCHAR` or `TEXT` column in which the last character in index values may be less than `ASCII(32)`, you should rebuild those indexes.

- MySQL 4.1.3

  `InnoDB` uses the same character set comparison functions as MySQL for non-`latin1_swedish_ci` character strings that are not `BINARY`. This changes the sorting order of space and characters with a code < ASCII(32) in those character sets. This affects `InnoDB` tables with an index on a non-`latin1_swedish_ci` character set and collation order column that is not `BINARY` if that column contains characters with a code < ASCII(32). (For MySQL 4.1.0 and 4.1.1, it affects indexes with any character set and collation).

- MySQL 5.0.48, 5.1.21 (Bug #29461)

  Affects indexes for columns that use any of these character sets: `eucjpms`, `euc_kr`, `gb2312`, `latin7`, `macce`, `ujis`

- MySQL 5.0.48, 5.1.23 (Bug #27562)

  Affects indexes that use the `ascii_general_ci` collation for columns that contain any of these characters: `'``'` GRAVE ACCENT, `'['` LEFT SQUARE BRACKET, `'\'` REVERSE SOLIDUS, `']'` RIGHT SQUARE BRACKET, `'~'` TILDE

- MySQL 5.1.24, 5.4.0 (Bug #27877)

  Affects indexes that use the `utf8_general_ci` or `ucs2_general_ci` collation for columns that contain `'ß'` LATIN SMALL LETTER SHARP S (German).

2.11.4 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild a table. This can be necessitated by changes to MySQL such as how data types are handled or changes to character set handling. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation. (For examples, see Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”.) It might also be that a table repair or upgrade should be done as indicated by a table check operation such as that performed by `CHECK TABLE` or `mysqlcheck`.

Methods for rebuilding a table include dumping and reloading it, or using `ALTER TABLE` or `REPAIR TABLE`.

Note

If you are rebuilding tables because a different version of MySQL will not handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before* upgrading or downgrading using your original version of MySQL. Then reload the tables *after* upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

To rebuild a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```
shell> mysqldump db_name t1 > dump.sql
shell> mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
shell> mysqldump db_name > dump.sql
shell> mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the `--all-databases` [293] option:

```
shell> mysqldump --all-databases > dump.sql
shell> mysql < dump.sql
```

Before MySQL 4.1, use the `--opt` [297] and `--quote-names` [298] options. As of 4.1, those options are enabled by default.

To rebuild a table with `ALTER TABLE`, use a “null” alteration; that is, an `ALTER TABLE` statement that “changes” the table to use the storage engine that it already has. For example, if `t1` is a `MyISAM` table, use this statement:

```
mysql> ALTER TABLE t1 ENGINE = MyISAM;
```

If you are not sure which storage engine to specify in the `ALTER TABLE` statement, use `SHOW CREATE TABLE` to display the table definition.

If you must rebuild a table because a table checking operation indicates that the table is corrupt or needs an upgrade, you can use `REPAIR TABLE` if that statement supports the table's storage engine. For example, to repair a `MyISAM` table, use this statement:

```
mysql> REPAIR TABLE t1;
```

For storage engines such as `InnoDB` that `REPAIR TABLE` does not support, use `mysqldump` to create a dump file and `mysql` to reload the file, as described earlier.

For specifics about which storage engines `REPAIR TABLE` supports, see Section 12.4.2.6, "`REPAIR TABLE` Syntax".

`mysqlcheck --repair` provides command-line access to the `REPAIR TABLE` statement. This can be a more convenient means of repairing tables because you can use the `--databases` [285] or `--all-databases` [285] option to repair all tables in specific databases or all databases, respectively:

```
shell> mysqlcheck --repair --databases db_name ...
shell> mysqlcheck --repair --all-databases
```

2.11.5 Copying MySQL Databases to Another Machine

If you are using MySQL 3.23 or later, you can copy the `.frm`, `.MYI`, and `.MYD` files for `MyISAM` tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See Section 13.1, "The `MyISAM` Storage Engine".

The MySQL `ISAM` data and index files (`.ISD` and `*.ISM`, respectively) are dependent upon the architecture and, in some cases, the operating system. If you want to move applications to another machine having a different architecture or operating system than that of the current machine, you should not try to move a database by simply copying the files to the other machine. Use `mysqldump` instead.

By default, `mysqldump` creates a file containing SQL statements. You can then transfer the file to the other machine and use it as input to the `mysql` client.

Try `mysqldump --help` to see what options are available. Before MySQL 4.1, if you are moving the data to a newer version of MySQL, you should add the `--opt` [297] option to the `mysqldump` commands shown here, to take advantage of any optimizations that result in a dump file that is smaller and can be processed faster. (`--opt` [297] is enabled by default as of MySQL 4.1.)

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
shell> mysqladmin -h 'other_hostname' create db_name
shell> mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
shell> mysqladmin create db_name
shell> mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
shell> mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
shell> mysqladmin create db_name
shell> gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For very large tables, this is much faster than simply using `mysqldump`. In the following commands, *`DUMPDIR`* represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
shell> mkdir DUMPDIR
shell> mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the *`DUMPDIR`* directory to a directory on the target machine and load the files into MySQL there:

```
shell> mysqladmin create db_name           # create database
shell> cat DUMPDIR/*.sql | mysql db_name   # create tables in database
shell> mysqlimport db_name DUMPDIR/*.txt   # load data into tables
```

Do not forget to copy the `mysql` database because that is where the `user`, `db`, and `host` grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

2.12 Operating System-Specific Notes

2.12.1 Linux Notes

This section discusses issues that have been found to occur on Linux. The first few subsections describe general operating system-related issues, problems that can occur when using binary or source distributions, and postinstallation issues. The remaining subsections discuss problems that occur with Linux on specific platforms.

Note that most of these problems occur on older versions of Linux. If you are running a recent version, you may see none of them.

2.12.1.1 Linux Operating System Notes

MySQL needs at least Linux version 2.0.

Warning

We have seen some strange problems with Linux 2.2.14 and MySQL on SMP systems. Some MySQL users have also reported that they have encountered serious stability problems using MySQL with kernel 2.2.14. If you are using this kernel, you should upgrade to 2.2.19 (or newer) or to a 2.4 or 2.6 kernel. If you have a multiple-CPU machine, you should seriously consider using 2.4 or 2.6 because it gives you a significant speed boost. Your system should also be more stable.

When using LinuxThreads, you should see a minimum of three `mysqld` processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

2.12.1.2 Linux Binary Distribution Notes

The Linux-Intel binary and RPM releases of MySQL are configured for the highest possible speed. We are always trying to use the fastest stable compiler available.

The binary release is linked with `-static`, which means you do not normally need to worry about which version of the system libraries you have. You need not install LinuxThreads, either. A program linked with `-static` is slightly larger than a dynamically linked program, but also slightly faster (3% to 5%). However, one problem with a statically linked program is that you cannot use user-defined functions (UDFs). If you are going to write or use UDFs (this is something for C or C++ programmers only), you must compile MySQL yourself using dynamic linking.

A known issue with binary distributions is that on older Linux systems that use `libc` (such as Red Hat 4.x or Slackware), you get some nonfatal problems with host name resolution. If your system uses `libc` rather than `glibc2`, you probably will encounter some difficulties with host name resolution and `getpwnam()`. This happens because `glibc` unfortunately depends on some external libraries to implement host name resolution and `getpwent()`, even when compiled with `-static`. These problems manifest themselves in two ways:

- You may see the following error message when you run `mysql_install_db`:

  ```
  Sorry, the host 'xxxx' could not be looked up
  ```

  You can deal with this by executing `mysql_install_db --force`, which does not execute the `resolveip` test in `mysql_install_db`. The downside is that you cannot use host names in the grant tables: Except for `localhost`, you must use IP addresses instead. If you are using an old version of MySQL that does not support `--force`, you must manually remove the `resolveip` test in `mysql_install_db` using a text editor.

- You also may see the following error when you try to run `mysqld` with the `--user` [395] option:

  ```
  getpwnam: No such file or directory
  ```

  To work around this problem, start `mysqld` by using the `su` command rather than by specifying the `--user` [395] option. This causes the system itself to change the user ID of the `mysqld` process so that `mysqld` need not do so.

Another solution, which solves both problems, is to not use a binary distribution. Get a MySQL source distribution (in RPM or `.tar.gz` format) and install that instead.

On some Linux 2.2 versions, you may get the error `Resource temporarily unavailable` when clients make a lot of new connections to a `mysqld` server over TCP/IP. The problem is that Linux has a delay between the time that you close a TCP/IP socket and the time that the system actually frees it. There is room for only a finite number of TCP/IP slots, so you encounter the resource-unavailable error if clients attempt too many new TCP/IP connections during a short time. For example, you may see the error when you run the MySQL `test-connect` benchmark over TCP/IP.

We have inquired about this problem a few times on different Linux mailing lists but have never been able to find a suitable resolution. The only known “fix” is for the clients to use persistent connections, or, if you are running the database server and clients on the same machine, to use Unix socket file connections rather than TCP/IP connections.

2.12.1.3 Linux Source Distribution Notes

The following notes regarding `glibc` apply only to the situation when you build MySQL yourself. If you are running Linux on an x86 machine, in most cases it is much better for you to just use our binary. We link our

binaries against the best patched version of `glibc` we can find and with the best compiler options, in an attempt to make it suitable for a high-load server. For a typical user, even for setups with a lot of concurrent connections or tables exceeding the 2GB limit, our binary is the best choice in most cases. After reading the following text, if you are in doubt about what to do, try our binary first to determine whether it meets your needs. If you discover that it is not good enough, you may want to try your own build. In that case, we would appreciate a note about it so that we can build a better binary next time.

MySQL uses LinuxThreads on Linux. If you are using an old Linux version that does not have `glibc2`, you must install LinuxThreads before trying to compile MySQL. You can obtain LinuxThreads at http://dev.mysql.com/downloads/os-linux.html.

Note that `glibc` versions before and including version 2.1.1 have a fatal bug in `pthread_mutex_timedwait()` handling, which is used when you issue `INSERT DELAYED` statements. Do not use `INSERT DELAYED` before upgrading `glibc`.

Note that Linux kernel and the LinuxThread library can by default have only 1,024 threads. If you plan to have more than 1,000 concurrent connections, you need to make some changes to LinuxThreads:

- Increase `PTHREAD_THREADS_MAX` in `sysdeps/unix/sysv/linux/bits/local_lim.h` to 4096 and decrease `STACK_SIZE` in `linuxthreads/internals.h` to 256KB. The paths are relative to the root of `glibc`. (Note that MySQL is not stable with around 600 to 1000 connections if `STACK_SIZE` is the default of 2MB.)
- Recompile LinuxThreads to produce a new `libpthread.a` library, and relink MySQL against it.

There is another issue that greatly hurts MySQL performance, especially on SMP systems. The mutex implementation in LinuxThreads in `glibc` 2.1 is very bad for programs with many threads that hold the mutex only for a short time. This produces a paradoxical result: If you link MySQL against an unmodified LinuxThreads, removing processors from an SMP actually improves MySQL performance in many cases. We have made a patch available for `glibc` 2.1.3 to correct this behavior (http://dev.mysql.com/Downloads/Linux/linuxthreads-2.1-patch).

With `glibc` 2.2.2, MySQL 3.23.36 uses the adaptive mutex, which is much better than even the patched one in `glibc` 2.1.3. Be warned, however, that under some conditions, the current mutex code in `glibc` 2.2.2 overspins, which hurts MySQL performance. The likelihood that this condition occurs can be reduced by renicing the `mysqld` process to the highest priority. We have also been able to correct the overspin behavior with a patch, available at http://dev.mysql.com/Downloads/Linux/linuxthreads-2.2.2.patch. It combines the correction of overspin, maximum number of threads, and stack spacing all in one. You need to apply it in the `linuxthreads` directory with `patch -p0 </tmp/linuxthreads-2.2.2.patch`. We hope it is included in some form in future releases of `glibc` 2.2. In any case, if you link against `glibc` 2.2.2, you still need to correct `STACK_SIZE` and `PTHREAD_THREADS_MAX`. We hope that the defaults is corrected to some more acceptable values for high-load MySQL setup in the future, so that the commands needed to produce your own build can be reduced to `./configure; make; make install`.

If you use these patches to build a special static version of `libpthread.a`, use it only for statically linking against MySQL. We know that the patches are safe for MySQL and significantly improve its performance, but we cannot say anything about other applications. If you link other applications that require LinuxThreads against the patched static version of the library, or build a patched shared version and install it on your system, you do so at your own risk.

If you experience any strange problems during the installation of MySQL, or with some common utilities hanging, it is very likely that they are either library or compiler related. If this is the case, using our binary resolves them.

If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

- Link clients with the `-Wl,r/full/path/to/libmysqlclient.so` flag rather than with `-Lpath`).
- Copy `libmysqclient.so` to `/usr/lib`.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable before running your client.

If you are using the Fujitsu compiler (`fcc/FCC`), you may have some problems compiling MySQL because the Linux header files are very `gcc` oriented. The following `configure` line should work with `fcc/FCC`:

```
CC=fcc CFLAGS="-O -K fast -K lib -K omitfp -Kpreex -D_GNU_SOURCE \
    -DCONST=const -DNO_STRTOLL_PROTO" \
CXX=FCC CXXFLAGS="-O -K fast -K lib \
    -K omitfp -K preex --no_exceptions --no_rtti -D_GNU_SOURCE \
    -DCONST=const -Dalloca=__builtin_alloca -DNO_STRTOLL_PROTO \
    '-D_EXTERN_INLINE=static __inline'" \
./configure \
    --prefix=/usr/local/mysql --enable-assembler \
    --with-mysqld-ldflags=-all-static --disable-shared \
    --with-low-memory
```

2.12.1.4 Linux Postinstallation Notes

`mysql.server` can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

If MySQL cannot open enough files or connections, it may be that you have not configured Linux to handle enough files.

In Linux 2.2 and onward, you can check the number of allocated file handles as follows:

```
shell> cat /proc/sys/fs/file-max
shell> cat /proc/sys/fs/dquot-max
shell> cat /proc/sys/fs/super-max
```

If you have more than 16MB of memory, you should add something like the following to your init scripts (for example, `/etc/init.d/boot.local` on SuSE Linux):

```
echo 65536 > /proc/sys/fs/file-max
echo 8192 > /proc/sys/fs/dquot-max
echo 1024 > /proc/sys/fs/super-max
```

You can also run the `echo` commands from the command line as `root`, but these settings are lost the next time your computer restarts.

Alternatively, you can set these parameters on startup by using the `sysctl` tool, which is used by many Linux distributions (SuSE has added it as well, beginning with SuSE Linux 8.0). Just put the following values into a file named `/etc/sysctl.conf`:

```
# Increase some values for MySQL
```

```
fs.file-max = 65536
fs.dquot-max = 8192
fs.super-max = 1024
```

You should also add the following to `/etc/my.cnf`:

```
[mysqld_safe]
open-files-limit=8192
```

This should enable a server limit of 8,192 for the combined number of connections and open files.

The `STACK_SIZE` constant in LinuxThreads controls the spacing of thread stacks in the address space. It needs to be large enough so that there is plenty of room for each individual thread stack, but small enough to keep the stack of some threads from running into the global `mysqld` data. Unfortunately, as we have discovered, the Linux implementation of `mmap()` successfully unmaps a mapped region if you ask it to map out an address currently in use, zeroing out the data on the entire page instead of returning an error. So, the safety of `mysqld` or any other threaded application depends on "gentlemanly" behavior of the code that creates threads. The user must take measures to make sure that the number of running threads at any time is sufficiently low for thread stacks to stay away from the global heap. With `mysqld`, you should enforce this behavior by setting a reasonable value for the `max_connections` [419] variable.

If you build MySQL yourself, you can patch LinuxThreads for better stack use. See Section 2.12.1.3, "Linux Source Distribution Notes". If you do not want to patch LinuxThreads, you should set `max_connections` [419] to a value no higher than 500. It should be even less if you have a large key buffer, large heap tables, or some other things that make `mysqld` allocate a lot of memory, or if you are running a 2.2 kernel with a 2GB patch. If you are using our binary or RPM version 3.23.25 or later, you can safely set `max_connections` [419] at 1500, assuming no large key buffer or heap tables with lots of data. The more you reduce `STACK_SIZE` in LinuxThreads the more threads you can safely create. Values between 128KB and 256KB are recommended.

If you use a lot of concurrent connections, you may suffer from a "feature" in the 2.2 kernel that attempts to prevent fork bomb attacks by penalizing a process for forking or cloning a child. This causes MySQL not to scale well as you increase the number of concurrent clients. On single-CPU systems, we have seen this manifested as very slow thread creation: It may take a long time to connect to MySQL (as long as one minute), and it may take just as long to shut it down. On multiple-CPU systems, we have observed a gradual drop in query speed as the number of clients increases. In the process of trying to find a solution, we have received a kernel patch from one of our users who claimed it made a lot of difference for his site. The patch is available at http://dev.mysql.com/Downloads/Patches/linux-fork.patch. We have done rather extensive testing of this patch on both development and production systems. It has significantly improved MySQL performance without causing any problems and is recommended for users who still run high-load servers on 2.2 kernels.

This issue has been fixed in the 2.4 kernel, so if you are not satisfied with the current performance of your system, rather than patching your 2.2 kernel, it might be easier to upgrade to 2.4. On SMP systems, upgrading also gives you a nice SMP boost in addition to fixing the fairness bug.

We have tested MySQL on the 2.4 kernel on a two-CPU machine and found MySQL scales *much* better. There was virtually no slowdown on query throughput all the way up to 1,000 clients, and the MySQL scaling factor (computed as the ratio of maximum throughput to the throughput for one client) was 180%. We have observed similar results on a four-CPU system: Virtually no slowdown as the number of clients was increased up to 1,000, and a 300% scaling factor. Based on these results, for a high-load SMP server using a 2.2 kernel, it is definitely recommended to upgrade to the 2.4 kernel at this point.

We have discovered that it is essential to run the `mysqld` process with the highest possible priority on the 2.4 kernel to achieve maximum performance. This can be done by adding a `renice -20 $$` command to

`mysqld_safe`. In our testing on a four-CPU machine, increasing the priority resulted in a 60% throughput increase with 400 clients.

We are currently also trying to collect more information on how well MySQL performs with a 2.4 kernel on four-way and eight-way systems. If you have access such a system and have done some benchmarks, please send an email message to `<benchmarks@mysql.com>` with the results. We will review them for inclusion in the manual.

If you see a dead `mysqld` server process with `ps`, this usually means that you have found a bug in MySQL or that you have a corrupted table. See Section B.5.4.2, “What to Do If MySQL Keeps Crashing”.

To get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` [385] option. Note that you also probably need to raise the core file size by adding `ulimit -c 1000000` to `mysqld_safe` or starting `mysqld_safe` with `--core-file-size=1000000` [244]. See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

2.12.1.5 Linux x86 Notes

MySQL requires `libc` 5.4.12 or newer. It is known to work with `libc` 5.4.46. `glibc` 2.0.6 and later should also work. There have been some problems with the `glibc` RPMs from Red Hat, so if you have problems, check whether there are any updates. The `glibc` 2.0.7-19 and 2.0.7-29 RPMs are known to work.

If you are using Red Hat 8.0 or a new `glibc` 2.2.x library, you may see `mysqld` die in `gethostbyaddr()`. This happens because the new `glibc` library requires a stack size greater than 128KB for this call. To fix the problem, start `mysqld` with the `--thread-stack=192K` [431] option. This stack size is the default on MySQL 4.0.10 and above, so you should not see the problem.

If you are using `gcc` 3.0 and above to compile MySQL, you must install the `libstdc++v3` library before compiling MySQL; if you do not do this, you get an error about a missing `__cxa_pure_virtual` symbol during linking.

On some older Linux distributions, `configure` may produce an error like this:

```
Syntax error in sched.h. Change _P to __P in the
/usr/include/sched.h file.
See the Installation chapter in the Reference Manual.
```

Just do what the error message says. Add an extra underscore to the `_P` macro name that has only one underscore, and then try again.

You may get some warnings when compiling. Those shown here can be ignored:

```
mysqld.cc -o objs-thread/mysqld.o
mysqld.cc: In function `void init_signals()':
mysqld.cc:315: warning: assignment of negative value `-1' to
`long unsigned int'
mysqld.cc: In function `void * signal_hand(void *)':
mysqld.cc:346: warning: assignment of negative value `-1' to
`long unsigned int'
```

If `mysqld` always dumps core when it starts, the problem may be that you have an old `/lib/libc.a`. Try renaming it, and then remove `sql/mysqld` and do a new `make install` and try again. This problem has been reported on some Slackware installations.

If you get the following error when linking `mysqld`, it means that your `libg++.a` is not installed correctly:

```
```

```
/usr/lib/libc.a(putc.o): In function `_IO_putc':
putc.o(.text+0x0): multiple definition of `_IO_putc'
```

You can avoid using `libg++.a` by running `configure` like this:

```
shell> CXX=gcc ./configure
```

If `mysqld` crashes immediately and you are running Red Hat 5.0 with a version of `glibc` older than 2.0.7-5, you should make sure that you have installed all `glibc` patches. There is a lot of information about this in the MySQL mail archives, available online at http://lists.mysql.com/.

2.12.1.6 Linux SPARC Notes

In some implementations, `readdir_r()` is broken. The symptom is that the `SHOW DATABASES` statement always returns an empty set. This can be fixed by removing `HAVE_READDIR_R` from `config.h` after configuring and before compiling.

2.12.1.7 Linux Alpha Notes

MySQL 3.23.12 is the first MySQL version that is tested on Linux-Alpha. If you plan to use MySQL on Linux-Alpha, you should ensure that you have this version or newer.

We have tested MySQL on Alpha with our benchmarks and test suite, and it appears to work nicely.

We currently build the MySQL binary packages on SuSE Linux 7.0 for AXP, kernel 2.4.4-SMP, Compaq C compiler (V6.2-505) and Compaq C++ compiler (V6.3-006) on a Compaq DS20 machine with an Alpha EV6 processor.

You can find the preceding compilers at http://www.support.compaq.com/alpha-tools/. By using these compilers rather than `gcc`, we get about 9% to 14% better MySQL performance.

Note that until MySQL version 3.23.52 and 4.0.2, we optimized the binary for the current CPU only (by using the `-fast` compile option). This means that for older versions, you can use our Alpha binaries only if you have an Alpha EV6 processor.

For all subsequent releases, we added the `-arch generic` flag to our compile options, which ensures that the binary runs on all Alpha processors. We also compile statically to avoid library problems. The `configure` command looks like this:

```
CC=ccc CFLAGS="-fast -arch generic" CXX=cxx \
CXXFLAGS="-fast -arch generic -noexceptions -nortti" \
./configure --prefix=/usr/local/mysql --disable-shared \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --with-mysqld-ldflags=-non_shared --with-client-ldflags=-non_shared
```

Some known problems when running MySQL on Linux-Alpha:

- Debugging threaded applications like MySQL does not work with `gdb 4.18`. You should use `gdb` 5.1 instead.
- If you try linking `mysqld` statically when using `gcc`, the resulting image dumps core at startup time. In other words, *do not* use `--with-mysqld-ldflags=-all-static` with `gcc`.

2.12.1.8 Linux PowerPC Notes

MySQL should work on MkLinux with the newest `glibc` package (tested with `glibc` 2.0.7).

2.12.1.9 Linux MIPS Notes

To get MySQL to work on Qube2 (Linux Mips), you need the newest `glibc` libraries. `glibc-2.0.7-29C2` is known to work. You must also use `gcc` 2.95.2 or newer).

2.12.1.10 Linux IA-64 Notes

To get MySQL to compile on Linux IA-64, we use the following `configure` command for building with `gcc` 2.96:

```
CC=gcc \
CFLAGS="-O3 -fno-omit-frame-pointer" \
CXX=gcc \
CXXFLAGS="-O3 -fno-omit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti" \
    ./configure --prefix=/usr/local/mysql \
    "--with-comment=Official MySQL binary" \
    --with-extra-charsets=complex
```

On IA-64, the MySQL client binaries use shared libraries. This means that if you install our binary distribution at a location other than `/usr/local/mysql`, you need to add the path of the directory where you have `libmysqlclient.so` installed either to the `/etc/ld.so.conf` file or to the value of your `LD_LIBRARY_PATH` environment variable.

See Section 17.6.3.1, “Building C API Client Programs”.

2.12.1.11 SELinux Notes

RHEL4 comes with SELinux, which supports tighter access control for processes. If SELinux is enabled (`SELINUX` in `/etc/selinux/config` is set to `enforcing`, `SELINUXTYPE` is set to either `targeted` or `strict`), you might encounter problems installing Oracle Corporation RPM packages.

Red Hat has an update that solves this. It involves an update of the “security policy” specification to handle the install structure of the RPMs provided by Oracle Corporation. For further information, see https://bugzilla.redhat.com/bugzilla/show_bug.cgi?id=167551 and http://rhn.redhat.com/errata/RHBA-2006-0049.html.

The preceding discussion applies only to RHEL4. The patch is unnecessary for RHEL5.

2.12.2 Mac OS X Notes

On Mac OS X, `tar` cannot handle long file names. If you need to unpack a `.tar.gz` distribution, use `gnutar` instead.

2.12.2.1 Mac OS X 10.x (Darwin)

MySQL should work without major problems on Mac OS X 10.x (Darwin).

Known issues:

- If you have problems with performance under heavy load, try using the `--skip-thread-priority` [394] option to `mysqld`. This runs all threads with the same priority. On Mac OS X, this gives better performance, at least until Apple fixes its thread scheduler.
- The connection times (`wait_timeout` [434], `interactive_timeout` [414] and `net_read_timeout` [422]) values are not honored. The symptom is that persistent connections can

hang for a very long time without getting closed down and that a 'kill' for a thread will not take affect until the thread does it a new command

This is probably a signal handling problem in the thread library where the signal does not break a pending read and we hope that a future update to the thread libraries will fix this.

Our binary for Mac OS X is compiled on Darwin 6.3 with the following `configure` line:

```
CC=gcc CFLAGS="-O3 -fno-omit-frame-pointer" CXX=gcc \
CXXFLAGS="-O3 -fno-omit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti" \
    ./configure --prefix=/usr/local/mysql \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --enable-local-infile --disable-shared
```

See Section 2.5, “Installing MySQL on Mac OS X”.

2.12.2.2 Mac OS X Server 1.2 (Rhapsody)

For current versions of Mac OS X Server, no operating system changes are necessary before compiling MySQL. Compiling for the Server platform is the same as for the client version of Mac OS X. (However, note that MySQL comes preinstalled on Mac OS X Server, so you need not build it yourself.)

For older versions (Mac OS X Server 1.2, a.k.a. Rhapsody), you must first install a pthread package before trying to configure MySQL.

See Section 2.5, “Installing MySQL on Mac OS X”.

2.12.3 Solaris Notes

For information about installing MySQL on Solaris using PKG distributions, see Section 2.6, “Installing MySQL on Solaris”.

On Solaris, you may run into trouble even before you get the MySQL distribution unpacked. Solaris `tar` cannot handle long file names, so you may see an error like this when you unpack MySQL:

```
x mysql-3.22.12-beta/bench/Results/ATIS-mysql_odbc-NT_4.0-cmp-db2,
informix,ms-sql,mysql,oracle,solid,sybase, 0 bytes, 0 tape blocks
tar: directory checksum error
```

In this case, you must use GNU `tar` (`gtar`) to unpack the distribution.

Sun native threads work only on Solaris 2.5 and higher. For Solaris 2.4 and earlier, MySQL automatically uses MIT-pthreads. See Section 2.9.6, “MIT-pthreads Notes”.

If you get the following error from `configure`, it means that you have something wrong with your compiler installation:

```
checking for restartable system calls... configure: error cannot
run test programs while cross compiling
```

In this case, you should upgrade your compiler to a newer version. You may also be able to solve this problem by inserting the following row into the `config.cache` file:

```
ac_cv_sys_restartable_syscalls=${ac_cv_sys_restartable_syscalls='no'}
```

If you are using Solaris on a SPARC, the recommended compiler is `gcc` 2.95.2 or 3.2. You can find this at http://gcc.gnu.org/. Note that `gcc` 2.8.1 does not work reliably on SPARC.

The recommended `configure` line when using `gcc` 2.95.2 is:

```
CC=gcc CFLAGS="-O3" \
CXX=gcc CXXFLAGS="-O3 -felide-constructors -fno-exceptions -fno-rtti" \
./configure --prefix=/usr/local/mysql --with-low-memory \
    --enable-assembler
```

If you have an UltraSPARC system, you can get 4% better performance by adding `-mcpu=v8 -Wa,-xarch=v8plusa` to the `CFLAGS` and `CXXFLAGS` environment variables.

If you have Sun's Forte 5.0 (or newer) compiler, you can run `configure` like this:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt" \
CXX=CC CXXFLAGS="-noex -mt" \
./configure --prefix=/usr/local/mysql --enable-assembler
```

To create a 64-bit binary with Sun's Forte compiler, use the following configuration options:

```
CC=cc CFLAGS="-Xa -fast -native -xstrconst -mt -xarch=v9" \
CXX=CC CXXFLAGS="-noex -mt -xarch=v9" ASFLAGS="-xarch=v9" \
./configure --prefix=/usr/local/mysql --enable-assembler
```

To create a 64-bit Solaris binary using `gcc`, add `-m64` to `CFLAGS` and `CXXFLAGS` and remove `--enable-assembler` from the `configure` line. This works only with MySQL 4.0 and up; MySQL 3.23 does not include the required modifications to support this.

In the MySQL benchmarks, we got a 4% speedup on an UltraSPARC when using Forte 5.0 in 32-bit mode compared to using `gcc` 3.2 with the `-mcpu` flag.

If you create a 64-bit `mysqld` binary, it is 4% slower than the 32-bit binary, but can handle more threads and memory.

When using Solaris 10 for x86_64, you should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the `InnoDB` storage engine on this platform.

If you get a problem with `fdatasync` or `sched_yield`, you can fix this by adding `LIBS=-lrt` to the `configure` line

For compilers older than WorkShop 5.3, you might have to edit the `configure` script. Change this line:

```
#if !defined(__STDC__) || __STDC__ != 1
```

To this:

```
#if !defined(__STDC__)
```

If you turn on `__STDC__` with the `-Xc` option, the Sun compiler cannot compile with the Solaris `pthread.h` header file. This is a Sun bug (broken compiler or broken include file).

If `mysqld` issues the following error message when you run it, you have tried to compile MySQL with the Sun compiler without enabling the `-mt` multi-thread option:

```
libc internal error: _rmutex_unlock: rmutex not held
```

Add `-mt` to `CFLAGS` and `CXXFLAGS` and recompile.

If you are using the SFW version of `gcc` (which comes with Solaris 8), you must add `/opt/sfw/lib` to the environment variable `LD_LIBRARY_PATH` before running `configure`.

If you are using the `gcc` available from `sunfreeware.com`, you may have many problems. To avoid this, you should recompile `gcc` and GNU `binutils` on the machine where you are running them.

If you get the following error when compiling MySQL with `gcc`, it means that your `gcc` is not configured for your version of Solaris:

```
shell> gcc -O3 -g -O2 -DDBUG_OFF  -o thr_alarm ...
./thr_alarm.c: In function `signal_hand':
./thr_alarm.c:556: too many arguments to function `sigwait'
```

The proper thing to do in this case is to get the newest version of `gcc` and compile it with your current `gcc` compiler. At least for Solaris 2.5, almost all binary versions of `gcc` have old, unusable include files that break all programs that use threads, and possibly other programs!

Solaris does not provide static versions of all system libraries (`libpthreads` and `libdl`), so you cannot compile MySQL with `--static`. If you try to do so, you get one of the following errors:

```
ld: fatal: library -ldl: not found
undefined reference to `dlopen'
cannot find -lrt
```

If you link your own MySQL client programs, you may see the following error at runtime:

```
ld.so.1: fatal: libmysqlclient.so.#:
open failed: No such file or directory
```

This problem can be avoided by one of the following methods:

- Link clients with the `-Wl,r`*`/full/path/to/`*`libmysqlclient.so` flag rather than with `-Lpath`).
- Copy `libmysqclient.so` to `/usr/lib`.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable before running your client.

If you have problems with `configure` trying to link with `-lz` when you do not have `zlib` installed, you have two options:

- If you want to be able to use the compressed communication protocol, you need to get and install `zlib` from `ftp.gnu.org`.
- Run `configure` with the `--with-named-z-libs=no` option when building MySQL.

If you are using `gcc` and have problems with loading user-defined functions (UDFs) into MySQL, try adding `-lgcc` to the link line for the UDF.

If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.

If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` [406] option as a workaround for this. (Use `-O back_log=50` before MySQL 4.)

Solaris does not support core files for `setuid()` applications, so you cannot get a core file from `mysqld` if you are using the `--user` [395] option.

2.12.3.1 Solaris 2.7/2.8 Notes

Normally, you can use a Solaris 2.6 binary on Solaris 2.7 and 2.8. Most of the Solaris 2.6 issues also apply for Solaris 2.7 and 2.8.

MySQL 3.23.4 and above should be able to detect new versions of Solaris automatically and enable workarounds for the following problems.

Solaris 2.7 and 2.8 have some bugs in the include files. You may see the following error when you use `gcc`:

```
/usr/include/widec.h:42: warning: `getwc' redefined
/usr/include/wchar.h:326: warning: this is the location of the previous
definition
```

If this occurs, you can fix the problem by copying `/usr/include/widec.h` to `.../lib/gcc-lib/os/gcc-version/include` and changing line 41 from this:

```
#if     !defined(lint) && !defined(__lint)
```

To this:

```
#if     !defined(lint) && !defined(__lint) && !defined(getwc)
```

Alternatively, you can edit `/usr/include/widec.h` directly. Either way, after you make the fix, you should remove `config.cache` and run `configure` again.

If you get the following errors when you run `make`, it is because `configure` did not detect the `curses.h` file (probably because of the error in `/usr/include/widec.h`):

```
In file included from mysql.cc:50:
/usr/include/term.h:1060: syntax error before `,'
/usr/include/term.h:1081: syntax error before `;'
```

The solution to this problem is to do one of the following:

1. Configure with `CFLAGS=-DHAVE_CURSES_H CXXFLAGS=-DHAVE_CURSES_H ./configure`.
2. Edit `/usr/include/widec.h` as indicated in the preceding discussion and re-run `configure`.
3. Remove the `#define HAVE_TERM` line from the `config.h` file and run `make` again.

If your linker cannot find `-lz` when linking client programs, the problem is probably that your `libz.so` file is installed in `/usr/local/lib`. You can fix this problem by one of the following methods:

- Add `/usr/local/lib` to `LD_LIBRARY_PATH`.

- Add a link to `libz.so` from `/lib`.
- If you are using Solaris 8, you can install the optional `zlib` from your Solaris 8 CD distribution.
- Run `configure` with the `--with-named-z-libs=no` option when building MySQL.

2.12.3.2 Solaris x86 Notes

On Solaris 8 on x86, `mysqld` dumps core if you remove the debug symbols using `strip`.

If you are using `gcc` on Solaris x86 and you experience problems with core dumps under load, you should use the following `configure` command:

```
CC=gcc CFLAGS="-O3 -fomit-frame-pointer -DHAVE_CURSES_H" \
CXX=gcc \
CXXFLAGS="-O3 -fomit-frame-pointer -felide-constructors \
    -fno-exceptions -fno-rtti -DHAVE_CURSES_H" \
./configure --prefix=/usr/local/mysql
```

This avoids problems with the `libstdc++` library and with C++ exceptions.

If this does not help, you should compile a debug version and run it with a trace file or under `gdb`. See Section 18.4, “Porting to Other Systems”.

2.12.4 BSD Notes

This section provides information about using MySQL on variants of BSD Unix.

2.12.4.1 FreeBSD Notes

FreeBSD 4.x or newer is recommended for running MySQL, because the thread package is much more integrated. To get a secure and stable system, you should use only FreeBSD kernels that are marked `-RELEASE`.

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at http://www.freebsd.org/. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.
- The ability to use `pkg_info -L` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

It is recommended you use MIT-pthreads on FreeBSD 2.x, and native threads on FreeBSD 3 and up. It is possible to run with native threads on some late 2.2.x versions, but you may encounter problems shutting down `mysqld`.

Unfortunately, certain function calls on FreeBSD are not yet fully thread-safe. Most notably, this includes the `gethostbyname()` function, which is used by MySQL to convert host names into IP addresses. Under certain circumstances, the `mysqld` process suddenly causes 100% CPU load and is unresponsive. If you encounter this problem, try to start MySQL using the `--skip-name-resolve` [393] option.

Alternatively, you can link MySQL on FreeBSD 4.x against the LinuxThreads library, which avoids a few of the problems that the native FreeBSD thread implementation has. For a very good comparison of

LinuxThreads versus native threads, see Jeremy Zawodny's article *FreeBSD or Linux for your MySQL Server?* at http://jeremy.zawodny.com/blog/archives/000697.html.

Known problem when using LinuxThreads on FreeBSD is:

- The connection times (`wait_timeout` [434], `interactive_timeout` [414] and `net_read_timeout` [422]) values are not honored. The symptom is that persistent connections can hang for a very long time without getting closed down and that a 'kill' for a thread will not take affect until the thread does it a new command

  This is probably a signal handling problem in the thread library where the signal does not break a pending read. This is supposed to be fixed in FreeBSD 5.0

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

The recommended way to compile and install MySQL on FreeBSD with `gcc` (2.95.2 and up) is:

```
CC=gcc CFLAGS="-O2 -fno-strength-reduce" \
    CXX=gcc CXXFLAGS="-O2 -fno-rtti -fno-exceptions \
    -felide-constructors -fno-strength-reduce" \
    ./configure --prefix=/usr/local/mysql --enable-assembler
gmake
gmake install
cd /usr/local/mysql
bin/mysql_install_db --user=mysql
bin/mysqld_safe &
```

If you notice that `configure` uses MIT-pthreads, you should read the MIT-pthreads notes. See Section 2.9.6, “MIT-pthreads Notes”.

If you get an error from `make install` that it cannot find `/usr/include/pthreads`, `configure` did not detect that you need MIT-pthreads. To fix this problem, remove `config.cache`, and then re-run `configure` with the `--with-mit-threads` option.

Be sure that your name resolver setup is correct. Otherwise, you may experience resolver delays or failures when connecting to `mysqld`. Also make sure that the `localhost` entry in the `/etc/hosts` file is correct. The file should start with a line similar to this:

```
127.0.0.1       localhost localhost.your.domain
```

FreeBSD is known to have a very low default file handle limit. See Section B.5.2.18, “`'File' Not Found` and Similar Errors”. Start the server by using the `--open-files-limit` [245] option for `mysqld_safe`, or raise the limits for the `mysqld` user in `/etc/login.conf` and rebuild it with `cap_mkdb /etc/login.conf`. Also be sure that you set the appropriate class for this user in the password file if you are not using the default (use `chpass mysqld-user-name`). See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

FreeBSD limits the size of a process to 512MB, even if you have much more RAM available on the system. So you may get an error such as this:

```
Out of memory (Needed 16391 bytes)
```

In current versions of FreeBSD (at least 4.x and greater), you may increase this limit by adding the following entries to the `/boot/loader.conf` file and rebooting the machine (these are not settings that can be changed at run time with the `sysctl` command):

```
kern.maxdsiz="1073741824" # 1GB
kern.dfldsiz="1073741824" # 1GB
kern.maxssiz="134217728" # 128MB
```

For older versions of FreeBSD, you must recompile your kernel to change the maximum data segment size for a process. In this case, you should look at the `MAXDSIZ` option in the `LINT` config file for more information.

If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Section 2.13, “Environment Variables”.

2.12.4.2 NetBSD Notes

To compile on NetBSD, you need GNU `make`. Otherwise, the build process fails when `make` tries to run `lint` on C++ files.

2.12.4.3 OpenBSD 2.5 Notes

On OpenBSD 2.5, you can compile MySQL with native threads with the following options:

```
CFLAGS=-pthread CXXFLAGS=-pthread ./configure --with-mit-threads=no
```

2.12.4.4 BSD/OS Version 2.x Notes

If you get the following error when compiling MySQL, your `ulimit` value for virtual memory is too low:

```
item_func.h: In method
`Item_func_ge::Item_func_ge(const Item_func_ge &)':
item_func.h:28: virtual memory exhausted
make[2]: *** [item_func.o] Error 1
```

Try using `ulimit -v 80000` and run `make` again. If this does not work and you are using `bash`, try switching to `csh` or `sh`; some BSDI users have reported problems with `bash` and `ulimit`.

If you are using `gcc`, you may also use have to use the `--with-low-memory` [99] flag for `configure` to be able to compile `sql_yacc.cc`.

If you get problems with the current date in MySQL, setting the `TZ` variable should help. See Section 2.13, “Environment Variables”.

2.12.4.5 BSD/OS Version 3.x Notes

Upgrade to BSD/OS 3.1. If that is not possible, install BSDIpatch M300-038.

Use the following command when configuring MySQL:

```
env CXX=shlicc++ CC=shlicc2 \
./configure \
    --prefix=/usr/local/mysql \
    --localstatedir=/var/mysql \
    --without-perl \
    --with-unix-socket-path=/var/mysql/mysql.sock
```

The following is also known to work:

```
env CC=gcc CXX=gcc CXXFLAGS=-O3 \
```

```
./configure \
    --prefix=/usr/local/mysql \
    --with-unix-socket-path=/var/mysql/mysql.sock
```

You can change the directory locations if you wish, or just use the defaults by not specifying any locations.

If you have problems with performance under heavy load, try using the `--skip-thread-priority` [394] option to `mysqld`. This runs all threads with the same priority. On BSDI 3.1, this gives better performance, at least until BSDI fixes its thread scheduler.

If you get the error `virtual memory exhausted` while compiling, you should try using `ulimit -v 80000` and running `make` again. If this does not work and you are using `bash`, try switching to `csh` or `sh`; some BSDI users have reported problems with `bash` and `ulimit`.

2.12.4.6 BSD/OS Version 4.x Notes

BSDI 4.x has some thread-related bugs. If you want to use MySQL on this, you should install all thread-related patches. At least M400-023 should be installed.

On some BSDI 4.x systems, you may get problems with shared libraries. The symptom is that you cannot execute any client programs, for example, `mysqladmin`. In this case, you need to reconfigure not to use shared libraries with the `--disable-shared` option to configure.

Some customers have had problems on BSDI 4.0.1 that the `mysqld` binary after a while cannot open tables. This occurs because some library/system-related bug causes `mysqld` to change current directory without having asked for that to happen.

The fix is to either upgrade MySQL to at least version 3.23.34 or, after running `configure`, remove the line `#define HAVE_REALPATH` from `config.h` before running `make`.

Note that this means that you cannot symbolically link a database directories to another database directory or symbolic link a table to another database on BSDI. (Making a symbolic link to another disk is okay).

2.12.5 Other Unix Notes

2.12.5.1 HP-UX Version 10.20 Notes

If you install MySQL using a binary tarball distribution on HP-UX, you may run into trouble even before you get the MySQL distribution unpacked, as the HP-UX `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

There are a couple of small problems when compiling MySQL on HP-UX. Use `gcc` instead of the HP-UX native compiler, because `gcc` produces better code.

Use `gcc` 2.95 on HP-UX. Do not use high optimization flags (such as `-O6`) because they may not be safe on HP-UX.

The following `configure` line should work with `gcc` 2.95:

```
CFLAGS="-I/opt/dce/include -fpic" \
CXXFLAGS="-I/opt/dce/include -felide-constructors -fno-exceptions \
-fno-rtti" \
CXX=gcc \
./configure --with-pthread \
    --with-named-thread-libs='-ldce' \
    --prefix=/usr/local/mysql --disable-shared
```

The following `configure` line should work with `gcc` 3.1:

```
CFLAGS="-DHPUX -I/opt/dce/include -O3 -fPIC" CXX=gcc \
CXXFLAGS="-DHPUX -I/opt/dce/include -felide-constructors \
    -fno-exceptions -fno-rtti -O3 -fPIC" \
./configure --prefix=/usr/local/mysql \
    --with-extra-charsets=complex --enable-thread-safe-client \
    --enable-local-infile  --with-pthread \
    --with-named-thread-libs=-ldce --with-lib-ccflags=-fPIC
    --disable-shared
```

2.12.5.2 HP-UX Version 11.x Notes

For HP-UX 11.x, use MySQL 3.23.15 or later.

If you install MySQL using a binary tarball distribution on HP-UX, you may run into trouble even before you get the MySQL distribution unpacked, as the HP-UX `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution.

Because of some critical bugs in the standard HP-UX libraries, you should install the following patches before trying to run MySQL on HP-UX 11.0:

```
PHKL_22840 Streams cumulative
PHNE_22397 ARPA cumulative
```

This solves the problem of getting `EWOULDBLOCK` from `recv()` and `EBADF` from `accept()` in threaded applications.

If you are using `gcc` 2.95.1 on an unpatched HP-UX 11.x system, you may get the following error:

```
In file included from /usr/include/unistd.h:11,
                 from ../include/global.h:125,
                 from mysql_priv.h:15,
                 from item.cc:19:
/usr/include/sys/unistd.h:184: declaration of C function ...
/usr/include/sys/pthread.h:440: previous declaration ...
In file included from item.h:306,
                 from mysql_priv.h:158,
                 from item.cc:19:
```

The problem is that HP-UX does not define `pthreads_atfork()` consistently. It has conflicting prototypes in `/usr/include/sys/unistd.h`:184 and `/usr/include/sys/pthread.h`:440.

One solution is to copy `/usr/include/sys/unistd.h` into `mysql/include` and edit `unistd.h` and change it to match the definition in `pthread.h`. Look for this line:

```
extern int pthread_atfork(void (*prepare)(), void (*parent)(),
                                          void (*child)());
```

Change it to look like this:

```
extern int pthread_atfork(void (*prepare)(void), void (*parent)(void),
                                          void (*child)(void));
```

After making the change, the following `configure` line should work:

```
CFLAGS="-fomit-frame-pointer -O3 -fpic" CXX=gcc \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti -O3" \
./configure --prefix=/usr/local/mysql --disable-shared
```

If you are using MySQL 4.0.5 with the HP-UX compiler, you can use the following command (which has been tested with `cc` B.11.11.04):

```
CC=cc CXX=aCC CFLAGS=+DD64 CXXFLAGS=+DD64 ./configure \
    --with-extra-character-set=complex
```

You can ignore any errors of the following type:

```
aCC: warning 901: unknown option: `-3': use +help for online
documentation
```

If you get the following error from `configure`, verify that you do not have the path to the K&R compiler before the path to the HP-UX C and C++ compiler:

```
checking for cc option to accept ANSI C... no
configure: error: MySQL requires an ANSI C compiler (and a C++ compiler).
Try gcc. See the Installation chapter in the Reference Manual.
```

Another reason for not being able to compile is that you did not define the `+DD64` flags as just described.

Another possibility for HP-UX 11 is to use MySQL binaries for HP-UX 10.20. We have received reports from some users that these binaries work fine on HP-UX 11.00. If you encounter problems, be sure to check your HP-UX patch level.

2.12.5.3 IBM-AIX notes

Automatic detection of `xlC` is missing from Autoconf, so a number of variables need to be set before running `configure`. The following example uses the IBM compiler:

```
export CC="xlc_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192 "
export CXX="xlC_r -ma -O3 -qstrict -qoptimize=3 -qmaxmem=8192"
export CFLAGS="-I /usr/local/include"
export LDFLAGS="-L /usr/local/lib"
export CPPFLAGS=$CFLAGS
export CXXFLAGS=$CFLAGS

./configure --prefix=/usr/local \
                --localstatedir=/var/mysql \
                --sbindir='/usr/local/bin' \
                --libexecdir='/usr/local/bin' \
                --enable-thread-safe-client \
                --enable-large-files
```

The preceding options are used to compile the MySQL distribution that can be found at http://www-frec.bull.com/.

If you change the `-O3` to `-O2` in the preceding `configure` line, you must also remove the `-qstrict` option. This is a limitation in the IBM C compiler.

If you are using `gcc` to compile MySQL, you *must* use the `-fno-exceptions` flag, because the exception handling in `gcc` is not thread-safe! There are also some known problems with IBM's assembler that may cause it to generate bad code when used with `gcc`.

Use the following `configure` line with `gcc` 2.95 on AIX:

```
CC="gcc -pipe -mcpu=power -Wa,-many" \
CXX="gcc -pipe -mcpu=power -Wa,-many" \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti" \
./configure --prefix=/usr/local/mysql --with-low-memory
```

The `-Wa,-many` option is necessary for the compile to be successful. IBM is aware of this problem but is in no hurry to fix it because of the workaround that is available. We do not know if the `-fno-exceptions` is required with `gcc` 2.95, but because MySQL does not use exceptions and the option generates faster code, you should always use it with `gcc`.

If you get a problem with assembler code, try changing the `-mcpu=xxx` option to match your CPU. Typically `power2`, `power`, or `powerpc` may need to be used. Alternatively, you might need to use `604` or `604e`. We are not positive but suspect that `power` would likely be safe most of the time, even on a power2 machine.

If you do not know which CPU is present, execute a `uname -m` command. It produces a string that looks like `000514676700` whose format is `xxyyyyyymmss` where `xx` and `ss` are always `00`, `yyyyyy` is a unique system ID and `mm` is the ID of the CPU Planar. A chart of these values can be found at http://www16.boulder.ibm.com/pseries/en_US/cmds/aixcmds5/uname.htm.

This gives you a machine type and model which you can use to determine what type of CPU you have.

If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring as follows:

```
CFLAGS=-DDONT_USE_THR_ALARM CXX=gcc \
CXXFLAGS="-felide-constructors -fno-exceptions -fno-rtti \
-DDONT_USE_THR_ALARM" \
./configure --prefix=/usr/local/mysql --with-debug \
    --with-low-memory
```

This does not affect the performance of MySQL, but has the side effect that you cannot kill clients that are “sleeping” on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

On some versions of AIX, linking with `libbind.a` makes `getservbyname()` dump core. This is an AIX bug and should be reported to IBM.

For AIX 4.2.1 and `gcc`, you have to make the following changes.

After configuring, edit `config.h` and `include/my_config.h` and change the line that says this:

```
#define HAVE_SNPRINTF 1
```

to this:

```
#undef HAVE_SNPRINTF
```

And finally, in `mysqld.cc`, you need to add a prototype for `initgroups()`.

```
#ifdef _AIX41
extern "C" int initgroups(const char *,int);
#endif
```

For 32-bit binaries, if you need to allocate a lot of memory to the `mysqld` process, it is not sufficient merely to use `ulimit -d unlimited`. You may also have to modify `mysqld_safe`, adding a line something like this:

```
export LDR_CNTRL='MAXDATA=0x80000000'
```

You can find more information about using very large amounts of memory at http://publib16.boulder.ibm.com/pseries/en_US/aixprggd/genprogc/lrg_prg_support.htm.

Users of AIX 4.3 should use `gmake` instead of the `make` utility included with AIX.

2.12.5.4 SunOS 4 Notes

On SunOS 4, MIT-pthreads is needed to compile MySQL. This in turn means you need GNU `make`.

Some SunOS 4 systems have problems with dynamic libraries and `libtool`. You can use the following `configure` line to avoid this problem:

```
./configure --disable-shared --with-mysqld-ldflags=-all-static
```

When compiling `readline`, you may get warnings about duplicate defines. These can be ignored.

When compiling `mysqld`, there are some `implicit declaration of function` warnings. These can be ignored.

2.12.5.5 Alpha-DEC-UNIX Notes (Tru64)

If you are using `egcs` 1.1.2 on Digital Unix, you should upgrade to `gcc` 2.95.2, because `egcs` on DEC has some serious bugs.

When compiling threaded programs under Digital Unix, the documentation recommends using the `-pthread` option for `cc` and `cxx` and the `-lmach -lexc` libraries (in addition to `-lpthread`). You should run `configure` something like this:

```
CC="cc -pthread" CXX="cxx -pthread -O" \
./configure --with-named-thread-libs="-lpthread -lmach -lexc -lc"
```

When compiling `mysqld`, you may see a couple of warnings like this:

```
mysqld.cc: In function void handle_connections()':
mysqld.cc:626: passing long unsigned int *' as argument 3 of
accept(int,sockadddr *, int *)'
```

You can safely ignore these warnings. They occur because `configure` can detect only errors, not warnings.

If you start the server directly from the command line, you may have problems with it dying when you log out. (When you log out, your outstanding processes receive a `SIGHUP` signal.) If so, try starting the server like this:

```
nohup mysqld [options] &
```

`nohup` causes the command following it to ignore any `SIGHUP` signal sent from the terminal. Alternatively, start the server by running `mysqld_safe`, which invokes `mysqld` using `nohup` for you. See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

If you get a problem when compiling `mysys/get_opt.c`, just remove the `#define _NO_PROTO` line from the start of that file.

If you are using Compaq's CC compiler, the following `configure` line should work:

```
CC="cc -pthread"
CFLAGS="-O4 -ansi_alias -ansi_args -fast -inline speed \
        -speculate all -arch host"
CXX="cxx -pthread"
CXXFLAGS="-O4 -ansi_alias -ansi_args -fast -inline speed \
          -speculate all -arch host -noexceptions -nortti"
export CC CFLAGS CXX CXXFLAGS
./configure \
    --prefix=/usr/local/mysql \
    --with-low-memory \
    --enable-large-files \
    --enable-shared=yes \
    --with-named-thread-libs="-lpthread -lmach -lexc -lc"
gnumake
```

If you get a problem with `libtool` when compiling with shared libraries as just shown, when linking `mysql`, you should be able to get around this by issuing these commands:

```
cd mysql
/bin/sh ../libtool --mode=link cxx -pthread  -O3 -DDBUG_OFF \
    -O4 -ansi_alias -ansi_args -fast -inline speed \
    -speculate all \ -arch host  -DUNDEF_HAVE_GETHOSTBYNAME_R \
    -o mysql  mysql.o readline.o sql_string.o completion_hash.o \
    ../readline/libreadline.a -lcurses \
    ../libmysql/.libs/libmysqlclient.so  -lm
cd ..
gnumake
gnumake install
scripts/mysql_install_db
```

2.12.5.6 Alpha-DEC-OSF/1 Notes

If you have problems compiling and have DEC `CC` and `gcc` installed, try running `configure` like this:

```
CC=cc CFLAGS=-O CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql
```

If you get problems with the `c_asm.h` file, you can create and use a 'dummy' `c_asm.h` file with:

```
touch include/c_asm.h
CC=gcc CFLAGS=-I./include \
CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql
```

Note that the following problems with the `ld` program can be fixed by downloading the latest DEC (Compaq) patch kit from: http://ftp.support.compaq.com/public/unix/.

On OSF/1 V4.0D and compiler "DEC C V5.6-071 on Digital Unix V4.0 (Rev. 878)," the compiler had some strange behavior (undefined `asm` symbols). `/bin/ld` also appears to be broken (problems with `_exit undefined` errors occurring while linking `mysqld`). On this system, we have managed to compile MySQL with the following `configure` line, after replacing `/bin/ld` with the version from OSF 4.0C:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 ./configure --prefix=/usr/local/mysql
```

With the Digital compiler "C++ V6.1-029," the following should work:

```
CC=cc -pthread
CFLAGS=-O4 -ansi_alias -ansi_args -fast -inline speed \
       -speculate all -arch host
CXX=cxx -pthread
CXXFLAGS=-O4 -ansi_alias -ansi_args -fast -inline speed \
         -speculate all -arch host -noexceptions -nortti
export CC CFLAGS CXX CXXFLAGS
./configure --prefix=/usr/mysql/mysql \
            --with-mysqld-ldflags=-all-static --disable-shared \
            --with-named-thread-libs="-lmach -lexc -lc"
```

In some versions of OSF/1, the `alloca()` function is broken. Fix this by removing the line in `config.h` that defines `'HAVE_ALLOCA'`.

The `alloca()` function also may have an incorrect prototype in `/usr/include/alloca.h`. This warning resulting from this can be ignored.

`configure` uses the following thread libraries automatically: `--with-named-thread-libs="-lpthread -lmach -lexc -lc"`.

When using `gcc`, you can also try running `configure` like this:

```
CFLAGS=-D_PTHREAD_USE_D4 CXX=gcc CXXFLAGS=-O3 ./configure ...
```

If you have problems with signals (MySQL dies unexpectedly under high load), you may have found an OS bug with threads and signals. In this case, you can tell MySQL not to use signals by configuring with:

```
CFLAGS=-DDONT_USE_THR_ALARM \
CXXFLAGS=-DDONT_USE_THR_ALARM \
./configure ...
```

This does not affect the performance of MySQL, but has the side effect that you cannot kill clients that are “sleeping” on a connection with `mysqladmin kill` or `mysqladmin shutdown`. Instead, the client dies when it issues its next command.

With `gcc` 2.95.2, you may encounter the following compile error:

```
sql_acl.cc:1456: Internal compiler error in `scan_region',
at except.c:2566
Please submit a full bug report.
```

To fix this, you should change to the `sql` directory and do a cut-and-paste of the last `gcc` line, but change `-O3` to `-O0` (or add `-O0` immediately after `gcc` if you do not have any `-O` option on your compile line). After this is done, you can just change back to the top-level directory and run `make` again.

2.12.5.7 SGI Irix Notes

If you are using Irix 6.5.3 or newer, `mysqld` is able to create threads only if you run it as a user that has `CAP_SCHED_MGT` privileges (such as `root`) or if you give the `mysqld` server this privilege with the following shell command:

```
chcap "CAP_SCHED_MGT+epi" /opt/mysql/libexec/mysqld
```

You may have to undefine some symbols in `config.h` after running `configure` and before compiling.

In some Irix implementations, the `alloca()` function is broken. If the `mysqld` server dies on some `SELECT` statements, remove the lines from `config.h` that define `HAVE_ALLOC` and `HAVE_ALLOCA_H`. If `mysqladmin create` does not work, remove the line from `config.h` that defines `HAVE_READDIR_R`. You may have to remove the `HAVE_TERM_H` line as well.

SGI recommends that you install all the patches on this page as a set:

http://support.sgi.com/surfzone/patches/patchset/6.2_indigo.rps.html

At the very minimum, you should install the latest kernel rollup, the latest `rld` rollup, and the latest `libc` rollup.

You definitely need all the POSIX patches on this page, for pthreads support:

http://support.sgi.com/surfzone/patches/patchset/6.2_posix.rps.html

If you get the something like the following error when compiling `mysql.cc`:

```
"/usr/include/curses.h", line 82: error(1084):
invalid combination of type
```

Type the following in the top-level directory of your MySQL source tree:

```
extra/replace bool curses_bool < /usr/include/curses.h > include/curses.h
make
```

There have also been reports of scheduling problems. If only one thread is running, performance is slow. Avoid this by starting another client. This may lead to a two-to-tenfold increase in execution speed thereafter for the other thread. This is a poorly understood problem with Irix threads; you may have to improvise to find solutions until this can be fixed.

If you are compiling with `gcc`, you can use the following `configure` command:

```
CC=gcc CXX=gcc CXXFLAGS=-O3 \
./configure --prefix=/usr/local/mysql --enable-thread-safe-client \
    --with-named-thread-libs=-lpthread
```

On Irix 6.5.11 with native Irix C and C++ compilers ver. 7.3.1.2, the following is reported to work

```
CC=cc CXX=CC CFLAGS='-O3 -n32 -TARG:platform=IP22 -I/usr/local/include \
-L/usr/local/lib' CXXFLAGS='-O3 -n32 -TARG:platform=IP22 \
-I/usr/local/include -L/usr/local/lib' \
./configure --prefix=/usr/local/mysql --with-innodb --with-berkeley-db \
    --with-libwrap=/usr/local \
    --with-named-curses-libs=/usr/local/lib/libncurses.a
```

2.12.5.8 SCO UNIX and OpenServer 5.0.x Notes

The current port is tested only on `sco3.2v5.0.5`, `sco3.2v5.0.6`, and `sco3.2v5.0.7` systems. There has also been progress on a port to `sco3.2v4.2`. Open Server 5.0.8 (Legend) has native threads and permits files greater than 2GB. The current maximum file size is 2GB.

We have been able to compile MySQL with the following `configure` command on OpenServer with `gcc` 2.95.3.

```
CC=gcc CFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
```

```
CXX=gcc CXXFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client --with-innodb \
    --with-openssl --with-vio --with-extra-charsets=complex
```

`gcc` is available at ftp://ftp.sco.com/pub/openserver5/opensrc/gnutools-5.0.7Kj.

This development system requires the OpenServer Execution Environment Supplement oss646B on OpenServer 5.0.6 and oss656B and the OpenSource libraries found in gwxlibs. All OpenSource tools are in the `opensrc` directory. They are available at ftp://ftp.sco.com/pub/openserver5/opensrc/.

Use the latest production release of MySQL.

SCO provides operating system patches at ftp://ftp.sco.com/pub/openserver5 for OpenServer 5.0.[0-6] and ftp://ftp.sco.com/pub/openserverv5/507 for OpenServer 5.0.7.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenServer for OpenServer 5.0.x.

The maximum file size on an OpenServer 5.0.x system is 2GB.

The total memory which can be allocated for streams buffers, clists, and lock records cannot exceed 60MB on OpenServer 5.0.x.

Streams buffers are allocated in units of 4096 byte pages, clists are 70 bytes each, and lock records are 64 bytes each, so:

```
(NSTRPAGES * 4096) + (NCLIST * 70) + (MAX_FLCKREC * 64) <= 62914560
```

Follow this procedure to configure the Database Services option. If you are unsure whether an application requires this, see the documentation provided with the application.

1. Log in as `root`.
2. Enable the SUDS driver by editing the `/etc/conf/sdevice.d/suds` file. Change the `N` in the second field to a `Y`.
3. Use `mkdev aio` or the Hardware/Kernel Manager to enable support for asynchronous I/O and relink the kernel. To enable users to lock down memory for use with this type of I/O, update the aiomemlock(F) file. This file should be updated to include the names of users that can use AIO and the maximum amounts of memory they can lock down.
4. Many applications use setuid binaries so that you need to specify only a single user. See the documentation provided with the application to determine whether this is the case for your application.

After you complete this process, reboot the system to create a new kernel incorporating these changes.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

```
Value           Default         Min             Max
-----           -------         ---             ---
NBUF            0               24              450000
NHBUF           0               32              524288
NMPBUF          0               12              512
MAX_INODE       0               100             64000
MAX_FILE        0               100             64000
CTBUFSIZE       128             0               256
MAX_PROC        0               50              16000
```

```
MAX_REGION      0               500             160000
NCLIST          170             120             16640

* Semaphore Parameters
SEMMAP          10              10              8192
SEMMNI          10              10              8192
SEMMNS          60              60              8192
SEMMNU          30              10              8192
SEMMSL          25              25              150
SEMOPM          10              10              1024
SEMUME          10              10              25
SEMVMX          32767           32767           32767
SEMAEM          16384           16384           16384
* Shared Memory Parameters
SHMMAX          524288          131072          2147483647
SHMMIN          1               1               1
SHMMNI          100             100             2000
FILE            0               100             64000
NMOUNT          0               4               256
NPROC           0               50              16000
NREGION         0               500             160000
```

Set these values as follows:

- `NOFILES` should be 4096 or 2048.
- `MAXUP` should be 2048.

To make changes to the kernel, use the `idtune` *`name parameter`* command. `idtune` modifies the `/etc/conf/cf.d/stune` file for you. For example, to change `SEMMS` to `200`, execute this command as `root`:

```
# /etc/conf/bin/idtune SEMMNS 200
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

To tune the system, the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- SHMMAX (recommended setting: 128MB) and SHMSEG (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- NOFILES and MAXUP should be set to at least 2048.
- MAXPROC should be set to at least 3000/4000 (depends on number of users) or more.
- The following formulas are recommended to calculate values for SEMMSL, SEMMNS, and SEMMNU:

```
SEMMSL = 13
```

13 is what has been found to be the best for both Progress and MySQL.

```
SEMMNS = SEMMSL * number of db servers to be run on the system
```

Set SEMMNS to the value of SEMMSL multiplied by the number of database servers (maximum) that you are running on the system at one time.

```
SEMMNU = SEMMNS
```

Set the value of SEMMNU to equal the value of SEMMNS. You could probably set this to 75% of SEMMNS, but this is a conservative estimate.

You need to at least install the SCO OpenServer Linker and Application Development Libraries or the OpenServer Development System to use gcc. You cannot use the GCC Dev system without installing one of these.

You should get the FSU Pthreads package and install it first. This can be found at http://moss.csc.ncsu.edu/~mueller/ftp/pub/PART/pthreads.tar.gz. You can also get a precompiled package from ftp://ftp.zenez.com/pub/zenez/prgms/FSU-threads-3.14.tar.gz.

FSU Pthreads can be compiled with SCO Unix 4.2 with tcpip, or using OpenServer 3.0 or Open Desktop 3.0 (OS 3.0 ODT 3.0) with the SCO Development System installed using a good port of GCC 2.5.x. For ODT or OS 3.0, you need a good port of GCC 2.5.x. There are a lot of problems without a good port. The port for this product requires the SCO Unix Development system. Without it, you are missing the libraries and the linker that is needed. You also need SCO-3.2v4.2-includes.tar.gz. This file contains the changes to the SCO Development include files that are needed to get MySQL to build. You need to replace the existing system include files with these modified header files. They can be obtained from ftp://ftp.zenez.com/pub/zenez/prgms/SCO-3.2v4.2-includes.tar.gz.

To build FSU Pthreads on your system, all you should need to do is run GNU make. The Makefile in FSU-threads-3.14.tar.gz is set up to make FSU-threads.

You can run ./configure in the threads/src directory and select the SCO OpenServer option. This command copies Makefile.SCO5 to Makefile. Then run make.

To install in the default /usr/include directory, log in as root, and then cd to the thread/src directory and run make install.

Remember that you must use GNU make to build MySQL.

Note

If you do not start mysqld_safe as root, you should get only the default 110 open files per process. mysqld writes a note about this in the log file.

With SCO 3.2V4.2, you should use FSU Pthreads version 3.14 or newer. The following `configure` command should work:

```
CFLAGS="-D_XOPEN_XPG4" CXX=gcc CXXFLAGS="-D_XOPEN_XPG4" \
./configure \
    --prefix=/usr/local/mysql \
    --with-named-thread-libs="-lgthreads -lsocket -lgen -lgthreads" \
    --with-named-curses-libs="-lcurses"
```

You may have problems with some include files. In this case, you can find new SCO-specific include files at ftp://ftp.zenez.com/pub/zenez/prgms/SCO-3.2v4.2-includes.tar.gz.

You should unpack this file in the `include` directory of your MySQL source tree.

SCO development notes:

- MySQL should automatically detect FSU Pthreads and link `mysqld` with `-lgthreads -lsocket -lgthreads`.
- The SCO development libraries are re-entrant in FSU Pthreads. SCO claims that its library functions are re-entrant, so they must be re-entrant with FSU Pthreads. FSU Pthreads on OpenServer tries to use the SCO scheme to make re-entrant libraries.
- FSU Pthreads (at least the version at ftp://ftp.zenez.com) comes linked with GNU `malloc`. If you encounter problems with memory usage, make sure that `gmalloc.o` is included in `libgthreads.a` and `libgthreads.so`.
- In FSU Pthreads, the following system calls are pthreads-aware: `read()`, `write()`, `getmsg()`, `connect()`, `accept()`, `select()`, and `wait()`.
- The CSSA-2001-SCO.35.2 (the patch is listed in custom as erg711905-dscr_remap security patch (version 2.0.0)) breaks FSU threads and makes `mysqld` unstable. You have to remove this one if you want to run `mysqld` on an OpenServer 5.0.6 machine.
- If you use SCO OpenServer 5, you may need to recompile FSU pthreads with `-DDRAFT7` in `CFLAGS`. Otherwise, `InnoDB` may hang at a `mysqld` startup.
- SCO provides operating system patches at ftp://ftp.sco.com/pub/openserver5 for OpenServer 5.0.x.
- SCO provides security fixes and `libsocket.so.2` at ftp://ftp.sco.com/pub/security/OpenServer and ftp://ftp.sco.com/pub/security/sse for OpenServer 5.0.x.
- Pre-OSR506 security fixes. Also, the `telnetd` fix at ftp://stage.caldera.com/pub/security/openserver/ or ftp://stage.caldera.com/pub/security/openserver/CSSA-2001-SCO.10/ as both `libsocket.so.2` and `libresolv.so.1` with instructions for installing on pre-OSR506 systems.

  It is probably a good idea to install these patches before trying to compile/use MySQL.

Beginning with Legend/OpenServer 6.0.0, there are native threads and no 2GB file size limit.

2.12.5.9 SCO OpenServer 6.0.x Notes

OpenServer 6 includes these key improvements:

- Larger file support up to 1 TB
- Multiprocessor support increased from 4 to 32 processors

- Increased memory support up to 64GB
- Extending the power of UnixWare into OpenServer 6
- Dramatic performance improvement

OpenServer 6.0.0 commands are organized as follows:

- `/bin` is for commands that behave exactly the same as on OpenServer 5.0.x.
- `/u95/bin` is for commands that have better standards conformance, for example Large File System (LFS) support.
- `/udk/bin` is for commands that behave the same as on UnixWare 7.1.4. The default is for the LFS support.

The following is a guide to setting `PATH` on OpenServer 6. If the user wants the traditional OpenServer 5.0.x then `PATH` should be `/bin` first. If the user wants LFS support, the path should be `/u95/bin:/bin`. If the user wants UnixWare 7 support first, the path would be `/udk/bin:/u95/bin:/bin:`.

Use the latest production release of MySQL. Should you choose to use an older release of MySQL on OpenServer 6.0.x, you must use a version of MySQL at least as recent as 3.22.13 to get fixes for some portability and OS problems.

MySQL distribution files with names of the following form are `tar` archives of media are tar archives of media images suitable for installation with the SCO Software Manager (`/etc/custom`) on SCO OpenServer 6:

```
mysql-PRODUCT-4.1.25-sco-osr6-i686.VOLS.tar
```

A distribution where *`PRODUCT`* is `pro-cert` is the Commercially licensed MySQL Pro Certified server. A distribution where *`PRODUCT`* is `pro-gpl-cert` is the MySQL Pro Certified server licensed under the terms of the General Public License (GPL).

Select whichever distribution you wish to install and, after download, extract the `tar` archive into an empty directory. For example:

```
shell> mkdir /tmp/mysql-pro
shell> cd /tmp/mysql-pro
shell> tar xf /tmp/mysql-pro-cert-4.1.25-sco-osr6-i686.VOLS.tar
```

Prior to installation, back up your data in accordance with the procedures outlined in Section 2.11.1, “Upgrading MySQL”.

Remove any previously installed `pkgadd` version of MySQL:

```
shell> pkginfo mysql 2>&1 > /dev/null && pkgrm mysql
```

Install MySQL Pro from media images using the SCO Software Manager:

```
shell> /etc/custom -p SCO:MySQL -i -z /tmp/mysql-pro
```

Alternatively, the SCO Software Manager can be displayed graphically by clicking the `Software Manager` icon on the desktop, selecting `Software -> Install New`, selecting the host, selecting `Media Images` for the Media Device, and entering `/tmp/mysql-pro` as the Image Directory.

After installation, run `mkdev mysql` as the `root` user to configure your newly installed MySQL Pro Certified server.

Note

The installation procedure for VOLS packages does not create the `mysql` user and group that the package uses by default. You should either create the `mysql` user and group, or else select a different user and group using an option in `mkdev mysql`.

If you wish to configure your MySQL Pro server to interface with the Apache Web server using PHP, download and install the PHP update from SCO at ftp://ftp.sco.com/pub/updates/OpenServer/SCOSA-2006.17/.

We have been able to compile MySQL with the following `configure` command on OpenServer 6.0.x:

```
CC=cc CFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
CXX=CC CXXFLAGS="-D_FILE_OFFSET_BITS=64 -O3" \
./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client --with-berkeley-db \
    --with-extra-charsets=complex \
    --build=i686-unknown-sysv5SCO_SV6.0.0
```

If you use `gcc`, you must use `gcc` 2.95.3 or newer.

```
CC=gcc CXX=g++ ... ./configure ...
```

The version of Berkeley DB that comes with either UnixWare 7.1.4 or OpenServer 6.0.0 is not used when building MySQL. MySQL instead uses its own version of Berkeley DB. The `configure` command needs to build both a static and a dynamic library in *`src_directory`*`/bdb/build_unix/`, but it does not with MySQL's own `BDB` version. The workaround is as follows.

1. Configure as normal for MySQL.
2. `cd bdb/build_unix/`
3. `cp -p Makefile Makefile.sav`
4. Use same options and run `../dist/configure`.
5. Run `gmake`.
6. `cp -p Makefile.sav Makefile`
7. Change location to the top source directory and run `gmake`.

This enables both the shared and dynamic libraries to be made and work.

SCO provides OpenServer 6 operating system patches at ftp://ftp.sco.com/pub/openserver6.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenServer.

By default, the maximum file size on a OpenServer 6.0.0 system is 1TB. Some operating system utilities have a limitation of 2GB. The maximum possible file size on UnixWare 7 is 1TB with VXFS or HTFS.

OpenServer 6 can be configured for large file support (file sizes greater than 2GB) by tuning the UNIX kernel.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

```
Value           Default         Min             Max
-----           -------         ---             ---
SVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
HVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
```

To make changes to the kernel, use the `idtune name parameter` command. `idtune` modifies the `/etc/conf/cf.d/stune` file for you. To set the kernel values, execute the following commands as `root`:

```
# /etc/conf/bin/idtune SDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SVMMLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HVMMLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SFNOLIM 2048
# /etc/conf/bin/idtune HFNOLIM 2048
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

To tune the system, the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- `SHMMAX` (recommended setting: 128MB) and `SHMSEG` (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- `SFNOLIM` and `HFNOLIM` should be at maximum 2048.
- `NPROC` should be set to at least 3000/4000 (depends on number of users).
- The following formulas are recommended to calculate values for `SEMMSL`, `SEMMNS`, and `SEMMNU`:

  ```
  SEMMSL = 13
  ```

  13 is what has been found to be the best for both Progress and MySQL.

  ```
  SEMMNS = SEMMSL * number of db servers to be run on the system
  ```

  Set `SEMMNS` to the value of `SEMMSL` multiplied by the number of database servers (maximum) that you are running on the system at one time.

  ```
  SEMMNU = SEMMNS
  ```

  Set the value of `SEMMNU` to equal the value of `SEMMNS`. You could probably set this to 75% of `SEMMNS`, but this is a conservative estimate.

2.12.5.10 SCO UnixWare 7.1.x and OpenUNIX 8.0.0 Notes

Use the latest production release of MySQL. Should you choose to use an older release of MySQL on UnixWare 7.1.x, you must use a version of MySQL at least as recent as 3.22.13 to get fixes for some portability and OS problems.

We have been able to compile MySQL with the following `configure` command on UnixWare 7.1.x:

```
CC="cc" CFLAGS="-I/usr/local/include" \
CXX="CC" CXXFLAGS="-I/usr/local/include" \
./configure --prefix=/usr/local/mysql \
    --enable-thread-safe-client --with-berkeley-db=./bdb \
    --with-innodb --with-openssl --with-extra-charsets=complex
```

If you want to use `gcc`, you must use `gcc` 2.95.3 or newer.

```
CC=gcc CXX=g++ ... ./configure ...
```

The version of Berkeley DB that comes with either UnixWare 7.1.4 or OpenServer 6.0.0 is not used when building MySQL. MySQL instead uses its own version of Berkeley DB. The `configure` command needs to build both a static and a dynamic library in *`src_directory`*`/bdb/build_unix/`, but it does not with MySQL's own `BDB` version. The workaround is as follows.

1. Configure as normal for MySQL.
2. `cd bdb/build_unix/`
3. `cp -p Makefile Makefile.sav`
4. Use same options and run `../dist/configure`.
5. Run `gmake`.
6. `cp -p Makefile.sav Makefile`
7. Change to top source directory and run `gmake`.

This enables both the shared and dynamic libraries to be made and work.

SCO provides operating system patches at ftp://ftp.sco.com/pub/unixware7 for UnixWare 7.1.1, ftp://ftp.sco.com/pub/unixware7/713/ for UnixWare 7.1.3, ftp://ftp.sco.com/pub/unixware7/714/ for UnixWare 7.1.4, and ftp://ftp.sco.com/pub/openunix8 for OpenUNIX 8.0.0.

SCO provides information about security fixes at ftp://ftp.sco.com/pub/security/OpenUNIX for OpenUNIX and ftp://ftp.sco.com/pub/security/UnixWare for UnixWare.

The UnixWare 7 file size limit is 1 TB with VXFS. Some OS utilities have a limitation of 2GB.

On UnixWare 7.1.4 you do not need to do anything to get large file support, but to enable large file support on prior versions of UnixWare 7.1.x, run `fsadm`.

```
# fsadm -Fvxfs -o largefiles /
# fsadm /         * Note
# ulimit unlimited
# /etc/conf/bin/idtune SFSZLIM 0x7FFFFFFF     ** Note
# /etc/conf/bin/idtune HFSZLIM 0x7FFFFFFF     ** Note
# /etc/conf/bin/idbuild -B

* This should report "largefiles".
** 0x7FFFFFFF represents infinity for these values.
```

Reboot the system using `shutdown`.

By default, the entries in `/etc/conf/cf.d/mtune` are set as follows:

```
Value           Default         Min             Max
```

```
-----           -------         ---             ---
SVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
HVMMLIM         0x9000000       0x1000000       0x7FFFFFFF
```

To make changes to the kernel, use the `idtune name parameter` command. `idtune` modifies the `/etc/conf/cf.d/stune` file for you. To set the kernel values, execute the following commands as `root`:

```
# /etc/conf/bin/idtune SDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HDATLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SVMMLIM 0x7FFFFFFF
# /etc/conf/bin/idtune HVMMLIM 0x7FFFFFFF
# /etc/conf/bin/idtune SFNOLIM 2048
# /etc/conf/bin/idtune HFNOLIM 2048
```

Then rebuild and reboot the kernel by issuing this command:

```
# /etc/conf/bin/idbuild -B && init 6
```

To tune the system, the proper parameter values to use depend on the number of users accessing the application or database and size the of the database (that is, the used buffer pool). The following kernel parameters can be set with `idtune`:

- `SHMMAX` (recommended setting: 128MB) and `SHMSEG` (recommended setting: 15). These parameters have an influence on the MySQL database engine to create user buffer pools.
- `SFNOLIM` and `HFNOLIM` should be at maximum 2048.
- `NPROC` should be set to at least 3000/4000 (depends on number of users).
- The following formulas are recommended to calculate values for `SEMMSL`, `SEMMNS`, and `SEMMNU`:

  ```
  SEMMSL = 13
  ```

  13 is what has been found to be the best for both Progress and MySQL.

  ```
  SEMMNS = SEMMSL * number of db servers to be run on the system
  ```

  Set `SEMMNS` to the value of `SEMMSL` multiplied by the number of database servers (maximum) that you are running on the system at one time.

  ```
  SEMMNU = SEMMNS
  ```

  Set the value of `SEMMNU` to equal the value of `SEMMNS`. You could probably set this to 75% of `SEMMNS`, but this is a conservative estimate.

2.12.6 OS/2 Notes

Note

We no longer test builds on OS/2. The notes in this section are provided for your information but may not work on your system.

MySQL uses quite a few open files. Because of this, you should add something like the following to your `CONFIG.SYS` file:

```
```

```
SET EMXOPT=-c -n -h1024
```

If you do not do this, you may encounter the following error:

```
File 'xxxx' not found (Errcode: 24)
```

When using MySQL with OS/2 Warp 3, FixPack 29 or above is required. With OS/2 Warp 4, FixPack 4 or above is required. This is a requirement of the Pthreads library. MySQL must be installed on a partition with a type that supports long file names, such as HPFS, FAT32, and so on.

The `INSTALL.CMD` script must be run from OS/2's own `CMD.EXE` and may not work with replacement shells such as `4OS2.EXE`.

The `scripts/mysql-install-db` script has been renamed. It is called `install.cmd` and is a REXX script, which sets up the default MySQL security settings and creates the WorkPlace Shell icons for MySQL.

Dynamic module support is compiled in but not fully tested. Dynamic modules should be compiled using the Pthreads runtime library.

```
gcc -Zdll -Zmt -Zcrtdll=pthrdrtl -I../include -I../regex -I.. \
    -o example udf_example.cc -L../lib -lmysqlclient udf_example.def
mv example.dll example.udf
```

Note

Due to limitations in OS/2, UDF module name stems must not exceed eight characters. Modules are stored in the `/mysql2/udf` directory; the `safe-mysqld.cmd` script puts this directory in the `BEGINLIBPATH` environment variable. When using UDF modules, specified extensions are ignored---it is assumed to be `.udf`. For example, in Unix, the shared module might be named `example.so` and you would load a function from it like this:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'example.so';
```

In OS/2, the module would be named `example.udf`, but you would not specify the module extension:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'example';
```

2.13 Environment Variables

This section lists all the environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables.

In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See Section 4.2.3.3, “Using Option Files”.

Variable	Description
`CXX`	The name of your C++ compiler (for running `configure`).
`CC`	The name of your C compiler (for running `configure`).

Variable	Description
CFLAGS	Flags for your C compiler (for running configure).
CXXFLAGS	Flags for your C++ compiler (for running configure).
DBI_USER	The default user name for Perl DBI.
DBI_TRACE	Trace options for Perl DBI.
HOME	The default path for the mysql history file is $HOME/.mysql_history.
LD_RUN_PATH	Used to specify the location of libmysqlclient.so.
MYSQL_DEBUG	Debug trace options when debugging.
MYSQL_GROUP_SUFFIX	Option group suffix value (like specifying --defaults-group-suffix).
MYSQL_HISTFILE	The path to the mysql history file. If this variable is set, its value overrides the default for $HOME/.mysql_history.
MYSQL_HOME	The path to the directory in which the server-specific my.cnf file resides (as of MySQL 5.0.3).
MYSQL_HOST	The default host name used by the mysql command-line client.
MYSQL_PS1	The command prompt to use in the mysql command-line client.
MYSQL_PWD	The default password when connecting to mysqld. Note that using this is insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”.
MYSQL_TCP_PORT	The default TCP/IP port number.
MYSQL_UNIX_PORT	The default Unix socket file name; used for connections to localhost.
PATH	Used by the shell to find MySQL programs.
TMPDIR	The directory where temporary files are created.
TZ	This should be set to your local time zone. See Section B.5.4.6, “Time Zone Problems”.
UMASK	The user-file creation mode when creating files. See note following table.
UMASK_DIR	The user-directory creation mode when creating directories. See note following table.
USER	The default user name on Windows and NetWare when connecting to mysqld.

For information about the mysql history file, see Section 4.5.1.3, “mysql Logging”.

The UMASK and UMASK_DIR variables, despite their names, are used as modes, not masks:

- If UMASK is set, mysqld uses ($UMASK | 0600) as the mode for file creation, so that newly created files have a mode in the range from 0600 to 0666 (all values octal).
- If UMASK_DIR is set, mysqld uses ($UMASK_DIR | 0700) as the base mode for directory creation, which then is AND-ed with ~(~$UMASK & 0666), so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

In MySQL 3.23.25 and above, MySQL assumes that the value for UMASK or UMASK_DIR is in octal if it starts with a zero.

2.14 Perl Installation Notes

Perl support for MySQL is provided by means of the DBI/DBD client interface. The interface requires Perl 5.6.0, and 5.6.1 or later is preferred. DBI *does not work* if you have an older version of Perl.

To use transactions with Perl DBI, you must use `DBD::mysql` 2.0900 or newer. To use the MySQL 4.1 or newer client library, you must use `DBD::mysql` 2.9003 or newer. Support for server-side prepared statements requires `DBD::mysql` 3.0009 or newer. Current versions of `DBD::mysql` on CPAN are 4.xxxx or higher and support all these capabilities.

As of MySQL 3.22.8, Perl support is no longer included with MySQL distributions. You can obtain the necessary modules from http://search.cpan.org for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

Perl support for MySQL must be installed if you want to run the MySQL benchmark scripts; see Section 7.1.3, “The MySQL Benchmark Suite”. It is also required for the MySQL Cluster `ndb_size.pl` utility; see Section 15.4.18, “`ndb_size.pl` — NDBCLUSTER Size Requirement Estimator”.

2.14.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. However, if you installed MySQL from RPM files on Linux, be sure that you've installed the developer RPM. The client programs are in the client RPM, but client programming support is in the developer RPM.

If you want to install Perl support, the files you need can be obtained from the CPAN (Comprehensive Perl Archive Network) at http://search.cpan.org.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and `ODBC` on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

`DBI` requires the `Data::Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a DBI distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

   ```
   shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
   ```

   This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

   ```
   shell> cd DBI-VERSION
   ```

3. Build the distribution and compile everything:

   ```
   shell> perl Makefile.PL
   shell> make
   ```

```
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL, particularly if you notice symptoms such as that all your `DBI` scripts fail after you upgrade MySQL.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: http://servers.digitaldaze.com/extensions/perl/modules.html#modules

Look under the heading “Installing New Modules that Require Locally Installed Modules.”

2.14.2 Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from http://www.activestate.com/Products/ActivePerl/ and install it.
2. Open a console window (a “DOS window”).
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

   ```
   set HTTP_proxy=my.proxy.com:3128
   ```

4. Start the PPM program:

   ```
   shell> C:\perl\bin\ppm.pl
   ```

5. If you have not previously done so, install `DBI`:

   ```
   ppm> install DBI
   ```

6. If this succeeds, run the following command:

   ```
   ppm> install DBD-mysql
   ```

This procedure should work with ActiveState Perl 5.6 or newer.

If you cannot get the procedure to work, you should install the MyODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
  die "Got error $DBI::errstr when connecting to $dsn\n";
```

2.14.3 Problems Using the Perl `DBI`/`DBD` Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Compile the DBD::mysql distribution with perl Makefile.PL -static -config rather than perl Makefile.PL.
- Copy libmysqlclient.so to the directory where your other shared libraries are located (probably /usr/lib or /lib).
- Modify the -L options used to compile DBD::mysql to reflect the actual location of libmysqlclient.so.
- On Linux, you can add the path name of the directory where libmysqlclient.so is located to the /etc/ld.so.conf file.
- Add the path name of the directory where libmysqlclient.so is located to the LD_RUN_PATH environment variable. Some systems use LD_LIBRARY_PATH instead.

Note that you may also need to modify the -L options if there are other libraries that the linker fails to find. For example, if the linker cannot find libc because it is in /lib and the link command specifies -L/usr/lib, change the -L option to -L/lib or add -L/lib to the existing link command.

If you get the following errors from DBD::mysql, you are probably using gcc (or using an old binary compiled with gcc):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add -L/usr/lib/gcc-lib/... -lgcc to the link command when the mysql.so library gets built (check the output from make for mysql.so when you compile the Perl client). The -L option should specify the path name of the directory where libgcc.a is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with gcc. In this case, you can solve the mismatch by compiling both with gcc.

You may see the following error from DBD::mysql when you run the tests:

```
t/00base............install_driver(mysql) failed:
Can't load '../blib/arch/auto/DBD/mysql/mysql.so' for module DBD::mysql:
../blib/arch/auto/DBD/mysql/mysql.so: undefined symbol:
uncompress at /usr/lib/perl5/5.00503/i586-linux/DynaLoader.pm line 169.
```

This means that you need to include the -lz compression library on the link line. That can be done by changing the following line in the file lib/DBD/mysql/Install.pm:

```
$sysliblist .= " -lm";
```

Change that line to:

```
$sysliblist .= " -lm -lz";
```

After this, you *must* run make realclean and then proceed with the installation from the beginning.

If you want to install DBI on SCO, you have to edit the Makefile in DBI-*xxx* and each subdirectory. Note that the following assumes gcc 2.95.2 or newer:

```
OLD:                                NEW:
CC = cc                             CC = gcc
```

```
CCCDLFLAGS = -KPIC -W1,-Bexport       CCCDLFLAGS = -fpic
CCDLFLAGS = -wl,-Bexport              CCDLFLAGS =

LD = ld                               LD = gcc -G -fpic
LDDLFLAGS = -G -L/usr/local/lib       LDDLFLAGS = -L/usr/local/lib
LDFLAGS = -belf -L/usr/local/lib      LDFLAGS = -L/usr/local/lib

LD = ld                               LD = gcc -G -fpic
OPTIMISE = -Od                        OPTIMISE = -O1

OLD:
CCCFLAGS = -belf -dy -w0 -U M_XENIX -DPERL_SCO5 -I/usr/local/include

NEW:
CCFLAGS = -U M_XENIX -DPERL_SCO5 -I/usr/local/include
```

These changes are necessary because the Perl dynaloader does not load the DBI modules if they were compiled with icc or cc.

If you want to use the Perl module on a system that does not support dynamic linking (such as SCO), you can generate a static version of Perl that includes DBI and DBD::mysql. The way this works is that you generate a version of Perl with the DBI code linked in and install it on top of your current Perl. Then you use that to build a version of Perl that additionally has the DBD code linked in, and install that.

On SCO, you must have the following environment variables set:

```
LD_LIBRARY_PATH=/lib:/usr/lib:/usr/local/lib:/usr/progressive/lib
```

Or:

```
LD_LIBRARY_PATH=/usr/lib:/lib:/usr/local/lib:/usr/ccs/lib:\
    /usr/progressive/lib:/usr/skunk/lib
LIBPATH=/usr/lib:/lib:/usr/local/lib:/usr/ccs/lib:\
    /usr/progressive/lib:/usr/skunk/lib
MANPATH=scohelp:/usr/man:/usr/local1/man:/usr/local/man:\
    /usr/skunk/man:
```

First, create a Perl that includes a statically linked DBI module by running these commands in the directory where your DBI distribution is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Then, you must install the new Perl. The output of make perl indicates the exact make command you need to execute to perform the installation. On SCO, this is make -f Makefile.aperl inst_perl MAP_TARGET=perl.

Next, use the just-created Perl to create another Perl that also includes a statically linked DBD::mysql by running these commands in the directory where your DBD::mysql distribution is located:

```
shell> perl Makefile.PL -static -config
shell> make
shell> make install
shell> make perl
```

Finally, you should install this new Perl. Again, the output of make perl indicates the command to use.

Chapter 3 Tutorial

Table of Contents

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` [260] option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as Chapter 5, *MySQL Server Administration*.)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1 Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you will

also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: ********
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `********` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: ********
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 4.1.25-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter commands.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of Chapter 2, *Installing and Upgrading MySQL* that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see Section B.5.2, “Common Errors When Using MySQL Programs”.

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control-D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

3.2 Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering commands, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple command that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+------------+--------------+
| VERSION()  | CURRENT_DATE |
+------------+--------------+
| 4.1.14-Max | 2005-09-03   |
+------------+--------------+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A command normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a command, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another command.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.
- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the “rows in set” line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-------------+---------+
| SIN(PI()/4) | (4+1)*5 |
+-------------+---------+
|    0.707107 |      25 |
+-------------+---------+
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
```

```
+------------+
| VERSION()  |
+------------+
| 4.1.14-Max |
+------------+

+---------------------+
| NOW()               |
+---------------------+
| 2005-09-03 12:27:16 |
+---------------------+
```

A command need not be given all on a single line, so lengthy commands that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
    -> USER()
    -> ,
    -> CURRENT_DATE;
+---------------+--------------+
| USER()        | CURRENT_DATE |
+---------------+--------------+
| jon@localhost | 2005-09-03   |
+---------------+--------------+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a command that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
    -> USER()
    -> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new command.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

Prompt	Meaning
`mysql>`	Ready for new command.
`->`	Waiting for next line of multiple-line command.
`'>`	Waiting for next line, waiting for completion of a string that began with a single quote (“`'`”).
`">`	Waiting for next line, waiting for completion of a string that began with a double quote (“`"`”).
`` `> ``	Waiting for next line, waiting for completion of an identifier that began with a backtick (“`` ` ``”).
`/*>`	Waiting for next line, waiting for completion of a comment that began with `/*`.

The `` `> `` prompt was implemented MySQL 4.0.16. The `/*>` prompt was implemented in MySQL 4.1.12.

Multiple-line statements commonly occur by accident when you intend to issue a command on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()
    ->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
    -> ;
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
```

The `'>` and `">` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either "`'`" or "`"`" characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `">` prompt, it means that you have entered a line containing a string that begins with a "`'`" or "`"`" quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    '>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the command. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
    '> '\c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new command.

The `` `> `` prompt is similar to the `'>` and `">` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `">`, and `` `> `` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current command.

3.3 Creating and Using a Database

Once you know how to enter commands, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It is available in both compressed `tar` file and Zip formats at http://dev.mysql.com/doc/.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+----------+
| Database |
+----------+
| mysql    |
| test     |
| tmp      |
+----------+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See Section 12.4.5.8, “`SHOW DATABASES` Syntax”.

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a command like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

3.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

Note

If you get an error such as `ERROR 1044 (42000): Access denied for user 'monty'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see Section 5.5, “The MySQL Access Privilege System”.

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this command:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: ********
```

Important

`menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, not as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

Note

You can see at any time which database is currently selected using `SELECT DATABASE()` [872].

3.3.2 Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
```

```
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
    -> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be `20`. You can pick any length from `1` to `255`, whatever seems most reasonable to you. (If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.)

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+----------------------+
| Tables in menagerie |
+----------------------+
| pet                  |
+----------------------+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
```

```
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see Chapter 10, *Data Types*.

3.3.3 Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in `'YYYY-MM-DD'` format; this may be different from what you are used to.)

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	
Claws	Gwen	cat	m	1994-03-17	
Buffy	Harold	dog	f	1989-05-13	
Fang	Benny	dog	m	1990-08-27	
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	
Whistler	Gwen	bird		1997-12-09	
Slim	Benny	snake	m	1996-04-29	

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler        Gwen    bird    \N      1997-12-09      \N
```

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
    -> LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'`.)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See Section 5.4.5, “Security Issues with `LOAD DATA LOCAL`”, for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
    -> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

3.3.4 Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

`what_to_select` indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” *`which_table`* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *`conditions_to_satisfy`* specifies one or more conditions that rows must satisfy to qualify for retrieval.

3.3.4.1 Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
+----------+--------+---------+------+------------+------------+
| name     | owner  | species | sex  | birth      | death      |
+----------+--------+---------+------+------------+------------+
| Fluffy   | Harold | cat     | f    | 1993-02-04 | NULL       |
| Claws    | Gwen   | cat     | m    | 1994-03-17 | NULL       |
| Buffy    | Harold | dog     | f    | 1989-05-13 | NULL       |
| Fang     | Benny  | dog     | m    | 1990-08-27 | NULL       |
| Bowser   | Diane  | dog     | m    | 1979-08-31 | 1995-07-29 |
| Chirpy   | Gwen   | bird    | f    | 1998-09-11 | NULL       |
| Whistler | Gwen   | bird    | NULL | 1997-12-09 | NULL       |
| Slim     | Benny  | snake   | m    | 1996-04-29 | NULL       |
| Puffball | Diane  | hamster | f    | 1999-03-30 | NULL       |
+----------+--------+---------+------+------------+------------+
```

This form of SELECT is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file pet.txt to correct the error, then empty the table and reload it using DELETE and LOAD DATA:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

  However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an UPDATE statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

  The UPDATE changes only the record in question and does not require you to reload the table.

3.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the WHERE clause from the SELECT statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+--------+-------+---------+------+------------+------------+
| name   | owner | species | sex  | birth      | death      |
+--------+-------+---------+------+------------+------------+
| Bowser | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+-------+---------+------+------------+------------+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as 'bowser', 'BOWSER', and so forth. The query result is the same.

You can specify conditions on any column, not just name. For example, if you want to know which animals were born during or after 1998, test the birth column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Puffball | Diane | hamster | f    | 1999-03-30 | NULL  |
+----------+-------+---------+------+------------+-------+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The preceding query uses the `AND` [787] logical operator. There is also an `OR` [787] operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
+----------+-------+---------+------+------------+-------+
| name     | owner | species | sex  | birth      | death |
+----------+-------+---------+------+------------+-------+
| Chirpy   | Gwen  | bird    | f    | 1998-09-11 | NULL  |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL  |
| Slim     | Benny | snake   | m    | 1996-04-29 | NULL  |
+----------+-------+---------+------+------------+-------+
```

`AND` [787] and `OR` [787] may be intermixed, although `AND` [787] has higher precedence than `OR` [787]. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
    -> OR (species = 'dog' AND sex = 'f');
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

3.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the `name` and `birth` columns:

```
mysql> SELECT name, birth FROM pet;
+----------+------------+
| name     | birth      |
+----------+------------+
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Buffy    | 1989-05-13 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Puffball | 1999-03-30 |
+----------+------------+
```

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
+--------+
| owner  |
+--------+
| Harold |
| Gwen   |
```

```
| Harold |
| Benny  |
| Diane  |
| Gwen   |
| Gwen   |
| Benny  |
| Diane  |
+--------+
```

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```
mysql> SELECT DISTINCT owner FROM pet;
+--------+
| owner  |
+--------+
| Benny  |
| Diane  |
| Gwen   |
| Harold |
+--------+
```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
    -> WHERE species = 'dog' OR species = 'cat';
+--------+---------+------------+
| name   | species | birth      |
+--------+---------+------------+
| Fluffy | cat     | 1993-02-04 |
| Claws  | cat     | 1994-03-17 |
| Buffy  | dog     | 1989-05-13 |
| Fang   | dog     | 1990-08-27 |
| Bowser | dog     | 1989-08-31 |
+--------+---------+------------+
```

3.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
+----------+------------+
| name     | birth      |
+----------+------------+
| Buffy    | 1989-05-13 |
| Bowser   | 1989-08-31 |
| Fang     | 1990-08-27 |
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Slim     | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy   | 1998-09-11 |
| Puffball | 1999-03-30 |
+----------+------------+
```

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` [859] like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+----------+------------+
| name     | birth      |
+----------+------------+
| Puffball | 1999-03-30 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Claws    | 1994-03-17 |
| Fluffy   | 1993-02-04 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Buffy    | 1989-05-13 |
+----------+------------+
```

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
    -> ORDER BY species, birth DESC;
+----------+---------+------------+
| name     | species | birth      |
+----------+---------+------------+
| Chirpy   | bird    | 1998-09-11 |
| Whistler | bird    | 1997-12-09 |
| Claws    | cat     | 1994-03-17 |
| Fluffy   | cat     | 1993-02-04 |
| Fang     | dog     | 1990-08-27 |
| Bowser   | dog     | 1989-08-31 |
| Buffy    | dog     | 1989-05-13 |
| Puffball | hamster | 1999-03-30 |
| Slim     | snake   | 1996-04-29 |
+----------+---------+------------+
```

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

3.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, compute the difference in the year part of the current date and the birth date, then subtract one if the current date occurs earlier in the calendar year than the birth date. The following query shows, for each pet, the birth date, the current date, and the age in years.

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
```

```
    -> FROM pet;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
+----------+------------+------------+------+
```

Here, `YEAR()` [844] pulls out the year part of a date and `RIGHT()` [800] pulls off the rightmost five characters that represent the `MM-DD` (calendar year) part of the date. The part of the expression that compares the `MM-DD` values evaluates to 1 or 0, which adjusts the year difference down a year if `CURDATE()` [828] occurs earlier in the year than `birth`. The full expression is somewhat ungainly, so an *alias* (`age`) is used to make the output column label more meaningful.

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet ORDER BY name;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
+----------+------------+------------+------+
```

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
    -> (YEAR(CURDATE())-YEAR(birth))
    -> - (RIGHT(CURDATE(),5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet ORDER BY age;
+----------+------------+------------+------+
| name     | birth      | CURDATE()  | age  |
+----------+------------+------------+------+
| Chirpy   | 1998-09-11 | 2003-08-19 |    4 |
| Puffball | 1999-03-30 | 2003-08-19 |    4 |
| Whistler | 1997-12-09 | 2003-08-19 |    5 |
| Slim     | 1996-04-29 | 2003-08-19 |    7 |
| Claws    | 1994-03-17 | 2003-08-19 |    9 |
| Fluffy   | 1993-02-04 | 2003-08-19 |   10 |
| Fang     | 1990-08-27 | 2003-08-19 |   12 |
| Bowser   | 1989-08-31 | 2003-08-19 |   13 |
| Buffy    | 1989-05-13 | 2003-08-19 |   14 |
+----------+------------+------------+------+
```

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```
mysql> SELECT name, birth, death,
    -> (YEAR(death)-YEAR(birth)) - (RIGHT(death,5)<RIGHT(birth,5))
    -> AS age
    -> FROM pet WHERE death IS NOT NULL ORDER BY age;
+--------+------------+------------+------+
| name   | birth      | death      | age  |
+--------+------------+------------+------+
| Bowser | 1989-08-31 | 1995-07-29 |    5 |
+--------+------------+------------+------+
```

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See Section 3.3.4.6, “Working with `NULL` Values”.

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()` [844], `MONTH()` [837], and `DAYOFMONTH()` [833]. `MONTH()` [837] is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)` [837]:

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
+----------+------------+--------------+
| name     | birth      | MONTH(birth) |
+----------+------------+--------------+
| Fluffy   | 1993-02-04 |            2 |
| Claws    | 1994-03-17 |            3 |
| Buffy    | 1989-05-13 |            5 |
| Fang     | 1990-08-27 |            8 |
| Bowser   | 1989-08-31 |            8 |
| Chirpy   | 1998-09-11 |            9 |
| Whistler | 1997-12-09 |           12 |
| Slim     | 1996-04-29 |            4 |
| Puffball | 1999-03-30 |            3 |
+----------+------------+--------------+
```

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is `4` and you can look for animals born in May (month `5`) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
+-------+------------+
| name  | birth      |
+-------+------------+
| Buffy | 1989-05-13 |
+-------+------------+
```

There is a small complication if the current month is December. You cannot merely add one to the month number (`12`) and look for animals born in month `13`, because there is no such month. Instead, you look for animals born in January (month `1`).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` [829] enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()` [828], then extract the month part with `MONTH()` [837], the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
```

```
    -> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add `1` to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to `0` if it is currently `12`:

```
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` [837] returns a number between `1` and `12`. And `MOD(something,12)` [821] returns a number between `0` and `11`. So the addition has to be after the `MOD()` [821], otherwise we would go from November (`11`) to January (`1`).

3.3.4.6 Working with `NULL` Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing unknown value” and it is treated somewhat differently from other values. To test for `NULL`, you cannot use the arithmetic comparison operators such as `=`, `<`, or `<>`. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+----------+-----------+----------+----------+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+----------+-----------+----------+----------+
|     NULL |      NULL |     NULL |     NULL |
+----------+-----------+----------+----------+
```

Clearly you get no meaningful results from these comparisons. Use the `IS NULL` [783] and `IS NOT NULL` [783] operators instead:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----------+---------------+
| 1 IS NULL | 1 IS NOT NULL |
+-----------+---------------+
|         0 |             1 |
+-----------+---------------+
```

In MySQL, `0` or `NULL` means false and anything else means true. The default truth value from a boolean operation is `1`.

This special treatment of `NULL` is why, in the previous section, it was necessary to determine which animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

Note that MySQL 4.0.2 to 4.0.10 incorrectly always sorts `NULL` values first regardless of the sort direction.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means “not having a value.” You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----------+---------------+------------+----------------+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----------+---------------+------------+----------------+
|         0 |             1 |          0 |              1 |
+-----------+---------------+------------+----------------+
```

```
+----------+--------------+-----------+---------------+
```

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are in fact `NOT NULL`. See Section B.5.5.3, “Problems with `NULL` Values”.

3.3.4.7 Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as `vi`, `grep`, and `sed`.

SQL pattern matching enables you to use “`_`” to match any single character and “`%`” to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. You do not use `=` or `<>` when you use SQL patterns; use the `LIKE` [804] or `NOT LIKE` [806] comparison operators instead.

To find names beginning with “`b`”:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

To find names ending with “`fy`”:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a “`w`”:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
```

To find names containing exactly five characters, use five instances of the “`_`” pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the `REGEXP` [808] and `NOT REGEXP` [808] operators (or `RLIKE` [808] and `NOT RLIKE` [808], which are synonyms).

The following list describes some characteristics of extended regular expressions:

- "`.`" matches any single character.
- A character class "`[...]`" matches any character within the brackets. For example, "`[abc]`" matches "`a`", "`b`", or "`c`". To name a range of characters, use a dash. "`[a-z]`" matches any letter, whereas "`[0-9]`" matches any digit.
- "`*`" matches zero or more instances of the thing preceding it. For example, "`x*`" matches any number of "`x`" characters, "`[0-9]*`" matches any number of digits, and "`.*`" matches any number of anything.
- A `REGEXP` [808] pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a `LIKE` [804] pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use "`^`" at the beginning or "`$`" at the end of the pattern.

To demonstrate how extended regular expressions work, the `LIKE` [804] queries shown previously are rewritten here to use `REGEXP` [808].

To find names beginning with "`b`", use "`^`" to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

Prior to MySQL 3.23.4, `REGEXP` [808] is case sensitive, and the previous query will return no rows. In this case, to match either lowercase or uppercase "`b`", use this query instead:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^[bB]';
```

From MySQL 3.23.4 on, if you really want to force a `REGEXP` [808] comparison to be case sensitive, use the `BINARY` [859] keyword to make one of the strings a binary string. This query matches only lowercase "`b`" at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with "`fy`", use "`$`" to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a "`w`", use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
```

```
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
```

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use "^" and "$" to match the beginning and end of the name, and five instances of "." in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

You could also write the previous query using the {*n*} ("repeat-*n*-times") operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
```

Section 11.5.2, "Regular Expressions", provides more information about the syntax for regular expressions.

3.3.4.8 Counting Rows

Databases are often used to answer the question, "How often does a certain type of data occur in a table?" For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as "How many rows are in the `pet` table?" because there is one record per pet. `COUNT(*)` [882] counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
+----------+
| COUNT(*) |
+----------+
|        9 |
+----------+
```

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` [882] if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
+--------+----------+
| owner  | COUNT(*) |
+--------+----------+
| Benny  |        2 |
| Diane  |        2 |
```

```
| Gwen   |        3 |
| Harold |        2 |
+--------+----------+
```

The preceding query uses `GROUP BY` to group all records for each `owner`. The use of `COUNT()` [882] in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
+---------+----------+
| species | COUNT(*) |
+---------+----------+
| bird    |        2 |
| cat     |        2 |
| dog     |        3 |
| hamster |        1 |
| snake   |        1 |
+---------+----------+
```

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
+------+----------+
| sex  | COUNT(*) |
+------+----------+
| NULL |        1 |
| f    |        4 |
| m    |        4 |
+------+----------+
```

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | NULL |        1 |
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

You need not retrieve an entire table when you use `COUNT()` [882]. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE species = 'dog' OR species = 'cat'
    -> GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| cat     | f    |        1 |
| cat     | m    |        1 |
```

```
| dog     | f    |        1 |
| dog     | m    |        2 |
+---------+------+----------+
```

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE sex IS NOT NULL
    -> GROUP BY species, sex;
+---------+------+----------+
| species | sex  | COUNT(*) |
+---------+------+----------+
| bird    | f    |        1 |
| cat     | f    |        1 |
| cat     | m    |        1 |
| dog     | f    |        1 |
| dog     | m    |        2 |
| hamster | f    |        1 |
| snake   | m    |        1 |
+---------+------+----------+
```

If you name columns to select in addition to the `COUNT()` [882] value, a `GROUP BY` clause should be present that names those same columns. Otherwise, an error occurs:

```
mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140: Mixing of GROUP columns (MIN(),MAX(),COUNT()...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

3.3.4.9 Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
    -> type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

name	date	type	remark
Fluffy	1995-05-15	litter	4 kittens, 3 female, 1 male
Buffy	1993-06-23	litter	5 puppies, 2 female, 3 male
Buffy	1994-06-19	litter	3 puppies, 3 female
Chirpy	1999-03-21	vet	needed beak straightened
Slim	1997-08-03	vet	broken rib

name	date	type	remark
Bowser	1991-10-12	kennel	
Fang	1991-10-12	kennel	
Fang	1998-08-28	birthday	Gave him a new chew toy
Claws	1998-03-17	birthday	Gave him a new flea collar
Whistler	1998-12-09	birthday	First birthday

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```
mysql> SELECT pet.name,
    -> (YEAR(date)-YEAR(birth)) - (RIGHT(date,5)<RIGHT(birth,5)) AS age,
    -> remark
    -> FROM pet INNER JOIN event
    ->   ON pet.name = event.name
    -> WHERE event.type = 'litter';
+--------+------+-----------------------------+
| name   | age  | remark                      |
+--------+------+-----------------------------+
| Fluffy |    2 | 4 kittens, 3 female, 1 male |
| Buffy  |    4 | 5 puppies, 2 female, 3 male |
| Buffy  |    5 | 3 puppies, 3 female         |
+--------+------+-----------------------------+
```

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses `ON` clause to match up records in the two tables based on the `name` values.

  The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.
- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
    -> FROM pet AS p1 INNER JOIN pet AS p2
    ->   ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
+--------+------+--------+------+---------+
| name   | sex  | name   | sex  | species |
+--------+------+--------+------+---------+
| Fluffy | f    | Claws  | m    | cat     |
| Buffy  | f    | Fang   | m    | dog     |
| Buffy  | f    | Bowser | m    | dog     |
+--------+------+--------+------+---------+
```

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

3.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` [872] function:

```
mysql> SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| menagerie  |
+------------+
```

If you have not yet selected any database, the result is `NULL` (or the empty string before MySQL 4.1.1).

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this command:

```
mysql> SHOW TABLES;
+---------------------+
| Tables_in_menagerie |
+---------------------+
| event               |
| pet                 |
+---------------------+
```

The name of the column in the output produced by this statement is always `Tables_in_`*`db_name`*, where *`db_name`* is the name of the database. See Section 12.4.5.24, “`SHOW TABLES` Syntax”, for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| Field   | Type        | Null | Key | Default | Extra |
+---------+-------------+------+-----+---------+-------+
| name    | varchar(20) | YES  |     | NULL    |       |
| owner   | varchar(20) | YES  |     | NULL    |       |
| species | varchar(20) | YES  |     | NULL    |       |
| sex     | char(1)     | YES  |     | NULL    |       |
```

```
| birth   | date        | YES  |     | NULL    |       |
| death   | date        | YES  |     | NULL    |       |
+---------+-------------+------+-----+---------+-------+
```

`Field` indicates the column name, `Type` is the data type for the column, `NULL` indicates whether the column can contain `NULL` values, `Key` indicates whether the column is indexed, and `Default` specifies the column's default value. `Extra` displays special information about columns: If a column was created with the `AUTO_INCREMENT` option, the value will be `auto_increment` rather than empty.

`DESC` is a short form of `DESCRIBE`. See Section 12.7.1, “`DESCRIBE` Syntax”, for more information.

You can obtain the `CREATE TABLE` statement necessary to create an existing table using the `SHOW CREATE TABLE` statement. See Section 12.4.5.7, “`SHOW CREATE TABLE` Syntax”.

If you have indexes on a table, `SHOW INDEX FROM tbl_name` produces information about them. See Section 12.4.5.13, “`SHOW INDEX` Syntax”, for more about this statement.

3.5 Using `mysql` in Batch Mode

In the previous sections, you used `mysql` interactively to enter queries and view the results. You can also run `mysql` in batch mode. To do this, put the commands you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: ********
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` [261] command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line commands or multiple-statement sequences of commands. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.
- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
shell> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
shell> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the commands.
- Some situations do not allow for interactive use, for example, when you run a query from a `cron` job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+---------+
| species |
+---------+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
+---------+
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the commands that are executed, use `mysql -vvv`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;
mysql> \. filename
```

See Section 4.5.1.5, “Executing SQL Statements from a Text File”, for more information.

3.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then (`article`, `dealer`) is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database named `test`).

You can create and populate the example table with these statements:

```
CREATE TABLE shop (
    article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
    dealer  CHAR(20)                 DEFAULT ''     NOT NULL,
    price   DOUBLE(16,2)             DEFAULT '0.00' NOT NULL,
    PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
    (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
    (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop;

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0001 | A      |  3.45 |
|    0001 | B      |  3.99 |
|    0002 | A      | 10.99 |
|    0003 | B      |  1.45 |
|    0003 | C      |  1.69 |
|    0003 | D      |  1.25 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

3.6.1 The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;

+---------+
| article |
+---------+
|       4 |
+---------+
```

3.6.2 The Row Holding the Maximum of a Certain Column

Task: Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM   shop
WHERE  price=(SELECT MAX(price) FROM shop);

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

Other solutions are to use a `LEFT JOIN` or to sort all rows descending by price and get only the first row using the MySQL-specific `LIMIT` clause:

```
SELECT s1.article, s1.dealer, s1.price
```

```
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;

SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

Note

If there were several most expensive articles, each with a price of 19.95, the `LIMIT` solution would show only one of them.

3.6.3 Maximum of Column per Group

Task: Find the highest price per article.

```
SELECT article, MAX(price) AS price
FROM   shop
GROUP BY article;

+---------+-------+
| article | price |
+---------+-------+
|    0001 |  3.99 |
|    0002 | 10.99 |
|    0003 |  1.69 |
|    0004 | 19.95 |
+---------+-------+
```

3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

Task: For each article, find the dealer or dealers with the most expensive price.

In standard SQL (and as of MySQL 4.1), the problem can be solved with a subquery like this:

```
SELECT article, dealer, price
FROM   shop s1
WHERE  price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article);
```

The preceding example uses a correlated subquery, which can be inefficient (see Section 12.2.8.7, “Correlated Subqueries”). Other possibilities for solving the problem are to use an uncorrelated subquery in the `FROM` clause or a `LEFT JOIN`.

Uncorrelated subquery:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (
  SELECT article, MAX(price) AS price
  FROM shop
  GROUP BY article) AS s2
  ON s1.article = s2.article AND s1.price = s2.price;

SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
```

```
WHERE s2.article IS NULL;
```

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and the `s2` rows values will be `NULL`. See Section 12.2.7.1, “`JOIN` Syntax”.

Before MySQL 4.1, subqueries are unavailable. Another approach is to solve the problem in several steps:

1. Get the list of (article,maxprice) pairs.
2. For each article, get the corresponding rows that have the stored maximum price.

This can easily be done with a temporary table and a join:

`LEFT JOIN`:

```
CREATE TEMPORARY TABLE tmp (
        article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
        price   DOUBLE(16,2)             DEFAULT '0.00' NOT NULL);

LOCK TABLES shop READ;

INSERT INTO tmp SELECT article, MAX(price) FROM shop GROUP BY article;

SELECT shop.article, dealer, shop.price FROM shop, tmp
WHERE shop.article=tmp.article AND shop.price=tmp.price;

UNLOCK TABLES;

DROP TABLE tmp;
```

If you don't use a `TEMPORARY` table, you must also lock the `tmp` table.

“Can it be done with a single query?”

Yes, but only by using a quite inefficient trick called the “MAX-CONCAT trick”:

```
SELECT article,
       SUBSTRING( MAX( CONCAT(LPAD(price,6,'0'),dealer) ), 7) AS dealer,
  0.00+LEFT(      MAX( CONCAT(LPAD(price,6,'0'),dealer) ), 6) AS price
FROM   shop
GROUP BY article;

+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0001 | B      |  3.99 |
|    0002 | A      | 10.99 |
|    0003 | C      |  1.69 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

The last example can be made a bit more efficient by doing the splitting of the concatenated column in the client.

3.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See Section 8.4, “User-Defined Variables”.)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0003 | D      |  1.25 |
|    0004 | D      | 19.95 |
+---------+--------+-------+
```

3.6.6 Using Foreign Keys

In MySQL 3.23.44 and up, `InnoDB` tables support checking of foreign key constraints. See Section 13.2, “The `InnoDB` Storage Engine”, and Section 1.9.5.6, “Foreign Keys”.

A foreign key constraint is not required merely to join two tables. For storage engines other than `InnoDB`, it is possible when defining a column to use a `REFERENCES` *`tbl_name(col_name)`* clause, which has no actual effect, and *serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table*. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of `CHECK` to make sure that *`col_name`* actually exists in *`tbl_name`* (or even that *`tbl_name`* itself exists).
- MySQL does not perform any sort of action on *`tbl_name`* such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no `ON DELETE` or `ON UPDATE` behavior whatsoever. (Although you can write an `ON DELETE` or `ON UPDATE` clause as part of the `REFERENCES` clause, it is also ignored.)
- This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    name CHAR(60) NOT NULL,
    PRIMARY KEY (id)
);

CREATE TABLE shirt (
    id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
    style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
    color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
    owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
    PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
```

```
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+----+--------------------+
| id | name               |
+----+--------------------+
|  1 | Antonio Paz        |
|  2 | Lilliana Angelovska |
+----+--------------------+

SELECT * FROM shirt;
+----+---------+--------+-------+
| id | style   | color  | owner |
+----+---------+--------+-------+
|  1 | polo    | blue   |     1 |
|  2 | dress   | white  |     1 |
|  3 | t-shirt | blue   |     1 |
|  4 | dress   | orange |     2 |
|  5 | polo    | red    |     2 |
|  6 | dress   | blue   |     2 |
|  7 | t-shirt | white  |     2 |
+----+---------+--------+-------+

SELECT s.* FROM person p INNER JOIN shirt s
   ON s.owner = p.id
 WHERE p.name LIKE 'Lilliana%'
   AND s.color <> 'white';

+----+-------+--------+-------+
| id | style | color  | owner |
+----+-------+--------+-------+
|  4 | dress | orange |     2 |
|  5 | polo  | red    |     2 |
|  6 | dress | blue   |     2 |
+----+-------+--------+-------+
```

When used in this fashion, the `REFERENCES` clause is not displayed in the output of `SHOW CREATE TABLE` or `DESCRIBE`:

```
SHOW CREATE TABLE shirt\G
*************************** 1. row ***************************
Table: shirt
Create Table: CREATE TABLE `shirt` (
`id` smallint(5) unsigned NOT NULL auto_increment,
`style` enum('t-shirt','polo','dress') NOT NULL,
`color` enum('red','blue','orange','white','black') NOT NULL,
`owner` smallint(5) unsigned NOT NULL,
PRIMARY KEY  (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

The use of `REFERENCES` in this way as a comment or “reminder” in a column definition works with both `MyISAM` and `BerkeleyDB` tables.

3.6.7 Searching on Two Keys

An `OR` [787] using a single key is well optimized, as is the handling of `AND` [787].

The one tricky case is that of searching on two different keys combined with `OR` [787]:

```
SELECT field1_index, field2_index FROM test_table
```

```
WHERE field1_index = '1' OR  field2_index = '1'
```

In MySQL 4.0 and up, you can solve the problem efficiently by using a `UNION` that combines the output of two separate `SELECT` statements. See Section 12.2.7.3, “`UNION` Syntax”.

Each `SELECT` searches only one key and can be optimized:

```
SELECT field1_index, field2_index
    FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
    FROM test_table WHERE field2_index = '1';
```

Prior to MySQL 4.0, you can achieve the same effect by using a `TEMPORARY` table and separate `SELECT` statements. This type of optimization is also very good if you are using very complicated queries where the SQL server does the optimizations in the wrong order.

```
CREATE TEMPORARY TABLE tmp
SELECT field1_index, field2_index
    FROM test_table WHERE field1_index = '1';
INSERT INTO tmp
SELECT field1_index, field2_index
    FROM test_table WHERE field2_index = '1';
SELECT * from tmp;
DROP TABLE tmp;
```

This method of solving the problem is in effect a `UNION` of two queries.

3.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
             day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
            (2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
       GROUP BY year,month;
```

Which returns:

```
+------+-------+------+
| year | month | days |
+------+-------+------+
| 2000 |    01 |    3 |
| 2000 |    02 |    2 |
+------+-------+------+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

3.6.9 Using `AUTO_INCREMENT`

The AUTO_INCREMENT attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
     id MEDIUMINT NOT NULL AUTO_INCREMENT,
     name CHAR(30) NOT NULL,
     PRIMARY KEY (id)
) ENGINE=MyISAM;

INSERT INTO animals (name) VALUES
    ('dog'),('cat'),('penguin'),
    ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```
+----+---------+
| id | name    |
+----+---------+
|  1 | dog     |
|  2 | cat     |
|  3 | penguin |
|  4 | lax     |
|  5 | whale   |
|  6 | ostrich |
+----+---------+
```

No value was specified for the AUTO_INCREMENT column, so MySQL assigned sequence numbers automatically. You can also explicitly assign NULL or 0 to the column to generate sequence numbers.

You can retrieve the most recent AUTO_INCREMENT value with the LAST_INSERT_ID() [874] SQL function or the mysql_insert_id() C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use a large enough integer data type for the AUTO_INCREMENT column to hold the maximum sequence value you will need. When the column reaches the upper limit of the data type, the next attempt to generate a sequence number fails. For example, if you use TINYINT, the maximum permissible sequence number is 127. For TINYINT UNSIGNED, the maximum is 255.

Note

For a multiple-row insert, LAST_INSERT_ID() [874] and mysql_insert_id() actually return the AUTO_INCREMENT key from the *first* of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

For MyISAM and BDB tables you can specify AUTO_INCREMENT on a secondary column in a multiple-column index. In this case, the generated value for the AUTO_INCREMENT column is calculated as MAX(*auto_increment_column*) + 1 WHERE prefix=*given-prefix* [884]. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
    grp ENUM('fish','mammal','bird') NOT NULL,
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
    name CHAR(30) NOT NULL,
    PRIMARY KEY (grp,id)
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
```

```
    ('mammal','dog'),('mammal','cat'),
    ('bird','penguin'),('fish','lax'),('mammal','whale'),
    ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

```
+--------+----+---------+
| grp    | id | name    |
+--------+----+---------+
| fish   |  1 | lax     |
| mammal |  1 | dog     |
| mammal |  2 | cat     |
| mammal |  3 | whale   |
| bird   |  1 | penguin |
| bird   |  2 | ostrich |
+--------+----+---------+
```

In this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL will generate sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

To start with an `AUTO_INCREMENT` value other than 1, you can set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

Note that this feature is available for `InnoDB` tables only as of MySQL 4.1.12.

More information about `AUTO_INCREMENT` is available here:

- How to assign the `AUTO_INCREMENT` attribute to a column: Section 12.1.5, “`CREATE TABLE` Syntax”, and Section 12.1.2, “`ALTER TABLE` Syntax”.
- How `AUTO_INCREMENT` behaves depending on the `NO_AUTO_VALUE_ON_ZERO` [458] SQL mode: Section 5.1.6, “Server SQL Modes”.
- How to use the `LAST_INSERT_ID()` [874] function to find the row that contains the most recent `AUTO_INCREMENT` value: Section 11.13, “Information Functions”.
- Setting the `AUTO_INCREMENT` value to be used: Section 5.1.3, “Server System Variables”.
- `AUTO_INCREMENT` and replication: Chapter 14, *Replication*.

3.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
        "\"%h\",%{%Y%m%d%H%M%S}t,%>s,\"%b\",\"%{Content-Type}o\",  \
        \"%U\",\"%{Referer}i\",\"%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

Chapter 4 MySQL Programs

Table of Contents

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

4.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of MySQL Cluster programs. Each program's description indicates its invocation syntax and the options that it supports. Chapter 15, *MySQL Cluster*, describes programs specific to MySQL Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see Chapter 2, *Installing and Upgrading MySQL*, for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See Section 4.2, “Using MySQL Programs”, for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

  The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See Section 4.3.1, “`mysqld` — The MySQL Server”.

- `mysqld-max`

  A version of the server that includes additional features. See Section 5.2, “The `mysqld-max` Extended MySQL Server”.

- `mysqld_safe`

  A server startup script. `mysqld_safe` attempts to start `mysqld-max` if it exists, and `mysqld` otherwise. See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”.

- `mysql.server`

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See Section 4.3.3, “`mysql.server` — MySQL Server Startup Script”.

- `mysqld_multi`

  A server startup script that can start or stop multiple servers installed on the system. See Section 4.3.4, “`mysqld_multi` — Manage Multiple MySQL Servers”.

There are several programs that perform setup operations during MySQL installation or upgrading:

- `comp_err`

  This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See Section 4.4.1, “`comp_err` — Compile MySQL Error Message File”.

- `make_binary_distribution`

  This program makes a binary release of a compiled MySQL. This could be sent by FTP to `/pub/mysql/upload/` on `ftp.mysql.com` for the convenience of other MySQL users.

- `mysql_create_system_tables`

  This script is invoked by `mysql_install_db` to generate the SQL statements required to initialize the grant tables with default privileges. See Section 4.4.3, “`mysql_create_system_tables` — Generate Statements to Initialize MySQL System Tables”.

- `mysql_fix_privilege_tables`

  This program is used after a MySQL upgrade operation. It updates the grant tables with any changes that have been made in newer versions of MySQL. See Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

- `mysql_install_db`

  This script creates the MySQL database and initializes the grant tables with default privileges. It is usually executed only once, when first installing MySQL on a system. See Section 4.4.6, “`mysql_install_db` — Initialize MySQL Data Directory”, Section 2.10.2, “Unix Postinstallation Procedures”, and Section 4.4.6, “`mysql_install_db` — Initialize MySQL Data Directory”.

- `mysql_secure_installation`

  This program enables you to improve the security of your MySQL installation. SQL. See Section 4.4.7, “`mysql_secure_installation` — Improve MySQL Installation Security”.

- `mysql_tzinfo_to_sql`

  This program loads the time zone tables in the `mysql` database using the contents of the host system *zoneinfo* database (the set of files describing time zones). SQL. See Section 4.4.8, “`mysql_tzinfo_to_sql` — Load the Time Zone Tables”.

- `make_win_src_distribution`

  This program is used on Unix or Unix-like systems to create a MySQL source distribution that can be compiled on Windows. See Section 2.9.7.2, “Creating a Windows Source Package from the Latest Development Source”, and Section 4.4.2, “`make_win_src_distribution` — Create Source Distribution for Windows”.

MySQL client programs:

- `mysql`

  The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See Section 4.5.1, “`mysql` — The MySQL Command-Line Tool”.

- `mysqladmin`

  A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See Section 4.5.2, “`mysqladmin` — Client for Administering a MySQL Server”.

- `mysqlcheck`

  A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See Section 4.5.3, “`mysqlcheck` — A Table Maintenance Program”.

- `mysqldump`

  A client that dumps a MySQL database into a file as SQL, text, or XML. See Section 4.5.4, “`mysqldump` — A Database Backup Program”.

- `mysqlimport`

  A client that imports text files into their respective tables using `LOAD DATA INFILE`. See Section 4.5.5, “`mysqlimport` — A Data Import Program”.

- `mysqlshow`

  A client that displays information about databases, tables, columns, and indexes. See Section 4.5.6, “`mysqlshow` — Display Database, Table, and Column Information”.

MySQL administrative and utility programs:

- `myisam_ftdump`

  A utility that displays information about full-text indexes in `MyISAM` tables. See Section 4.6.1, “`myisam_ftdump` — Display Full-Text Index information”.

- `myisamchk`, `isamchk`

  A utility to describe, check, optimize, and repair `MyISAM` tables. `isamchk` is a similar program for `ISAM` tables. See Section 4.6.2, “`myisamchk` — MyISAM Table-Maintenance Utility”.

- `myisamlog`, `isamlog`

  Utilities that process the contents of a `MyISAM` or `ISAM` log file. See Section 4.6.3, “`myisamlog` — Display MyISAM Log File Contents”.

- `myisampack`, `pack_isam`

  Utilities that compress `MyISAM` or `ISAM` tables to produce smaller read-only tables. See Section 4.6.4, “`myisampack` — Generate Compressed, Read-Only MyISAM Tables”.

- `mysqlaccess`

A script that checks the access privileges for a host name, user name, and database combination. See Section 4.6.5, “`mysqlaccess` — Client for Checking Access Privileges”.

- `mysqlbinlog`

  A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See Section 4.6.6, “`mysqlbinlog` — Utility for Processing Binary Log Files”.

- `mysqldumpslow`

  A utility to read and summarize the contents of a slow query log. See Section 4.6.7, “`mysqldumpslow` — Summarize Slow Query Log Files”.

- `mysqlhotcopy`

  A utility that quickly makes backups of `MyISAM` or `ISAM` tables while the server is running. See Section 4.6.8, “`mysqlhotcopy` — A Database Backup Program”.

- `mysql_convert_table_format`

  A utility that converts tables in a database to use a given storage engine. See Section 4.6.11, “`mysql_convert_table_format` — Convert Tables to Use a Given Storage Engine”.

- `mysql_explain_log`

  A utility that analyzes queries in the MySQL query log using `EXPLAIN` See Section 4.6.12, “`mysql_explain_log` — Use EXPLAIN on Statements in Query Log”.

- `mysql_find_rows`

  A utility that reads files containing SQL statements (such as update logs) and extracts statements that match a given regular expression. See Section 4.6.13, “`mysql_find_rows` — Extract SQL Statements from Files”.

- `mysql_fix_extensions`

  A utility that converts the extensions for `MyISAM` (or `ISAM`) table files to lowercase. This can be useful after transferring the files from a system with case-insensitive file names to a system with case-sensitive file names. See Section 4.6.14, “`mysql_fix_extensions` — Normalize Table File Name Extensions”.

- `mysql_setpermission`

  A utility for interactively setting permissions in the MySQL grant tables. See Section 4.6.15, “`mysql_setpermission` — Interactively Set Permissions in Grant Tables”.

- `mysql_tableinfo`

  A utility that generates database metadata. Section 4.6.16, “`mysql_tableinfo` — Generate Database Metadata”.

- `mysql_waitpid`

  A utility that kills the process with a given process ID. See Section 4.6.17, “`mysql_waitpid` — Kill Process and Wait for Its Termination”.

- `mysql_zap`

A utility that kills processes that match a pattern. See Section 4.6.18, “`mysql_zap` — Kill Processes That Match a Pattern”.

MySQL program-development utilities:

- `msql2mysql`

  A shell script that converts `mSQL` programs to MySQL. It doesn't handle every case, but it gives a good start when converting. See Section 4.7.1, “`msql2mysql` — Convert mSQL Programs for Use with MySQL”.

- `mysql_config`

  A shell script that produces the option values needed when compiling MySQL programs. See Section 4.7.2, “`mysql_config` — Display Options for Compiling Clients”.

- `my_print_defaults`

  A utility that shows which options are present in option groups of option files. See Section 4.7.3, “`my_print_defaults` — Display Options from Option Files”.

- `resolve_stack_dump`

  A utility program that resolves a numeric stack trace dump to symbols. See Section 4.7.4, “`resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols”.

Miscellaneous utilities:

- `perror`

  A utility that displays the meaning of system or MySQL error codes. See Section 4.8.1, “`perror` — Explain Error Codes”.

- `replace`

  A utility program that performs string replacement in the input text. See Section 4.8.2, “`replace` — A String-Replacement Utility”.

- `resolveip`

  A utility program that resolves a host name to an IP address or vice versa. See Section 4.8.3, “`resolveip` — Resolve Host name to IP Address or Vice Versa”.

Oracle Corporation also provides several GUI tools for administering and otherwise working with MySQL Server:

- MySQL Workbench: This is the latest graphical tool for working with MySQL databases.
- MySQL Administrator: This tool is used for administering MySQL servers, databases, tables, and user accounts.
- MySQL Query Browser: This graphical tool is used for creating, executing, and optimizing queries on MySQL databases.
- MySQL Migration Toolkit: This tool helps you migrate schemas and data from other relational database management systems for use with MySQL.

These GUI programs are available at http://dev.mysql.com/downloads/. Each has its own manual that you can access at http://dev.mysql.com/doc/.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

Environment Variable	Meaning
`MYSQL_UNIX_PORT`	The default Unix socket file; used for connections to `localhost`
`MYSQL_TCP_PORT`	The default port number; used for TCP/IP connections
`MYSQL_PWD`	The default password
`MYSQL_DEBUG`	Debug trace options when debugging
`TMPDIR`	The directory where temporary tables and files are created

For a full list of environment variables used by MySQL programs, see Section 2.13, “Environment Variables”.

Use of `MYSQL_PWD` is insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”.

4.2 Using MySQL Programs

4.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. “`shell>`” represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh` or `bash`, `%` for `csh` or `tcsh`, and `C:\>` for the Windows `command.com` or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (“`-`”, “`--`”) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in Section 4.2.3, “Specifying Program Options”.

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nonoption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` [226] (or `-h`), `--user` [227] (or `-u`), and `--password` [226] (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port` [226] (or `-P`) to specify a TCP/IP port number and `--socket` [227] (or `-S`) to specify a Unix socket file on Unix (or named pipe name on Windows). For more information on options that specify connection options, see Section 4.2.2, “Connecting to the MySQL Server”.

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in Section 4.2.4, “Setting Environment Variables”.) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.2.2 Connecting to the MySQL Server

For a client program to be able to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override them as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any connection parameters explicitly:

```
shell> mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.
- No password is sent if neither `-p` nor `--password` [226] is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. If there is no such option, `mysql` does not select a default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line:

```
shell> mysql --host=localhost --user=myname --password=mypass mydb
shell> mysql -h localhost -u myname -pmypass mydb
```

For password options, the password value is optional:

- If you use a `-p` or `--password` [226] option and specify the password value, there must be *no space* between `-p` or `--password=` [226] and the password following it.
- If you use a `-p` or `--password` [226] option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Other users on your system may be able to see a password specified on the command line by executing a command such as `ps auxw`. See Section 5.4.2.2, “End-User Guidelines for Password Security”.

As just mentioned, including the password value on the command line can be a security risk. To avoid this problem, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --host=localhost --user=myname --password mydb
shell> mysql -h localhost -u myname -p mydb
```

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file. This occurs even if a `--port` [226] or `-P` option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use `--host` [226] or `-h` to specify a host name value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=TCP` [226] option. For example:

```
shell> mysql --host=127.0.0.1
shell> mysql --protocol=TCP
```

The `--protocol` [226] option enables you to establish a particular type of connection even when the other options would normally default to some other protocol.

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the `--pipe` [226] or `--protocol=PIPE` [226] option, or by specifying `.` (period) as the host name. If named-pipe connections are not enabled, an error occurs. Use the `--socket` [227] option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers always use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
shell> mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` [226] or `-P` option:

```
shell> mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix will use a socket file by default. You will need to force a TCP/IP connection as already described or any option that specifies a port number will be ignored.

For this command, the program uses a socket file on Unix and the `--port` [226] option is ignored:

```
shell> mysql --port=13306 --host=localhost
```

To cause the port number to be used, invoke the program in either of these ways:

```
```

```
shell> mysql --port=13306 --host=127.0.0.1
shell> mysql --port=13306 --protocol=TCP
```

The following list summarizes the options that can be used to control how client programs connect to the server:

- `--host=host_name` [226], `-h host_name`

  The host where the server is running. The default value is `localhost`.

- `--password[=pass_val]` [226], `-p[pass_val]`

  The password of the MySQL account. As described earlier, the password value is optional, but if given, there must be *no space* between `-p` or `--password=` [226] and the password following it. The default is to send no password.

- `--pipe` [226], `-W`

  On Windows, connect to the server using a named pipe. The server must be started with the `--enable-named-pipe` [386] option to enable named-pipe connections.

- `--port=port_num` [226], `-P port_num`

  The port number to use for the connection, for connections made using TCP/IP. The default port number is 3306.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [226]

  This option explicitly specifies a protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

  ```
  shell> mysql --host=localhost
  ```

  To force a TCP/IP connection to be used instead, specify a `--protocol` [226] option:

  ```
  shell> mysql --host=localhost --protocol=TCP
  ```

  The following table shows the permissible `--protocol` [226] option values and indicates the platforms on which each value may be used. The values are not case sensitive.

`--protocol` [226] Value	Connection Protocol	Permissible Operating Systems
`TCP`	TCP/IP connection to local or remote server	All
`SOCKET`	Unix socket file connection to local server	Unix only
`PIPE`	Named-pipe connection to local or remote server	Windows only
`MEMORY`	Shared-memory connection to local server	Windows only

  The `--protocol` [226] option was added in MySQL 4.1.

- `--shared-memory-base-name=name` [226]

  On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` [392] option to enable shared-memory connections.

- `--socket=file_name` [227], `-S file_name`

  On Unix, the name of the Unix socket file to use, for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

  On Windows, the name of the named pipe to use, for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case sensitive.

  The server must be started with the `--enable-named-pipe` [386] option to enable named-pipe connections.

- `--ssl*`

  Options that begin with `--ssl` [521] are used for establishing a secure connection to the server using SSL, if the server is configured with SSL support. For details, see Section 5.6.6.3, "SSL Command Options".

- `--user=user_name` [227], `-u user_name`

  The user name of the MySQL account you want to use. The default user name is `ODBC` on Windows or your Unix login name on Unix.

It is possible to specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=your_pass
```

  Section 4.2.3.3, "Using Option Files", discusses option files further.

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL user name can be specified using `USER` (this is for Windows and NetWare only). The password can be specified using `MYSQL_PWD`, although this is insecure; see Section 5.4.2.2, "End-User Guidelines for Password Security". For a list of variables, see Section 2.13, "Environment Variables".

4.2.3 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables (see Section 4.2.4, "Setting Environment Variables"). This method is useful for options that you want to apply each time the program runs. In practice, option

files are used more commonly for this purpose, but Section 5.7.2, “Running Multiple Servers on Unix”, discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
shell> mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
shell> mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by reading option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

An option can be specified by writing it in full or as any unambiguous prefix. For example, the `--compress` [293] option can be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous:

```
shell> mysqldump --comp
mysqldump: ambiguous option '--comp' (compatible, compress)
```

Be aware that the use of option prefixes can cause problems in the event that new options are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

4.2.3.1 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` [226] indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an “`=`” sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=`*`pass_val`* [226] or as `--password` [226]. In the latter case (with no password value

given), the program prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
shell> mysql -ptest
shell> mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash ("`-`") and underscore ("`_`") may be used interchangeably. For example, `--skip-grant-tables` [392] and `--skip_grant_tables` [392] are equivalent. (However, the leading dashes cannot be given as underscores.)

- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024^2 or 1024^3. For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
mysql> mysqladmin --count=1K --sleep=10 ping
```

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` [261] (or `-e`) option can be used with `mysql` to pass SQL statements to the server. When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

```
mysql> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
Enter password: ******
+------+-----------+
| User | Host      |
+------+-----------+
|      | gigan     |
| root | gigan     |
|      | localhost |
| jon  | localhost |
| root | localhost |
+------+-----------+
shell>
```

Note that the long form (`--execute` [261]) is followed by an equal sign (`=`).

If you wish to use quoted values within a statement, you will either need to escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

Multiple SQL statements may be passed in the option value on the command line, separated by semicolons:

```
shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
Enter password: ******
```

```
+------------+
| VERSION()  |
+------------+
| 4.1.17-log |
+------------+
+---------------------+
| NOW()               |
+---------------------+
| 2006-01-05 21:19:04 |
+---------------------+
```

The `--execute` or `-e` option may also be used to pass commands in an analogous fashion to the `ndb_mgm` management client for MySQL Cluster. See Section 15.2.5, “Safe Shutdown and Restart of MySQL Cluster”, for an example.

4.2.3.2 Program Option Modifiers

MySQL 4.0.2 introduced some additional flexibility in the way you specify options. SQL 4.0.2. Some of these changes relate to the way you specify options that have “enabled” and “disabled” states, and to the use of options that might be present in one version of MySQL but not another. Those capabilities are discussed in this section.

Some options are “boolean” and control behavior that can be turned on or off. Some options control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` [260] option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
--column-names=1
```

Another change to option processing introduced in MySQL 4.0.2 is that you can use the `--loose` prefix for command-line options. If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file, An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it. This strategy requires that all versions involved be 4.0.2 or later, because earlier versions know nothing of the `--loose` convention.

As of MySQL 4.0.2, `mysqld` enables a limit to be placed on how large client programs can set dynamic system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-query_cache_size=4M` prevents any client from making the query cache size larger than 4MB.

4.2.3.3 Using Option Files

Most MySQL programs can read startup options from option files (also sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program. Option file capability is available from MySQL 3.22 on. For the MySQL server, MySQL provides a number of preconfigured option files.

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` [395] and `--help` [384] as of MySQL 4.1.1.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

Note

Option files used with MySQL Cluster programs are covered in Section 15.3, "MySQL Cluster Configuration".

On Windows, MySQL programs read startup options from the following files.

File Name	Purpose
`%WINDIR%\my.ini`, `%WINDIR%\my.cnf`	Global options
`C:\my.ini`, `C:\my.cnf`	Global options
`INSTALLDIR``\my.ini`, *`INSTALLDIR`*`\my.cnf`	Global options
`defaults-extra-file`	The file specified with `--defaults-extra-file=`*`path`* [235], if any

Note

Programs look for option files using both extensions (`.ini`, `.cnf`) in all locations only as of MySQL 4.0.23 and 4.1.8. Before MySQL 4.0.23 and 4.1.8, programs look in *`WINDIR`* and *`INSTALLDIR`* only for `my.ini`, and in `C:\` only for `my.cnf`.

`%WINDIR%` represents the location of your Windows directory. This is commonly `C:\WINDOWS` or `C:\WINNT`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

`INSTALLDIR` represents the MySQL installation directory. With MySQL 4.1.5 and up, this is typically `C:\`*`PROGRAMDIR`*`\MySQL\MySQL 4.1 Server` where *`PROGRAMDIR`* represents the programs directory (usually `Program Files` on English-language versions of Windows), when MySQL 4.1 has been installed using the installation and configuration wizards. See Section 2.3.4.14, "The Location of the my.ini File".

On Unix, MySQL programs read startup options from the following files.

File Name	Purpose
`/etc/my.cnf`	Global options
`DATADIR/my.cnf`	Server-specific options
`defaults-extra-file`	The file specified with `--defaults-extra-file=`*`path`* [235], if any

File Name	Purpose
`~/.my.cnf`	User-specific options

`~` represents the current user's home directory (the value of `$HOME`).

`DATADIR` represents the path to the directory in which the server-specific `my.cnf` file resides.

Typically, *`DATADIR`* is `/usr/local/mysql/data` for a binary installation or `/usr/local/var` for a source installation. Note that this is the data directory location that was specified at configuration time, not the one specified with the `--datadir` [385] option when `mysqld` starts. Use of `--datadir` [385] at runtime has no effect on where the server looks for option files, because it looks for them before processing any options.

MySQL looks for option files in the order just described and reads any that exist. If an option file that you want to use does not exist, create it with a plain text editor.

If multiple instances of a given option are found, the last instance takes precedence. There is one exception: For `mysqld`, the *first* instance of the `--user` [395] option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

Note

On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option.

The syntax for specifying options in an option file is similar to command-line syntax (see Section 4.2.3.1, “Using Options on the Command Line”). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-`*`opt_name`* in an option file, write it as `loose-`*`opt_name`*.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- *`#comment`*, *`;comment`*

  Comment lines start with “`#`” or “`;`”. As of MySQL 4.0.14, a “`#`” comment can start in the middle of a line as well.

- `[`*`group`*`]`

  `group` is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given.

- *`opt_name`*

  This is equivalent to `--`*`opt_name`* on the command line.

- *`opt_name=value`*

  This is equivalent to `--`*`opt_name=value`* on the command line. In an option file, you can have spaces around the “`=`” character, something that is not true on the command line. As of MySQL 4.0.16, you can

optionally enclose the value within double quotation marks or single quotation marks. This is useful if the value contains a "#" comment character.

- `set-variable = var_name=value`

  Set the program variable *var_name* to the given value. This is equivalent to `--set-variable=var_name=value` on the command line. Spaces are permitted around the first "=" character but not around the second. This syntax is deprecated as of MySQL 4.0. See Section 4.2.3.4, "Using Options to Set Program Variables", for more information on setting program variables.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences "\b", "\t", "\n", "\r", "\\", and "\s" in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. The escaping rules in option files are:

- If a backslash is followed by a valid escape sequence character, the sequence is converted to the character represented by the sequence. For example, "\s" is converted to a space.
- If a backslash is not followed by a valid escape sequence character, it remains unchanged. For example, "\S" is retained as is.

The preceding rules mean that a literal backslash can be given as "\\", or as "\" if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if "*x*" is not a value escape sequence character, "*x*" becomes "*x*" rather than "*x*". See Section 8.1.1, "String Literals".

The escaping rules for option file values are especially pertinent for Windows path names, which use "\" as a path name separator. A separator in a Windows path name must be written as "\\" if it is followed by an escape sequence character. It can be written as "\\" or "\" if it is not. Alternatively, "/" may be used in Windows path names and will be treated as "\". Suppose that you want to specify a base directory of `C:\Program Files\MySQL\MySQL Server 4.1` in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 4.1"
basedir="C:\\Program Files\\MySQL\\MySQL Server 4.1"
basedir="C:/Program Files/MySQL/MySQL Server 4.1"
basedir=C:\\Program\sFiles\\MySQL\\MySQL\sServer\s4.1
```

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs (but *not* by `mysqld`). This enables you to specify options that apply to all clients. For example, `[client]` is the perfect group to use to specify the password that you use to connect to the server. (But make sure that the option file is readable and writable only by yourself, so that other people cannot find out your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock
```

```
[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

The preceding option file uses *`var_name=value`* syntax for the lines that set the `key_buffer_size` [415] and `max_allowed_packet` [418] variables. Prior to MySQL 4.0.2, you must use `set-variable` syntax instead (described earlier in this section).

Here is a typical user option file:

```
[client]
# The following password will be sent to all standard MySQL clients
password="my_password"

[mysql]
no-auto-rehash
set-variable = connect_timeout=2

[mysqlhotcopy]
interactive-timeout
```

This option file uses `set-variable` syntax to set the `connect_timeout` [409] variable. For MySQL 4.0.2 and up, you can also set the variable using just `connect_timeout = 2` [409].

As of MySQL 4.0.14, if you want to create option groups that should be read only by `mysqld` servers from a specific MySQL release series only, you can do this by using groups with names of `[mysqld-4.0]`, `[mysqld-4.1]`, and so forth. The following group indicates that the `--new` option should be used only by MySQL servers with 4.0.x version numbers:

```
[mysqld-4.0]
new
```

Beginning with MySQL 4.1.11, it is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

There is no guarantee about the order in which the option files in the directory will be read.

Note

Currently, any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqldamin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. They affect option-file handling, so they must be given on the command line and not in an option file. To work properly, each of these options must immediately follow the command name, with these exceptions:

- `--print-defaults` [235] may be used immediately after `--defaults-file` [235] or `--defaults-extra-file` [235].
- On Windows, if the `--defaults-file` [235] and `--install` options are given, `--install` option must be first. See Section 2.3.11, “Starting MySQL as a Windows Service”.

When specifying file names, you should avoid the use of the “~” shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=`*`file_name`* [235]

  Read this option file after the global option file but (on Unix) before the user option file. *`file_name`* is the full path name to the file.

- `--defaults-file=`*`file_name`* [235]

  Use only the given option file. *`file_name`* is the full path name to the file. If the file does not exist, the program exits with an error.

- `--no-defaults` [235]

  Do not read any option files. If a program does not start because it is reading unknown options from an option file, `--no-defaults` [235] can be used to prevent the program from reading them.

- `--print-defaults` [235]

  Print the program name and all options that it gets from option files.

Preconfigured Option Files

MySQL provides a number of preconfigured option files that can be used as a basis for tuning the MySQL server. Look for files such as `my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`,

which are sample option files for small, medium, large, and very large systems. On Windows, the extension is `.ini` rather than `.cnf`.

Note

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

For a binary distribution, look for the files in or under your installation directory. If you have a source distribution, look in the `support-files` directory. You can rename a copy of a sample file and place it in the appropriate location for use as a base configuration file. Regarding names and appropriate location, see the general information provided in Section 4.2.3.3, “Using Option Files”.

4.2.3.4 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See Section 12.4.4, “`SET` Syntax”, and Section 5.1.4, “Using System Variables”.

As of MySQL 4.0.2, most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024^2 or 1024^3. (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M

[mysqld]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
```

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

Prior to MySQL 4.0.2, program variable names are not recognized as option names. Instead, use the `--set-variable` option to assign a value to a variable:

```
shell> mysql --set-variable=max_allowed_packet=16777216
shell> mysql --set-variable=max_allowed_packet=16M
```

In an option file, omit the leading dashes:

```
[mysql]
set-variable = max_allowed_packet=16777216
```

Or:

```
[mysql]
set-variable = max_allowed_packet=16M
```

With `--set-variable`, underscores in variable names cannot be given as dashes for versions of MySQL older than 4.0.2, and the variable name must be specified in full.

The `--set-variable` option is still recognized in MySQL 4.0.2 and up, but is deprecated.

4.2.3.5 Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (`=`) sign, like this:

```
shell> mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equal sign is not required, and so the following is also valid:

```
shell> mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named “tonfisk” using an account with the user name “jon”.

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```
shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 4.1.25 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| jon@%          |
+----------------+
1 row in set (0.00 sec)
```

Omitting the required value for one of these option yields an error, such as the one shown here:

```
shell> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument
```

In this case, `mysql` was unable to find a value following the `--user` [227] option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```
shell> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

Because `mysql` assumes that any string following `--host` [226] on the command line is a host name, `--host` [226] `--user` [227] is interpreted as `--host=--user` [226], and the client attempts to connect to a MySQL server running on a host named “--user”.

Options having default values always require an equal sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` [388] option has the default value *`host_name`*`.err`, where *`host_name`* is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “tonfisk”, and consider the following invocation of `mysqld_safe`:

```
shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

After shutting down the server, restart it as follows:

```
shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>
```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the

background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```
shell> mysqld_safe --log-error my-errors &
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended

[1]+  Done                    ./mysqld_safe --log-error my-errors
```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
shell> tail /usr/local/mysql/var/tonfisk.err
080111 22:53:32  InnoDB: Started; log sequence number 0 46409
/usr/local/mysql/libexec/mysqld: Too many arguments (first extra is 'my-errors').
Use --verbose --help to get a list of available options
080111 22:53:32 [ERROR] Aborting

080111 22:53:32  InnoDB: Starting shutdown...
080111 22:53:34  InnoDB: Shutdown completed; log sequence number 0 46409
080111 22:53:34 [Note] /usr/local/mysql/libexec/mysqld: Shutdown complete

080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```

Because the `--log-error` option supplies a default value, you must use an equal sign to assign a different value to it, as shown here:

```
shell> mysqld_safe --log-error=my-errors &
[1] 31437
shell> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var

shell>
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]

host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host` [261] `--user` [265] or `--host=--user` [261], with the result shown here:

```
shell> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equal sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]
```

```
user jon
```

Trying to start `mysql` in this case causes a different error:

```
shell> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equal sign:

```
[mysql]

user=jon
```

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 4.1.25 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equal sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 4.1.25 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@tonfisk   |
+---------------+
1 row in set (0.00 sec)
```

4.2.4 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. Section 2.13, “Environment Variables”, lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows or NetWare, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.3 MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

4.3.1 `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The mysqld program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

For versions older than MySQL 4.1.1, leave out the --verbose [395] option.

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see Section 5.1, “The MySQL Server”. For information about installing MySQL and setting up the initial configuration, see Chapter 2, *Installing and Upgrading MySQL*.

4.3.2 mysqld_safe — MySQL Server Startup Script

mysqld_safe is the recommended way to start a mysqld server on Unix and NetWare. mysqld_safe adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. NetWare-specific behaviors are listed later in this section.

Note

Before MySQL 4.0, mysqld_safe is named safe_mysqld. To preserve backward compatibility, MySQL binary distributions include safe_mysqld as a symbolic link to mysqld_safe until MySQL 5.1.

By default, mysqld_safe tries to start an executable named mysqld-max if it exists, and mysqld otherwise. Be aware of the implications of this behavior:

- On Linux, the MySQL-Max RPM relies on this mysqld_safe behavior. The RPM installs an executable named mysqld-max, which causes mysqld_safe to automatically use that executable rather than mysqld from that point on.
- If you install a MySQL-Max distribution that includes a server named mysqld-max, and then upgrade later to a non-Max version of MySQL, mysqld_safe will still attempt to run the old mysqld-max server. If you perform such an upgrade, you should manually remove the old mysqld-max server to ensure that mysqld_safe runs the new mysqld server.

To override the default behavior and specify explicitly the name of the server you want to run, specify a --mysqld [244] or --mysqld-version [244] option to mysqld_safe. You can also use --ledir [244] to indicate the directory where mysqld_safe should look for the server.

Many of the options to mysqld_safe are the same as the options to mysqld. See Section 5.1.2, “Server Command Options”.

Options unknown to mysqld_safe are passed to mysqld if they are specified on the command line, but ignored if they are specified in the [mysqld_safe] group of an option file. See Section 4.2.3.3, “Using Option Files”.

mysqld_safe reads all options from the [mysqld], [server], and [mysqld_safe] sections in option files. For example, if you specify a [mysqld] section like this, mysqld_safe will find and use the --log-error option:

```
[mysqld]
```

```
log-error=error.log
```

For backward compatibility, mysqld_safe also reads [safe_mysqld] sections, although you should rename such sections to [mysqld_safe] when you begin using MySQL 4.0 or later.

mysqld_safe supports the following options. It also reads option files and supports the options for processing them described at Command-Line Options that Affect Option-File Handling.

Table 4.1 mysqld_safe Options

Format	Option File	Description
--autoclose [243]	autoclose [243]	On NetWare, mysqld_safe provides a screen presence
--basedir=path [244]	basedir [244]	The path to the MySQL installation directory
--core-file-size=size [244]	core-file-size [244]	The size of the core file that mysqld should be able to create
--datadir=path [244]	datadir [244]	The path to the data directory
--defaults-extra-file=path [244]	defaults-extra-file [244]	The name of an option file to be read in addition to the usual option files
--defaults-file=file_name [244]	defaults-file [244]	The name of an option file to be read instead of the usual option files
--help		Display a help message and exit
--ledir=path [244]	ledir [244]	Use this option to indicate the path name to the directory where the server is located
--log-error=file_name	log-error	Write the error log to the given file
--mysqld=prog_name [244]	mysqld [244]	The name of the server program (in the ledir directory) that you want to start
--mysqld-version=suffix [244]	mysqld-version [244]	This option is similar to the --mysqld option, but you specify only the suffix for the server program name
--nice=priority [245]	nice [245]	Use the nice program to set the server's scheduling priority to the given value
--no-defaults [245]	no-defaults [245]	Do not read any option files
--open-files-limit=count [245]	open-files-limit [245]	The number of files that mysqld should be able to open
--pid-file=file_name [245]	pid-file=file_name [245]	The path name of the process ID file
--port=number [245]	port [245]	The port number that the server should use when listening for TCP/IP connections
--skip-kill-mysqld [245]	skip-kill-mysqld [245]	Do not try to kill stray mysqld processes
--socket=path [245]	socket [245]	The Unix socket file that the server should use when listening for local connections
--timezone=timezone [245]	timezone [245]	Set the TZ time zone environment variable to the given option value
--user={user_name|user_id} [245]	user [245]	Run the mysqld server as the user having the name user_name or the numeric user ID user_id

- --autoclose [243]

(NetWare only) On NetWare, mysqld_safe provides a screen presence. When you unload (shut down) the mysqld_safe NLM, the screen does not by default go away. Instead, it prompts for user input:

```
*<NLM has terminated; Press any key to close the screen>*
```

If you want NetWare to close the screen automatically instead, use the --autoclose [243] option to mysqld_safe.

- --basedir=*path* [244]

  The path to the MySQL installation directory.

- --core-file-size=*size* [244]

  The size of the core file that mysqld should be able to create. The option value is passed to ulimit -c.

- --datadir=*path* [244]

  The path to the data directory.

- --defaults-extra-file=*path* [244]

  The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used.

- --defaults-file=*file_name* [244]

  The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.

- --err-log=*file_name* [244]

  The old form of the --log-error option, to be used before MySQL 4.0.

- --ledir=*path* [244]

  If mysqld_safe cannot find the server, use this option to indicate the path name to the directory where the server is located.

- --log-error=*file_name*

  Write the error log to the given file. See Section 5.3.1, “The Error Log”.

- --mysqld=*prog_name* [244]

  The name of the server program (in the ledir directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If mysqld_safe cannot find the server, use the --ledir [244] option to indicate the path name to the directory where the server is located.

- --mysqld-version=*suffix* [244]

  This option is similar to the --mysqld [244] option, but you specify only the suffix for the server program name. The basename is assumed to be mysqld. For example, if you use --mysqld-version=max [244], mysqld_safe starts the mysqld-max program in the ledir directory. If the argument to --mysqld-version [244] is empty, mysqld_safe uses mysqld in the ledir directory.

- `--nice=priority` [245]

  Use the `nice` program to set the server's scheduling priority to the given value. This option was added in MySQL 4.0.14.

- `--no-defaults` [245]

  Do not read any option files. This must be the first option on the command line if it is used.

- `--open-files-limit=count` [245]

  The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as `root` for this to work properly.

- `--pid-file=file_name` [245]

  The path name of the process ID file.

- `--port=port_num` [245]

  The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--skip-kill-mysqld` [245]

  Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=path` [245]

  The Unix socket file that the server should use when listening for local connections.

- `--timezone=timezone` [245]

  Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}` [245]

  Run the `mysqld` server as the user having the name *`user_name`* or the numeric user ID *`user_id`*. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` [244] or `--defaults-extra-file` [244] option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the server in slightly different locations. (See Section 2.1.5, “Installation Layouts”.) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory

for bin and data directories. For source distributions, it looks for libexec and var directories. This condition should be met if you execute mysqld_safe from your MySQL installation directory (for example, /usr/local/mysql for a binary distribution).

- If the server and databases cannot be found relative to the working directory, mysqld_safe attempts to locate them by absolute path names. Typical locations are /usr/local/libexec and /usr/local/var. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because mysqld_safe tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run mysqld_safe from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If mysqld_safe fails, even when invoked from the MySQL installation directory, you can specify the --ledir [244] and --datadir [244] options to indicate the directories in which the server and databases are located on your system.

Normally, you should not edit the mysqld_safe script. Instead, configure mysqld_safe by using command-line options or options in the [mysqld_safe] section of a my.cnf option file. In rare cases, it might be necessary to edit mysqld_safe to get it to start the server properly. However, if you do this, your modified version of mysqld_safe might be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.

On NetWare, mysqld_safe is a NetWare Loadable Module (NLM) that is ported from the original Unix shell script. It starts the server as follows:

1. Runs a number of system and option checks.
2. Runs a check on MyISAM and ISAM tables.
3. Provides a screen presence for the MySQL server.
4. Starts mysqld, monitors it, and restarts it if it terminates in error.
5. Sends error messages from mysqld to the *host_name*.err file in the data directory.
6. Sends mysqld_safe screen output to the *host_name*.safe file in the data directory.

4.3.3 mysql.server — MySQL Server Startup Script

MySQL distributions on Unix include a script named mysql.server. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the Mac OS X Startup Item for MySQL.

mysql.server can be found in the support-files directory under your MySQL installation directory or in a MySQL source distribution.

If you use the Linux server RPM package (MySQL-server-*VERSION*.rpm), the mysql.server script will be installed in the /etc/init.d directory with the name mysql. You need not install it manually. See Section 2.4, “Installing MySQL from RPM Packages on Linux”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as mysqld.

If you install MySQL from a source distribution or using a binary distribution format that does not install mysql.server automatically, you can install it manually. Instructions are provided in Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.

mysql.server reads options from the [mysql.server] and [mysqld] sections of option files. For backward compatibility, it also reads [mysql_server] sections, although you should rename such sections to [mysql.server] when you begin using MySQL 4.0 or later.

mysql.server supports the following options.

- --basedir=*path* [247]

  The path to the MySQL installation directory.

- --datadir=*path* [247]

  The path to the MySQL data directory.

- --pid-file=*file_name* [247]

  The path name of the file in which the server should write its process ID.

4.3.4 mysqld_multi — Manage Multiple MySQL Servers

mysqld_multi is designed to manage several mysqld processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

mysqld_multi searches for groups named [mysqld*N*] in my.cnf (or in the file named by the --config-file [248] option). *N* can be any positive integer. This number is referred to in the following discussion as the option group number, or *GNR*. Group numbers distinguish option groups from one another and are used as arguments to mysqld_multi to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the [mysqld] group used for starting mysqld. (See, for example, Section 2.10.2.2, “Starting and Stopping MySQL Automatically”.) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Section 5.7, “Running Multiple MySQL Servers on the Same Machine”.

To invoke mysqld_multi, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

start, stop, and report indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, mysqld_multi performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named [mysqld17] is 17. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value 10-13 represents groups [mysqld10] through [mysqld13]. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group [mysqld17]:

```
```

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups [mysqld8] and [mysqld10] through [mysqld13]:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

Option files read are searched for [mysqld_multi] and [mysqldN] option groups. The [mysqld_multi] group can be used for options to mysqld_multi itself. [mysqldN] groups can be used for options passed to specific mysqld instances.

mysqld_multi supports the following options.

- --help [248]

  Display a help message and exit.

- --config-file=*file_name* [248]

  Specify the name of an alternative option file. This affects where mysqld_multi looks for [mysqldN] option groups. Without this option, all options are read from the usual my.cnf file. The option does not affect where mysqld_multi reads its own options, which are always taken from the [mysqld_multi] group in the usual my.cnf file.

- --example [248]

  Display a sample option file.

- --log=*file_name* [248]

  Specify the name of the log file. If the file exists, log output is appended to it.

- --mysqladmin=*prog_name* [248]

  The mysqladmin binary to be used to stop servers.

- --mysqld=*prog_name* [248]

  The mysqld binary to be used. Note that you can specify mysqld_safe as the value for this option also. If you use mysqld_safe to start the server, you can include the mysqld or ledir options in the corresponding [mysqldN] option group. These options indicate the name of the server that mysqld_safe should start and the path name of the directory where the server is located. (See the descriptions for these options in Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”.) Example:

  ```
  [mysqld38]
  mysqld = mysqld-max
  ledir  = /opt/local/mysql/libexec
  ```

- --no-log [248]

  Print log information to stdout rather than to the log file. By default, output goes to the log file.

- `--password=password` [249]

  The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent` [249]

  Silent mode; disable warnings. This option was added in MySQL 4.1.6.

- `--tcp-ip` [249]

  Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

  The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose` [249]

  Be more verbose. This option was added in MySQL 4.1.6.

- `--version` [249]

  Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important**: Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See Section 5.7, “Running Multiple MySQL Servers on the Same Machine”.

- 

  Important

  Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See Section 5.4.6, “How to Run MySQL as a Normal User”.

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` [492] privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

  ```
  shell> mysql -u root -S /tmp/mysql.sock -p
  Enter password:
  mysql> GRANT SHUTDOWN ON *.*
      -> TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
  ```

  See Section 5.5, “The MySQL Access Privilege System”. You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host name

part of the account name must permit you to connect as multi_admin from the host where you want to run mysqld_multi.

- The Unix socket file and the TCP/IP port number must be different for every mysqld. (Alternatively, if the host has multiple network addresses, you can use --bind-address [384] to cause different servers to listen to different interfaces.)
- The --pid-file [245] option is very important if you are using mysqld_safe to start mysqld (for example, --mysqld=mysqld_safe [244]) Every mysqld should have its own process ID file. The advantage of using mysqld_safe instead of mysqld is that mysqld_safe monitors its mysqld process and restarts it if the process terminates due to a signal sent using kill -9 or for other reasons, such as a segmentation fault. Please note that the mysqld_safe script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running mysqld_multi. If you have problems starting, please see the mysqld_safe script. Check especially the lines:

```
----------------------------------------------------------------
MY_PWD=`pwd`
# Check if we are starting this relative (for the binary release)
if test -d $MY_PWD/data/mysql -a -f ./share/mysql/english/errmsg.sys -a \
 -x ./bin/mysqld
----------------------------------------------------------------
```

  The test performed by these lines should be successful, or you might encounter problems. See Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”.

- You might want to use the --user [395] option for mysqld, but to do this you need to run the mysqld_multi script as the Unix superuser (root). Having the option in the option file does not matter; you merely get a warning if you are not the superuser and the mysqld processes are started under your own Unix account.

The following example shows how you might set up an option file for use with mysqld_multi. The order in which the mysqld programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth [mysqldN] groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This file should probably be in your home dir (~/.my.cnf)
# or /etc/my.cnf
# Version 2.1 by Jani Tolonen

[mysqld_multi]
mysqld     = /usr/local/bin/mysqld_safe
mysqladmin = /usr/local/bin/mysqladmin
user       = multi_admin
password   = multipass

[mysqld2]
socket     = /tmp/mysql.sock2
port       = 3307
pid-file   = /usr/local/mysql/var2/hostname.pid2
datadir    = /usr/local/mysql/var2
language   = /usr/local/share/mysql/english
user       = john

[mysqld3]
socket     = /tmp/mysql.sock3
port       = 3308
pid-file   = /usr/local/mysql/var3/hostname.pid3
datadir    = /usr/local/mysql/var3
```

```
language   = /usr/local/share/mysql/swedish
user       = monty

[mysqld4]
socket     = /tmp/mysql.sock4
port       = 3309
pid-file   = /usr/local/mysql/var4/hostname.pid4
datadir    = /usr/local/mysql/var4
language   = /usr/local/share/mysql/estonia
user       = tonu

[mysqld6]
socket     = /tmp/mysql.sock6
port       = 3311
pid-file   = /usr/local/mysql/var6/hostname.pid6
datadir    = /usr/local/mysql/var6
language   = /usr/local/share/mysql/japanese
user       = jani
```

See Section 4.2.3.3, “Using Option Files”.

4.4 MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

4.4.1 `comp_err` — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the plaintext file or files located in the `sql/share/language` directories in MySQL source distributions.

For more information about how error messages are defined, see the MySQL Internals Manual.

Invoke `comp_err` like this:

```
shell> comp_err [options] from_file ... to_file
```

The *`from_file`* arguments are the input files. *`to_file`* is the name of the output file.

`comp_err` supports the following options.

- `-?`, `-I`

  Display a help message and exit.

- `-# debug_options`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:O,file_name'`.

- `-V`

  Display version information and exit.

4.4.2 `make_win_src_distribution` — Create Source Distribution for Windows

`make_win_src_distribution` creates a Windows source package to be used on Windows systems. It is used after you configure and build the source distribution on a Unix or Unix-like system so that you have

a server binary to work with. (See the instructions at Section 2.9.7.2, “Creating a Windows Source Package from the Latest Development Source”.)

Invoke `make_win_src_distribution` like this from the top-level directory of a MySQL source distribution:

```
shell> make_win_src_distribution [options]
```

`make_win_src_distribution` understands the following options:

- `--help` [252]

  Display a help message and exit.

- `--debug` [252]

  Print information about script operations; do not create a package.

- `--dirname` [252]

  Directory name to copy files (intermediate).

- `--silent` [252]

  Do not print verbose list of files processed.

- `--suffix` [252]

  The suffix name for the package.

- `--tar` [252]

  Create a `.tar.gz` package instead of a `.zip` package.

  By default, `make_win_src_distribution` creates a Zip-format archive with the name `mysql-VERSION-win-src.zip`, where *`VERSION`* represents the version of your MySQL source tree.

- `--tmp` [252]

  Specify the temporary location.

4.4.3 `mysql_create_system_tables` — Generate Statements to Initialize MySQL System Tables

`mysql_create_system_tables` is a helper script that is invoked by `mysql_install_db` to generate the SQL statements required to initialize any grant tables that do not exist.

Invoke `mysql_create_system_tables` like this:

```
shell> mysql_create_system_tables {test|verbose} path_to_mysql_database host_name windows_option
```

The first argument is `test` (create entries for the `test` database) or `verbose` (display more information while the script runs. The second argument is the path to the `mysql` database directory. The third argument is the host name to use in grant table entries. The fourth argument is 1 if the script is being run to create tables for use on Windows, 0 otherwise.

4.4.4 `mysqlbug` — Generate Bug Report

This program enables you to generate a bug report and send it to Oracle Corporation. It is a shell script and runs on Unix.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports. If you have no Web access, you can generate a bug report by using the `mysqlbug` script.

`mysqlbug` helps you generate a report by determining much of the following information automatically, but if something important is missing, please include it with your message. `mysqlbug` can be found in the `scripts` directory (source distribution) and in the `bin` directory under your MySQL installation directory (binary distribution).

Invoke `mysqlbug` without arguments:

```
shell> mysqlbug
```

The script will place you in an editor with a copy of the report to be sent. Edit the lines near the beginning that indicate the nature of the problem. Then write the file to save your changes, quit the editor, and `mysqlbug` will send the report by email.

4.4.5 `mysql_fix_privilege_tables` — Upgrade MySQL System Tables

Some releases of MySQL introduce changes to the structure of the system tables in the `mysql` database to add new privileges or support new features. When you update to a new version of MySQL, you should update your system tables as well to make sure that their structure is up to date. Otherwise, there might be capabilities that you cannot take advantage of. First, make a backup of your `mysql` database, and then use the following procedure.

On Unix or Unix-like systems, update the system tables by running the `mysql_fix_privilege_tables` script:

```
shell> mysql_fix_privilege_tables
```

You must run this script while the server is running. It attempts to connect to the server running on the local host as `root`. If your `root` account requires a password, indicate the password on the command line. For MySQL 4.1 and up, specify the password like this:

```
shell> mysql_fix_privilege_tables --password=root_password
```

Prior to MySQL 4.1, specify the password like this:

```
shell> mysql_fix_privilege_tables root_password
```

The `mysql_fix_privilege_tables` script performs any actions necessary to convert your system tables to the current format. You might see some `Duplicate column name` warnings as it runs; you can ignore them.

After running the script, stop the server and restart it so that it uses any changes that were made to the system tables.

On Windows systems, there isn't an easy way to update the system tables until MySQL 4.0.15. From version 4.0.15 on, MySQL distributions include a `mysql_fix_privilege_tables.sql` SQL script that

you can run using the mysql client. For example, if your MySQL installation is located at C:\Program Files\MySQL\MySQL Server 4.1, the commands look like this:

```
C:\> cd "C:\Program Files\MySQL\MySQL Server 4.1"
C:\> bin\mysql -u root -p mysql
mysql> SOURCE scripts/mysql_fix_privilege_tables.sql
```

The mysql command will prompt you for the root password; enter it when prompted.

If your installation is located in some other directory, adjust the path names appropriately.

As with the Unix procedure, you might see some Duplicate column name warnings as mysql processes the statements in the mysql_fix_privilege_tables.sql script; you can ignore them.

After running the script, stop the server and restart it.

4.4.6 mysql_install_db — Initialize MySQL Data Directory

mysql_install_db initializes the MySQL data directory and creates the system tables that it contains, if they do not exist.

To invoke mysql_install_db, use the following syntax:

```
shell> mysql_install_db [options]
```

Because the MySQL server, mysqld, needs to access the data directory when it runs later, you should either run mysql_install_db from the same account that will be used for running mysqld or run it as root and use the --user [255] option to indicate the user name that mysqld will run as. It might be necessary to specify other options such as --basedir [254] or --datadir [254] if mysql_install_db does not use the correct locations for the installation directory or data directory. For example:

```
shell> bin/mysql_install_db --user=mysql \
         --basedir=/opt/mysql/mysql \
         --datadir=/opt/mysql/mysql/data
```

mysql_install_db supports the following options, which can be specified on the command line or in the [mysql_install_db] and (if they are common to mysqld) [mysqld] option file groups.

- --basedir=*path* [254]

  The path to the MySQL installation directory.

- --force [254]

  Cause mysql_install_db to run even if DNS does not work. In that case, grant table entries that normally use host names will use IP addresses.

- --datadir=*path* [254], --ldata=*path* [254]

  The path to the MySQL data directory.

- --rpm [254]

  For internal use. This option is used by RPM files during the MySQL installation process.

- `--skip-name-resolve` [255]

  Use IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

- `--user=user_name` [255]

  The login user name to use for running `mysqld`. Files and directories created by `mysqld` will be owned by this user. You must be `root` to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates will be owned by you.

- `--verbose` [255]

  Verbose mode. Print more information about what the program does.

- `--windows` [255]

  For internal use. This option is used for creating Windows distributions.

4.4.7 `mysql_secure_installation` — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.
- You can remove `root` accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at Section 2.10.3, “Securing the Initial MySQL Accounts”.

Invoke `mysql_secure_installation` without arguments:

```
shell> mysql_secure_installation
```

The script will prompt you to determine which actions to perform.

`mysql_secure_installation` is not available on Windows.

4.4.8 `mysql_tzinfo_to_sql` — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a *zoneinfo* database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a zoneinfo database, you can use the downloadable package described in Section 9.7, “MySQL Server Time Zone Support”.

`mysql_tzinfo_to_sql` can be invoked several ways:

```
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the zoneinfo directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file *`tz_file`* that corresponds to a time zone name *`tz_name`*:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. *`tz_file`* is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

`mysql_tzinfo_to_sql` was added in MySQL 4.1.3.

4.5 MySQL Client Programs

This section describes client programs that connect to the MySQL server.

4.5.1 `mysql` — The MySQL Command-Line Tool

`mysql` is a simple SQL shell (with GNU `readline` capabilities). It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` [263] option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with “`;`”, `\g`, or `\G` and press Enter.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

On Unix, the mysql client logs statements executed interactively to a history file. See Section 4.5.1.3, "mysql Logging".

4.5.1.1 mysql Options

mysql supports the following options, which can be specified on the command line or in the [mysql] and [client] option file groups. mysql also supports the options for processing option files described at Command-Line Options that Affect Option-File Handling.

Table 4.2 mysql Options

Format	Option File	Description	Introduced	Deprecated
--auto-rehash [260]	auto-rehash [260]	Enable automatic rehashing		
--batch [260]	batch [260]	Don't use history file		
--character-sets-dir=path [260]	character-sets-dir [260]	Set the default character set		
--column-names [260]	column-names [260]	Write column names in results		
--compress [260]	compress [260]	Compress all information sent between the client and the server		
--connect_timeout=value [265]	connect_timeout [265]	The number of seconds before connection timeout		
--database=dbname [260]	database [260]	The database to use		
--debug[=debug_options] [260]	debug [260]	Write a debugging log		
--debug-info [260]	debug-info [260]	Print debugging information, memory and CPU statistics when the program exits		
--default-character-set=charset_name [260]	default-character-set [260]	Use charset_name as the default character set		
--delimiter=str [261]	delimiter [261]	Set the statement delimiter		
--execute=statement [261]	execute [261]	Execute the statement and quit		
--force [261]	force [261]	Continue even if an SQL error occurs		
--help [260]		Display help message and exit		
--host=host_name [261]	host [261]	Connect to the MySQL server on the given host		
--html [261]	html [261]	Produce HTML output		
--ignore-spaces [261]	ignore-spaces [261]	Ignore spaces after function names		
--line-numbers [261]	line-numbers [261]	Write line numbers for errors		
--local-infile[={0|1}] [261]	local-infile [261]	Enable or disable for LOCAL capability for LOAD DATA INFILE		

Format	Option File	Description	Introduced	Deprecated
--max_allowed_packet=value [265]	max_allowed_packet [265]	The maximum packet length to send to or receive from the server		
--max_join_size=value [265]	max_join_size [265]	The automatic limit for rows in a join when using --safe-updates		
--named-commands [261]	named-commands [261]	Enable named mysql commands		
--net_buffer_length=value [265]	net_buffer_length [265]	The buffer size for TCP/IP and socket communication		
--no-auto-rehash [261]		Disable automatic rehashing		4.1.0
--no-beep [261]	no-beep [261]	Do not beep when errors occur		
--no-named-commands [261]	no-named-commands [261]	Disable named mysql commands		4.1.0
--no-pager [262]	no-pager [262]	Deprecated form of --skip-pager		4.1.0
--no-tee [262]	no-tee [262]	Do not copy output to a file		
--one-database [262]	one-database [262]	Ignore statements except those for the default database named on the command line		
--pager[=command] [262]	pager [262]	Use the given command for paging query output		
--password[=password] [262]	password [262]	The password to use when connecting to the server		
--pipe [263]		On Windows, connect to server using a named pipe		
--port=port_num [263]	port [263]	The TCP/IP port number to use for the connection		
--prompt=format_str [263]	prompt [263]	Set the prompt to the specified format		
--protocol=type [263]	protocol [263]	The connection protocol to use		
--quick [263]	quick [263]	Do not cache each query result		
--raw [263]	raw [263]	Write column values without escape conversion		
--reconnect [264]	reconnect [264]	If the connection to the server is lost, automatically try to reconnect		
--safe-updates [264]	safe-updates [264]	Allow only UPDATE and DELETE statements that specify key values		
--secure-auth [264]	secure-auth [264]	Do not send passwords to the server in old (pre-4.1.1) format	4.1.1	
--select_limit=value [265]	select_limit [265]	The automatic limit for SELECT statements when using --safe-updates		
--sigint-ignore [264]	sigint-ignore [264]	Ignore SIGINT signals (typically the result of typing Control+C)	4.1.6	

Format	Option File	Description	Introduced	Deprecated
--silent [264]	silent [264]	Silent mode		
--skip-auto-rehash [260]	skip-auto-rehash [260]	Disable automatic rehashing		
--skip-column-names [264]	skip-column-names [264]	Do not write column names in results		
--skip-line-numbers [264]	skip-line-numbers [264]	Skip line numbers for errors		
--skip-named-commands [261]	skip-named-commands [261]	Disable named mysql commands		
--skip-pager [262]	skip-pager [262]	Disable paging		
--skip-reconnect [264]	skip-reconnect [264]	Disable reconnecting		
--socket=path [264]	socket [264]	For connections to localhost		
--ssl[=TRUE|FALSE] [264]		Enable an SSL connection to the server. This option is set to TRUE when any other SSL option is used, and so is normally not needed.		
--ssl-ca=file_name [264]	ssl-ca [264]	The path to a file that contains a list of trusted SSL CAs		
--ssl-capath=dir_name [264]	ssl-capath [264]	The path to a directory that contains trusted SSL CA certificates in PEM format		
--ssl-cert=file_name [264]	ssl-cert [264]	The name of the SSL certificate file to use for establishing a secure connection		
--ssl-cipher=cipher_list [264]	ssl-cipher [264]	A list of allowable ciphers to use for SSL encryption		
--ssl-key=file_name [264]	ssl-key [264]	The name of the SSL key file to use for establishing a secure connection		
--ssl-verify-server-cert [264]	ssl-verify-server-cert [264]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server		
--table [264]	table [264]	Display output in tabular format		
--tee=file_name [264]	tee [264]	Append a copy of output to the given file		
--unbuffered [265]	unbuffered [265]	Flush the buffer after each query		
--user=user_name [265]	user [265]	MySQL user name to use when connecting to server		
--verbose [265]		Verbose mode		
--version [265]		Display version information and exit		
--vertical [265]	vertical [265]	Print query output rows vertically (one line per column value)		

Format	Option File	Description	Introduced	Deprecated
--wait [265]	wait [265]	If the connection cannot be established, wait and retry instead of aborting		
--xml [265]	xml [265]	Produce XML output		

- `--help` [260], `-?`

  Display a help message and exit.

- `--auto-rehash` [260]

  Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--skip-auto-rehash` [260] to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command if you want to use name completion.

  To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

- `--batch` [260], `-B`

  Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

  Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` [263] option.

- `--character-sets-dir=`*`path`* [260]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--column-names` [260]

  Write column names in results.

- `--compress` [260], `-C`

  Compress all information sent between the client and the server if both support compression.

- `--database=`*`db_name`* [260], `-D` *`db_name`*

  The database to use. This is useful primarily in an option file.

- `--debug[=`*`debug_options`*`]` [260], `-#` `[`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o,/tmp/mysql.trace'`.

- `--debug-info` [260], `-T`

  Print some debugging information when the program exits.

- `--default-character-set=`*`charset_name`* [260]

  Use *`charset_name`* as the default character set for the client and connection.

  A common issue that can occur when the operating system uses `utf8` or another multi-byte character set is that output from the `mysql` client is formatted incorrectly, due to the fact that the MySQL client

uses the latin1 character set by default. You can usually fix such issues by using this option to force the client to use the system character set instead.

See Section 9.6, “Character Set Configuration”, for more information.

- --delimiter=*str* [261]

  Set the statement delimiter. The default is the semicolon character (“;”).

- --execute=*statement* [261], -e *statement*

  Execute the statement and quit. The default output format is like that produced with --batch [260]. See Section 4.2.3.1, “Using Options on the Command Line”, for some examples. With this option, mysql does not use the history file.

- --force [261], -f

  Continue even if an SQL error occurs.

- --host=*host_name* [261], -h *host_name*

  Connect to the MySQL server on the given host.

- --html [261], -H

  Produce HTML output.

- --ignore-spaces [261], -i

  Ignore spaces after function names. The effect of this is described in the discussion for the IGNORE_SPACE [458] SQL mode (see Section 5.1.6, “Server SQL Modes”).

- --line-numbers [261]

  Write line numbers for errors. Disable this with --skip-line-numbers [264].

- --local-infile[={0|1}] [261]

  Enable or disable LOCAL capability for LOAD DATA INFILE. With no value, the option enables LOCAL. The option may be given as --local-infile=0 [261] or --local-infile=1 [261] to explicitly disable or enable LOCAL. Enabling LOCAL has no effect if the server does not also support it.

- --named-commands [261], -G

  Enable named mysql commands. Long-format commands are permitted, not just short-format commands. For example, quit and \q both are recognized. Use --skip-named-commands [261] to disable named commands. See Section 4.5.1.2, “mysql Commands”.

- --no-auto-rehash [260], -A

  This has the same effect as -skip-auto-rehash. See the description for --auto-rehash [260].

- --no-beep [261], -b

  Do not beep when errors occur.

- --no-named-commands [261], -g

  Disable named commands. Use the * form only, or use named commands only at the beginning of a line ending with a semicolon (“;”). As of MySQL 3.23.22, mysql starts with this option *enabled*

by default. However, even with this option, long-format commands still work from the first line. See Section 4.5.1.2, “mysql Commands”.

- --no-pager [262]

  Deprecated form of --skip-pager [262]. See the --pager [262] option. --no-pager [262] is removed in MySQL 5.5.

- --no-tee [262]

  Deprecated form of --skip-tee [264]. See the --tee [264] option. --no-tee [262] is removed in MySQL 5.5.

- --one-database [262], -o

  Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on USE statements.

  Initially, mysql executes statements in the input because specifying a database *db_name* on the command line is equivalent to inserting USE *db_name* at the beginning of the input. Then, for each USE statement encountered, mysql accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

  Suppose that mysql is invoked to process this set of statements:

```
DELETE FROM db2.t2;
USE db2;
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

  If the command line is mysql --force --one-database db1, mysql handles the input as follows:

  - The DELETE statement is executed because the default database is db1, even though the statement names a table in a different database.
  - The DROP TABLE and CREATE TABLE statements are not executed because the default database is not db1, even though the statements name a table in db1.
  - The INSERT and CREATE TABLE statements are executed because the default database is db1, even though the CREATE TABLE statement names a table in a different database.

- --pager[=*command*] [262]

  Use the given command for paging query output. If the command is omitted, the default pager is the value of your PAGER environment variable. Valid pagers are less, more, cat [> filename], and so forth. This option works only on Unix and only in interactive mode. To disable paging, use --skip-pager [262]. Section 4.5.1.2, “mysql Commands”, discusses output paging further.

- --password[=*password*] [262], -p[*password*]

  The password to use when connecting to the server. If you use the short option form (-p), you *cannot* have a space between the option and the password. If you omit the *password* value following the --password [262] or -p option on the command line, mysql prompts for one.

Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--pipe` [263], `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=port_num` [263], `-P port_num`

  The TCP/IP port number to use for the connection.

- `--prompt=format_str` [263]

  Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in Section 4.5.1.2, “`mysql` Commands”.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [263]

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”. This option was added in MySQL 4.1.

- `--quick` [263], `-q`

  Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw` [263], `-r`

  For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` [260] or `--silent` [264] option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` [263] option disables this character escaping.

  The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+----------+
| CHAR(92) |
+----------+
| \        |
+----------+

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\
```

- --reconnect [264]

  If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use --skip-reconnect [264]. Added in MySQL 4.1.0.

- --safe-updates [264], --i-am-a-dummy [264], -U

  Permit only those UPDATE and DELETE statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using --safe-updates [264] on the command line. See Section 4.5.1.6, "mysql Tips", for more information about this option.

- --secure-auth [264]

  Do not send passwords to the server in old (pre-4.1.1) format. This prevents connections except for servers that use the newer password format. This option was added in MySQL 4.1.1.

- --sigint-ignore [264]

  Ignore SIGINT signals (typically the result of typing Control-C). This option was added in MySQL 4.1.6.

- --silent [264], -s

  Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

  This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the --raw [263] option.

- --skip-column-names [264], -N

  Do not write column names in results.

- --skip-line-numbers [264], -L

  Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- --socket=*path* [264], -S *path*

  For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- --ssl*

  Options that begin with --ssl [521] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 5.6.6.3, "SSL Command Options".

- --table [264], -t

  Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- --tee=*file_name* [264]

  Append a copy of output to the given file. This option works only in interactive mode. Section 4.5.1.2, "mysql Commands", discusses tee files further.

- `--unbuffered` [265], `-n`

  Flush the buffer after each query.

- `--user=user_name` [265], `-u user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose` [265], `-v`

  Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version` [265], `-V`

  Display version information and exit.

- `--vertical` [265], `-E`

  Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait` [265], `-w`

  If the connection cannot be established, wait and retry instead of aborting.

- `--xml` [265], `-X`

  Produce XML output.

You can also set the following variables by using `--var_name=value` syntax:

- `connect_timeout`

  The number of seconds before connection timeout. (Default value is `0`.)

- `max_allowed_packet`

  The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

- `max_join_size`

  The automatic limit for rows in a join when using `--safe-updates` [264]. (Default value is 1,000,000.)

- `net_buffer_length`

  The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `select_limit`

  The automatic limit for `SELECT` statements when using `--safe-updates` [264]. (Default value is 1,000.)

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. In MySQL 4.1, this syntax is deprecated.

4.5.1.2 mysql Commands

mysql sends each SQL statement that you issue to the server to be executed. There is also a set of commands that mysql itself interprets. For a list of these commands, type help or \h at the mysql> prompt:

```
mysql> help

List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?         (\?) Synonym for `help'.
clear     (\c) Clear command.
connect   (\r) Reconnect to the server. Optional arguments are db and host.
delimiter (\d) Set query delimiter.
edit      (\e) Edit command with $EDITOR.
ego       (\G) Send command to mysql server, display result vertically.
exit      (\q) Exit mysql. Same as quit.
go        (\g) Send command to mysql server.
help      (\h) Display this help.
nopager   (\n) Disable pager, print to stdout.
notee     (\t) Don't write into outfile.
pager     (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print     (\p) Print current command.
prompt    (\R) Change your mysql prompt.
quit      (\q) Quit mysql.
rehash    (\#) Rebuild completion hash.
source    (\.) Execute an SQL script file. Takes a file name as an argument.
status    (\s) Get status information from the server.
system    (\!) Execute a system shell command.
tee       (\T) Set outfile [to_outfile]. Append everything into given
               outfile.
use       (\u) Use another database. Takes database name as argument.
charset_name(\C) Switch to another charset. Might be needed for processing
               binlog.

For server side help, type 'help contents'
```

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multi-line /* ... */ comments is not supported.

- help [*arg*], \h [*arg*], \? [*arg*], ? [*arg*]

  Display a help message listing the available mysql commands.

  If you provide an argument to the help command, mysql uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see Section 4.5.1.4, “mysql Server-Side Help”.

- charset_name *charset_name*, \C *charset_name*

  Change the default character set and issue a SET NAMES statement. This enables the character set to remain synchronized on the client and server if mysql is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

  This command was added in MySQL 4.1.19. In MySQL 5.0 and up, the command name is charset

- clear, \c

  Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name host_name]`, `\r [db_name host_name]`

  Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- `delimiter str`, `\d str`

  Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (“`;`”).

  The delimiter can be specified as an unquoted or quoted argument. Quoting can be done with either single quote (`'`) or douple quote (`"`) characters. To include a quote within a quoted string, either quote the string with the other quote character or escape the quote with a backslash (“`\`”) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delmiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

  When the delimiter recognized by `mysql` is set to something other than the default of “`;`”, instances of that character are sent to the server without interpretation. However, the server itself still interprets “`;`” as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see Section 17.6.15, “C API Support for Multiple Statement Execution”).

- `edit`, `\e`

  Edit the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine which editor to use. The default editor is `vi` if neither variable is set.

  The `edit` command works only in Unix.

- `ego`, `\G`

  Send the current statement to the server to be executed and display the result using vertical format.

- `exit`, `\q`

  Exit `mysql`.

- `go`, `\g`

  Send the current statement to the server to be executed.

- `nopager`, `\n`

  Disable output paging. See the description for `pager`.

  The `nopager` command works only in Unix.

- `notee`, `\t`

  Disable output copying to the tee file. See the description for `tee`.

- `pager [command]`, `\P [command]`

  Enable output paging. By using the `--pager` [262] option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any

other similar program. If you specify no value for the option, mysql checks the value of the PAGER environment variable and sets the pager to that. Pager functionality works only in interactive mode.

Output paging can be enabled interactively with the pager command and disabled with nopager. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or stdout if no pager was specified.

Output paging works only in Unix because it uses the popen() function, which does not exist on Windows. For Windows, the tee option can be used instead to save query output, although it is not as convenient as pager for browsing output in some situations.

- print, \p

  Print the current input statement without executing it.

- prompt [*str*], \R [*str*]

  Reconfigure the mysql prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

  If you specify the prompt command with no argument, mysql resets the prompt to the default of mysql>.

- quit, \q

  Exit mysql.

- rehash, \#

  Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the --auto-rehash [260] option.)

- source *file_name*, \. *file_name*

  Read the named file and executes the statements contained therein. On Windows, you can specify path name separators as / or \\.

- status, \s

  Provide status information about the connection and the server you are using. If you are running in --safe-updates [264] mode, status also prints the values for the mysql variables that affect your queries.

- system *command*, \! *command*

  Execute the given command using your default command interpreter.

  The system command works only in Unix.

- tee [*file_name*], \T [*file_name*]

  By using the --tee [264] option when you invoke mysql, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. mysql flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

  You can enable this feature interactively with the tee command. Without a parameter, the previous file is used. The tee file can be disabled with the notee command. Executing tee again re-enables logging.

- `use db_name`, `\u db_name`

  Use *db_name* as the default database.

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

  You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -S
```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
shell> man less
```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -S -F -X
```

- You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \
         | tee /dr2/tmp/res2.txt | less -n -i -S
```

  In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

From MySQL 4.0.2 on, the `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

Option	Description
`\c`	A counter that increments for each statement you issue
`\D`	The full current date
`\d`	The default database
`\h`	The server host
`\m`	Minutes of the current time

Option	Description
\n	A newline character
\O	The current month in three-letter format (Jan, Feb, …)
\o	The current month in numeric format
\P	am/pm
\p	The current TCP/IP port or socket file
\R	The current time, in 24-hour military time (0–23)
\r	The current time, standard 12-hour time (1–12)
\S	Semicolon
\s	Seconds of the current time
\t	A tab character
\U	Your full *user_name@host_name* account name
\u	Your user name
\v	The server version
\w	The current day of the week in three-letter format (Mon, Tue, …)
\Y	The current year, four digits
\y	The current year, two digits
_	A space
\	A space (a space follows the backslash)
\'	Single quote
\"	Double quote
\\	A literal "\" backslash character
\x	*x*, for any "*x*" not listed above

You can set the prompt in several ways:

- *Use an environment variable.* You can set the MYSQL_PS1 environment variable to a prompt string. For example:

```
shell> export MYSQL_PS1="(\u@\h) [\d]> "
```

- *Use a command-line option.* You can set the --prompt [263] option on the command line to mysql. For example:

```
shell> mysql --prompt="(\u@\h) [\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the prompt option in the [mysql] group of any MySQL option file, such as /etc/my.cnf or the .my.cnf file in your home directory. For example:

```
[mysql]
prompt=(\\u@\\h) [\\d]>\\_
```

  In this example, note that the backslashes are doubled. If you set the prompt using the prompt option in an option file, it is advisable to double the backslashes when using the special prompt options. There is

some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in Section 4.2.3.3, “Using Option Files”.) The overlap may cause you problems if you use single backslashes. For example, `\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS>` format:

```
[mysql]
prompt="\\r:\\m:\\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

```
mysql> prompt (\u@\h) [\d]>\_
PROMPT set to '(\u@\h) [\d]>\_'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

4.5.1.3 mysql Logging

On Unix, the `mysql` client logs statements executed interactively to a history file. By default, this file is named `.mysql_history` in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

How Logging Occurs

Statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the `--batch` [260] or `--execute` [261] option.
- `mysql` logs each nonempty statement line individually.
- If a statement spans multiple lines (not including the terminating delimiter), `mysql` concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```
mysql> SELECT
    -> 'Today is'
    -> ,
    -> CONCAT()
    -> ;
```

In this case, `mysql` logs the “SELECT”, “'Today is'”, “,”, “CONCAT()”, and “;” lines as it reads them. It also logs the complete statement, after mapping `SELECT\n'Today is'\n,\nCURDATE()` to `SELECT 'Today is' , CURDATE()`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT
'Today is'
,
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

Controlling the History File

The `.mysql_history` file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See Section 5.4.2.2, “End-User Guidelines for Password Security”.

If you do not want to maintain a history file, first remove `.mysql_history` if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the `MYSQL_HISTFILE` environment variable to `/dev/null`. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`; this need be done only once:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

4.5.1.4 `mysql` Server-Side Help

```
mysql> help search_string
```

As of MySQL 4.1, if you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.7, “Server-Side Help”).

If there is no match for the search string, the search fails:

```
mysql> help me

Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the
following categories:
   Account Management
   Administration
   Data Definition
   Data Manipulation
   Data Types
   Functions
   Functions and Modifiers for Use with GROUP BY
   Geographic Features
   Language Structure
   Storage Engines
   Table Maintenance
   Transactions
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
```

```
where <item> is one of the following topics:
   SHOW
   SHOW BINARY LOGS
   SHOW ENGINE
   SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as
part of the procedure described in [purge-binary-logs], that shows how
to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 |    724935 |
| binlog.000016 |    733481 |
+---------------+-----------+
```

4.5.1.5 Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file *`text_file`* that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE` *`db_name`* statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke mysql with the --verbose [265] option, which causes each statement to be displayed before the result that it produces.

For more information about batch mode, see Section 3.5, “Using mysql in Batch Mode”.

4.5.1.6 mysql Tips

This section describes some techniques that can help you use mysql more effectively.

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with \G instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
*************************** 1. row ***************************
  msg_nro: 3068
     date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
    reply: monty@no.spam.com
  mail_to: "Thimble Smith" <tim@no.spam.com>
      sbj: UTF-8

Thimble> TODO list and see what happens.

Yes, please do that.

Regards,
Monty

Using the --safe-updates [264] Option

For beginners, a useful startup option is --safe-updates [264] (or --i-am-a-dummy [264], which has the same effect). This option was introduced in MySQL 3.23.11. It is helpful for cases when you might have issued a DELETE FROM *tbl_name* statement but forgotten the WHERE clause. Normally, such a statement deletes all rows from the table. With --safe-updates [264], you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the --safe-updates [264] option, mysql issues the following statement when it connects to the MySQL server:

```
SET sql_safe_updates=1, sql_select_limit=1000, sql_max_join_size=1000000;
```

See Section 5.1.3, “Server System Variables”.

The SET statement has the following effects:

- You are not permitted to execute an UPDATE or DELETE statement unless you specify a key constraint in the WHERE clause or provide a LIMIT clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;

UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large SELECT results to 1,000 rows unless the statement includes a LIMIT clause.
- The server aborts multiple-table SELECT statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the --select_limit and --max_join_size options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

Disabling mysql Auto-Reconnect

If the mysql client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if mysql succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id:    1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+------+
| a    |
+------+
| NULL |
+------+
1 row in set (0.05 sec)
```

The @a user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have mysql terminate with an error if the connection has been lost, you can start the mysql client with the --skip-reconnect [264] option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see Section 17.6.14, “Controlling Automatic Reconnection Behavior”.

4.5.2 mysqladmin — Client for Administering a MySQL Server

mysqladmin is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke mysqladmin like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

mysqladmin supports the following commands. Some of the commands take an argument following the command name.

- create *db_name*

  Create a new database named *db_name*.

- debug

  Tell the server to write debug information to the error log. Format and content of this information is subject to change.

- drop *db_name*

  Delete the database named *db_name* and all its tables.

- extended-status

  Display the server status variables and their values.

- flush-hosts

  Flush all information in the host cache.

- flush-logs

  Flush all logs.

- flush-privileges

  Reload the grant tables (same as reload).

- flush-status

  Clear status variables.

- flush-tables

  Flush all tables.

- flush-threads

  Flush the thread cache. (Added in MySQL 3.23.16.)

- kill *id,id,...*

  Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

- old-password *new-password*

  This is like the password command but stores the password using the old (pre-4.1) password-hashing format. This command was added in MySQL 4.1.0. (See Section 5.4.2.3, “Password Hashing in MySQL”.)

- password *new-password*

  Set a new password. This changes the password to *new-password* for the account that you use with mysqladmin for connecting to the server. Thus, the next time you invoke mysqladmin (or any other client program) using the same account, you will need to specify the new password.

If the *new-password* value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
shell> mysqladmin password "my new password"
```

Caution

Do not use this command used if the server was started with the `--skip-grant-tables` [392] option. No password change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- `ping`

  Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. Beginning with MySQL 4.0.22, the status is 0 even in case of an error such as `Access denied`, because that means the server is running but refused the connection, which is different from the server not running.

- `processlist`

  Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` [281] option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See Section 12.4.5.19, “`SHOW PROCESSLIST` Syntax”.)

- `reload`

  Reload the grant tables.

- `refresh`

  Flush all tables and close and open log files.

- `shutdown`

  Stop the server.

- `start-slave`

  Start replication on a slave server. (Added in MySQL 3.23.16.)

- `status`

  Display a short server status message.

- `stop-slave`

  Stop replication on a slave server. (Added in MySQL 3.23.16.)

- `variables`

  Display the server system variables and their values.

- version

  Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+----+-------+-----------+----+---------+------+-------+------------------+
| Id | User  | Host      | db | Command | Time | State | Info             |
+----+-------+-----------+----+---------+------+-------+------------------+
| 51 | monty | localhost |    | Query   | 0    |       | show processlist |
+----+-------+-----------+----+---------+------+-------+------------------+
Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268
```

The mysqladmin status command result displays the following values:

- Uptime [457]

  The number of seconds the MySQL server has been running.

- Threads

  The number of active threads (clients).

- Questions [454]

  The number of questions (queries) from clients since the server was started.

- Slow queries

  The number of queries that have taken more than long_query_time [417] seconds. See Section 5.3.5, “The Slow Query Log”.

- Opens

  The number of tables the server has opened.

- Flush tables

  The number of flush-*, refresh, and reload commands the server has executed.

- Open tables

  The number of tables that currently are open.

- Memory in use

  The amount of memory allocated directly by mysqld. This value is displayed only when MySQL has been compiled with --with-debug=full [98].

- Maximum memory used

  The maximum amount of memory allocated directly by mysqld. This value is displayed only when MySQL has been compiled with --with-debug=full [98].

If you execute mysqladmin shutdown when connecting to a local server using a Unix socket file, mysqladmin waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

mysqladmin supports the following options, which can be specified on the command line or in the [mysqladmin] and [client] option file groups. mysqladmin also supports the options for processing option files described at Command-Line Options that Affect Option-File Handling.

Table 4.3 mysqladmin Options

Format	Option File	Description	Introduced
--compress [280]	compress [280]	Compress all information sent between the client and the server	
--connect_timeout=seconds [282]	connect_timeout [282]	The number of seconds before connection timeout	
--count=# [280]	count [280]	The number of iterations to make for repeated command execution	
--debug[=debug_options] [280]	debug [280]	Write a debugging log	
--default-character-set=charset_name [280]	default-character-set [280]	Use charset_name as the default character set	4.1.9
--force [280]	force [280]	Continue even if an SQL error occurs	
--help [280]		Display help message and exit	
--host=host_name [280]	host [280]	Connect to the MySQL server on the given host	
--password[=password] [280]	password [280]	The password to use when connecting to the server	
--pipe [281]		On Windows, connect to server using a named pipe	
--port=port_num [281]	port [281]	The TCP/IP port number to use for the connection	
--protocol=type [281]	protocol [281]	The connection protocol to use	
--relative [281]	relative [281]	Show the difference between the current and previous values when used with the --sleep option	
--shutdown_timeout=seconds [282]	shutdown_timeout [282]	The maximum number of seconds to wait for server shutdown	
--silent [281]	silent [281]	Silent mode	
--sleep=delay [281]	sleep [281]	Execute commands repeatedly, sleeping for delay seconds in between	
--socket=path [281]	socket [281]	For connections to localhost	
--ssl-ca=file_name [281]	ssl-ca [281]	The path to a file that contains a list of trusted SSL CAs	
--ssl-capath=dir_name [281]	ssl-capath [281]	The path to a directory that contains trusted SSL CA certificates in PEM format	
--ssl-cert=file_name [281]	ssl-cert [281]	The name of the SSL certificate file to use for establishing a secure connection	
--ssl-cipher=cipher_list [281]	ssl-cipher [281]	A list of allowable ciphers to use for SSL encryption	

Format	Option File	Description	Introduced
--ssl-key=file_name [281]	ssl-key [281]	The name of the SSL key file to use for establishing a secure connection	
--ssl-verify-server-cert [281]	ssl-verify-server-cert [281]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
--user=user_name, [281]	user [281]	MySQL user name to use when connecting to server	
--verbose [281]		Verbose mode	
--version [281]		Display version information and exit	
--vertical [282]	vertical [282]	Print query output rows vertically (one line per column value)	
--wait [282]	wait [282]	If the connection cannot be established, wait and retry instead of aborting	

- `--help` [280], `-?`

  Display a help message and exit.

- `--character-sets-dir=`*`path`* [280]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--compress` [280], `-C`

  Compress all information sent between the client and the server if both support compression.

- `--count=`*`N`* [280], `-c` *`N`*

  The number of iterations to make for repeated command execution if the `--sleep` [281] option is given.

- `--debug[=`*`debug_options`*`]` [280], `-#` `[`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o,/tmp/mysqladmin.trace'`.

- `--default-character-set=`*`charset_name`* [280]

  Use *`charset_name`* as the default character set. See Section 9.6, “Character Set Configuration”. Added in MySQL 4.1.9.

- `--force` [280], `-f`

  Do not ask for confirmation for the `drop` *`db_name`* command. With multiple commands, continue even if an error occurs.

- `--host=`*`host_name`* [280], `-h` *`host_name`*

  Connect to the MySQL server on the given host.

- `--password[=`*`password`*`]` [280], `-p[`*`password`*`]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` [280] or `-p` option on the command line, `mysqladmin` prompts for one.

Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--pipe` [281], `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=`*`port_num`* [281], `-P` *`port_num`*

  The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [281]

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”. This option was added in MySQL 4.1.

- `--relative` [281], `-r`

  Show the difference between the current and previous values when used with the `--sleep` [281] option. This option works only with the `extended-status` command.

- `--silent` [281], `-s`

  Exit silently if a connection to the server cannot be established.

- `--sleep=`*`delay`* [281], `-i` *`delay`*

  Execute commands repeatedly, sleeping for *`delay`* seconds in between. The `--count` [280] option determines the number of iterations. If `--count` [280] is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=`*`path`* [281], `-S` *`path`*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` [521] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 5.6.6.3, “SSL Command Options”.

- `--user=`*`user_name`* [281], `-u` *`user_name`*

  The MySQL user name to use when connecting to the server.

- `--verbose` [281], `-v`

  Verbose mode. Print more information about what the program does.

- `--version` [281], `-V`

Display version information and exit.

- `--vertical` [282], `-E`

  Print output vertically. This is similar to `--relative` [281], but prints output vertically.

- `--wait[=count]` [282], `-w[count]`

  If the connection cannot be established, wait and retry instead of aborting. If a *`count`* value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value` syntax:

- `connect_timeout`

  The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `shutdown_timeout`

  The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. However, this syntax is deprecated as of MySQL 4.0.

4.5.3 mysqlcheck — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, and analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see Section 12.3.5, “`LOCK TABLES` and `UNLOCK TABLES` Syntax”, for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. `mysqlcheck` is available as of MySQL 3.23.38.

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to check or repair your tables.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in Section 12.4.2, “Table Maintenance Statements”.

The `MyISAM` storage engine supports all four maintenance operations, so `mysqlcheck` can be used to perform any of them on `MyISAM` tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a `MEMORY` table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
test.t
note     : The storage engine for the table doesn't support check
```

If mysqlcheck is unable to repair a table, see Section 2.11.4, “Rebuilding or Repairing Tables or Indexes” for manual table repair strategies. This will be the case, for example, for InnoDB tables, which can be checked with CHECK TABLE, but not repaired with REPAIR TABLE.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke mysqlcheck:

```
shell> mysqlcheck [options] db_name [tbl_name ...]
shell> mysqlcheck [options] --databases db_name ...
shell> mysqlcheck [options] --all-databases
```

If you do not name any tables following *db_name* or if you use the --databases [285] or --all-databases [285] option, entire databases are checked.

mysqlcheck has a special feature compared to other client programs. The default behavior of checking tables (--check [285]) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of mysqlcheck named mysqlrepair, or make a symbolic link to mysqlcheck named mysqlrepair. If you invoke mysqlrepair, it repairs tables.

The names shown in the following table can be used to change mysqlcheck default behavior.

Command	Meaning
mysqlrepair	The default option is --repair [287]
mysqlanalyze	The default option is --analyze [285]
mysqloptimize	The default option is --optimize [286]

mysqlcheck supports the following options, which can be specified on the command line or in the [mysqlcheck] and [client] option file groups. mysqlcheck also supports the options for processing option files described at Command-Line Options that Affect Option-File Handling.

Table 4.4 mysqlcheck Options

Format	Option File	Description
--all-databases [285]	all-databases [285]	Check all tables in all databases
--all-in-1 [285]	all-in-1 [285]	Execute a single statement for each database that names all the tables from that database
--analyze [285]	analyze [285]	Analyze the tables
--auto-repair [285]	auto-repair [285]	If a checked table is corrupted, automatically fix it
--character-sets-dir=path [285]	character-sets-dir [285]	The directory where character sets are installed
--check [285]	check [285]	Check the tables for errors
--check-only-changed [285]	check-only-changed [285]	Check only tables that have changed since the last check
--compress [285]	compress [285]	Compress all information sent between the client and the server
--databases [285]	databases [285]	Process all tables in the named databases

Format	Option File	Description
--debug[=debug_options] [285]	debug [285]	Write a debugging log
--default-character-set=charset_name [285]	default-character-set [285]	Use charset_name as the default character set
--extended [286]	extended [286]	Check and repair tables
--fast [286]	fast [286]	Check only tables that have not been closed properly
--force [286]	force [286]	Continue even if an SQL error occurs
--help [285]		Display help message and exit
--host=host_name [286]	host [286]	Connect to the MySQL server on the given host
--medium-check [286]	medium-check [286]	Do a check that is faster than an --extended operation
--optimize [286]	optimize [286]	Optimize the tables
--password[=password] [286]	password [286]	The password to use when connecting to the server
--pipe [286]		On Windows, connect to server using a named pipe
--port=port_num [286]	port [286]	The TCP/IP port number to use for the connection
--protocol=type [286]	protocol [286]	The connection protocol to use
--quick [286]	quick [286]	The fastest method of checking
--repair [287]	repair [287]	Perform a repair that can fix almost anything except unique keys that are not unique
--silent [287]	silent [287]	Silent mode
--socket=path [287]	socket [287]	For connections to localhost
--ssl-ca=file_name [287]	ssl-ca [287]	The path to a file that contains a list of trusted SSL CAs
--ssl-capath=dir_name [287]	ssl-capath [287]	The path to a directory that contains trusted SSL CA certificates in PEM format
--ssl-cert=file_name [287]	ssl-cert [287]	The name of the SSL certificate file to use for establishing a secure connection
--ssl-cipher=cipher_list [287]	ssl-cipher [287]	A list of allowable ciphers to use for SSL encryption
--ssl-key=file_name [287]	ssl-key [287]	The name of the SSL key file to use for establishing a secure connection
--ssl-verify-server-cert [287]	ssl-verify-server-cert [287]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server
--tables [287]	tables [287]	Overrides the --databases or -B option
--use-frm [287]	use-frm [287]	For repair operations on MyISAM tables
--user=user_name, [287]	user [287]	MySQL user name to use when connecting to server

Format	Option File	Description
--verbose [287]		Verbose mode
--version [287]		Display version information and exit

- `--help` [285], `-?`

  Display a help message and exit.

- `--all-databases` [285], `-A`

  Check all tables in all databases. This is the same as using the `--databases` [285] option and naming all the databases on the command line.

- `--all-in-1` [285], `-1`

  Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze` [285], `-a`

  Analyze the tables.

- `--auto-repair` [285]

  If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--character-sets-dir=`*`path`* [285]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--check` [285], `-c`

  Check the tables for errors. This is the default operation.

- `--check-only-changed` [285], `-C`

  Check only tables that have changed since the last check or that have not been closed properly.

- `--compress` [285]

  Compress all information sent between the client and the server if both support compression.

- `--databases` [285], `-B`

  Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names.

- `--debug[=`*`debug_options`*`]` [285], `-# [`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o'`.

- `--default-character-set=`*`charset_name`* [285]

  Use *`charset_name`* as the default character set. See Section 9.6, “Character Set Configuration”.

- `--extended` [286], `-e`

  If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

  If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--fast` [286], `-F`

  Check only tables that have not been closed properly.

- `--force` [286], `-f`

  Continue even if an SQL error occurs.

- `--host=host_name` [286], `-h host_name`

  Connect to the MySQL server on the given host.

- `--medium-check` [286], `-m`

  Do a check that is faster than an `--extended` [286] operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--optimize` [286], `-o`

  Optimize the tables.

- `--password[=password]` [286], `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` [286] or `-p` option on the command line, `mysqlcheck` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--pipe` [286], `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=port_num` [286], `-P port_num`

  The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [286]

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”. This option was added in MySQL 4.1.

- `--quick` [286], `-q`

  If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair` [287], `-r`

  Perform a repair that can fix almost anything except unique keys that are not unique.

- `--silent` [287], `-s`

  Silent mode. Print only error messages.

- `--socket=path` [287], `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` [521] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 5.6.6.3, “SSL Command Options”.

- `--tables` [287]

  Override the `--databases` [285] or `-B` option. All name arguments following the option are regarded as table names.

- `--use-frm` [287]

  For repair operations on `MyISAM` tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted. This option was added in MySQL 4.0.5.

- `--user=user_name` [287], `-u user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose` [287], `-v`

  Verbose mode. Print information about the various stages of program operation.

- `--version` [287], `-V`

  Display version information and exit.

4.5.4 `mysqldump` — A Database Backup Program

The `mysqldump` client is a backup program originally written by Igor Romanenko. It can be used to dump a database or a collection of databases for backup or transfer to another SQL server (not necessarily a MySQL server). The dump typically contains SQL statements to create the table, populate it, or both. However, `mysqldump` can also be used to generate files in CSV, other delimited text, or XML format.

If you are doing a backup on the server and your tables all are `MyISAM` tables, consider using the `mysqlhotcopy` instead because it can accomplish faster backups and faster restores. See Section 4.6.8, “`mysqlhotcopy` — A Database Backup Program”.

There are three general ways to invoke `mysqldump`:

```
shell> mysqldump [options] db_name [tbl_name ...]
shell> mysqldump [options] --databases db_name ...
```

```
shell> mysqldump [options] --all-databases
```

If you do not name any tables following *db_name* or if you use the --databases [294] or --all-databases [293] option, entire databases are dumped.

To see a list of the options your version of mysqldump supports, execute mysqldump --help.

Some mysqldump options are shorthand for groups of other options:

- Use of --opt [297] is the same as specifying --add-drop-table [293], --add-locks [293], --create-options [294], --disable-keys [294], --extended-insert [294], --lock-tables [295], --quick [298], and --set-charset [298]. As of MySQL 4.1, all of the options that --opt [297] stands for also are on by default because --opt [297] is on by default.
- Use of --compact [293] is the same as specifying --skip-add-drop-table [293], --skip-add-locks [293], --skip-comments [299], --skip-disable-keys [294], and --skip-set-charset [298] options.

To reverse the effect of a group option, uses its --skip-*xxx* form (--skip-opt [299] or --skip-compact [293]). It is also possible to select only part of the effect of a group option by following it with options that enable or disable specific features. Here are some examples:

- To select the effect of --opt [297] except for some features, use the --skip option for each feature. To disable extended inserts and memory buffering, use --opt [297] --skip-extended-insert [294] --skip-quick [298]. (As of MySQL 4.1, --skip-extended-insert [294] --skip-quick [298] is sufficient because --opt [297] is on by default.)
- To reverse --opt [297] for all features except index disabling and table locking, use --skip-opt [299] --disable-keys [294] --lock-tables [295].

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, --disable-keys [294] --lock-tables [295] --skip-opt [299] would not have the intended effect; it is the same as --skip-opt [299] by itself.

mysqldump can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the --quick [298] option (or --opt [297], which enables --quick [298]). The --opt [297] option (and hence --quick [298]) is enabled by default as of MySQL 4.1, so to enable memory buffering, use --skip-quick [298].

If you are using a recent version of mysqldump to generate a dump to be reloaded into a very old MySQL server, you should not use the --opt [297] or --extended-insert [294] option. Use --skip-opt [299] instead.

Before MySQL 4.1.2, out-of-range numeric values such as -inf and inf, as well as NaN (not-a-number) values are dumped by mysqldump as NULL. You can see this using the following sample table:

```
mysql> CREATE TABLE t (f DOUBLE);
mysql> INSERT INTO t VALUES(1e+11111111111111111111);
mysql> INSERT INTO t VALUES(-1e11111111111111111111);
mysql> SELECT f FROM t;
+------+
| f    |
+------+
|  inf |
| -inf |
+------+
```

For this table, mysqldump produces the following data output:

```
--
-- Dumping data for table `t`
--

INSERT INTO t VALUES (NULL);
INSERT INTO t VALUES (NULL);
```

The significance of this behavior is that if you dump and restore the table, the new table has contents that differ from the original contents. This problem is fixed as of MySQL 4.1.2; you cannot insert `inf` in the table, so this `mysqldump` behavior is only relevant when you deal with old servers.

For additional information about `mysqldump`, see Section 6.4, “Using mysqldump for Backups”.

`mysqldump` supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` option file groups. `mysqldump` also supports the options for processing option files described at Command-Line Options that Affect Option-File Handling.

Table 4.5 `mysqldump` Options

Format	Option File	Description	Introduced	Deprecated
--add-drop-database [292]	add-drop-database [292]	Add a DROP DATABASE statement before each CREATE DATABASE statement	4.1.13	
--add-drop-table [293]	add-drop-table [293]	Add a DROP TABLE statement before each CREATE TABLE statement		
--add-locks [293]	add-locks [293]	Surround each table dump with LOCK TABLES and UNLOCK TABLES statements		
--all-databases [293]	all-databases [293]	Dump all tables in all databases		
--allow-keywords [293]	allow-keywords [293]	Allow creation of column names that are keywords		
--comments [293]	comments [293]	Add comments to the dump file		
--compact [293]	compact [293]	Produce more compact output		
--compatible=name[,name,...] [293]	compatible [293]	Produce output that is more compatible with other database systems or with older MySQL servers		
--complete-insert [293]	complete-insert [293]	Use complete INSERT statements that include column names		
--create-options [294]	create-options [294]	Include all MySQL-specific table options in CREATE TABLE statements		
--databases [294]	databases [294]	Dump several databases		
--debug[=debug_options] [294]	debug [294]	Write a debugging log		
--default-character-set=charset_name [294]	default-character-set [294]	Use charset_name as the default character set		
--delayed-insert [294]	delayed-insert [294]	Write INSERT DELAYED statements rather than INSERT statements		

Format	Option File	Description	Introduced	Deprecated
--delete-master-logs [294]	delete-master-logs [294]	On a master replication server, delete the binary logs after performing the dump operation		
--disable-keys [294]	disable-keys [294]	For each table, surround the INSERT statements with statements to disable and enable keys		
--extended-insert [294]	extended-insert [294]	Use multiple-row INSERT syntax that include several VALUES lists		
--fields-enclosed-by=string [294]	fields-enclosed-by [294]	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--fields-escaped-by [294]	fields-escaped-by [294]	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--fields-optionally-enclosed-by=string [294]	fields-optionally-enclosed-by [294]	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--fields-terminated-by=string [294]	fields-terminated-by [294]	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--first-slave [294]	first-slave [294]	Deprecated; use --lock-all-tables instead		4.1.0
--flush-logs [294]	flush-logs [294]	Flush the MySQL server log files before starting the dump		
--help [292]		Display help message and exit		
--hex-blob [295]	hex-blob [295]	Dump binary columns using hexadecimal notation (for example, 'abc' becomes 0x616263)		
--host [295]	host [295]	Host to connect to (IP address or hostname)		
--ignore-table=db_name.tbl_name [295]	ignore-table [295]	Do not dump the given table		
--insert-ignore [295]	insert-ignore [295]	Write INSERT IGNORE statements rather than INSERT statements	4.1.12	
--lines-terminated-by=string [295]	lines-terminated-by [295]	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--lock-all-tables [295]	lock-all-tables [295]	Lock all tables across all databases		
--lock-tables [295]	lock-tables [295]	Lock all tables before dumping them		
--master-data[=value] [296]	master-data [296]	Write the binary log file name and position to the output		
--max_allowed_packet=value [300]	max_allowed_packet [300]	The maximum packet length to send to or receive from the server		

Format	Option File	Description	Introduced	Deprecated
--net_buffer_length=value [300]	net_buffer_length [300]	The buffer size for TCP/IP and socket communication		
--no-autocommit [297]	no-autocommit [297]	Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements		
--no-create-db [297]	no-create-db [297]	This option suppresses the CREATE DATABASE statements		
--no-create-info [297]	no-create-info [297]	Do not write CREATE TABLE statements that re-create each dumped table		
--no-data [297]	no-data [297]	Do not dump table contents		
--no-set-names [297]	no-set-names [297]	Same as --skip-set-charset		4.1.0
--opt [297]	opt [297]	Shorthand for --add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset.		
--order-by-primary [297]	order-by-primary [297]	Dump each table's rows sorted by its primary key, or by its first unique index		
--password[=password] [297]	password [297]	The password to use when connecting to the server		
--pipe [297]		On Windows, connect to server using a named pipe		
--port=port_num [297]	port [297]	The TCP/IP port number to use for the connection		
--protocol=type [298]	protocol [298]	The connection protocol to use		
--quick [298]	quick [298]	Retrieve rows for a table from the server a row at a time		
--quote-names [298]	quote-names [298]	Quote identifiers within backtick characters		
--result-file=file [298]	result-file [298]	Direct output to a given file		
--set-charset [298]	set-charset [298]	Add SET NAMES default_character_set to output		
--single-transaction [298]	single-transaction [298]	This option issues a BEGIN SQL statement before dumping data from the server		
--skip-add-drop-table [293]	skip-add-drop-table [293]	Do not add a DROP TABLE statement before each CREATE TABLE statement		
--skip-add-locks [293]	skip-add-locks [293]	Do not add locks		
--skip-comments [299]	skip-comments [299]	Do not add comments to the dump file		
--skip-compact [293]	skip-compact [293]	Do not produce more compact output		

Format	Option File	Description	Introduced	Deprecated
--skip-disable-keys [294]	skip-disable-keys [294]	Do not disable keys		
--skip-extended-insert [294]	skip-extended-insert [294]	Turn off extended-insert		
--skip-opt [299]	skip-opt [299]	Turn off the options set by --opt		
--skip-quick [298]	skip-quick [298]	Do not retrieve rows for a table from the server a row at a time		
--skip-quote-names [298]	skip-quote-names [298]	Do not quote identifiers		
--skip-set-charset [298]	skip-set-charset [298]	Suppress the SET NAMES statement		
--socket=path [299]	socket [299]	For connections to localhost		
--ssl-ca=file_name [299]	ssl-ca [299]	The path to a file that contains a list of trusted SSL CAs		
--ssl-capath=dir_name [299]	ssl-capath [299]	The path to a directory that contains trusted SSL CA certificates in PEM format		
--ssl-cert=file_name [299]	ssl-cert [299]	The name of the SSL certificate file to use for establishing a secure connection		
--ssl-cipher=cipher_list [299]	ssl-cipher [299]	A list of allowable ciphers to use for SSL encryption		
--ssl-key=file_name [299]	ssl-key [299]	The name of the SSL key file to use for establishing a secure connection		
--ssl-verify-server-cert [299]	ssl-verify-server-cert [299]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server		
--tab=path [299]	tab [299]	Produce tab-separated data files		
--tables [299]	tables [299]	Override the --databases or -B option		
--user=user_name [299]	user [299]	MySQL user name to use when connecting to server		
--verbose [299]		Verbose mode		
--version [299]		Display version information and exit		
--where='where_condition' [300]	where [300]	Dump only rows selected by the given WHERE condition		
--xml [300]	xml [300]	Produce XML output		

- `--help` [292], `-?`

  Display a help message and exit.

- `--add-drop-database` [292]

  Add a `DROP DATABASE` statement before each `CREATE DATABASE` statement. Added in MySQL 4.1.13.

- --add-drop-table [293]

  Add a DROP TABLE statement before each CREATE TABLE statement. This option is typically used in conjunction with the --all-databases [293] or --databases [294] option because no CREATE DATABASE statements are written unless one of those options is specified.

- --add-locks [293]

  Surround each table dump with LOCK TABLES and UNLOCK TABLES statements. This results in faster inserts when the dump file is reloaded. See Section 7.3.2.1, “Speed of INSERT Statements”.

- --all-databases [293], -A

  Dump all tables in all databases. This is the same as using the --databases [294] option and naming all the databases on the command line.

- --allow-keywords [293]

  Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- --character-sets-dir=*path* [293]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- --comments [293], -i

  Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use --skip-comments [299]. This option was added in MySQL 4.0.17.

- --compact [293]

  Produce more compact output. This option enables the --skip-add-drop-table [293], --skip-add-locks [293], --skip-comments [299], --skip-disable-keys [294], and --skip-set-charset [298] options. Added in MySQL 4.1.2.

- --compatible=*name* [293]

  Produce output that is more compatible with other database systems or with older MySQL servers. The value of *name* can be ansi, mysql323, mysql40, postgresql, oracle, mssql, db2, maxdb, no_key_options, no_table_options, or no_field_options. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See Section 5.1.6, “Server SQL Modes”.

  This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, --compatible=oracle [293] does not map data types to Oracle types or use Oracle comment syntax.

  This option requires a server version of 4.1.0 or higher. With older servers, it does nothing.

- --complete-insert [293], -c

  Use complete INSERT statements that include column names.

- --compress [293], -C

  Compress all information sent between the client and the server if both support compression.

- --create-options [294]

  Include all MySQL-specific table options in the CREATE TABLE statements. Before MySQL 4.1.2, use --all instead.

- --databases [294], -B

  Dump several databases. Normally, mysqldump treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. CREATE DATABASE and USE statements are included in the output before each new database.

- --debug[=*debug_options*] [294], -# [*debug_options*]

  Write a debugging log. A typical *debug_options* string is 'd:t:o,*file_name*'. The default value is 'd:t:o,/tmp/mysqldump.trace'.

- --default-character-set=*charset_name* [294]

  Use *charset_name* as the default character set. See Section 9.6, “Character Set Configuration”. If no character set is specified, mysqldump from MySQL 4.1.2 or later uses utf8, and earlier versions use latin1.

- --delayed-insert [294]

  Write INSERT DELAYED statements rather than INSERT statements.

- --delete-master-logs [294]

  On a master replication server, delete the binary logs by sending a RESET MASTER statement to the server after performing the dump operation. This option automatically enables --first-slave [294] before MySQL 4.1.8 and enables --master-data [296] thereafter. It was added in MySQL 3.23.57 (for MySQL 3.23) and MySQL 4.0.13 (for MySQL 4.0).

- --disable-keys [294], -K

  For each table, surround the INSERT statements with /*!40000 ALTER TABLE *tbl_name* DISABLE KEYS */; and /*!40000 ALTER TABLE *tbl_name* ENABLE KEYS */; statements. This makes loading the dump file into a MySQL 4.0 or newer server faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of MyISAM tables. only.

- --extended-insert [294], -e

  Use multiple-row INSERT syntax that include several VALUES lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- --fields-terminated-by=... [294], --fields-enclosed-by=... [294], --fields-optionally-enclosed-by=... [294], --fields-escaped-by=... [294]

  These options are used with the --tab [299] option and have the same meaning as the corresponding FIELDS clauses for LOAD DATA INFILE. See Section 12.2.5, “LOAD DATA INFILE Syntax”.

- --first-slave [294]

  Deprecated. Use --lock-all-tables [295] instead as of MySQL 4.1.8.

- --flush-logs [294], -F

Flush the MySQL server log files before starting the dump. This option requires the RELOAD [492] privilege. If you use this option in combination with the --all-databases [293] option, the logs are flushed *for each database dumped*. The exception is when using --lock-all-tables [295] or --master-data [296]: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked. If you want your dump and the log flush to happen at exactly the same moment, you should use --flush-logs [294] together with either --lock-all-tables [295] or --master-data [296].

- --force [295], -f

  Continue even if an SQL error occurs during a table dump.

- --host=*host_name* [295], -h *host_name*

  Dump data from the MySQL server on the given host. The default host is localhost.

- --hex-blob [295]

  Dump binary columns using hexadecimal notation (for example, 'abc' becomes 0x616263). The affected data types are BINARY, VARBINARY, and the BLOB types in MySQL 4.1 and up, and CHAR BINARY, VARCHAR BINARY, and BLOB in MySQL 4.0. This option was added in MySQL 4.0.23 and 4.1.8.

- --ignore-table=*db_name.tbl_name* [295]

  Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option was added in MySQL 4.1.9.

- --insert-ignore [295]

  Write INSERT IGNORE statements rather than INSERT statements. This option was added in MySQL 4.1.12.

- --lines-terminated-by=... [295]

  This option is used with the --tab [299] option and has the same meaning as the corresponding LINES clause for LOAD DATA INFILE. See Section 12.2.5, “LOAD DATA INFILE Syntax”.

- --lock-all-tables [295], -x

  Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off --single-transaction [298] and --lock-tables [295]. Added in MySQL 4.1.8.

- --lock-tables [295], -l

  For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with READ LOCAL to permit concurrent inserts in the case of MyISAM tables. For transactional tables such as InnoDB and BDB, --single-transaction [298] is a much better option than --lock-tables [295] because it does not need to lock the tables at all.

  Because --lock-tables [295] locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

  This option has no effect for output data files produced by using the --tab [299] option. See the description for that option.

- `--master-data[=value]` [296]

  Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the master server coordinates from which the slave should start replicating after you load the dump file into the slave.

  If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1. The value may be given as of MySQL 4.1.8; before that, do not specify an option value.

  This option requires the `RELOAD` [492] privilege and the binary log must be enabled.

  The `--master-data` [296] option automatically turns off `--lock-tables` [295]. It also turns on `--lock-all-tables` [295], unless `--single-transaction` [298] also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction` [298]). In all cases, any action on logs happens at the exact moment of the dump.

  It is also possible to set up a slave by dumping an existing slave of the master. To do this, use the following procedure on the existing slave:

  1. Stop the slave's SQL thread and get its current status:

     ```
     mysql> STOP SLAVE SQL_THREAD;
     mysql> SHOW SLAVE STATUS;
     ```

  2. From the output of the `SHOW SLAVE STATUS` statement, the binary log coordinates of the master server from which the new slave should start replicating are the values of the `Relay_Master_Log_File` and `Exec_Master_Log_Pos` fields. Denote those values as *`file_name`* and *`file_pos`*.

  3. Dump the slave server:

     ```
     shell> mysqldump --master-data=2 --all-databases > dumpfile
     ```

  4. Restart the slave:

     ```
     mysql> START SLAVE;
     ```

  5. On the new slave, load the dump file:

     ```
     shell> mysql < dumpfile
     ```

  6. On the new slave, set the replication coordinates to those of the master server obtained earlier:

     ```
     mysql> CHANGE MASTER TO
         -> MASTER_LOG_FILE = 'file_name', MASTER_LOG_POS = file_pos;
     ```

     The `CHANGE MASTER TO` statement might also need other parameters, such as `MASTER_HOST` to point the slave to the correct master server host. Add any such parameters as necessary.

- `--no-autocommit` [297]

  Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- `--no-create-db` [297], `-n`

  This option suppresses the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` [294] or `--all-databases` [293] option is given.

- `--no-create-info` [297], `-t`

  Do not write `CREATE TABLE` statements that re-create each dumped table.

- `--no-data` [297], `-d`

  Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- `--no-set-names` [297], `-N`

  This has the same effect as `--skip-set-charset` [298].

- `--opt` [297]

  This option is shorthand. It is the same as specifying `--add-drop-table` [293] `--add-locks` [293] `--create-options` [294] `--disable-keys` [294] `--extended-insert` [294] `--lock-tables` [295] `--quick` [298] `--set-charset` [298]. It should give you a fast dump operation and produce a dump file that can be reloaded into a MySQL server quickly.

  As of MySQL 4.1, `--opt` [297] is enabled by default. Use `--skip-opt` [299] to disable it. See the discussion at the beginning of this section for information about selectively enabling or disabling a subset of the options affected by `--opt` [297].

- `--order-by-primary` [297]

  Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a `MyISAM` table to be loaded into an `InnoDB` table, but will make the dump operation take considerably longer. This option was added in MySQL 4.1.8.

- `--password[=`*`password`*`]` [297], `-p[`*`password`*`]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` [297] or `-p` option on the command line, `mysqldump` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--pipe` [297], `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=`*`port_num`* [297], `-P` *`port_num`*

  The TCP/IP port number to use for the connection.

- --protocol={TCP|SOCKET|PIPE|MEMORY} [298]

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”. This option was added in MySQL 4.1.

- --quick [298], -q

  This option is useful for dumping large tables. It forces mysqldump to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- --quote-names [298], -Q

  Quote identifiers (such as database, table, and column names) within “`” characters. If the ANSI_QUOTES [458] SQL mode is enabled, identifiers are quoted within “"” characters. As of MySQL 4.1.1, --quote-names [298] is enabled by default. It can be disabled with --skip-quote-names [298], but this option should be given after any option such as --compatible [293] that may enable --quote-names [298].

- --result-file=*file_name* [298], -r *file_name*

  Direct output to a given file. This option should be used on Windows to prevent newline “\n” characters from being converted to “\r\n” carriage return/newline sequences. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

- --set-charset [298]

  Add SET NAMES *default_character_set* to the output. This option is enabled by default. To suppress the SET NAMES statement, use --skip-set-charset [298]. This option was added in MySQL 4.1.2.

- --single-transaction [298]

  This option sends a START TRANSACTION SQL statement to the server before dumping data. It is useful only with transactional tables such as InnoDB and BDB, because then it dumps the consistent state of the database at the time when BEGIN was issued without blocking any applications.

  When using this option, you should keep in mind that only InnoDB tables are dumped in a consistent state. For example, any MyISAM or MEMORY tables dumped while using this option may still change state.

  While a --single-transaction [298] dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: ALTER TABLE, CREATE TABLE, DROP TABLE, RENAME TABLE, TRUNCATE TABLE. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the SELECT that is performed by mysqldump to retrieve the table contents to obtain incorrect contents or fail.

  The --single-transaction [298] option was added in MySQL 4.0.2. This option is mutually exclusive with the --lock-tables [295] option because LOCK TABLES causes any pending transactions to be committed implicitly.

  This option is not supported for MySQL Cluster tables; the results cannot be guaranteed to be consistent due to the fact that the NDBCLUSTER storage engine supports only the READ_COMMITTED transaction isolation level. You should always use NDB backup and restore instead.

To dump large tables, combine the --single-transaction [298] option with the --quick [298] option.

- --skip-comments [299]

  See the description for the --comments [293] option.

- --skip-opt [299]

  See the description for the --opt [297] option.

- --socket=*path* [299], -S *path*

  For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- --ssl*

  Options that begin with --ssl [521] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 5.6.6.3, “SSL Command Options”.

- --tab=*path* [299], -T *path*

  Produce tab-separated text-format data files. For each dumped table, mysqldump creates a *tbl_name*.sql file that contains the CREATE TABLE statement that creates the table, and the server writes a *tbl_name*.txt file that contains its data. The option value is the directory in which to write the files.

  

  Note

  This option should be used only when mysqldump is run on the same machine as the mysqld server. You must have the FILE [491] privilege, and the server must have permission to write files in the directory that you specify.

  By default, the .txt data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the --fields-*xxx* and --lines-terminated-by [295] options.

  Column values are dumped using the binary character set and the --default-character-set [294] option is ignored. In effect, there is no character set conversion. If a table contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

- --tables [299]

  Override the --databases [294] or -B option. mysqldump regards all name arguments following the option as table names.

- --user=*user_name* [299], -u *user_name*

  The MySQL user name to use when connecting to the server.

- --verbose [299], -v

  Verbose mode. Print more information about what the program does.

- --version [299], -V

Display version information and exit.

- --where='*where_condition*' [300], -w '*where_condition*'

  Dump only rows selected by the given WHERE condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

  Examples:

```
--where="user='jimf'"
-w"userid>1"
-w"userid<1"
```

- --xml [300], -X

  Write dump output as well-formed XML.

You can also set the following variables by using --*var_name*=*value* syntax:

- max_allowed_packet

  The maximum size of the buffer for client/server communication. The default is 24MB. The maximum can be up to 16MB before MySQL 4.0, and up to 1GB from MySQL 4.0 on.

- net_buffer_length [422]

  The initial size of the buffer for client/server communication. When creating multiple-row INSERT statements (as with the --extended-insert [294] or --opt [297] option), mysqldump creates rows up to net_buffer_length [422] length. If you increase this variable, you should also ensure that the net_buffer_length [422] variable in the MySQL server is at least this large.

It is also possible to set variables by using --set-variable=*var_name*=*value* or -O *var_name*=*value* syntax. However, this syntax is deprecated as of MySQL 4.0.

A common use of mysqldump is for making a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

You can load the dump file back into the server like this:

```
shell> mysql db_name < backup-file.sql
```

Or like this:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

mysqldump is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the --all-databases [293] option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, mysqldump provides a way of making an online backup:

```
shell> mysqldump --all-databases --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using FLUSH TABLES WITH READ LOCK) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the FLUSH statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see Section 5.3.4, “The Binary Log”) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2
            > all_databases.sql
```

The --master-data [296] and --single-transaction [298] options can be used simultaneously as of MySQL 4.1.8, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

For more information on making backups, see Section 6.2, “Database Backup Methods”, and Section 6.3, “Example Backup and Recovery Strategy”.

4.5.5 mysqlimport — A Data Import Program

The mysqlimport client provides a command-line interface to the LOAD DATA INFILE SQL statement. Most options to mysqlimport correspond directly to clauses of LOAD DATA INFILE syntax. See Section 12.2.5, “LOAD DATA INFILE Syntax”.

Invoke mysqlimport like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, mysqlimport strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named patient.txt, patient.text, and patient all would be imported into a table named patient.

mysqlimport supports the following options, which can be specified on the command line or in the [mysqlimport] and [client] option file groups. mysqlimport also supports the options for processing option files described at Command-Line Options that Affect Option-File Handling.

Table 4.6 mysqlimport Options

Format	Option File	Description
--columns=column_list [303]	columns [303]	This option takes a comma-separated list of column names as its value
--compress [303]	compress [303]	Compress all information sent between the client and the server
--debug[=debug_options] [303]	debug [303]	Write a debugging log
--default-character-set=charset_name [303]	default-character-set [303]	Use charset_name as the default character set
--delete [303]	delete [303]	Empty the table before importing the text file
--fields-enclosed-by=string [303]	fields-enclosed-by [303]	This option has the same meaning as the corresponding clause for LOAD DATA INFILE
--fields-escaped-by [303]	fields-escaped-by [303]	This option has the same meaning as the corresponding clause for LOAD DATA INFILE
--fields-optionally-enclosed-by=string [303]	fields-optionally-enclosed-by [303]	This option has the same meaning as the corresponding clause for LOAD DATA INFILE
--fields-terminated-by=string [303]	fields-terminated-by [303]	-- This option has the same meaning as the corresponding clause for LOAD DATA INFILE
--force [304]	force [304]	Continue even if an SQL error occurs
--help [303]		Display help message and exit
--host=host_name [304]	host [304]	Connect to the MySQL server on the given host
--ignore [304]	ignore [304]	See the description for the --replace option
--ignore-lines=# [304]	ignore-lines [304]	Ignore the first N lines of the data file
--lines-terminated-by=string [304]	lines-terminated-by [304]	This option has the same meaning as the corresponding clause for LOAD DATA INFILE
--local [304]	local [304]	Read input files locally from the client host
--lock-tables [304]	lock-tables [304]	Lock all tables for writing before processing any text files
--low-priority [304]	low-priority [304]	Use LOW_PRIORITY when loading the table.
--password[=password] [304]	password [304]	The password to use when connecting to the server
--pipe [304]		On Windows, connect to server using a named pipe
--port=port_num [304]	port [304]	The TCP/IP port number to use for the connection
--protocol=type [304]	protocol [304]	The connection protocol to use
--replace [305]	replace [305]	The --replace and --ignore options control handling of input rows that duplicate existing rows on unique key values
--silent [305]	silent [305]	Produce output only when errors occur
--socket=path [305]	socket [305]	For connections to localhost

Format	Option File	Description
--ssl-ca=file_name [305]	ssl-ca [305]	The path to a file that contains a list of trusted SSL CAs
--ssl-capath=dir_name [305]	ssl-capath [305]	The path to a directory that contains trusted SSL CA certificates in PEM format
--ssl-cert=file_name [305]	ssl-cert [305]	The name of the SSL certificate file to use for establishing a secure connection
--ssl-cipher=cipher_list [305]	ssl-cipher [305]	A list of allowable ciphers to use for SSL encryption
--ssl-key=file_name [305]	ssl-key [305]	The name of the SSL key file to use for establishing a secure connection
--ssl-verify-server-cert [305]	ssl-verify-server-cert [305]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server
--user=user_name, [305]	user [305]	MySQL user name to use when connecting to server
--verbose [305]		Verbose mode
--version [305]		Display version information and exit

- `--help` [303], `-?`

  Display a help message and exit.

- `--character-sets-dir=`*`path`* [303]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--columns=`*`column_list`* [303], `-c` *`column_list`*

  This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress` [303], `-C`

  Compress all information sent between the client and the server if both support compression.

- `--debug[=`*`debug_options`*`]` [303], `-#` `[`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o'`.

- `--default-character-set=`*`charset_name`* [303]

  Use *`charset_name`* as the default character set. See Section 9.6, “Character Set Configuration”.

- `--delete` [303], `-D`

  Empty the table before importing the text file.

- `--fields-terminated-by=...` [303], `--fields-enclosed-by=...` [303], `--fields-optionally-enclosed-by=...` [303], `--fields-escaped-by=...` [303]

  These options have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See Section 12.2.5, “`LOAD DATA INFILE` Syntax”.

- `--force` [304], `-f`

  Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force` [304], `mysqlimport` exits if a table does not exist.

- `--host=host_name` [304], `-h host_name`

  Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore` [304], `-i`

  See the description for the `--replace` [305] option.

- `--ignore-lines=N` [304]

  Ignore the first `N` lines of the data file.

- `--lines-terminated-by=...` [304]

  This option has the same meaning as the corresponding clause for `LOAD DATA INFILE`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n"` [304]. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See Section 12.2.5, “`LOAD DATA INFILE` Syntax”.

- `--local` [304], `-L`

  Read input files locally from the client host.

- `--lock-tables` [295], `-l`

  Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--low-priority` [304]

  Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `--password[=password]` [304], `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` [304] or `-p` option on the command line, `mysqlimport` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--pipe` [304], `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=port_num` [304], `-P port_num`

  The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [304]

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”. This option was added in MySQL 4.1.

- `--replace` [305], `-r`

  The `--replace` [305] and `--ignore` [304] options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace` [305], new rows replace existing rows that have the same unique key value. If you specify `--ignore` [304], input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--silent` [305], `-s`

  Silent mode. Produce output only when errors occur.

- `--socket=`*`path`* [305], `-S` *`path`*

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` [521] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 5.6.6.3, “SSL Command Options”.

- `--user=`*`user_name`* [305], `-u` *`user_name`*

  The MySQL user name to use when connecting to the server.

- `--verbose` [305], `-v`

  Verbose mode. Print more information about what the program does.

- `--version` [305], `-V`

  Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE imptest(id INT, n VARCHAR(30))' test
shell> ed
a
100     Max Sydow
101     Count Dracula
.
w imptest.txt
32
q
shell> od -c imptest.txt
0000000   1   0   0  \t   M   a   x       S   y   d   o   w  \n   1   0
0000020   1  \t   C   o   u   n   t       D   r   a   c   u   l   a  \n
0000040
shell> mysqlimport --local test imptest.txt
test.imptest: Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
shell> mysql -e 'SELECT * FROM imptest' test
+------+---------------+
| id   | n             |
+------+---------------+
```

```
|  100 | Max Sydow     |
|  101 | Count Dracula |
+------+---------------+
```

4.5.6 mysqlshow — Display Database, Table, and Column Information

The mysqlshow client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

mysqlshow provides a command-line interface to several SQL SHOW statements. See Section 12.4.5, “SHOW Syntax”. The same information can be obtained by using those statements directly. For example, you can issue them from the mysql client program.

Invoke mysqlshow like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (“*”, “?”, “%”, or “_”), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. “*” and “?” characters are converted into SQL “%” and “_” wildcard characters. This might cause some confusion when you try to display the columns for a table with a “_” in the name, because in this case, mysqlshow shows you only the table names that match the pattern. This is easily fixed by adding an extra “%” last on the command line as a separate argument.

mysqlshow supports the following options, which can be specified on the command line or in the [mysqlshow] and [client] option file groups. mysqlshow also supports the options for processing option files described at Command-Line Options that Affect Option-File Handling.

Table 4.7 mysqlshow Options

Format	Option File	Description
--compress [307]	compress [307]	Compress all information sent between the client and the server
--debug[=debug_options] [307]	debug [307]	Write a debugging log
--default-character-set=charset_name [307]	default-character-set [307]	Use charset_name as the default character set
--help [307]		Display help message and exit
--host=host_name [307]	host [307]	Connect to the MySQL server on the given host
--keys [307]	keys [307]	Show table indexes
--password[=password] [308]	password [308]	The password to use when connecting to the server
--pipe [308]		On Windows, connect to server using a named pipe

Format	Option File	Description
--port=port_num [308]	port [308]	The TCP/IP port number to use for the connection
--protocol=type [308]	protocol [308]	The connection protocol to use
--socket=path [308]	socket [308]	For connections to localhost
--ssl-ca=file_name [308]	ssl-ca [308]	The path to a file that contains a list of trusted SSL CAs
--ssl-capath=dir_name [308]	ssl-capath [308]	The path to a directory that contains trusted SSL CA certificates in PEM format
--ssl-cert=file_name [308]	ssl-cert [308]	The name of the SSL certificate file to use for establishing a secure connection
--ssl-cipher=cipher_list [308]	ssl-cipher [308]	A list of allowable ciphers to use for SSL encryption
--ssl-key=file_name [308]	ssl-key [308]	The name of the SSL key file to use for establishing a secure connection
--ssl-verify-server-cert [308]	ssl-verify-server-cert [308]	The server's Common Name value in its certificate is verified against the host name used when connecting to the server
--status [308]	status [308]	Display extra information about each table
--user=user_name, [308]	user [308]	MySQL user name to use when connecting to server
--verbose [308]		Verbose mode
--version [308]		Display version information and exit

- `--help` [307], `-?`

  Display a help message and exit.

- `--character-sets-dir=`*`path`* [307]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--compress` [307], `-C`

  Compress all information sent between the client and the server if both support compression.

- `--debug[=`*`debug_options`*`]` [307], `-# [`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o'`.

- `--default-character-set=`*`charset_name`* [307]

  Use *`charset_name`* as the default character set. See Section 9.6, “Character Set Configuration”.

- `--host=`*`host_name`* [307], `-h` *`host_name`*

  Connect to the MySQL server on the given host.

- `--keys` [307], `-k`

Show table indexes.

- `--password[=password]` [308], `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` [308] or `-p` option on the command line, `mysqlshow` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line. You can use an option file to avoid giving the password on the command line.

- `--pipe` [308], `-W`

  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--port=port_num` [308], `-P port_num`

  The TCP/IP port number to use for the connection.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [308]

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”. This option was added in MySQL 4.1.

- `--socket=path` [308], `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` [521] specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 5.6.6.3, “SSL Command Options”.

- `--status` [308], `-i`

  Display extra information about each table.

- `--user=user_name` [308], `-u user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose` [308], `-v`

  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version` [308], `-V`

  Display version information and exit.

  Some options, such as `--opt` [297], automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

4.6 MySQL Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

4.6.1 `myisam_ftdump` — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The *`tbl_name`* argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable` that has the following definition:

```
CREATE TABLE mytexttable
(
  id   INT NOT NULL,
  txt  TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
) ENGINE=MyISAM;
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this:

```
shell> myisam_ftdump -c mytexttable 1 | sort -r
```

`myisam_ftdump` supports the following options:

- `--help` [309], `-h` `-?`

  Display a help message and exit.

- `--count` [310], `-c`

  Calculate per-word statistics (counts and global weights).

- `--dump` [310], `-d`

  Dump the index, including data offsets and word weights.

- `--length` [310], `-l`

  Report the length distribution.

- `--stats` [310], `-s`

  Report global index statistics. This is the default operation if no other operation is specified.

- `--verbose` [310], `-v`

  Verbose mode. Print more output about what the program does.

4.6.2 myisamchk — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with `MyISAM` tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). A related utility, `isamchk`, works with `ISAM` tables (tables that have `.ISD` and `.ISM` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables. See Section 12.4.2.3, “`CHECK TABLE` Syntax”, and Section 12.4.2.6, “`REPAIR TABLE` Syntax”.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The *`options`* specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the `MyISAM` tables in that directory like this:

```
```

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all MyISAM and ISAM tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
shell> isamchk --silent /path/to/datadir/*/*.ISM
```

If you want to check all MyISAM and ISAM tables and repair any that are corrupted, you can use the following commands:

```
shell> myisamchk --silent --force --fast --update-state \
          --key_buffer_size=64M --sort_buffer_size=64M \
          --read_buffer_size=1M --write_buffer_size=1M \
          /path/to/datadir/*/*.MYI
shell> isamchk --silent --force --key_buffer_size=64M \
          --sort_buffer_size=64M --read_buffer_size=1M --write_buffer_size=1M \
          /path/to/datadir/*/*.ISM
```

These commands assume that you have more than 64MB free. For more information about memory allocation with myisamchk, see Section 4.6.2.6, “myisamchk Memory Usage”.

For additional information about using myisamchk, see Section 6.6, “MyISAM Table Maintenance and Crash Recovery”.

Important

You must ensure that no other program is using the tables while you are running myisamchk. The most effective means of doing so is to shut down the MySQL server while running myisamchk, or to lock all tables that myisamchk is being used on.

Otherwise, when you run myisamchk, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the mysqld server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more MyISAM tables.

If mysqld is running, you must force it to flush any table modifications that are still buffered in memory by using FLUSH TABLES. You should then ensure that no one is using the tables while you are running myisamchk

However, the easiest way to avoid this problem is to use CHECK TABLE instead of myisamchk to check tables. See Section 12.4.2.3, “CHECK TABLE Syntax”.

myisamchk supports the following options, which can be specified on the command line or in the [myisamchk] option file group. myisamchk also supports the options for processing option files described at Command-Line Options that Affect Option-File Handling.

Table 4.8 myisamchk Options

Format	Option File	Description
--analyze [318]	analyze [318]	Analyze the distribution of key values
--backup [317]	backup [317]	Make a backup of the .MYD file as file_name-time.BAK
--block-search=offset [318]	block-search [318]	Find the record that a block at the given offset belongs to
--check [316]	check [316]	Check the table for errors
--check-only-changed [316]	check-only-changed [316]	Check only tables that have changed since the last check
--correct-checksum [317]	correct-checksum [317]	Correct the checksum information for the table
--data-file-length=len [317]	data-file-length [317]	Maximum length of the data file (when re-creating data file when it is full)
--debug[=debug_options] [314]	debug [314]	Write a debugging log
decode_bits=#	decode_bits	Decode_bits
--description [319]	description [319]	Print some descriptive information about the table
--extend-check [316]	extend-check [316]	Do very thorough table check or repair that tries to recover every possible row from the data file
--fast [316]	fast [316]	Check only tables that haven't been closed properly
--force [316]	force [316]	Do a repair operation automatically if myisamchk finds any errors in the table
--force	force-recover	Overwrite old temporary files. For use with the -r or -o option
ft_max_word_len=#	ft_max_word_len	Maximum word length for FULLTEXT indexes
ft_min_word_len=#	ft_min_word_len	Minimum word length for FULLTEXT indexes
ft_stopword_file=value	ft_stopword_file	Use stopwords from this file instead of built-in list
--HELP [313]		Display help message and exit
--help [313]		Display help message and exit
--information [316]	information [316]	Print informational statistics about the table that is checked
key_buffer_size=#	key_buffer_size	The size of the buffer used for index blocks for MyISAM tables
--keys-used=val [317]	keys-used [317]	A bit-value that indicates which indexes to update
--medium-check [316]	medium-check [316]	Do a check that is faster than an --extend-check operation
myisam_block_size=#	myisam_block_size	Block size to be used for MyISAM index pages
--parallel-recover [317]	parallel-recover [317]	Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta)

Format	Option File	Description
--quick [317]	quick [317]	Achieve a faster repair by not modifying the data file.
read_buffer_size=#	read_buffer_size	Each thread that does a sequential scan allocates a buffer of this size for each table it scans
--read-only [316]	read-only [316]	Don't mark the table as checked
--recover [317]	recover [317]	Do a repair that can fix almost any problem except unique keys that aren't unique
--safe-recover [318]	safe-recover [318]	Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found
--set-auto-increment[=value] [319]	set-auto-increment [319]	Force AUTO_INCREMENT numbering for new records to start at the given value
--set-character-set=name [318]	set-character-set [318]	Change the character set used by the table indexes
--set-collation=name [318]	set-collation [318]	Specify the collation to use for sorting table indexes
--silent [314]	silent [314]	Silent mode
sort_buffer_size=#	sort_buffer_size	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE
--sort-index [319]	sort-index [319]	Sort the index tree blocks in high-low order
sort_key_blocks=#	sort_key_blocks	sort_key_blocks
--sort-records=# [319]	sort-records [319]	Sort records according to a particular index
--sort-recover [318]	sort-recover [318]	Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large
stats_method=value	stats_method	Specifies how MyISAM index statistics collection code should treat NULLs
--tmpdir=path [318]	tmpdir [318]	Path of the directory to be used for storing temporary files
--unpack [318]	unpack [318]	Unpack a table that was packed with myisampack
--update-state [316]	update-state [316]	Store information in the .MYI file to indicate when the table was checked and whether the table crashed
--verbose [314]		Verbose mode
--version [314]		Display version information and exit
write_buffer_size=#	write_buffer_size	Write buffer size

4.6.2.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by myisamchk. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- --help [313], -?

  Display a help message and exit. Options are grouped by type of operation.

- --HELP [313], -H

Display a help message and exit. Options are presented in a single list.

- `--debug=debug_options` [314], `-# debug_options`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,file_name'`. The default is `'d:t:o,/tmp/myisamchk.trace'`.

- `--silent` [314], `-s`

  Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose` [314], `-v`

  Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version` [314], `-V`

  Display version information and exit.

- `--wait` [314], `-w`

  Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

Variable	Default Value
`decode_bits`	9
`ft_max_word_len`	version-dependent
`ft_min_word_len`	4
`ft_stopword_file`	built-in list
`key_buffer_size`	523264
`myisam_block_size`	1024
`read_buffer_size`	262136
`sort_buffer_size`	2097144
`sort_key_blocks`	16
`stats_method`	nulls_unequal
`write_buffer_size`	262136

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. However, this syntax is deprecated as of MySQL 4.0.

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover` [317].

`key_buffer_size` is used when you are checking the table with `--extend-check` [316] or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover` [318].
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` [318] option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks. It is available as of MySQL 4.0.0.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` [318] option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in Section 5.1.3, “Server System Variables”, and Section 7.4.4, “`MyISAM` Index Statistics Collection”. `stats_method` was added in MySQL 4.1.15/5.0.14. For older versions, the statistics collection method is equivalent to `nulls_equal`.

The `ft_min_word_len` and `ft_max_word_len` variables are available as of MySQL 4.0.0. `ft_stopword_file` is available as of MySQL 4.0.19.

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

4.6.2.2 `myisamchk` Check Options

myisamchk supports the following options for table checking operations:

- --check [316], -c

  Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- --check-only-changed [316], -C

  Check only tables that have changed since the last check.

- --extend-check [316], -e

  Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, myisamchk or myisamchk --medium-check should be able to determine whether there are any errors in the table.

  If you are using --extend-check [316] and have plenty of memory, setting the key_buffer_size variable to a large value helps the repair operation run faster.

  For a description of the output format, see Section 4.6.2.5, “Obtaining Table Information with myisamchk”.

- --fast [316], -F

  Check only tables that haven't been closed properly.

- --force [316], -f

  Do a repair operation automatically if myisamchk finds any errors in the table. The repair type is the same as that specified with the --recover [317] or -r option.

- --information [316], -i

  Print informational statistics about the table that is checked.

- --medium-check [316], -m

  Do a check that is faster than an --extend-check [316] operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- --read-only [316], -T

  Do not mark the table as checked. This is useful if you use myisamchk to check a table that is in use by some other application that does not use locking, such as mysqld when run with external locking disabled.

- --update-state [316], -U

  Store information in the .MYI file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the --check-only-changed [316] option, but you shouldn't use this option if the mysqld server is using the table and you are running it with external locking disabled.

4.6.2.3 myisamchk Repair Options

myisamchk supports the following options for table repair operations (operations performed when an option such as --recover [317] or --safe-recover [318] is given):

- `--backup` [317], `-B`

  Make a backup of the `.MYD` file as *`file_name-time`*`.BAK`

- `--character-sets-dir=`*`path`* [317]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--correct-checksum` [317]

  Correct the checksum information for the table.

- `--data-file-length=`*`len`* [317], `-D` *`len`*

  The maximum length of the data file (when re-creating data file when it is “full”).

- `--extend-check` [316], `-e`

  Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

  For a description of the output format, see Section 4.6.2.5, “Obtaining Table Information with `myisamchk`”.

- `--force` [316], `-f`

  Overwrite old intermediate files (files with names like *`tbl_name`*`.TMD`) instead of aborting.

- `--keys-used=`*`val`* [317], `-k` *`val`*

  For `myisamchk`, the option value is a bit-value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. For `isamchk`, the option value indicates that only the first *`val`* of the table indexes should be updated. In either case, an option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r` or (`isamchk -r`).

- `--no-symlinks` [317], `-l`

  Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=`*`len`* [317]

  Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them. This option was added in MySQL 4.1.1.

- `--parallel-recover` [317], `-p`

  Uses the same technique as `-r` and `-n`, but creates all the keys in parallel, using different threads. This option was added in MySQL 4.0.2. *This is beta-quality code; use at your own risk!*.

- `--quick` [317], `-q`

  Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover` [317], `-r`

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with ISAM/MyISAM tables). If you want to recover a table, this is the option to try first. You should try --safe-recover [318] only if myisamchk reports that the table cannot be recovered by --recover [317]. (In the unlikely case that --recover [317] fails, the data file remains intact.)

If you have lots of memory, you should increase the value of sort_buffer_size.

- --safe-recover [318], -o

  Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than --recover [317], but can handle a couple of very unlikely cases that --recover [317] cannot. This recovery method also uses much less disk space than --recover [317]. Normally, you should repair first using --recover [317], and then with --safe-recover [318] only if --recover [317] fails.

  If you have lots of memory, you should increase the value of key_buffer_size.

- --set-character-set=*name* [318]

  Change the character set used by the table indexes. This option was replaced by --set-collation [318] in MySQL 4.1.1.

- --set-collation=*name* [318]

  Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name. This option was added in MySQL 4.1.11.

- --sort-recover [318], -n

  Force myisamchk to use sorting to resolve the keys even if the temporary files should be very large.

- --tmpdir=*path* [318], -t *path*

  The path of the directory to be used for storing temporary files. If this is not set, myisamchk uses the value of the TMPDIR environment variable. Starting from MySQL 4.1, --tmpdir [318] can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names should be colon (":") on Unix and semicolon (";") on Windows, NetWare, and OS/2.

- --unpack [318], -u

  Unpack a table that was packed with myisampack.

4.6.2.4 Other myisamchk Options

myisamchk supports the following options for actions other than table checks and repairs:

- --analyze [318], -a

  Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a myisamchk --description --verbose *tbl_name* command or the SHOW INDEX FROM *tbl_name* statement.

- --block-search=*offset* [318], -b *offset*

Find the record that a block at the given offset belongs to.

- `--description` [319], `-d`

  Print some descriptive information about the table. Specifying the `--verbose` [314] option once or twice produces additional information. See Section 4.6.2.5, “Obtaining Table Information with myisamchk”.

- `--set-auto-increment[=value]` [319], `-A[value]`

  Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If *`value`* is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index` [319], `-S`

  Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N` [319], `-R N`

  Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

  If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

4.6.2.5 Obtaining Table Information with `myisamchk`

To obtain a description of a `MyISAM` table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- `myisamchk -d tbl_name`

  Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -dv tbl_name`

  Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- `myisamchk -eis tbl_name`

  Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

  This is like `-eis`, but tells you what is being done.

The *tbl_name* argument can be either the name of a MyISAM table or the name of its index file, as described in Section 4.6.2, “myisamchk — MyISAM Table-Maintenance Utility”. Multiple *tbl_name* arguments can be given.

Suppose that a table named person has the following structure. (The MAX_ROWS table option is included so that in the example output from myisamchk shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
  id         INT NOT NULL AUTO_INCREMENT,
  last_name  VARCHAR(20) NOT NULL,
  first_name VARCHAR(20) NOT NULL,
  birth      DATE,
  death      DATE,
  PRIMARY KEY (id),
  INDEX (last_name, first_name),
  INDEX (birth)
) MAX_ROWS = 1000000;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw----  1 mysql  mysql  9347072 Aug 19 11:47 person.MYD
-rw-rw----  1 mysql  mysql  8705024 Aug 19 11:47 person.MYI
```

Example of myisamchk -dvv output:

```
MyISAM file:         person

```

Explanations for the types of information myisamchk produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- `MyISAM file`

  Name of the `MyISAM` (index) file.

- `Record format`

  The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`. (`Packed` corresponds to what `SHOW TABLE STATUS` reports as `Dynamic`.)

- `Chararacter set`

  The table default character set.

- `File-version`

  Version of `MyISAM` format. Currently always 1.

- `Creation time`

  When the data file was created.

- `Recover time`

  When the index/data file was last reconstructed.

- `Status`

  Table status flags. Possible values are `crashed`, `open`, `changed`, `analyzed`, `optimized keys`, and `sorted index pages`.

- `Auto increment key`, `Last value`

  The key number associated the table's `AUTO_INCREMENT` column, and the most recently generated value for this column. These fields do not appear if there is no such column.

- `Data records`

  The number of rows in the table.

- `Deleted blocks`

  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 6.6.4, “`MyISAM` Table Optimization”.

- `Datafile parts`

  For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as `Data records`.

- `Deleted data`

  How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See Section 6.6.4, “`MyISAM` Table Optimization”.

- `Datafile pointer`

  The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

  The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

  How long the table data file can become, in bytes.

- `Max keyfile length`

  How long the table index file can become, in bytes.

- `Recordlength`

  How much space each row takes, in bytes.

The `table description` part of the output includes a list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- `Key`

  This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two `table description` lines for the second index. This indicates that it is a multiple-part index with two parts.

- `Start`

  Where in the row this portion of the index starts.

- `Len`

  How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the `Len` values for all key parts.

- `Index`

  Whether a key value can exist multiple times in the index. Possible values are `unique` or `multip.` (multiple).

- `Type`

  What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- `Root`

  Address of the root index block.

- `Blocksize`

  The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- `Rec/key`

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- `Field`

  The column number.

- `Start`

  The byte position of the column within table rows.

- `Length`

  The length of the column in bytes.

- `Nullpos`, `Nullbit`

  For columns that can be `NULL`, `MyISAM` stores `NULL` values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The `Nullpos` and `Nullbit` values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is `NULL`.

  The position and number of bytes used to store `NULL` flags is shown in the line for field 1. This is why there are six `Field` lines for the `person` table even though it has only five columns.

- `Type`

  The data type. The value may contain any of the following descriptors:

  - `constant`

    All rows have the same value.

  - `no endspace`

    Do not store endspace.

  - `no endspace, not_always`

    Do not store endspace and do not do endspace compression for all values.

  - `no endspace, no empty`

    Do not store endspace. Do not store empty values.

  - `table-lookup`

    The column was converted to an `ENUM`.

  - `zerofill(N)`

    The most significant *`N`* bytes in the value are always 0 and are not stored.

  - `no zeros`

Do not store zeros.

- `always zero`

  Zero values are stored using one bit.

- `Huff tree`

  The number of the Huffman tree associated with the column.

- `Bits`

  The number of bits used in the Huffman tree.

The `Huff tree` and `Bits` fields are displayed if the table has been compressed with `myisampack`. See Section 4.6.4, “`myisampack` — Generate Compressed, Read-Only MyISAM Tables”, for an example of this information.

Example of `myisamchk -eiv` output:

```

Voluntary context switches 464, Involuntary context switches 0
Maximum memory usage: 804149 bytes (786k)
```

`myisamchk -eiv` output includes the following information:

- `Data records`

  The number of rows in the table.

- `Deleted blocks`

  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 6.6.4, “`MyISAM` Table Optimization”.

- `Key`

  The key number.

- `Keyblocks used`

  What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

- `Packed`

  MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 73% reduction in space is achieved.

- `Max levels`

  How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

  How many rows are in the table.

- `M.recordlength`

  The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

  MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

  What percentage of the data file is used.

- `Empty space`

  What percentage of the data file is unused.

- `Blocks/Record`

  Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See Section 6.6.4, “`MyISAM` Table Optimization”.

- `Recordblocks`

  How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- `Deleteblocks`

  How many blocks (links) are deleted.

- `Recorddata`

  How many bytes in the data file are used.

- `Deleted data`

  How many bytes in the data file are deleted (unused).

- `Lost space`

  If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- `Linkdata`

  When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

4.6.2.6 `myisamchk` Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than 512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk --sort_buffer_size=256M \
           --key_buffer_size=512M \
           --read_buffer_size=64M \
           --write_buffer_size=64M ...
```

Using `--sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=path` [318] option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick` [317]; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.

- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.

- When using `--recover` [317] or `--sort-recover` [318] (but not when using `--safe-recover` [318]), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=path` [318]). The following formula yields the amount of space required:

  ```
  (largest_key + row_pointer_length) * number_of_rows * 2
  ```

  You can check the length of the keys and the *`row_pointer_length`* with `myisamchk -dv tbl_name` (see Section 4.6.2.5, “Obtaining Table Information with `myisamchk`”). The *`row_pointer_length`* and *`number_of_rows`* values are the `Datafile pointer` and `Data records` values in the table description. To determine the *`largest_key`* value, check the `Key` lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` [318] instead of `--recover` [317].

4.6.3 myisamlog — Display MyISAM Log File Contents

`myisamlog` processes the contents of a `MyISAM` log file. `isamlog` is similar, but is used with `ISAM` log files.

Invoke `myisamlog` or `isamlog`like this:

```
shell> myisamlog [options] [log_file [tbl_name] ...]
shell> isamlog [options] [log_file [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` for `myisamlog` and `isam.log` for `isamlog` if no *`log_file`* argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` and `isamlog` understand the following options:

- `-?`, `-I`

  Display a help message and exit.

- `-c N`

  Execute only *`N`* commands.

- `-f N`

  Specify the maximum number of open files.

- `-i`

  Display extra information before exiting.

- `-o offset`

  Specify the starting offset.

- `-p N`

  Remove *`N`* components from path.

- `-r`

  Perform a recovery operation.

- `-R record_pos_file record_pos`

  Specify record position file and record position.

- `-u`

  Perform an update operation.

- `-v`

Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.

- `-w write_file`

  Specify the write file.

- `-V`

  Display version information.

4.6.4 myisampack — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses `MyISAM` tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

A similar utility, `pack_isam`, compresses `ISAM` tables. Because `ISAM` tables are deprecated, this section discusses only `myisampack`, but the general procedures for using `myisampack` are also true for `pack_isam` unless otherwise specified. References to `myisamchk` should be read as references to `isamchk` if you are using `pack_isam`.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).
- `myisampack` can pack `BLOB` or `TEXT` columns. (The older `pack_isam` program for `ISAM` tables does not have this capability.)
- `myisampack` does not support partitioned tables.

Invoke `myisampack` like this:

```
shell> myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, you should use `myisamchk -rq` to rebuild its indexes. Section 4.6.2, “myisamchk — MyISAM Table-Maintenance Utility”.

`myisampack` supports the following options. It also reads option files and supports the options for processing them described at Command-Line Options that Affect Option-File Handling.

- `--help` [328], `-?`

  Display a help message and exit.

- `--backup` [329], `-b`

  Make a backup of each table's data file using the name *`tbl_name`*`.OLD`.

- `--character-sets-dir=`*`path`* [329]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--debug[=`*`debug_options`*`]` [329], `-# [`*`debug_options`*`]`

  Write a debugging log. A typical *`debug_options`* string is `'d:t:o,`*`file_name`*`'`. The default is `'d:t:o'`.

- `--force` [329], `-f`

  Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named *`tbl_name`*`.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the `.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that *`tbl_name`*`.TMD` exists. With `--force` [329], `myisampack` packs the table anyway.

- `--join=`*`big_tbl_name`* [329], `-j` *`big_tbl_name`*

  Join all tables named on the command line into a single packed table *`big_tbl_name`*. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

  `big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into *`big_tbl_name`* must exist. The source tables are read for the join operation but not modified. The join operation does not create a `.frm` file for *`big_tbl_name`*, so after the join operation finishes, copy the `.frm` file from one of the source tables and name it *`big_tbl_name`*`.frm`.

- `--packlength=`*`len`*, `-p` *`len`*

  (`pack_isam` only) Specify the row length storage size, in bytes. The value should be 1, 2, or 3. `pack_isam` stores all rows with length pointers of 1, 2, or 3 bytes. In most normal cases, `pack_isam` can determine the correct length value before it begins packing the file, but it may notice during the packing process that it could have used a shorter length. In this case, `pack_isam` prints a note that you could use a shorter row length the next time you pack the same file.

- `--silent` [329], `-s`

  Silent mode. Write output only when errors occur.

- `--test` [329], `-t`

  Do not actually pack the table, just test packing it.

- `--tmpdir=`*`path`* [329], `-T` *`path`*

  Use the named directory as the location where `myisampack` creates temporary files.

- `--verbose` [329], `-v`

  Verbose mode. Write information about the progress of the packing operation and its result.

- `--version` [329], `-V`

  Display version information and exit.

- `--wait` [330], `-w`

  Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r--   1 monty    my         994128 Apr 17 19:00 station.MYD
-rw-rw-r--   1 monty    my          53248 Apr 17 19:00 station.MYI
-rw-rw-r--   1 monty    my           5767 Apr 17 19:00 station.frm

shell> myisamchk -dvv station

57    831   4      no zeros, zerofill(1)                2     9
```

`myisampack` displays the following kinds of information:

- `normal`

  The number of columns for which no extra packing is used.

- `empty-space`

  The number of columns containing values that are only spaces. These occupy one bit.

- `empty-zero`

  The number of columns containing values that are only binary zeros. These occupy one bit.

- `empty-fill`

  The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.

- `pre-space`

  The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- `end-space`

  The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- `table-lookup`

  The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- `zero`

  The number of columns for which all values are zero.

- `Original trees`

  The initial number of Huffman trees.

- `After join`

  The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the `Field` lines displayed by `myisamchk -dvv` include additional information about each column:

- `Type`

  The data type. The value may contain any of the following descriptors:

  - `constant`

    All rows have the same value.

  - `no endspace`

    Do not store endspace.

  - `no endspace, not_always`

    Do not store endspace and do not do endspace compression for all values.

  - `no endspace, no empty`

    Do not store endspace. Do not store empty values.

  - `table-lookup`

    The column was converted to an `ENUM`.

- `zerofill(N)`

  The most significant *N* bytes in the value are always 0 and are not stored.

- `no zeros`

  Do not store zeros.

- `always zero`

  Zero values are stored using one bit.

- `Huff tree`

  The number of the Huffman tree associated with the column.

- `Bits`

  The number of bits used in the Huffman tree.

After you run `myisampack`, you must run `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

A similar procedure applies for `ISAM` tables. After using `pack_isam`, use `isamchk` to re-create the indexes:

```
shell> isamchk -rq --sort-index --analyze tbl_name.ISM
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` [318] option to `myisamchk` or `isamchk`.

4.6.5 `mysqlaccess` — Client for Checking Access Privileges

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a host name, user name, and database combination. Note that `mysqlaccess` checks access using only the `user`, `db`, and `host` tables. It does not check table, column, or routine privileges specified in the `tables_priv` or `columns_priv` tables.

Invoke `mysqlaccess` like this:

```
shell> mysqlaccess [host_name [user_name [db_name]]] [options]
```

`mysqlaccess` supports the following options.

Table 4.9 `mysqlaccess` Options

Format	Option File	Description
--brief [335]	brief [335]	Generate reports in single-line tabular format
--commit [335]	commit [335]	Copy the new access privileges from the temporary tables to the original grant tables

Format	Option File	Description
--copy [335]	copy [335]	Reload the temporary grant tables from original ones
--db=db_name [335]	db [335]	Specify the database name
--debug=# [336]	debug [336]	Specify the debug level
--help [335]		Display help message and exit
--host=host_name [336]	host [336]	Connect to the MySQL server on the given host
--howto [336]	howto [336]	Display some examples that show how to use mysqlaccess
--old_server [336]	old_server [336]	Assume that the server is an old MySQL server (prior to MySQL 3.21)
--password[=password] [336]	password [336]	The password to use when connecting to the server
--plan [336]	plan [336]	Display suggestions and ideas for future releases
--preview [336]	preview [336]	Show the privilege differences after making changes to the temporary grant tables
--relnotes [336]	relnotes [336]	Display the release notes
--rhost=host_name [336]	rhost [336]	Connect to the MySQL server on the given host
--rollback [336]	rollback [336]	Undo the most recent changes to the temporary grant tables.
--spassword[=password] [336]	spassword [336]	The password to use when connecting to the server as the superuser
--superuser=user_name [336]	superuser [336]	Specify the user name for connecting as the superuser
--table [337]	table [337]	Generate reports in table format
--user=user_name, [337]	user [337]	MySQL user name to use when connecting to server
--version [337]		Display version information and exit

- `--help` [335], `-?`

  Display a help message and exit.

- `--brief` [335], `-b`

  Generate reports in single-line tabular format.

- `--commit` [335]

  Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)

- `--copy` [335]

  Reload the temporary grant tables from original ones.

- `--db=`*`db_name`* [335], `-d` *`db_name`*

Specify the database name.

- `--debug=N` [336]

  Specify the debug level. *`N`* can be an integer from 0 to 3.

- `--host=host_name` [336], `-h host_name`

  The host name to use in the access privileges.

- `--howto` [336]

  Display some examples that show how to use `mysqlaccess`.

- `--old_server` [336]

  Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full `WHERE` clauses.

- `--password[=password]` [336], `-p[password]`

  The password to use when connecting to the server. If you omit the *`password`* value following the `--password` [336] or `-p` option on the command line, `mysqlaccess` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”.

- `--plan` [336]

  Display suggestions and ideas for future releases.

- `--preview` [336]

  Show the privilege differences after making changes to the temporary grant tables.

- `--relnotes` [336]

  Display the release notes.

- `--rhost=host_name` [336], `-H host_name`

  Connect to the MySQL server on the given host.

- `--rollback` [336]

  Undo the most recent changes to the temporary grant tables.

- `--spassword[=password]` [336], `-P[password]`

  The password to use when connecting to the server as the superuser. If you omit the *`password`* value following the `--spassword` [336] or `-p` option on the command line, `mysqlaccess` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”.

- `--superuser=user_name` [336], `-U user_name`

  Specify the user name for connecting as the superuser.

- `--table` [337], `-t`

  Generate reports in table format.

- `--user=user_name` [337], `-u user_name`

  The user name to use in the access privileges.

- `--version` [337], `-v`

  Display version information and exit.

If your MySQL distribution is installed in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL     = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

4.6.6 mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility, which is available as of MySQL 3.23.14. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in Section 5.3.4, “The Binary Log”, and Section 14.3.1, “Replication Relay and Status Files”.

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.0000003
```

The output includes events contained in `binlog.000003`. Event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309  9:28:36 server id 123  end_log_pos 245
  Query thread_id=3350  exec_time=11  error_code=0
```

In the first line, the number following `at` indicates the starting position of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to slave servers. `server id` is the `server_id` [426] value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a master server. On a slave, it is the difference of the end execution time on the slave minus the beginning execution time on the master.

The difference serves as an indicator of how much replication lags behind the master. error_code indicates the result from executing the event. Zero means that no error occurred.

The output from mysqlbinlog can be re-executed (for example, by using it as input to mysql) to redo the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section and in Section 6.5, "Point-in-Time (Incremental) Recovery Using the Binary Log".

Normally, you use mysqlbinlog to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the --read-from-remote-server [341] option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are --host [340], --password [341], --port [341], --protocol [341], --socket [341], and --user [342]; they are ignored except when you also use the --read-from-remote-server [341] option.

mysqlbinlog supports the following options, which can be specified on the command line or in the [mysqlbinlog] and [client] option file groups. mysqlbinlog also supports the options for processing option files described at Command-Line Options that Affect Option-File Handling.

Table 4.10 mysqlbinlog Options

Format	Option File	Description	Introduced	Deprecated
--character-sets-dir=path [339]	character-sets-dir [339]	The directory where character sets are installed		
--database=db_name [339]	database [339]	List entries for just this database		
--debug[=debug_options] [340]	debug [340]	Write a debugging log		
--disable-log-bin [340]	disable-log-bin [340]	Disable binary logging		
--force-read [340]	force-read [340]	If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning		
--help [339]		Display help message and exit		
--host=host_name [340]	host [340]	Connect to the MySQL server on the given host		
--local-load=path [340]	local-load [340]	Prepare local temporary files for LOAD DATA INFILE in the specified directory		
--offset=# [340]	offset [340]	Skip the first N entries in the log		
--password[=password] [341]	password [341]	The password to use when connecting to the server		
--port=port_num [341]	port [341]	The TCP/IP port number to use for the connection		
--position=# [341]	position [341]	Deprecated. Use --start-position		4.1.3
--protocol=type [341]	protocol [341]	The connection protocol to use		
--read-from-remote-server [341]	read-from-remote-server [341]	Read binary log from MySQL server rather than local log file		

Format	Option File	Description	Introduced	Deprecated
--result-file=name [341]	result-file [341]	Direct output to the given file		
--set-charset=charset_name [341]	set-charset [341]	Add a SET NAMES charset_name statement to the output	4.1.21	
--short-form [341]	short-form [341]	Display only the statements contained in the log		
--socket=path [341]	socket [341]	For connections to localhost		
--start-datetime=datetime [341]	start-datetime [341]	Read binary log from first event with timestamp equal to or later than datetime argument		
--start-position=# [342]	start-position [342]	Read binary log from first event with position equal to or greater than argument	4.1.4	
--stop-datetime=datetime [342]	stop-datetime [342]	Stop reading binary log at first event with timestamp equal to or greater than datetime argument	4.1.4	
--stop-position=# [342]	stop-position [342]	Stop reading binary log at first event with position equal to or greater than argument	4.1.4	
--to-last-log [342]	to-last-log [342]	Do not stop at the end of requested binary log from a MySQL server, but rather continue printing to end of last binary log	4.1.2	
--user=user_name, [342]	user [342]	MySQL user name to use when connecting to server		
--version [342]		Display version information and exit		

- `--help` [339], `-?`

  Display a help message and exit.

- `--character-sets-dir=`*`path`* [339]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--database=`*`db_name`* [339], `-d` *`db_name`*

  This option causes `mysqlbinlog` to output entries from the binary log (local log only) that occur while *`db_name`* is been selected as the default database by `USE`.

  The `--database` [339] option for `mysqlbinlog` is similar to the `--binlog-do-db` [1182] option for `mysqld`, but can be used to specify only one database. If `--database` [339] is given multiple times, only the last instance is used.

  The `--database` [339] option works as follows:

  - While *`db_name`* is the default database, statements are output whether they modify tables in *`db_name`* or a different database.
  - Unless *`db_name`* is selected as the default database, statements are not output, even if they modify tables in *`db_name`*.

- There is an exception for CREATE DATABASE, ALTER DATABASE, and DROP DATABASE. The database being *created, altered, or dropped* is considered to be the default database when determining whether to output the statement.

Suppose that the binary log contains these statements:

```
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j)  VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i)      VALUES(102);
INSERT INTO db2.t2 (j)  VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
INSERT INTO db2.t2 (j)  VALUES(202);
INSERT INTO t2 (j)      VALUES(203);
```

mysqlbinlog --database=test does not output the first two INSERT statements because there is no default database. It outputs the three INSERT statements following USE test, but not the three INSERT statements following USE db2.

mysqlbinlog --database=db2 does not output the first two INSERT statements because there is no default database. It does not output the three INSERT statements following USE test, but does output the three INSERT statements following USE db2.

- --debug[=*debug_options*] [340], -# [*debug_options*]

  Write a debugging log. A typical *debug_options* string is 'd:t:o,*file_name*'. The default is 'd:t:o,/tmp/mysqlbinlog.trace'.

- --disable-log-bin [340], -D

  Disable binary logging. This is useful for avoiding an endless loop if you use the --to-last-log [342] option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged. This option is available as of MySQL 4.1.8.

  This option requires that you have the SUPER [493] privilege. It causes mysqlbinlog to include a SET sql_log_bin = 0 statement in its output to disable binary logging of the remaining output. The SET statement is ineffective unless you have the SUPER [493] privilege.

- --force-read [340], -f

  With this option, if mysqlbinlog reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, mysqlbinlog stops if it reads such an event.

- --host=*host_name* [340], -h *host_name*

  Get the binary log from the MySQL server on the given host.

- --local-load=*path* [340], -l *path*

  Prepare local temporary files for LOAD DATA INFILE in the specified directory.

- --offset=*N* [340], -o *N*

  Skip the first *N* entries in the log.

- `--password[=password]` [341], `-p[password]`

  The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *`password`* value following the `--password` [341] or `-p` option on the command line, `mysqlbinlog` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, "End-User Guidelines for Password Security". You can use an option file to avoid giving the password on the command line.

- `--port=port_num` [341], `-P port_num`

  The TCP/IP port number to use for connecting to a remote server.

- `--position=N` [341]

  Deprecated. Use `--start-position` [342] instead (starting from MySQL 4.1.4).

- `--protocol={TCP|SOCKET|PIPE|MEMORY}` [341]

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, "Connecting to the MySQL Server". This option was added in MySQL 4.1.

- `--read-from-remote-server` [341], `-R`

  Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host` [340], `--password` [341], `--port` [341], `--protocol` [341], `--socket` [341], and `--user` [342].

  This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

- `--result-file=name` [341], `-r name`

  Direct output to the given file.

- `--set-charset=charset_name` [341]

  Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files. This option was added in MySQL 4.1.21.

- `--short-form` [341], `-s`

  Display only the statements contained in the log, without any extra information. This is for testing only, and should not be used in production systems.

- `--socket=path` [341], `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--start-datetime=datetime` [341]

  Start reading the binary log at the first event having a timestamp equal to or later than the *`datetime`* argument. The *`datetime`* value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is available as of MySQL 4.1.4. It is useful for point-in-time recovery. See Section 6.3, “Example Backup and Recovery Strategy”.

- `--start-position=N` [342], `-j N`

  Start reading the binary log at the first event having a position equal to or greater than *`N`*. This option applies to the first log file named on the command line. Available as of MySQL 4.1.4 (previously named `--position` [341]).

  This option is useful for point-in-time recovery. See Section 6.3, “Example Backup and Recovery Strategy”.

- `--stop-datetime=datetime` [342]

  Stop reading the binary log at the first event having a timestamp equal to or later than the *`datetime`* argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` [341] option for information about the *`datetime`* value. This option is available as of MySQL 4.1.4.

  This option is useful for point-in-time recovery. See Section 6.3, “Example Backup and Recovery Strategy”.

- `--stop-position=N` [342]

  Stop reading the binary log at the first event having a position equal to or greater than *`N`*. This option applies to the last log file named on the command line. Available as of MySQL 4.1.4.

  This option is useful for point-in-time recovery. See Section 6.3, “Example Backup and Recovery Strategy”.

- `--to-last-log` [342], `-t`

  Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server` [341]. Available as of MySQL 4.1.2.

- `--user=user_name` [342], `-u user_name`

  The MySQL user name to use when connecting to a remote server.

- `--version` [342], `-V`

  Display version information and exit.

You can also set the following variable by using `--var_name=value` syntax:

- `open_files_limit`

  Specify the number of open file descriptors to reserve.

It is also possible to set variables by using `--set-variable=var_name=value` or `-O var_name=value` syntax. *This syntax is deprecated*.

You can pipe the output of mysqlbinlog into the mysql client to execute the events contained in the binary log. This technique is used to recover from a crash when you have an old backup (see Section 6.5, "Point-in-Time (Incremental) Recovery Using the Binary Log"). For example:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

You can also redirect the output of mysqlbinlog to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the mysql program:

```
shell> mysqlbinlog binlog.000001 > tmpfile
shell> ... edit tmpfile ...
shell> mysql -u root -p < tmpfile
```

When mysqlbinlog is invoked with the --start-position [342] option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the --stop-datetime [342] option (to be able to say, for example, "roll forward my databases to how they were today at 10:30 a.m.").

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a CREATE TEMPORARY TABLE statement and the second log contains a statement that uses the temporary table. When the first mysql process terminates, the server drops the temporary table. When the second mysql process attempts to use the table, the server reports "unknown table."

To avoid problems like this, use a *single* mysql process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 >  /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

In MySQL 3.23, the binary log did not contain the data to load for LOAD DATA INFILE statements. To execute such a statement from a binary log file, the original data file was needed. Starting from MySQL 4.0.14, the binary log does contain the data, so mysqlbinlog can produce output that reproduces the LOAD DATA INFILE operation without the original data file. mysqlbinlog copies the data to a temporary file and writes a LOAD DATA LOCAL INFILE statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the --local-load [340] option.

Because mysqlbinlog converts LOAD DATA INFILE statements to LOAD DATA LOCAL INFILE statements (that is, it adds LOCAL), both the client and the server that you use to process the statements must be configured with the LOCAL capability enabled. See Section 5.4.5, “Security Issues with LOAD DATA LOCAL”.

Warning

The temporary files created for LOAD DATA LOCAL statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like *original_file_name-#-#*.

Before MySQL 4.1, mysqlbinlog could not prepare output suitable for mysql if the binary log contained interlaced statements originating from different clients that used temporary tables of the same name. This is fixed in MySQL 4.1. However, the problem still existed for LOAD DATA INFILE statements until it was fixed in MySQL 4.1.8.

4.6.7 mysqldumpslow — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see Section 5.3.5, “The Slow Query Log”). mysqldumpslow parses MySQL slow query log files and prints a summary of their contents.

Normally, mysqldumpslow groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to N and 'S' when displaying summary output. The -a and -n options can be used to modify value abstracting behavior.

Invoke mysqldumpslow like this:

```
shell> mysqldumpslow [options] [log_file ...]
```

mysqldumpslow supports the following options.

Table 4.11 mysqldumpslow Options

Format	Option File	Description
-a [345]		Do not abstract all numbers to N and strings to S
-n num [345]		Abstract numbers with at least the specified digits
--debug [345]	debug [345]	Write debugging information
-g pattern [345]		Only consider statements that match the pattern
--help [344]		Display help message and exit
-h name [345]		Host name of the server in the log file name
-i name [345]		Name of the server instance
-l [345]		Do not subtract lock time from total time
-r [345]		Reverse the sort order
-s value [345]		How to sort output
-t num [345]		Display only first num queries
--verbose [345]	verbose [345]	Verbose mode

- --help [344]

Display a help message and exit.

- `-a`

  Do not abstract all numbers to `N` and strings to `'S'`.

- `--debug` [345], `-d`

  Run in debug mode.

- `-g` *`pattern`*

  Consider only queries that match the (`grep`-style) pattern.

- `-h` *`host_name`*

  Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcard. The default is `*` (match all).

- `-i` *`name`*

  Name of server instance (if using `mysql.server` startup script).

- `-l`

  Do not subtract lock time from total time.

- `-n` *`N`*

  Abstract numbers with at least *`N`* digits within names.

- `-r`

  Reverse the sort order.

- `-s` *`sort_type`*

  How to sort the output. The value of *`sort_type`* should be chosen from the following list:

  - `t`, `at`: Sort by query time or average query time
  - `l`, `al`: Sort by lock time or average lock time
  - `s`, `as`: Sort by rows sent or average rows sent
  - `c`: Sort by count

  By default, `mysqldumpslow` sorts by average query time (equivalent to `-s at`).

- `-t` *`N`*

  Display only the first *`N`* queries in the output.

- `--verbose` [345], `-v`

  Verbose mode. Print more information about what the program does.

Example of usage:

```
shell> mysqldumpslow

Reading mysql slow query log from /usr/local/mysql/data/mysqld51-apple-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t2 select * from t1 limit N

Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
 insert into t1 select * from t1
```

4.6.8 mysqlhotcopy — A Database Backup Program

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `FLUSH TABLES`, `LOCK TABLES`, and `cp` or `scp` to make a database backup. It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up `MyISAM` and `ISAM` tables, and `ARCHIVE` tables as of MySQL 4.1. `mysqlhotcopy` runs on Unix, and also on NetWare as of MySQL 4.0.18.

To use `mysqlhotcopy`, you must have read access to the files for the tables that you are backing up, the `SELECT` [492] privilege for those tables, the `RELOAD` [492] privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` [492] privilege (to be able to lock the tables).

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (“~”):

```
shell> mysqlhotcopy db_name./~regex/
```

`mysqlhotcopy` supports the following options, which can be specified on the command line or in the `[mysqlhotcopy]` and `[client]` option file groups.

Table 4.12 mysqlhotcopy Options

Format	Option File	Description
--addtodest [347]	addtodest [347]	Do not rename target directory (if it exists); merely add files to it
--allowold [347]	allowold [347]	Do not abort if a target exists; rename it by adding an _old suffix
--checkpoint=db_name.tbl_name [347]	checkpoint [347]	Insert checkpoint entries
--chroot=path [347]	chroot [347]	Base directory of the chroot jail in which mysqld operates
--debug [347]	debug [347]	Write a debugging log
--dryrun [347]	dryrun [347]	Report actions without performing them

Format	Option File	Description
--flushlog [348]	flushlog [348]	Flush logs after all tables are locked
--help [347]		Display help message and exit
--host=host_name [348]	host [348]	Connect to the MySQL server on the given host
--keepold [348]	keepold [348]	Do not delete previous (renamed) target when done
--method [348]	method [348]	The method for copying files
--noindices [348]	noindices [348]	Do not include full index files in the backup
--password[=password] [348]	password [348] [348]	The password to use when connecting to the server
--port=port_num [348]	port [348]	The TCP/IP port number to use for the connection
--quiet [348]	quiet [348]	Be silent except for errors
--regexp [348]	regexp [348]	Copy all databases with names that match the given regular expression
--resetmaster [348]	resetmaster [348]	Reset the binary log after locking all the tables
--resetslave [348]	resetslave [348]	Reset the master.info file after locking all the tables
--socket=path [348]	socket [348]	For connections to localhost
--tmpdir=path [349]	tmpdir [349]	The temporary directory
--user=user_name, [349]	user [349]	MySQL user name to use when connecting to server

- `--help` [347], `-?`

  Display a help message and exit.

- `--addtodest` [347]

  Do not rename target directory (if it exists); merely add files to it. This option was added in MySQL 4.0.13.

- `--allowold` [347]

  Do not abort if a target exists; rename it by adding an `_old` suffix.

- `--checkpoint=`*`db_name.tbl_name`* [347]

  Insert checkpoint entries into the specified database *`db_name`* and table *`tbl_name`*.

- `--chroot=`*`path`* [347]

  Base directory of the `chroot` jail in which `mysqld` operates. The *`path`* value should match that of the `--chroot` [385] option given to `mysqld`. This option was added in MySQL 4.0.19.

- `--debug` [347]

  Enable debug output.

- `--dryrun` [347], `-n`

  Report actions without performing them.

- `--flushlog` [348]

  Flush logs after all tables are locked.

- `--host=host_name` [348], `-h host_name`

  The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to `localhost` using a Unix socket file.

- `--keepold` [348]

  Do not delete previous (renamed) target when done.

- `--method=command` [348]

  The method for copying files (`cp` or `scp`). The default is `cp`.

- `--noindices` [348]

  Do not include full index files for `MyISAM` and `ISAM` tables in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with `myisamchk -rq` for `MyISAM` tables or `isamchk -rq` for `ISAM` tables.

- `--password=password` [348], `-ppassword`

  The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--port=port_num` [348], `-P port_num`

  The TCP/IP port number to use when connecting to the local server.

- `--quiet` [348], `-q`

  Be silent except for errors.

- `--record_log_pos=db_name.tbl_name` [348]

  Record master and slave status in the specified database *`db_name`* and table *`tbl_name`*.

- `--regexp=expr` [348]

  Copy all databases with names that match the given regular expression.

- `--resetmaster` [348]

  Reset the binary log after locking all the tables.

- `--resetslave` [348]

  Reset the `master.info` file after locking all the tables.

- `--socket=path` [348], `-S path`

  The Unix socket file to use for connections to `localhost`.

- `--suffix=str` [349]

  The suffix to use for names of copied databases.

- `--tmpdir=path` [349]

  The temporary directory. The default is `/tmp`.

- `--user=user_name` [349], `-u user_name`

  The MySQL user name to use when connecting to the server.

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` [347] and `--record_log_pos` [348] options:

```
shell> perldoc mysqlhotcopy
```

4.6.9 mysqlmanagerc — Internal Test-Suite Program

This program was used internally for test purposes. As of MySQL 5.0, it is no longer used.

4.6.10 mysqlmanager-pwgen — Internal Test-Suite Program

This program was used internally for test purposes. As of MySQL 5.0, it is no longer used.

4.6.11 mysql_convert_table_format — Convert Tables to Use a Given Storage Engine

`mysql_convert_table_format` converts the tables in a database to use a particular storage engine (`MyISAM` by default). `mysql_convert_table_format` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see Section 2.14, “Perl Installation Notes”).

Invoke `mysql_convert_table_format` like this:

```
shell> mysql_convert_table_format [options]db_name
```

The *db_name* argument indicates the database containing the tables to be converted.

`mysql_convert_table_format` supports the options described in the following list.

- `--help` [349]

  Display a help message and exit.

- `--force` [349]

  Continue even if errors occur.

- `--host=host_name` [349]

  Connect to the MySQL server on the given host.

- `--password=password` [349]

  The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--port=port_num` [350]

  The TCP/IP port number to use for the connection.

- `--socket=path` [350]

  For connections to `localhost`, the Unix socket file to use.

- `--type=engine_name` [350]

  Specify the storage engine that the tables should be converted to use. The default is `MyISAM` if this option is not given.

- `--user=user_name` [350]

  The MySQL user name to use when connecting to the server.

- `--verbose` [350]

  Verbose mode. Print more information about what the program does.

- `--version` [350]

  Display version information and exit.

4.6.12 mysql_explain_log — Use EXPLAIN on Statements in Query Log

`mysql_explain_log` reads its standard input for query log contents. It uses `EXPLAIN` to analyze `SELECT` statements found in the input. `UPDATE` statements are rewritten to `SELECT` statements and also analyzed with `EXPLAIN`. `mysql_explain_log` then displays a summary of its results.

The results may assist you in determining which queries result in table scans and where it would be beneficial to add indexes to your tables.

Invoke `mysql_explain_log` like this, where *`log_file`* contains all or part of a MySQL query log:

```
shell> mysql_explain_log [options] < log_file
```

`mysql_explain_log` supports the following options:

- `--help` [350], `-?`

  Display a help message and exit.

- `--date=YYMMDD` [350], `-d YYMMDD`

  Select entries from the log only for the given date.

- `--host=host_name` [350], `-h host_name`

  Connect to the MySQL server on the given host.

- `--password=password` [350], `-p password`

The password to use when connecting to the server.

Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”.

- `--printerror=1` [351], `-e 1`

  Enable error output.

- `--socket=path` [351], `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--user=user_name` [351], `-u user_name`

  The MySQL user name to use when connecting to the server.

4.6.13 mysql_find_rows — Extract SQL Statements from Files

`mysql_find_rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain `USE db_name` or `SET` statements. The utility was written for use with update log files and as such expects statements to be terminated with semicolon (`;`) characters. It may be useful with other files that contain SQL statements as long as statements are terminated with semicolons.

Invoke `mysql_find_rows` like this:

```
shell> mysql_find_rows [options] [file_name ...]
```

Each *`file_name`* argument should be the name of file containing SQL statements. If no file names are given, `mysql_find_rows` reads the standard input.

Examples:

```
mysql_find_rows --regexp=problem_table --rows=20 < update.log
mysql_find_rows --regexp=problem_table  update-log.1 update-log.2
```

`mysql_find_rows` supports the following options:

- `--help` [351], `--Information` [351]

  Display a help message and exit.

- `--regexp=pattern` [351]

  Display queries that match the pattern.

- `--rows=N` [351]

  Quit after displaying *`N`* queries.

- `--skip-use-db` [351]

  Do not include `USE db_name` statements in the output.

- `--start_row=N` [351]

Start output from this row.

4.6.14 mysql_fix_extensions — Normalize Table File Name Extensions

mysql_fix_extensions converts the extensions for MyISAM (or ISAM) table files to their canonical forms. It looks for files with extensions matching any lettercase variant of .frm, .myd, .myi, .isd, and .ism and renames them to have extensions of .frm, .MYD, .MYI, .ISD, and .ISM, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke mysql_fix_extensions like this, where *data_dir* is the path name to the MySQL data directory.

```
shell> mysql_fix_extensions data_dir
```

4.6.15 mysql_setpermission — Interactively Set Permissions in Grant Tables

mysql_setpermission is a Perl script that was originally written and contributed by Luuk de Boer. It interactively sets permissions in the MySQL grant tables. mysql_setpermission is written in Perl and requires that the DBI and DBD::mysql Perl modules be installed (see Section 2.14, “Perl Installation Notes”).

Invoke mysql_setpermission like this:

```
shell> mysql_setpermission [options]
```

options should be either --help [352] to display the help message, or options that indicate how to connect to the MySQL server. The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

mysql_setpermissions also reads options from the [client] and [perl] groups in the .my.cnf file in your home directory, if the file exists.

mysql_setpermission supports the following options:

- --help [352]

  Display a help message and exit.

- --host=*host_name* [352]

  Connect to the MySQL server on the given host.

- --password=*password* [352]

  The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- --port=*port_num* [352]

The TCP/IP port number to use for the connection.

- `--socket=path` [353]

  For connections to `localhost`, the Unix socket file to use.

- `--user=user_name` [353]

  The MySQL user name to use when connecting to the server.

4.6.16 mysql_tableinfo — Generate Database Metadata

`mysql_tableinfo` creates tables and populates them with database metadata. It uses `SHOW DATABASES`, `SHOW TABLES`, `SHOW TABLE STATUS`, `SHOW COLUMNS`, and `SHOW INDEX` to obtain the metadata.

Invoke `mysql_tableinfo` like this:

```
shell> mysql_tableinfo [options] db_name [db_like [tbl_like]]
```

The *db_name* argument indicates which database `mysql_tableinfo` should use as the location for the metadata tables. The database will be created if it does not exist. The tables will be named `db`, `tbl` (or `tbl_status`), `col`, and `idx`.

If the *db_like* or *tbl_like* arguments are given, they are used as patterns and metadata is generated only for databases or tables that match the patterns. These arguments default to `%` if not given.

Examples:

```
mysql_tableinfo info
mysql_tableinfo info world
mysql_tableinfo info mydb tmp%
```

Each of the commands stores information into tables in the `info` database. The first stores information for all databases and tables. The second stores information for all tables in the `world` database. The third stores information for tables in the `mydb` database that have names matching the pattern `tmp%`.

Table 4.13 mysql_tableinfo Options

Format	Option File	Description
--clear [354]	clear [354]	Before populating each metadata table, drop it if it exists
--clear-only [354]	clear-only [354]	Similar to --clear, but exits after dropping the metadata tables to be populated.
--col [354]	col [354]	Generate column metadata into the col table
--help [354]		Display help message and exit
--host=host_name [354]	host [354]	Connect to the MySQL server on the given host
--idx [354]	idx [354]	Generate index metadata into the idx table
--password=password [354]	password [354]	The password to use when connecting to the server -- not optional
--port=port_num [354]	port [354]	The TCP/IP port number to use for the connection

Format	Option File	Description
--prefix=prefix_str [354]	prefix [354]	Add prefix_str at the beginning of each metadata table name
--quiet [354]	quiet [354]	Be silent except for errors
--socket=path [354]	socket [354]	Display version information and exit
--tbl-status [355]	tbl-status [355]	Use SHOW TABLE STATUS instead of SHOW TABLES
--user=user_name, [355]	user [355]	The mysql_tableinfo user name to use when connecting to the server

`mysql_tableinfo` supports the following options:

- `--help` [354]

  Display a help message and exit.

- `--clear` [354]

  Before populating each metadata table, drop it if it exists.

- `--clear-only` [354]

  Similar to `--clear` [354], but exits after dropping the metadata tables to be populated.

- `--col` [354]

  Generate column metadata into the `col` table.

- `--host=host_name` [354], `-h host_name`

  Connect to the MySQL server on the given host.

- `--idx` [354]

  Generate index metadata into the `idx` table.

- `--password=password` [354], `-ppassword`

  The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--port=port_num` [354], `-P port_num`

  The TCP/IP port number to use for the connection.

- `--prefix=prefix_str` [354]

  Add *`prefix_str`* at the beginning of each metadata table name.

- `--quiet` [354], `-q`

  Be silent except for errors.

- `--socket=path` [354], `-S path`

The Unix socket file to use for the connection.

- `--tbl-status` [355]

  Use `SHOW TABLE STATUS` instead of `SHOW TABLES`. This provides more complete information, but is slower.

- `--user=user_name` [355], `-u user_name`

  The MySQL user name to use when connecting to the server.

4.6.17 mysql_waitpid — Kill Process and Wait for Its Termination

`mysql_waitpid` signals a process to terminate and waits for the process to exit. It uses the `kill()` system call and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_waitpid` like this:

```
shell> mysql_waitpid [options] pid wait_time
```

`mysql_waitpid` sends signal 0 to the process identified by *`pid`* and waits up to *`wait_time`* seconds for the process to terminate. *`pid`* and *`wait_time`* must be positive integers.

If process termination occurs within the wait time or the process does not exist, `mysql_waitpid` returns 0. Otherwise, it returns 1.

If the `kill()` system call cannot handle signal 0, `mysql_waitpid()` uses signal 1 instead.

`mysql_waitpid` supports the following options:

- `--help` [355], `-?`, `-I`

  Display a help message and exit.

- `--verbose` [355], `-v`

  Verbose mode. Display a warning if signal 0 could not be used and signal 1 is used instead.

- `--version` [355], `-V`

  Display version information and exit.

4.6.18 mysql_zap — Kill Processes That Match a Pattern

`mysql_zap` kills processes that match a pattern. It uses the `ps` command and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_zap` like this:

```
shell> mysql_zap [-signal] [-?Ift] pattern
```

A process matches if its output line from the `ps` command contains the pattern. By default, `mysql_zap` asks for confirmation for each process. Respond `y` to kill the process, or `q` to exit `mysql_zap`. For any other response, `mysql_zap` does not attempt to kill the process.

If the *-signal* option is given, it specifies the name or number of the signal to send to each process. Otherwise, mysql_zap tries first with TERM (signal 15) and then with KILL (signal 9).

mysql_zap supports the following additional options:

- --help [356], -?, -I

  Display a help message and exit.

- -f

  Force mode. mysql_zap attempts to kill each process without confirmation.

- -t

  Test mode. Display information about each process but do not kill it.

4.7 MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the my_print_defaults program to parse option files and see what options would be used by a given program. The following example shows the output that my_print_defaults might produce when asked to show the options found in the [client] and [mysql] groups:

```
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

4.7.1 msql2mysql — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The msql2mysql utility performs the conversion of mSQL C API function calls to their MySQL equivalents. msql2mysql converts the input file in place, so make a copy of the original before converting it. For example, use msql2mysql like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine client-prog.c and make any post-conversion revisions that may be necessary.

msql2mysql uses the replace utility to make the function name substitutions. See Section 4.8.2, “replace — A String-Replacement Utility”.

4.7.2 mysql_config — Display Options for Compiling Clients

mysql_config provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

mysql_config supports the following options.

- --cflags [357]

  Compiler flags to find include files and critical compiler flags and defines used when compiling the libmysqlclient library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use --include [357] for more portable options that contain only include paths.

- --include [357]

  Compiler options to find MySQL include files.

- --libmysqld-libs [357], --embedded [357]

  Libraries and options required to link with the MySQL embedded server.

- --libs [357]

  Libraries and options required to link with the MySQL client library.

- --libs_r [357]

  Libraries and options required to link with the thread-safe MySQL client library.

- --port [357]

  The default TCP/IP port number, defined when configuring MySQL.

- --socket [357]

  The default Unix socket file, defined when configuring MySQL.

- --version [357]

  Version number for the MySQL distribution.

If you invoke mysql_config with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
  --cflags         [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --include        [-I/usr/local/mysql/include/mysql]
  --libs           [-L/usr/local/mysql/lib/mysql -lmysqlclient -lz
                    -lcrypt -lnsl -lm -L/usr/lib -lssl -lcrypto]
  --libs_r         [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                    -lpthread -lz -lcrypt -lnsl -lm -lpthread]
  --socket         [/tmp/mysql.sock]
  --port           [3306]
```

```
  --version        [4.0.16]
  --libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld -lpthread -lz
                    -lcrypt -lnsl -lm -lpthread -lrt]
```

You can use mysql_config within a command line using backticks to include the output that it produces for a particular option. For example, to compile and link a MySQL client program, use mysql_config as follows:

```
shell> gcc -c `mysql_config --cflags` progname.c
shell> gcc -o progname progname.o `mysql_config --libs`
```

4.7.3 my_print_defaults — Display Options from Option Files

my_print_defaults displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the mysqlcheck program reads the [mysqlcheck] and [client] option groups. To see what options are present in those groups in the standard option files, invoke my_print_defaults like this:

```
shell> my_print_defaults mysqlcheck client
--user=myusername
--password=secret
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

my_print_defaults supports the following options.

- --help [358], -?

  Display a help message and exit.

- --config-file=*file_name* [358], --defaults-file=*file_name* [358], -c *file_name*

  Read only the given option file.

- --debug=*debug_options* [358], -# *debug_options*

  Write a debugging log. A typical *debug_options* string is 'd:t:o,*file_name*'. The default is 'd:t:o,/tmp/my_print_defaults.trace'.

- --defaults-extra-file=*file_name* [358], --extra-file=*file_name* [358], -e *file_name*

  Read this option file after the global option file but (on Unix) before the user option file.

- --defaults-group-suffix=*suffix* [358], -g *suffix*

  In addition to the groups named on the command line, read groups that have the given suffix.

- --no-defaults [235], -n

  Return an empty string.

- --verbose [358], -v

  Verbose mode. Print more information about what the program does.

- --version [358], -V

Display version information and exit.

4.7.4 resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols

resolve_stack_dump resolves a numeric stack dump to symbols.

Invoke resolve_stack_dump like this:

```
shell> resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the nm --numeric-sort mysqld command. The numeric dump file should contain a numeric stack track from mysqld. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

resolve_stack_dump supports the following options.

- --help [359], -h

  Display a help message and exit.

- --numeric-dump-file=*file_name* [359], -n *file_name*

  Read the stack trace from the given file.

- --symbols-file=*file_name* [359], -s *file_name*

  Use the given symbols file.

- --version [359], -V

  Display version information and exit.

4.8 Miscellaneous Programs

4.8.1 perror — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the perror utility.

perror prints a description for a system error code or for a storage engine (table handler) error code.

Invoke perror like this:

```
shell> perror [options] errorcode ...
```

Example:

```
shell> perror 13 64
OS error code  13:  Permission denied
OS error code  64:  Machine is not on the network
```

To obtain the error message for a MySQL Cluster error code, invoke perror with the --ndb [360] option:

```
shell> perror --ndb errorcode
```

Note that the meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

perror supports the following options.

- --help [360], --info [360], -I, -?

  Display a help message and exit.

- --ndb [360]

  Print the error message for a MySQL Cluster error code.

- --silent [360], -s

  Silent mode. Print only the error message.

- --verbose [360], -v

  Verbose mode. Print error code and message. This is the default behavior.

- --version [360], -V

  Display version information and exit.

4.8.2 replace — A String-Replacement Utility

The replace utility program changes strings in place in files or on the standard input.

Invoke replace in one of the following ways:

```
shell> replace from to [from to] ... -- file_name [file_name] ...
shell> replace from to [from to] ... < file_name
```

from represents a string to look for and *to* represents its replacement. There can be one or more pairs of strings.

Use the -- option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. *replace* prints a message indicating which of the input files it actually modifies.

If the -- option is not given, replace reads the standard input and writes to the standard output.

replace uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps a and b in the given files, file1 and file2:

```
```

```
shell> replace a b b a -- file1 file2 ...
```

The replace program is used by msql2mysql. See Section 4.7.1, “msql2mysql — Convert mSQL Programs for Use with MySQL”.

replace supports the following options.

- -?, -I

  Display a help message and exit.

- -#debug_options

  Enable debugging.

- -s

  Silent mode. Print less information what the program does.

- -v

  Verbose mode. Print more information about what the program does.

- -V

  Display version information and exit.

4.8.3 resolveip — Resolve Host name to IP Address or Vice Versa

The resolveip utility resolves host names to IP addresses and vice versa.

Invoke resolveip like this:

```
shell> resolveip [options] {host_name|ip-addr} ...
```

resolveip supports the following options.

- --help [361], --info [361], -?, -I

  Display a help message and exit.

- --silent [361], -s

  Silent mode. Produce less output.

- --version [361], -V

  Display version information and exit.

Chapter 5 MySQL Server Administration

Table of Contents

End of Product Lifecycle. Active development and support for MySQL Database Server versions 3.23, 4.0, and 4.1 has ended. For details, see http://www.mysql.com/about/legal/lifecycle/#calendar. Please consider upgrading to a recent version. Further updates to the content of this manual will be minimal. All formats of this manual will continue to be available until 31 Dec 2010.

MySQL Server (`mysqld`) is the main program that does most of the work in a MySQL installation. This section provides an overview of MySQL Server and covers topics that deal with administering a MySQL installation:

- Server configuration
- The server log files
- Security issues and user-account management
- Management of multiple servers on a single machine

5.1 The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports
- Server system variables
- Server status variables
- How to set the server SQL mode
- The server shutdown process

Note

Not all storage engines (also known in older versions of MySQL as “table types”) are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see Section 12.4.5.10, “`SHOW ENGINES` Syntax”.

5.1.1 Server Option and Variable Reference

The following table provides a list of all the command line options, server and status variables applicable within `mysqld`.

For a version of this table that is specific to MySQL Cluster, see Section 15.3.4.1, “MySQL Cluster Server Option and Variable Reference”.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with notification of where each option/variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding server system or status variable, the variable name is noted immediately below the corresponding option. For status variables, the scope of the variable is shown (Scope) as either global, session, or both. Please see the corresponding sections for details on setting and using the options and variables. Where appropriate, a direct link to further information on the item as available.

Table 5.1 Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
abort-slave-event-count [1173]	Yes	Yes				
Aborted_clients [449]				Yes	Global	No
Aborted_connects [449]				Yes	Global	No
allow-suspicious-udfs [384]	Yes	Yes				
ansi [384]	Yes	Yes				
autocommit [406]	Yes	Yes	Yes		Session	Yes
back_log [406]			Yes		Global	No
basedir [384]	Yes	Yes	Yes		Global	No
bdb_cache_size [406]			Yes		Global	No
bdb-home [1138]	Yes	Yes			Global	No
- *Variable*: bdb_home [407]			Yes		Global	No
bdb-lock-detect [1138]	Yes	Yes	Yes		Global	No
bdb_log_buffer_size [407]			Yes		Global	No
bdb-logdir [1138]	Yes	Yes			Global	No
- *Variable*: bdb_logdir [407]			Yes		Global	No
bdb_max_lock [407]			Yes		Global	No
bdb-no-recover [1138]	Yes	Yes				
bdb-no-sync [1138]	Yes	Yes				
bdb-shared-data [1138]	Yes	Yes			Global	No
- *Variable*: bdb_shared_data [407]			Yes		Global	No
bdb-tmpdir [1138]	Yes	Yes			Global	No
- *Variable*: bdb_tmpdir [407]			Yes		Global	No
big-tables [384]	Yes	Yes			Session	Yes
- *Variable*: big_tables [407]			Yes		Session	Yes
bind-address [384]	Yes	Yes	Yes		Global	No

[a] This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

[b] This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

5.1.2 Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in Section 4.2.3, “Specifying Program Options”. The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See Section 4.2.3.3, “Using Option Files”.

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxx_SERVER]` groups, where *xxxxx* is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a list, execute `mysqld --help`. Before MySQL 4.1.1, `--help` [384] prints the full help message. As of 4.1.1, it prints a brief message; to see the full list, use `mysqld --verbose --help`.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See Section 5.4.4, “Security-Related `mysqld` Options”.
- SSL-related options: See Section 5.6.6.3, “SSL Command Options”.
- Binary log control options: See Section 14.8.4, “Binary Log Options and Variables”.
- Replication-related options: See Section 14.8, “Replication and Binary Logging Options and Variables”.
- Options specific to particular storage engines: See Section 13.1.1, “`MyISAM` Startup Options”, Section 13.5.3, “`BDB` Startup Options”, Section 13.2.4, “`InnoDB` Startup Options and System Variables”, and Section 15.3.4.2, “`mysqld` Command Options for MySQL Cluster”.

You can also set the values of server system variables by using variable names as options, as described at the end of this section.

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `--help` [384], `-?`

  Display a short help message and exit. Before MySQL 4.1.1, `--help` [384] displays the full help message. As of 4.1.1, it displays an abbreviated message only. Use both the `--verbose` [395] and `--help` [384] options to see the full message.

- `--allow-suspicious-udfs` [384]

  This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. This option was added in MySQL 4.0.24, and 4.1.10a. See Section 18.2.2.6, “User-Defined Function Security Precautions”.

- `--ansi` [384]

  Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` [394] option instead. See Section 1.9.3, “Running MySQL in ANSI Mode”, and Section 5.1.6, “Server SQL Modes”.

- `--basedir=`*`path`* [384], `-b` *`path`* [384]

  The path to the MySQL installation directory. All paths are usually resolved relative to this directory.

- `--big-tables` [384]

  Enable large result sets by saving all temporary sets in files. This option prevents most “table full” errors, but also slows down queries for which in-memory tables would suffice. Since MySQL 3.23.2, the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- `--bind-address=`*`IP`* [384]

  The IP address to bind to. Only one address can be selected. If this option is specified multiple times, the last address given is used.

  If no address or `0.0.0.0` is specified, the server listens on all interfaces.

- `--bootstrap` [384]

  This option is used by the `mysql_install_db` script to create the MySQL privilege tables without having to start a full MySQL server.

- `--character-sets-dir=path` [385]

  The directory where character sets are installed. See Section 9.6, “Character Set Configuration”.

- `--character-set-client-handshake` [385]

  Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake` [385]; this makes MySQL 4.1 and higher behave like MySQL 4.0. This option was added in MySQL 4.1.15.

- `--character-set-server=charset_name` [385], `-C charset_name`

  Use `charset_name` as the default server character set. See Section 9.6, “Character Set Configuration”. If you use this option to specify a nondefault character set, you should also use `--collation-server` [385] to specify the collation. This option is available as of MySQL 4.1.3.

- `--chroot=path` [385], `-r path`

  Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure as of MySQL 4.0. (MySQL 3.23 is not able to provide a `chroot()` jail that is 100% closed.) Note that use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--collation-server=collation_name` [385]

  Use `collation_name` as the default server collation. This option is available as of MySQL 4.1.3. See Section 9.6, “Character Set Configuration”.

- `--console` [385]

  (Windows only.) Write error log messages to `stderr` and `stdout` even if `--log-error` [388] is specified. `mysqld` does not close the console window if this option is used.

- `--core-file` [385]

  Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On Mac OS X, a core file named `core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

  For some systems, to get a core file you must also specify the `--core-file-size` [244] option to `mysqld_safe`. See Section 4.3.2, “`mysqld_safe` — MySQL Server Startup Script”. On some systems, such as Solaris, you do not get a core file if you are also using the `--user` [395] option. There might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

- `--datadir=path` [385], `-h path`

  The path to the data directory.

- `--debug[=debug_options]` [385], `-# [debug_options]`

  If MySQL is configured with `--with-debug` [98], you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `'d:t:o,file_name'`. The default is `'d:t:i:o,mysqld.trace'`.

- `--default-character-set=charset_name` [385], `-C charset_name`

Use *`charset_name`* as the default character set. This option is deprecated in favor of `--character-set-server` [385] as of MySQL 4.1.3. See Section 9.6, “Character Set Configuration”.

For more information, see Section 18.4.3, “The DBUG Package”.

- `--default-collation=`*`collation_name`* [386]

  Use *`collation_name`* as the default collation. This option is deprecated in favor of `--collation-server` [385] as of MySQL 4.1.3. See Section 9.6, “Character Set Configuration”.

- `--default-storage-engine=`*`type`* [386]

  This option is a synonym for `--default-table-type` [386]. It is available as of MySQL 4.1.2.

- `--default-table-type=`*`type`* [386]

  Set the default table type (storage engine) for tables. See Chapter 13, *Storage Engines*.

- `--default-time-zone=`*`timezone`* [386]

  Set the default server time zone. This option sets the global `time_zone` [431] system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` [430] system variable. This option is available as of MySQL 4.1.3.

- `--delay-key-write[={OFF|ON|ALL}]` [386]

  Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for `MyISAM` tables. `OFF` disables delayed key writes. `ON` enables delayed key writes for those tables that were created with the `DELAY_KEY_WRITE` option. `ALL` delays key writes for all `MyISAM` tables. Available as of MySQL 4.0.3. See Section 7.8.2, “Tuning Server Parameters”, and Section 13.1.1, “`MyISAM` Startup Options”.

  

  Note

  If you set this variable to `ALL`, you should not use `MyISAM` tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

- `--delay-key-write-for-all-tables` [386]

  Old form of `--delay-key-write=ALL` [386] for use prior to MySQL 4.0.3. As of 4.0.3, use `--delay-key-write=ALL` [386] instead. `--delay-key-write-for-all-tables` [386] is removed in MySQL 5.5.

- `--des-key-file=`*`file_name`* [386]

  Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` [866] and `DES_DECRYPT()` [866] functions.

- `--enable-locking` [386]

  This option is deprecated. Use `--external-locking` [387] instead.

- `--enable-named-pipe` [386]

  Enable support for named pipes. This option applies only on Windows NT, 2000, XP, and 2003 systems, and can be used only with the `mysqld-nt` and `mysqld-max-nt` servers that support named-pipe connections.

- `--enable-pstack` [387]

  Print a symbolic stack trace on failure. This capability is available only on Intel Linux systems, and only if MySQL was configured with the `--with-pstack` option.

- `--exit-info[=flags]` [387], `-T [flags]`

  This is a bit mask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- `--external-locking` [387]

  Enable external locking (system locking), which is disabled by default as of MySQL 4.0. Note that if you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock. This option was named `--enable-locking` before MySQL 4.0.3.

  For more information about external locking, including conditions under which it can and cannot be used, see Section 7.6.4, “External Locking”.

- `--flush` [387]

  Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.5.4.2, “What to Do If MySQL Keeps Crashing”.

- `--gdb` [387]

  Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See Section 18.4, “Porting to Other Systems”. This option was added in MySQL 4.0.14.

- `--init-file=file_name` [387]

  Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

- `--innodb-safe-binlog` [387]

  If this option is given, then after a crash recovery by `InnoDB`, `mysqld` truncates the binary log after the last not-rolled-back transaction in the log. The option also causes `InnoDB` to print an error if the binary log is smaller or shorter than it should be. See Section 5.3.4, “The Binary Log”.

- `--innodb-xxx`

  Set an option for the `InnoDB` storage engine. The `InnoDB` options are listed in Section 13.2.4, “`InnoDB` Startup Options and System Variables”.

- `--install [service_name]` [387]

Command-Line Format	`--install [service_name]`

  (Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see Section 2.3.11, “Starting MySQL as a Windows Service”.

- `--install-manual [service_name]` [387]

Command-Line Format	`--install-manual [service_name]`

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is `MySQL` if no *`service_name`* value is given. For more information, see Section 2.3.11, “Starting MySQL as a Windows Service”.

- `--language=`*`lang_name`*`, -L` *`lang_name`* [388]

  The language to use for error messages. *`lang_name`* can be given as the language name or as the full path name to the directory where the language files are installed. See Section 9.3, “Setting the Error Message Language”.

- `--log[=`*`file_name`*`]` [388], `-l [`*`file_name`*`]`

  Log connections and SQL statements received from clients to this file. See Section 5.3.2, “The General Query Log”. If you omit the file name, MySQL uses *`host_name`*`.log` as the file name.

- `--log-error[=`*`file_name`*`]` [388]

  Log errors and startup messages to this file. See Section 5.3.1, “The Error Log”. If you omit the file name, MySQL uses *`host_name`*`.err`. If the file name has no extension, the server adds an extension of `.err`.

- `--log-isam[=`*`file_name`*`]` [388]

  Log all `ISAM`/`MyISAM` changes to this file (used only when debugging `ISAM`/`MyISAM`).

- `--log-long-format` [388]

  Log extra information to the update log, binary update log, and slow query log, if they have been activated. For example, the user name and timestamp are logged for queries. Before MySQL 4.1, if you are using `--log-slow-queries` [388] and `--log-long-format` [388], queries that are not using indexes also are logged to the slow query log. `--log-long-format` [388] is deprecated as of MySQL version 4.1, when `--log-short-format` [388] was introduced. (Long log format is the default setting since version 4.1.) Also note that starting with MySQL 4.1, the `--log-queries-not-using-indexes` [388] option is available for the purpose of logging queries that do not use indexes to the slow query log.

- `--log-queries-not-using-indexes` [388]

  If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See Section 5.3.5, “The Slow Query Log”. This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows. This option is available as of MySQL 4.1.

- `--log-short-format` [388]

  Originally intended to log less information to the update log, binary log and slow query log, if they have been activated. This option was introduced in MySQL 4.1, but is not operational.

- `--log-slow-admin-statements` [388]

  Log slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` to the slow query log.

  This option was added in MySQL 4.1.13. (It is unnecessary in MySQL 4.0 because slow administrative statements are logged by default.)

- `--log-slow-queries[=`*`file_name`*`]` [388]

Log all queries that have taken more than `long_query_time` [417] seconds to execute to this file. See Section 5.3.5, “The Slow Query Log”. Note that the default for the amount of information logged has changed in MySQL 4.1. See the `--log-long-format` [388] and `--log-short-format` [388] options for details.

- `--log-update[=file_name]` [389]

  Log updates to *`fileN`* where *`N`* is a unique number if not given. See Section 5.3.3, “The Update Log”. The update log is now deprecated; you should use the binary log instead (`--log-bin` [1181]). See Section 5.3.4, “The Binary Log”.

- `--log-warnings[=level]` [389], `-W [level]`

  Print out warnings such as `Aborted connection...` to the error log. Enabling this option by setting it greater than 0 is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). This option is enabled by default as of MySQL 4.0.19 and 4.1.2; to disable it, use `--log-warnings=0` [389]. As of MySQL 4.0.21 and 4.1.3, a *`level`* argument can be given. If omitted, the default *`level`* is 1. If the value is greater than 1, aborted connections are written to the error log. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

  If a slave server was started with `--log-warnings` [389] enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

  Before MySQL 4.0.21 and 4.1.3, this is a boolean option, not an integer-valued option. Before 4.0, this option was named `--warnings` [389].

- `--low-priority-updates` [389]

  Give table-modifying operations (`INSERT`, `REPLACE`, `DELETE`, `UPDATE`) lower priority than selects. This can also be done using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`). See Section 7.6.2, “Table Locking Issues”.

- `--memlock` [389]

  Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

  `--memlock` [389] works on systems that support the `mlockall()` system call; this includes Solaris as well as most Linux distributions that use a 2.4 or newer kernel. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
shell> grep mlockall /usr/include/sys/mman.h
```

  If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

Important

Using this option requires that you run the server as `root`, which, for reasons of security, is normally not a good idea. See Section 5.4.6, "How to Run MySQL as a Normal User".

You must not try to use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` will very likely crash as soon as you try to start it.

- `--myisam-block-size=N` [390]

  The block size to be used for `MyISAM` index pages.

- `--myisam-recover[=option[,option]...]]` [390]

  Set the `MyISAM` storage engine recovery mode. The option value is any combination of the values of `DEFAULT`, `BACKUP`, `FORCE`, or `QUICK`. If you specify multiple values, separate them by commas. You can also use a value of `""` to disable this option. If this option is used, each time `mysqld` opens a `MyISAM` table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

  The following options affect how the repair works.

Option	Description
`DEFAULT`	Recovery without backup, forcing, or quick checking.
`BACKUP`	If the data file was changed during recovery, save a backup of the *`tbl_name`*`.MYD` file as *`tbl_name-datetime`*`.BAK`.
`FORCE`	Run recovery even if we would lose more than one row from the `.MYD` file.
`QUICK`	do not check the rows in the table if there are not any delete blocks.

  Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP,FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

  See Section 13.1.1, "`MyISAM` Startup Options".

  This option is available as of MySQL 3.23.25.

- `--new`

  The `--new` option can be used to make the server behave as 4.1 in certain respects, easing a 4.0 to 4.1 upgrade:

  - Hexadecimal strings such as `0xFF` are treated as strings by default rather than as numbers. (Works in 4.0.12 and up.)
  - `TIMESTAMP` is returned as a string with the format `'YYYY-MM-DD HH:MM:SS'`. (Works in 4.0.13 and up.) See Chapter 10, *Data Types*.

  This option can be used to help you see how your applications behave in MySQL 4.1, without actually upgrading to 4.1.

- `--old-passwords` [391]

  Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See Section 5.4.2.3, “Password Hashing in MySQL”.

- `--old-protocol` [391], `-o`

  Use the 3.20 protocol for compatibility with some very old clients. This option was removed in MySQL 4.1.1.

- `--one-thread`

  Only use one thread (for debugging under Linux). This option is available only if the server is built with debugging enabled. See Section 18.4, “Porting to Other Systems”.

- `--open-files-limit=`*`count`* [391]

  Changes the number of file descriptors available to `mysqld`. You should try increasing the value of this option if `mysqld` gives you the error `Too many open files`. `mysqld` uses the option value to reserve descriptors with `setrlimit()`. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

  `mysqld` may attempt to allocate more than the requested number of descriptors (if they are available), using the values of `max_connections` [419] and `table_cache` [431] to estimate whether more descriptors will be needed.

- `--pid-file=`*`path`* [391]

  The path name of the process ID file. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. This file is used by other programs such as `mysqld_safe` to determine the server's process ID.

- `--port=`*`port_num`* [391], `-P` *`port_num`*

  The port number to use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--remove [`*`service_name`*`]` [391]

Command-Line Format	`--remove [service_name]`

  (Windows only) Remove a MySQL Windows service. The default service name is `MySQL` if no *`service_name`* value is given. For more information, see Section 2.3.11, “Starting MySQL as a Windows Service”.

- `--safe-mode` [391]

  Skip some optimization stages.

- `--safe-show-database` [391]

  With this option, the `SHOW DATABASES` statement displays only the names of those databases for which the user has some kind of privilege. As of MySQL 4.0.2, this option is deprecated and does not do anything (it is enabled by default), because there is a `SHOW DATABASES` privilege that can be used to control access to database names on a per-account basis. See Section 5.5.1, “Privileges Provided by MySQL”.

- `--safe-user-create` [392]

  If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement, if the user does not have the `INSERT` [492] privilege for the `mysql.user` table or any column in the table.

- `--secure-auth` [392]

  Disallow authentication by clients that attempt to use accounts that have old (pre-4.1) passwords. This option is available as of MySQL 4.1.1.

- `--shared-memory` [392]

  Enable shared-memory connections by local clients. This option is available only on Windows. It was added in MySQL 4.1.0.

- `--shared-memory-base-name=`*name* [392]

  The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive. This option was added in MySQL 4.1.0.

- `--skip-bdb` [392]

  Disable the `BDB` storage engine. This saves memory and might speed up some operations. Do not use this option if you require `BDB` tables.

- `--skip-concurrent-insert` [392]

  Turn off the ability to select and insert at the same time on `MyISAM` tables. (This is to be used only if you think you have found a bug in this feature.) See Section 7.6.3, “Concurrent Inserts”.

- `--skip-delay-key-write` [392]

  Ignore the `DELAY_KEY_WRITE` option for all tables. As of MySQL 4.0.3, you should use `--delay-key-write=OFF` [386] instead. See Section 7.8.2, “Tuning Server Parameters”.

- `--skip-external-locking` [392]

  Do not use external locking (system locking). For more information about external locking, including conditions under which it can and cannot be used, see Section 7.6.4, “External Locking”.

  External locking has been disabled by default since MySQL 4.0.

- `--skip-grant-tables` [392]

  This option causes the server to start without using the privilege system at all, which gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server. This option also suppresses loading of user-defined functions (UDFs).

- `--skip-host-cache` [392]

  Do not use the internal host name cache for faster name-to-IP resolution. Instead, query the DNS server every time a client connects. See Section 7.8.5, “How MySQL Uses DNS”.

- `--skip-innodb` [1066]

Disable the `InnoDB` storage engine. In this case, the server will not start if the default storage engine is set to `InnoDB`. Use `--default-storage-engine` [386] to set the default to some other engine if necessary.

- `--skip-isam` [393]

  Disable the `ISAM` storage engine. As of MySQL 4.1, `ISAM` is disabled by default, so this option applies only if the server was configured with support for `ISAM`. This option was added in MySQL 4.1.1.

- `--skip-merge` [393]

  Disable the `MERGE` storage engine. This option was added in MySQL 4.1.21. It can be used if the following behavior is undesirable: If a user has access to `MyISAM` table *`t`*, that user can create a `MERGE` table *`m`* that accesses *`t`*. However, if the user's privileges on *`t`* are subsequently revoked, the user can continue to access *`t`* by doing so through *`m`*.

- `--skip-name-resolve` [393]

  Do not resolve host names when checking client connections. Use only IP addresses. If you use this option, all `Host` column values in the grant tables must be IP addresses or `localhost`. See Section 7.8.5, “How MySQL Uses DNS”.

- `--skip-networking` [393]

  Do not listen for TCP/IP connections at all. All interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See Section 7.8.5, “How MySQL Uses DNS”.

- `--skip-new`

  Do not use new, possibly wrong routines.

- `--skip-symlink` [393]

  This is the old form of `--skip-symbolic-links` [393], for use before MySQL 4.0.13. `--skip-symlink` [393] is deprecated as of 4.0.13 and is removed in MySQL 5.5.

- `--ssl*`

  Options that begin with `--ssl` [521] specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See Section 5.6.6.3, “SSL Command Options”.

- `--standalone` [393]

  Available on Windows NT-based systems only; instructs the MySQL server not to run as a service.

- `--symbolic-links` [393], `--skip-symbolic-links` [393]

  Enable or disable symbolic link support. This option has different effects on Windows and Unix:

  - On Windows, enabling symbolic links enables you to establish a symbolic link to a database directory by creating a *`db_name`*`.sym` file that contains the path to the real directory. See Section 7.10.3, “Using Symbolic Links for Databases on Windows”.

  - On Unix, enabling symbolic links means that you can link a `MyISAM` index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Section 7.10.2, “Using Symbolic Links for Tables on Unix”.

This option was added in MySQL 4.0.13.

- `--skip-safemalloc` [394]

  If MySQL is configured with `--with-debug=full` [98], all MySQL programs check for memory overruns during each memory allocation and memory freeing operation. This checking is very slow, so for the server you can avoid it when you do not need it by using the `--skip-safemalloc` [394] option.

- `--skip-show-database` [394]

  This option sets the `skip_show_database` [427] system variable that controls who is permitted to use the `SHOW DATABASES` statement. See Section 5.1.3, “Server System Variables”.

- `--skip-stack-trace` [394]

  do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See Section 18.4, “Porting to Other Systems”.

- `--skip-thread-priority` [394]

  Disable using thread priorities for faster response time.

  `mysqld` makes a large number of invalid calls to thread scheduling routines on Linux. These calls do not affect performance noticeably but may be a source of “noise” for debugging tools. For example, they can overwhelm other information of more interest in kernel logs. To avoid these calls, start the server with the `--skip-thread-priority` [394] option.

- `--socket=`*`path`* [394]

  On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=`*`value`*`[,`*`value`*`[,`*`value`*`...]]` [394]

  Set the SQL mode. See Section 5.1.6, “Server SQL Modes”. This option was added in 3.23.41.

- `--temp-pool` [394]

  This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to “leak” memory, because it is being allocated to the directory entry cache rather than to the disk cache.

- `--transaction-isolation=`*`level`* [394]

  Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED` [975], `READ-COMMITTED` [975], `REPEATABLE-READ` [976], or `SERIALIZABLE` [976]. See Section 12.3.6, “`SET TRANSACTION` Syntax”.

- `--tmpdir=`*`path`* [394], `-t` *`path`*

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. Starting from MySQL 4.1.0, this option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (“`:`”) on Unix and semicolon characters (“`;`”) on Windows, NetWare, and OS/2. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` [394] to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see Section B.5.4.4, “Where MySQL Stores Temporary Files”. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name|user_id}` [395], `-u {user_name|user_id}`

  Run the `mysqld` server as the user having the name *`user_name`* or the numeric user ID *`user_id`*. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

  This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See Section 5.4.1, “General Security Guidelines”.

  Starting from MySQL 3.23.56 and 4.0.12: To avoid a possible security hole where a user adds a `--user=root` [395] option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` [395] option specified and produces a warning if there are multiple `--user` [395] options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` [395] option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` [395] options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` [395] option is found.

- `--verbose` [395], `-v` [395]

  As of MySQL 4.1.1, use this option with the `--help` [384] option for detailed help.

- `--version` [395], `-V`

  Display version information and exit.

As of MySQL 4.0, you can assign a value to a server system variable by using an option of the form `--var_name=value`. For example, `--key_buffer_size=32M` [415] sets the `key_buffer_size` [415] variable to a value of 32MB.

Note that when you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

If you want to restrict the maximum value to which a variable can be set at runtime with `SET`, you can define this by using the `--maximum-var_name=value` command-line option.

It is also possible to set variables by using `--set-variable=var_name=value` or `--var_name=value` syntax. *This syntax is deprecated as of MySQL 4.0.*

You can change the values of most system variables for a running server with the `SET` statement. See Section 12.4.4, “`SET` Syntax”.

Section 5.1.3, “Server System Variables”, provides a full description for all variables, and additional information for setting them at server startup and runtime. Section 7.8.2, “Tuning Server Parameters”, includes information on optimizing the server by tuning system variables.

5.1.3 Server System Variables

The MySQL server maintains many system variables that indicate how it is configured. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. As of MySQL 4.0.3, most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command (omit `--verbose` [395] before MySQL 4.1.1):

```
mysqld --verbose --help
```

- To see the values that a server will use based on its compiled-in defaults, ignoring the settings in any option files, use this command (omit `--verbose` [395] before MySQL 4.1.1):

```
mysqld --no-defaults --verbose --help
```

  For more information, see Section 18.4.3, “The DBUG Package”.

- To see the current values used by a running server, use the `SHOW VARIABLES` statement.

This section provides a description of each system variable. Variables with no version indicated have been present since at least MySQL 3.22.

The following table lists all available system variables.

Table 5.2 System Variable Summary

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
autocommit [406]	Yes	Yes	Yes	Session	Yes
back_log [406]			Yes	Global	No
basedir [384]	Yes	Yes	Yes	Global	No
bdb_cache_size [406]			Yes	Global	No
bdb-home [1138]	Yes	Yes			No
- *Variable*: bdb_home [407]			Yes	Global	No
bdb-lock-detect [1138]	Yes	Yes	Yes	Global	No
bdb_log_buffer_size [407]			Yes	Global	No
bdb-logdir [1138]	Yes	Yes			No
- *Variable*: bdb_logdir [407]			Yes	Global	No
bdb_max_lock [407]			Yes	Global	No
bdb-shared-data [1138]	Yes	Yes			No
- *Variable*: bdb_shared_data [407]			Yes	Global	No

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
bdb-tmpdir [1138]	Yes	Yes			No
- *Variable*: bdb_tmpdir [407]			Yes	Global	No
big-tables [384]	Yes	Yes			Yes
- *Variable*: big_tables [407]			Yes	Session	Yes
bind-address [384]	Yes	Yes	Yes	Global	No
binlog_cache_size [407]	Yes	Yes	Yes	Global	Yes
bulk_insert_buffer_size [408]	Yes	Yes	Yes	Both	Yes
character_set [408]	Yes		Yes	Global	No
character_set_client [408]			Yes	Both	Yes
character_set_connection [408]			Yes	Both	Yes
character_set_database [408][a]			Yes	Both	Yes
character_set_results [408]			Yes	Both	Yes
character-set-server [385]	Yes	Yes			Yes
- *Variable*: character_set_server [408]			Yes	Both	Yes
character_set_system [409]			Yes	Global	No
character-sets-dir [385]	Yes	Yes			No
- *Variable*: character_sets_dir [409]			Yes	Global	No
collation_connection [409]			Yes	Both	Yes
collation_database [409][b]			Yes	Both	Yes
collation-server [385]	Yes	Yes			Yes
- *Variable*: collation_server [409]			Yes	Both	Yes
concurrent_insert [409]	Yes	Yes	Yes	Global	Yes
connect_timeout [409]	Yes	Yes	Yes	Global	Yes
datadir [385]	Yes	Yes	Yes	Global	No
date_format [409]			Yes	Both	No
datetime_format [410]			Yes	Both	No
debug [385]	Yes	Yes	Yes	Both	Yes
default-storage-engine [386]	Yes	Yes	Yes	Both	Yes
default_week_format [410]	Yes	Yes	Yes	Both	Yes
delay-key-write [386]	Yes	Yes			Yes

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
- *Variable*: delay_key_write [410]			Yes	Global	Yes
delayed_insert_limit [410]	Yes	Yes	Yes	Global	Yes
delayed_insert_timeout [410]	Yes	Yes	Yes	Global	Yes
delayed_queue_size [410]	Yes	Yes	Yes	Global	Yes
error_count [410]			Yes	Session	No
expire_logs_days [411]	Yes	Yes	Yes	Global	Yes
flush [411]	Yes	Yes	Yes	Global	Yes
flush_time [411]	Yes	Yes	Yes	Global	Yes

[a] This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

[b] This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

For additional system variable information, see these sections:

- Section 5.1.4, “Using System Variables”, discusses the syntax for setting and displaying system variable values.
- Section 5.1.4.2, “Dynamic System Variables”, lists the variables that can be set at runtime.
- Information on tuning system variables can be found in Section 7.8.2, “Tuning Server Parameters”.
- Section 13.2.4, “`InnoDB` Startup Options and System Variables”, lists `InnoDB` system variables.
- Section 15.3.4.3, “MySQL Cluster System Variables”, lists system variables which are specific to MySQL Cluster.
- For information on server system variables specific to replication, see Section 14.8, “Replication and Binary Logging Options and Variables”.

Note

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` [410] works but `--delay_key_write=ON` [410] does not.

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also

possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `ansi_mode`

  This is `ON` if `mysqld` was started with `--ansi` [384]. See Section 1.9.3, “Running MySQL in ANSI Mode”. This variable was added in MySQL 3.23.6 and removed in 3.23.41. See the description for `sql_mode` [429].

  Depending on the network configuration of your system and the `Host` values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=localhost` or `--host=127.0.0.1`.

- `autocommit` [406]

  The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` [406] is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 12.3.1, “`START TRANSACTION`, `COMMIT`, and `ROLLBACK` Syntax”.

  By default, client connections begin with `autocommit` [406] set to 1. To cause clients to begin with a default of 0, set the server's `init_connect` [414] system variable. See the description of that variable for instructions that show how to do this.

- `back_log` [406]

  The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` [406] value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

  In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` [406] cannot be set higher than your operating system limit.

- `basedir` [406]

  The MySQL installation base directory. This variable can be set with the `--basedir` [384] option. Relative path names for other variables usually are resolved relative to the base directory.

- `bdb_cache_size` [406]

  The size of the buffer that is allocated for caching indexes and rows for `BDB` tables. If you do not use `BDB` tables, you should start `mysqld` with `--skip-bdb` [392] to not allocate memory for this cache. This variable was added in MySQL 3.23.14.

- `bdb_home` [407]

  The base directory for `BDB` tables. This should be assigned the same value as the `datadir` [409] variable. This variable was added in MySQL 3.23.14.

- `bdb_log_buffer_size` [407]

  The size of the buffer that is allocated for caching indexes and rows for `BDB` tables. If you do not use `BDB` tables, you should set this to 0 or start `mysqld` with `--skip-bdb` [392] in order not to allocate memory for this cache. This variable was added in MySQL 3.23.31.

- `bdb_logdir` [407]

  The directory where the `BDB` storage engine writes its log files. This variable can be set with the `--bdb-logdir` [1138] option. This variable was added in MySQL 3.23.14.

- `bdb_max_lock` [407]

  The maximum number of locks that can be active for a `BDB` table (10,000 by default). You should increase this value if errors such as the following occur when you perform long transactions or when `mysqld` has to examine many rows to calculate a query:

  ```
  bdb: Lock table is out of available locks
  Got error 12 from ...
  ```

  This variable was added in MySQL 3.23.29.

- `bdb_shared_data` [407]

  This is `ON` if you are using `--bdb-shared-data` [1138] to start Berkeley DB in multi-process mode. (Do not use `DB_PRIVATE` when initializing Berkeley DB.) This variable was added in MySQL 3.23.29.

- `bdb_tmpdir` [407]

  The `BDB` temporary file directory. This variable was added in MySQL 3.23.14.

- `bdb_version` [407]

  See the description for `version_bdb` [433].

- `big_tables` [407]

  If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). As of MySQL 4.0, you should normally never need to set this variable, because MySQL automatically converts in-memory tables to disk-based tables as necessary.

  

  Note

  This variable was formerly named `sql_big_tables`.

- `binlog_cache_size` [407]

  The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and, starting from MySQL 4.1.2, if the server has the binary log enabled (`--log-bin` [1181] option). If you often use

large, multiple-statement transactions, you can increase this cache size to get more performance. The `Binlog_cache_use` [449] and `Binlog_cache_disk_use` [449] status variables can be useful for tuning the size of this variable. This variable was added in MySQL 3.23.29. See Section 5.3.4, "The Binary Log".

- `bulk_insert_buffer_size` [408]

  `MyISAM` uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB. Before MySQL 4.0.3. this variable was named `myisam_bulk_insert_tree_size`.

- `character_set` [408]

  The default character set. This variable was added in MySQL 3.23.3, then removed in MySQL 4.1.1 and replaced by the various `character_set_`*`xxx`* variables.

- `character_set_client` [408]

  The character set for statements that arrive from the client. This variable was added in MySQL 4.1.1.

  The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also Section 9.1.4, "Connection Character Sets and Collations".) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

  - The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
  - The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
  - `mysqld` was started with the `--skip-character-set-client-handshake` [385] option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

  `ucs2` cannot be used as a client character set, which means that it also does not work for `SET NAMES` or `SET CHARACTER SET`.

- `character_set_connection` [408]

  The character set used for literals that do not have a character set introducer and for number-to-string conversion. This variable was added in MySQL 4.1.1.

- `character_set_database` [408]

  The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server` [408]. This variable was added in MySQL 4.1.1.

- `character_set_results` [408]

  The character set used for returning query results such as result sets or error messages to the client. This variable was added in MySQL 4.1.1.

- `character_set_server` [408]

The server default character set. This variable was added in MySQL 4.1.1.

- `character_set_system` [409]

  The character set used by the server for storing identifiers. The value is always `utf8`. This variable was added in MySQL 4.1.1.

- `character_sets` [409]

  The supported character sets. This variable was added in MySQL 3.23.15 and removed in MySQL 4.1.1. (Use `SHOW CHARACTER SET` for a list of character sets.)

- `character_sets_dir` [409]

  The directory where character sets are installed. This variable was added in MySQL 4.1.2.

- `collation_connection` [409]

  The collation of the connection character set. This variable was added in MySQL 4.1.1.

- `collation_database` [409]

  The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server` [409]. This variable was added in MySQL 4.1.1.

- `collation_server` [409]

  The server default collation. This variable was added in MySQL 4.1.1.

- `concurrent_insert` [409]

  If `ON` (the default), MySQL permits `INSERT` and `SELECT` statements to run concurrently for `MyISAM` tables that have no free blocks in the middle of the data file. If `OFF`, concurrent inserts are disabled. If you start `mysqld` with `--skip-new` [390], this variable is set to `OFF`. This variable was added in MySQL 3.23.7.

  See also Section 7.6.3, “Concurrent Inserts”.

- `connect_timeout` [409]

  The number of seconds that the `mysqld` server waits for a connect packet before responding with `Bad handshake`. The default value is 5 seconds.

  Increasing the `connect_timeout` [409] value might help if clients frequently encounter errors of the form `Lost connection to MySQL server at '`*`XXX`*`', system error: `*`errno`*.

- `convert_character_set` [409]

  The current character set mapping that was set by `SET CHARACTER SET`. This variable was removed in MySQL 4.1.

- `datadir` [409]

  The MySQL data directory. This variable can be set with the `--datadir` [385] option.

- `date_format` [409]

  This variable is unused.

- `datetime_format` [410]

  This variable is unused.

- `default_week_format` [410]

  The default mode value to use for the `WEEK()` [843] function. See Section 11.7, “Date and Time Functions”. This variable is available as of MySQL 4.0.14.

- `delay_key_write` [410]

  This option applies only to `MyISAM` tables. It can have one of the following values to affect handling of the `DELAY_KEY_WRITE` table option that can be used in `CREATE TABLE` statements.

Option	Description
`OFF`	`DELAY_KEY_WRITE` is ignored.
`ON`	MySQL honors any `DELAY_KEY_WRITE` option specified in `CREATE TABLE` statements. This is the default value.
`ALL`	All new opened tables are treated as if they were created with the `DELAY_KEY_WRITE` option enabled.

  If `DELAY_KEY_WRITE` is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all `MyISAM` tables by starting the server with the `--myisam-recover` [390] option (for example, `--myisam-recover=BACKUP,FORCE` [390]). See Section 5.1.2, “Server Command Options”, and Section 13.1.1, “`MyISAM` Startup Options”.

  Warning

  If you enable external locking with `--external-locking` [387], there is no protection against index corruption for tables that use delayed key writes.

  This variable was added in MySQL 3.23.8.

- `delayed_insert_limit` [410]

  After inserting `delayed_insert_limit` [410] delayed rows, the `INSERT DELAYED` handler thread checks whether there are any `SELECT` statements pending. If so, it permits them to execute before continuing to insert delayed rows.

- `delayed_insert_timeout` [410]

  How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

- `delayed_queue_size` [410]

  This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

- `error_count` [410]

  The number of errors that resulted from the last statement that generated messages. This variable is read only. See Section 12.4.5.11, “`SHOW ERRORS` Syntax”.

This variable was added in MySQL 4.1.0.

- `expire_logs_days` [411]

  The number of days for automatic binary log file removal. The default is 0, which means "no automatic removal." Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in Section 5.3, "MySQL Server Logs". This variable was added in MySQL 4.1.0.

  To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See Section 12.5.1.1, "`PURGE BINARY LOGS` Syntax".

- `flush` [411]

  If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.5.4.2, "What to Do If MySQL Keeps Crashing". This variable is set to `ON` if you start `mysqld` with the `--flush` [387] option. This variable was added in MySQL 3.22.9.

- `flush_time` [411]

  If this is set to a nonzero value, all tables are closed every `flush_time` [411] seconds to free up resources and synchronize unflushed data to disk. This option is best used only on Windows 9x or Me, or on systems with minimal resources. This variable was added in MySQL 3.22.18.

- `foreign_key_checks` [411]

  If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. This variable was added in MySQL 3.23.52. See Section 13.2.5.4, "`FOREIGN KEY` Constraints".

  Setting `foreign_key_checks` [411] to 0 also affects data definition statements: `DROP DATABASE` drops a database even if it contains tables that have foreign keys that are referred to by tables outside the database, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

  

  Note

  Setting `foreign_key_checks` [411] to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` [411] will not be verified for consistency.

- `ft_boolean_syntax` [411]

  The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See Section 11.9.2, "Boolean Full-Text Searches". This variable was added as a read-only variable in MySQL 4.0.1. It can be modified as of MySQL 4.1.2.

  The default variable value is `'+ -><()~*:""&|'`. The rules for changing the value are as follows:

  - Operator function is determined by position within the string.
  - The replacement value must be 14 characters.
  - Each character must be an ASCII nonalphanumeric character.
  - Either the first or second character must be a space.

  - No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
  - Positions 10, 13, and 14 (which by default are set to ":", "&", and "|") are reserved for future extensions.

- `ft_max_word_len` [412]

  The maximum length of the word to be included in a `FULLTEXT` index. This variable was added in MySQL 4.0.0.

  

  Note

  `FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_min_word_len` [412]

  The minimum length of the word to be included in a `FULLTEXT` index. This variable was added in MySQL 4.0.0.

  

  Note

  `FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_query_expansion_limit` [412]

  The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`. This variable was added in MySQL 4.1.1.

- `ft_stopword_file` [412]

  The file from which to read the list of stopwords for full-text searches. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `myisam/ft_static.c` file). Setting this variable to the empty string (`''`) disables stopword filtering. See also Section 11.9.4, "Full-Text Stopwords". This variable was added in MySQL 4.0.10.

  

  Note

  `FULLTEXT` indexes must be rebuilt after changing this variable or the contents of the stopword file. Use `REPAIR TABLE tbl_name QUICK`.

- `group_concat_max_len` [412]

  The maximum permitted result length in bytes for the `GROUP_CONCAT()` [883] function. The default is 1024. This variable was added in MySQL 4.1.0.

- `have_archive` [412]

  `YES` if `mysqld` supports `ARCHIVE` tables, `NO` if not. This variable was added in MySQL 4.1.3.

- `have_bdb` [412]

  `YES` if `mysqld` supports `BDB` tables. `DISABLED` if `--skip-bdb` [392] is used. This variable was added in MySQL 3.23.30.

- have_blackhole_engine [413]

  YES if mysqld supports BLACKHOLE tables, NO if not. This variable was added in MySQL 4.1.11.

- have_compress [413]

  YES if the zlib compression library is available to the server, NO if not. If not, the COMPRESS() [866] and UNCOMPRESS() [869] functions cannot be used. This variable was added in MySQL 4.1.1.

- have_crypt [413]

  YES if the crypt() system call is available to the server, NO if not. If not, the ENCRYPT() [867] function cannot be used. This variable was added in MySQL 4.0.10.

- have_csv [413]

  YES if mysqld supports ARCHIVE tables, NO if not. This variable was added in MySQL 4.1.4.

- have_example_engine [413]

  YES if mysqld supports EXAMPLE tables, NO if not. This variable was added in MySQL 4.1.4.

- have_geometry [413]

  YES if the server supports spatial data types, NO if not. This variable was added in MySQL 4.1.3.

- have_innodb [413]

  YES if mysqld supports InnoDB tables. DISABLED if --skip-innodb [1066] is used. This variable was added in MySQL 3.23.37.

- have_isam [413]

  YES if mysqld supports ISAM tables. DISABLED if --skip-isam [393] is used. This variable was added in MySQL 3.23.30.

- have_merge_engine [413]

  YES if mysqld supports MERGE tables. DISABLED if --skip-merge [393] is used. This variable was added in MySQL 4.1.21.

- have_openssl [413]

  YES if mysqld supports SSL (encryption) connections, NO if not. This variable was added in MySQL 3.23.43.

- have_query_cache [413]

  YES if mysqld supports the query cache, NO if not. This variable was added in MySQL 4.0.2.

- have_raid [413]

  YES if mysqld supports the RAID option, NO if not. This variable was added in MySQL 3.23.30.

- have_rtree_keys [413]

  YES if RTREE indexes are available, NO if not. (These are used for spatial indexes in MyISAM tables.) This variable was added in MySQL 4.1.3.

- have_symlink [413]

YES if symbolic link support is enabled, NO if not. This is required on Unix for support of the DATA DIRECTORY and INDEX DIRECTORY table options, and on Windows for support of data directory symlinks.

This variable was added in MySQL 4.0.0.

- identity [414]

  This variable is a synonym for the last_insert_id [416] variable. It exists for compatibility with other database systems. As of MySQL 3.23.25, you can read its value with SELECT @@identity. As of MySQL 4.0.3, you can also set its value with SET identity.

- init_connect [414]

  A string to be executed by the server for each client that connects. The string consists of one or more SQL statements. To specify multiple statements, separate them by semicolon characters. For example, each client begins by default with autocommit mode enabled. There is no global system variable to specify that autocommit should be disabled by default, but init_connect [414] can be used to achieve the same effect:

  ```
  SET GLOBAL init_connect='SET autocommit=0';
  ```

  This variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

  ```
  [mysqld]
  init_connect='SET autocommit=0'
  ```

  The content of init_connect [414] is not executed for users that have the SUPER [493] privilege. This is done so that an erroneous value for init_connect [414] does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing init_connect [414] for users that have the SUPER [493] privilege enables them to open a connection and fix the init_connect [414] value.

  This variable was added in MySQL 4.1.2.

- init_file [414]

  The name of the file specified with the --init-file [387] option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. No statement terminator such as ;, \g, or \G should be given at the end of each statement. This variable was added in MySQL 3.23.2.

- innodb_*xxx*

  InnoDB system variables are listed in Section 13.2.4, “InnoDB Startup Options and System Variables”.

- insert_id [414]

  The value to be used by the following INSERT or ALTER TABLE statement when inserting an AUTO_INCREMENT value. This is mainly used with the binary log.

- interactive_timeout [414]

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout` [434].

- `join_buffer_size` [415]

  The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` [415] to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary. There is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

  For additional information about join buffering, see Section 7.3.1.6, “Nested-Loop Join Algorithms”.

- `key_buffer_size` [415]

  Index blocks for `MyISAM` and `ISAM` tables are buffered and are shared by all threads. `key_buffer_size` [415] is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

  The maximum permissible setting for `key_buffer_size` [415] is 4GB. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

  You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the `MyISAM` storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to `MyISAM`.

  For even more speed when writing many rows at the same time, use `LOCK TABLES`. See Section 7.3.2.1, “Speed of `INSERT` Statements”.

  You can check the performance of the key buffer by issuing a `SHOW STATUS` statement and examining the `Key_read_requests` [452], `Key_reads` [452], `Key_write_requests` [452], and `Key_writes` [452] status variables. (See Section 12.4.5, “`SHOW` Syntax”.) The `Key_reads/Key_read_requests` ratio should normally be less than 0.01. The `Key_writes/Key_write_requests` ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the `DELAY_KEY_WRITE` table option.

  The fraction of the key buffer in use can be determined using `key_buffer_size` [415] in conjunction with the `Key_blocks_unused` [452] status variable and the buffer block size. From MySQL 4.1.1 on, the buffer block size is available from the `key_cache_block_size` [416] server variable. The fraction of the buffer in use is:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

Before MySQL 4.1.1, key cache blocks are 1024 bytes, and before MySQL 4.1.2, `Key_blocks_unused` [452] is unavailable. The `Key_blocks_used` [452] variable can be used as follows to determine the fraction of the key buffer in use:

```
(Key_blocks_used × 1024) / key_buffer_size
```

However, `Key_blocks_used` [452] indicates the maximum number of blocks that have ever been in use at once, so this formula does not necessarily represent the current fraction of the buffer that is in use.

As of MySQL 4.1, it is possible to create multiple `MyISAM` key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 7.5.1, “The `MyISAM` Key Cache”.

- `key_cache_age_threshold` [416]

  This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. This variable was added in MySQL 4.1.1. See Section 7.5.1, “The `MyISAM` Key Cache”.

- `key_cache_block_size` [416]

  The size in bytes of blocks in the key cache. The default value is 1024. This variable was added in MySQL 4.1.1. See Section 7.5.1, “The `MyISAM` Key Cache”.

- `key_cache_division_limit` [416]

  The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. This variable was added in MySQL 4.1.1. See Section 7.5.1, “The `MyISAM` Key Cache”.

- `language` [416]

  The directory where error messages are located. See Section 9.3, “Setting the Error Message Language”.

- `large_files_support` [416]

  Whether `mysqld` was compiled with options for large file support. This variable was added in MySQL 3.23.28.

- `last_insert_id` [416]

  The value to be returned from `LAST_INSERT_ID()` [874]. This is stored in the binary log when you use `LAST_INSERT_ID()` [874] in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `lc_time_names` [417]

  This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()` [832], `DAYNAME()` [833] and `MONTHNAME()` [837] functions. Locale names are POSIX-style values such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting. For further information, see Section 9.8, “MySQL Server Locale Support”. This variable was added in MySQL 4.1.21.

- `license` [417]

  The type of license the server has. This variable was added in MySQL 4.0.19.

- `local_infile` [417]

  Whether `LOCAL` is supported for `LOAD DATA INFILE` statements. See Section 5.4.5, “Security Issues with `LOAD DATA LOCAL`”. This variable was added in MySQL 4.0.3.

- `locked_in_memory` [417]

  Whether `mysqld` was locked in memory with `--memlock` [389]. This variable was added in MySQL 3.23.25.

- `log` [417]

  Whether logging of all statements to the general query log is enabled. See Section 5.3.2, “The General Query Log”.

- `log_error` [417]

  The location of the error log. This variable was added in MySQL 4.0.10.

- `log_slow_queries` [417]

  Whether slow queries should be logged. “Slow” is determined by the value of the `long_query_time` [417] variable. This variable was added in MySQL 4.0.2. See Section 5.3.5, “The Slow Query Log”.

- `log_update` [417]

  Whether the update log is enabled. This variable was added in MySQL 3.22.18. Note that the binary log is preferable to the update log, which is unavailable as of MySQL 5.0. See Section 5.3.3, “The Update Log”.

- `log_warnings` [417]

  Whether to produce additional warning messages. This variable was added in MySQL 4.0.3. It is enabled by default as of MySQL 4.0.19 and 4.1.2. As of MySQL 4.0.21 and 4.1.3, the variable can take values greater than 1 and aborted connections are not logged to the error log unless the value is greater than 1.

- `long_query_time` [417]

  If a query takes longer than this many seconds, the server increments the `Slow_queries` [455] status variable. If you are using the `--log-slow-queries` [388] option, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum value is 1. The default is 10. See Section 5.3.5, “The Slow Query Log”.

- `low_priority_updates` [418]

  If set to `1`, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`). Before MySQL 3.22.5, this variable was named `sql_low_priority_updates`.

- `lower_case_file_system` [418]

  This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case sensitive, `ON` means they are not case sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system. This variable was added in MySQL 4.0.19.

- `lower_case_table_names` [418]

  If set to 0, table names are stored as specified and comparisons are case sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. This variable was added in MySQL 3.23.6. If set to 2 (new in 4.0.18), table names are stored as given but compared in lowercase. From MySQL 4.0.2, this option also applies to database names. From 4.1.1, it also applies to table aliases. For additional information, see Section 8.2.2, “Identifier Case Sensitivity”.

  You should *not* set this variable to 0 if you are running MySQL on a system that does not have case-sensitive file names (such as Windows or Mac OS X). If you set this variable to 0 on such a system and access `MyISAM` tablenames using different lettercases, index corruption may result. *New in 4.0.18*: If this variable is not set at startup and the file system on which the data directory is located does not have case-sensitive file names, MySQL automatically sets `lower_case_table_names` [418] to 2.

  If you are using `InnoDB` tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

  The setting of this variable has no effect on replication filtering options. See Section 14.9, “How Servers Evaluate Replication Filtering Rules”, for more information.

  You should not use different settings for `lower_case_table_names` on replication masters and slaves. In particular, you should not do this when the slave uses a case-sensitive file system, as this can cause replication to fail. For more information, see Section 14.7.20, “Replication and Variables”.

- `max_allowed_packet` [418]

  The maximum size of one packet or any generated/intermediate string.

  The packet message buffer is initialized to `net_buffer_length` [422] bytes, but can grow up to `max_allowed_packet` [418] bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

  You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` [418] is 16MB before MySQL 4.0 and 1GB thereafter. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

  When you change the message buffer size by changing the value of the `max_allowed_packet` [418] variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` [418] value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults

of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` [418] on the command line or in an option file.

- `max_connect_errors` [419]

  If there are more than this number of interrupted connections from a host, that host is blocked from further connections. You can unblock blocked hosts with the `FLUSH HOSTS` statement. If a connection is established successfully within fewer than `max_connect_errors` [419] attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, the `FLUSH HOSTS` statement is the only way to unblock it.

- `max_connections` [419]

  The maximum permitted number of simultaneous client connections. By default, this is 100. See Section B.5.2.7, “`Too many connections`”, for more information.

  Increasing this value increases the number of file descriptors that `mysqld` requires. See Section 7.7.2, “How MySQL Opens and Closes Tables”, for comments on file descriptor limits.

- `max_delayed_threads` [419]

  Do not start more than this number of threads to handle `INSERT DELAYED` statements. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute was not specified. If you set this to 0, MySQL never creates a thread to handle `DELAYED` rows; in effect, doing so disables `DELAYED` entirely. This variable was added in MySQL 3.23.0.

  For the `SESSION` value of this variable, the only valid values are 0 or the `GLOBAL` value.

- `max_error_count` [419]

  The maximum number of error, warning, and note messages to be stored for display by the `SHOW ERRORS` or `SHOW WARNINGS` statements. This variable was added in MySQL 4.1.0.

- `max_heap_table_size` [419]

  This variable sets the maximum size to which user-created `MEMORY` (`HEAP`) tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE`, or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` [419] value. This variable was added in MySQL 3.23.0.

  This variable is also used in conjunction with `tmp_table_size` [432] to limit the size of internal in-memory tables. See Section 7.7.4, “How MySQL Uses Internal Temporary Tables”.

- `max_insert_delayed_threads` [419]

  This variable is a synonym for `max_delayed_threads` [419]. It was added in MySQL 4.0.19.

- `max_join_size` [419]

  Do not permit statements that probably need to examine more than `max_join_size` [419] rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` [419] disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` [428] to `0`. If you set the `sql_big_selects` [428] value again, the `max_join_size` [419] variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

This variable previously was named `sql_max_join_size`.

- `max_length_for_sort_data` [420]

  The cutoff on the size of index values that determines which `filesort` algorithm to use. See Section 7.3.1.7, "`ORDER BY` Optimization". This variable was added in MySQL 4.1.1

- `max_prepared_stmt_count` [420]

  This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements. This variable was added in MySQL 4.1.19.

- `max_relay_log_size` [420]

  If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` [420] is 0, the server uses `max_binlog_size` [1184] for both the binary log and the relay log. If `max_relay_log_size` [420] is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` [420] to between 4096 bytes and 1GB (inclusive), or to `0`. The default value is `0`. This variable was added in MySQL 4.0.14. See Section 14.3, "Replication Implementation Details".

- `max_seeks_for_key` [420]

  Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see Section 12.4.5.13, "`SHOW INDEX` Syntax"). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

  This variable was added in MySQL 4.0.14.

- `max_sort_length` [420]

  The number of bytes to use when sorting `BLOB` or `TEXT` values. Only the first `max_sort_length` [420] bytes of each value are used; the rest are ignored.

- `max_tmp_tables` [420]

  The maximum number of temporary tables a client can keep open at the same time. (This variable does not yet do anything.)

- `max_user_connections` [420]

  The maximum number of simultaneous connections permitted to any given MySQL user account. A value of `0` means "no limit." This variable was added in MySQL 3.23.34.

This variable has only a global form.

- `max_write_lock_count` [421]

  After this many write locks, permit some pending read lock requests to be processed in between. This variable was added in MySQL 3.23.7.

- `myisam_data_pointer_size` [421]

  The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is `4`. This variable was added in MySQL 4.1.2. See Section B.5.2.12, “`The table is full`”.

- `myisam_max_extra_sort_file_size` [421]

  If the temporary file used for fast `MyISAM` index creation would be larger than using the key cache by the amount specified here, prefer the key cache method. This is mainly used to force long character keys in large tables to use the slower key cache method to create the index. This variable was added in MySQL 3.23.37.

  

  Note

  The value is given in megabytes before 4.0.3 and in bytes thereafter.

- `myisam_max_sort_file_size` [421]

  The maximum size of the temporary file that MySQL is permitted to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. This variable was added in MySQL 3.23.37.

  

  Note

  The value is given in megabytes before 4.0.3 and in bytes thereafter.

  The default value is 2GB. If `MyISAM` index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_recover_options` [421]

  The value of the `--myisam-recover` [390] option. See Section 5.1.2, “Server Command Options”. This variable was added in MySQL 3.23.36.

- `myisam_repair_threads` [421]

  If this value is greater than 1, `MyISAM` table indexes are created in parallel (each index in its own thread) during the `Repair by sorting` process. The default value is 1.

  

  Note

  Multi-threaded repair is still *beta-quality* code. This variable was added in MySQL 4.0.13.

- `myisam_sort_buffer_size` [421]

The size of the buffer that is allocated when sorting MyISAM indexes during a REPAIR TABLE or when creating indexes with CREATE INDEX or ALTER TABLE. This variable was added in MySQL 3.23.16.

- myisam_stats_method [422]

  How the server treats NULL values when collecting statistics about the distribution of index values for MyISAM tables. This variable has three possible values, nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For nulls_unequal, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For nulls_ignored, NULL values are ignored.

  The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 7.4.4, “MyISAM Index Statistics Collection”.

  Any unique prefix of a valid value may be used to set the value of this variable.

  This variable was added in MySQL 4.1.15. For older versions, the statistics collection method is equivalent to nulls_equal.

- named_pipe [422]

  On Windows, indicates whether the server supports connections over named pipes. This variable was added in MySQL 3.23.50.

- net_buffer_length [422]

  Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by net_buffer_length [422] but are dynamically enlarged up to max_allowed_packet [418] bytes as needed. The result buffer shrinks to net_buffer_length [422] after each SQL statement.

  This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which net_buffer_length [422] can be set is 1MB.

- net_read_timeout [422]

  The number of seconds to wait for more data from a connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made through Unix socket files, named pipes, or shared memory. When the server is reading from the client, net_read_timeout [422] is the timeout value controlling when to abort. When the server is writing to the client, net_write_timeout [422] is the timeout value controlling when to abort. See also slave_net_timeout [1181]. This variable was added in MySQL 3.23.20.

- net_retry_count [422]

  If a read on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads. This variable was added in MySQL 3.23.7.

- net_write_timeout [422]

  The number of seconds to wait for a block to be written to a connection before aborting the write. This timeout applies only to TCP/IP connections, not to connections made using Unix socket files, named pipes, or shared memory. See also net_read_timeout [422]. This variable was added in MySQL 3.23.20.

- `new` [390]

  This variable is used in MySQL 4.0 to turn on some 4.1 behaviors. This variable was added in MySQL 4.0.12.

- `old_passwords` [423]

  Whether the server should use pre-4.1-style passwords for MySQL user accounts. This variable was added in MySQL 4.1.1.

- `one_shot` [423]

  This is not a variable, but it can be used when setting some variables. It is described in Section 12.4.4, "`SET` Syntax".

- `open_files_limit` [423]

  The number of files that the operating system permits `mysqld` to open. This is the real value permitted by the system and might be different from the value you gave using the `--open-files-limit` [391] option to `mysqld` or `mysqld_safe`. The value is 0 on systems where MySQL cannot change the number of open files. This variable was added in MySQL 3.23.20.

- `pid_file` [423]

  The path name of the process ID (PID) file. This variable can be set with the `--pid-file` [391] option. This variable was added in MySQL 3.23.23.

- `plugin_dir` [423]

  The path name of the plugin directory. This variable was added in MySQL 4.1.25. If the value is nonempty, user-defined function object files must be located in this directory. If the value is empty, the behavior that is used before 4.1.25 applies: The UDF object files must be located in a directory that is searched by your system's dynamic linker.

  If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` [423] read only to the server.

- `port` [423]

  The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` [391] option.

- `preload_buffer_size` [423]

  The size of the buffer that is allocated when preloading indexes. This variable was added in MySQL 4.1.1.

- `prepared_stmt_count` [423]

  The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` [420] system variable.) This variable was added in MySQL 4.1.19. In MySQL 4.1.23, it was converted to the global `Prepared_stmt_count` [453] status variable.

- `protocol_version` [423]

  The version of the client/server protocol used by the MySQL server. This variable was added in MySQL 3.23.18.

- `pseudo_thread_id` [424]

System Variable Name	`pseudo_thread_id` [424]	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`

This variable is for internal server use.

- `query_alloc_block_size` [424]

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter. This variable was added in MySQL 4.0.16.

- `query_cache_limit` [424]

Do not cache results that are larger than this number of bytes. The default value is 1MB. This variable was added in MySQL 4.0.1.

- `query_cache_min_res_unit` [424]

The minimum size for blocks allocated by the query cache. The default value is 4KB. Tuning information for this variable is given in Section 7.5.3.3, “Query Cache Configuration”. This variable is present from MySQL 4.1.

- `query_cache_size` [424]

The amount of memory allocated for caching query results. The default value is `0`, which disables the query cache. The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. Note that `query_cache_size` [424] bytes of memory are allocated even if `query_cache_type` [424] is set to `0`. This variable was added in MySQL 4.0.1.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` [424] too small, a warning will occur, as described in Section 7.5.3.3, “Query Cache Configuration”.

- `query_cache_type` [424]

Set the query cache type. Setting the `GLOBAL` value sets the type for all clients that connect thereafter. Individual clients can set the `SESSION` value to affect their own use of the query cache.

Option	Description
`0` or `OFF`	Do not cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set `query_cache_size` [424] to 0.
`1` or `ON`	Cache all cacheable query results except for those that begin with `SELECT SQL_NO_CACHE`.
`2` or `DEMAND`	Cache results only for cacheable queries that begin with `SELECT SQL_CACHE`.

This variable defaults to `ON`.

Any unique prefix of a valid value may be used to set the value of this variable.

This variable was added in MySQL 4.0.3.

- `query_cache_wlock_invalidate` [425]

  Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect. This variable was added in MySQL 4.0.19.

- `query_prealloc_size` [425]

  The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` [425] value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

  This variable was added in MySQL 4.0.16.

- `rand_seed1` [425]

  The `rand_seed1` [425] and `rand_seed2` [425] variables exist as session variables only, and can be set but not read. They are not shown in the output of `SHOW VARIABLES`. These two variables were added in MySQL 4.0.5.

  The purpose of these variables is to support replication of the `RAND()` [822] function. For statements that invoke `RAND()` [822], the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` [425] and `rand_seed2` [425] so that `RAND()` [822] on the slave generates the same value as on the master.

- `rand_seed2` [425]

  See the description for `rand_seed1` [425].

- `range_alloc_block_size` [425]

  The size of blocks that are allocated when doing range optimization. This variable was added in MySQL 4.0.16.

- `read_buffer_size` [425]

  Each thread that does a sequential scan allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value.

  `read_buffer_size` [425] and `read_rnd_buffer_size` [426] are not specific to any storage engine and apply in a general manner for optimization. See Section 7.8.4, “How MySQL Uses Memory”, for example.

  Before MySQL 4.0.3, this variable was named `record_buffer`.

- `read_only` [425]

  This variable is off by default. When it is enabled, the server permits no updates except from users that have the `SUPER` [493] privilege or (on a slave server) from updates performed by slave threads. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients.

`read_only` [425] exists only as a `GLOBAL` variable, so changes to its value require the `SUPER` [493] privilege. Changes to `read_only` [425] on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

This variable was added in MySQL 4.0.14.

- `read_rnd_buffer_size` [426]

  When reading rows in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See Section 7.3.1.7, "`ORDER BY` Optimization". Setting the variable to a large value can improve `ORDER BY` performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

  `read_buffer_size` [425] and `read_rnd_buffer_size` [426] are not specific to any storage engine and apply in a general manner for optimization. See Section 7.8.4, "How MySQL Uses Memory", for example.

  Before MySQL 4.0.3, this variable was named `record_rnd_buffer`.

- `relay_log_purge` [426]

  Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- `relay_log_space_limit` [426]

  The maximum amount of space to use for all relay logs.

- `safe_show_database` [426]

  Do not show databases for which the user has no database or table privileges. This can improve security if you are concerned about people being able to see what databases other users have. See also `skip_show_database` [427].

  This variable was removed in MySQL 4.0.5. Beginning with this version, you should instead use the `SHOW DATABASES` [492] privilege to control access by MySQL accounts to databases.

- `secure_auth` [426]

  If the MySQL server has been started with the `--secure-auth` [392] option, it blocks connections from all accounts that have passwords stored in the old (pre-4.1) format. In that case, the value of this variable is `ON`, otherwise it is `OFF`.

  You should enable this option if you want to prevent all use of passwords in the old format (and hence insecure communication over the network). This variable was added in MySQL 4.1.1.

  Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format.

- `server_id` [426]

  The server ID, used in replication to give each master and slave a unique identity. This variable is set by the `--server-id` [1167] option. For each server participating in replication, you should pick a positive integer in the range from 1 to 2^{32} – 1 to act as that server's ID.

- `shared_memory` [426]

(Windows only.) Whether the server permits shared-memory connections. This variable was added in MySQL 4.1.1.

- `shared_memory_base_name` [427]

  (Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. This variable was added in MySQL 4.1.0.

- `skip_external_locking` [427]

  This is `OFF` if `mysqld` uses external locking, `ON` if external locking is disabled. Before MySQL 4.0.3, this variable was named `skip_locking`.

- `skip_networking` [427]

  This is `ON` if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. On NetWare, only TCP/IP connections are supported, so do not set this variable to `ON`. This variable can be set to `ON` with the `--skip-networking` [393] option. This variable was added in MySQL 3.22.23.

- `skip_show_database` [427]

  This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` [492] privilege. This can improve security if you are concerned about people being able to see what databases other users have. See also `safe_show_database` [426]. This variable was added in MySQL 3.23.4. As of MySQL 4.0.2, its effect also depends on the `SHOW DATABASES` [492] privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` [492] privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays each database name only if the user has the `SHOW DATABASES` [492] privilege or some privilege for the database. (Note that *any* global privilege is considered a privilege for the database.)

- `slow_launch_time` [427]

  If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` [455] status variable. This variable was added in MySQL 3.23.15.

- `socket` [427]

  On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

  On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case sensitive).

- `sort_buffer_size` [427]

  Each session that needs to do a sort allocates a buffer of this size. `sort_buffer_size` [427] is not specific to any storage engine and applies in a general manner for optimization. See Section 7.3.1.7, “`ORDER BY` Optimization”, for example.

  If you see many `Sort_merge_passes` [455] per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` [427] value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing. The entire buffer is allocated even if it is not all needed, so setting it larger than required globally will slow down most

queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See Section B.5.4.4, “Where MySQL Stores Temporary Files”.

- `sql_auto_is_null` [428]

System Variable Name	`sql_auto_is_null` [428]	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`1`

If this variable is set to 1 (the default), then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` [874] function. For details, including the return value after a multiple-row insert, see Section 11.13, “Information Functions”. If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` [783] comparison is used by some ODBC programs, such as Access. See Obtaining Auto-Increment Values. This behavior can be disabled by setting `sql_auto_is_null` [428] to 0.

- `sql_big_selects` [428]

System Variable Name	`sql_big_selects` [428]	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`1`

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size` [419]). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which permits all `SELECT` statements.

If you set the `max_join_size` [419] system variable to a value other than `DEFAULT`, `sql_big_selects` [428] is set to 0.

- `sql_buffer_result` [428]

System Variable Name	`sql_buffer_result` [428]
Variable Scope	Session
Dynamic Variable	Yes

	Permitted Values	
	Type	`boolean`
	Default	`0`

If set to 1, `sql_buffer_result` [428] forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0. This variable was added in MySQL 3.23.13.

- `sql_log_bin` [429]

System Variable Name	`sql_log_bin` [429]	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`

If set to 0, no logging is done to the binary log for the client. The client must have the `SUPER` [493] privilege to set this option. The default value is 1. This variable was added in MySQL 3.23.16.

- `sql_log_off` [429]

System Variable Name	`sql_log_off` [429]	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`0`

If set to 1, no logging is done to the general query log for this client. The client must have the `SUPER` [493] privilege to set this option. The default value is 0.

- `sql_log_update` [429]

System Variable Name	`sql_log_update` [429]	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`

If set to `0`, no logging is done to the update log for the client. The client must have the `SUPER` [493] privilege to set this option. The default value is 1. This variable was added in MySQL 3.22.5.

- `sql_mode` [429]

The current server SQL mode. This variable was added in MySQL 3.23.41. It can be set dynamically as of MySQL 4.1.1. See Section 5.1.6, “Server SQL Modes”.

- `sql_notes` [429]

If set to 1 (the default), warnings of `Note` level are recorded. If set to 0, `Note` warnings are suppressed. `mysqldump` includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation. `sql_notes` [429] was added in MySQL 4.1.11.

- `sql_quote_show_create` [430]

  If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See Section 12.4.5.7, "`SHOW CREATE TABLE` Syntax", and Section 12.4.5.6, "`SHOW CREATE DATABASE` Syntax". This variable was added in MySQL 3.23.26.

- `sql_safe_updates` [430]

  If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0. This variable was added in MySQL 3.22.32.

- `sql_select_limit` [430]

  The maximum number of rows to return from `SELECT` statements. The default value for a new connection is the maximum number of rows that the server permits per table, which depends on the server configuration and may be affected if the server build was configured with `--with-big-tables` [98]. Typical default values are (2^{32})–1 or (2^{64})–1. If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

  If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit` [430].

  `sql_select_limit` [430] does not apply to `SELECT` statements executed within stored routines. It also does not apply to `SELECT` statements that do not produce a result set to be returned to the client. These include `SELECT` statements in subqueries, `CREATE TABLE ... SELECT`, and `INSERT INTO ... SELECT`.

- `sql_warnings` [430]

  This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string. This variable was added in MySQL 3.22.11.

- `storage_engine` [430]

  This variable is a synonym for `table_type` [431]. It was added in MySQL 4.1.2.

- `sync_frm` [430]

  If this variable is set to 1, when any nontemporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1. This was added as a command-line option in MySQL 4.0.18. It is also a settable global variable as of MySQL 4.1.3.

- `system_time_zone` [430]

  The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone` [430]. Typically the time zone is

specified by the TZ environment variable. It also can be specified using the --timezone [245] option of the mysqld_safe script.

The system_time_zone [430] variable differs from time_zone [431]. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 9.7, “MySQL Server Time Zone Support”.

system_time_zone [430] was added in MySQL 4.1.3.

- table_cache [431]

  The number of open tables for all threads. Increasing this value increases the number of file descriptors that mysqld requires. You can check whether you need to increase the table cache by checking the Opened_tables [453] status variable. See Section 5.1.5, “Server Status Variables”. If the value of Opened_tables [453] is large and you do not do FLUSH TABLES often (which just forces all tables to be closed and reopened), then you should increase the value of the table_cache [431] variable. For more information about the table cache, see Section 7.7.2, “How MySQL Opens and Closes Tables”.

- table_type [431]

  The default table type (storage engine). To set the table type at server startup, use the --default-table-type [386] option. This variable was added in MySQL 3.23.0. See Section 5.1.2, “Server Command Options”.

- thread_cache_size [431]

  How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than thread_cache_size [431] threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set thread_cache_size [431] high enough so that most new connections use cached threads. By examining the difference between the Connections [450] and Threads_created [457] status variables, you can see how efficient the thread cache is. For details, see Section 5.1.5, “Server Status Variables”. This variable was added in MySQL 3.23.16.

- thread_concurrency [431]

  This variable is specific to Solaris systems, for which mysqld invokes the thr_setconcurrency() with the variable value. This function enables applications to give the threads system a hint about the desired number of threads that should be run at the same time. This variable was added in MySQL 3.23.7.

- thread_stack [431]

  The stack size for each thread. Many of the limits detected by the crash-me test are dependent on this value. The default is large enough for normal operation. See Section 7.1.3, “The MySQL Benchmark Suite”. The default is 64KB before MySQL 4.0.10 and 192KB thereafter. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- time_format [431]

  This variable is unused.

- time_zone [431]

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is `'SYSTEM'` (which means, "use the value of `system_time_zone` [430]"). The value can be specified explicitly at server startup with the `--default-time-zone` [386] option. See Section 9.7, "MySQL Server Time Zone Support". This variable was added in MySQL 4.1.3.

- `timestamp = {timestamp_value | DEFAULT}` [432]

  Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. *`timestamp_value`* should be a Unix epoch timestamp, not a MySQL timestamp.

- `timezone` [432]

  The time zone for the server. This is set from the `TZ` environment variable when `mysqld` is started. The time zone also can be set by giving a `--timezone` [245] argument to `mysqld_safe`. This variable was added in MySQL 3.23.15. As of MySQL 4.1.3, it is obsolete and has been replaced by the `system_time_zone` [430] variable. See Section B.5.4.6, "Time Zone Problems".

- `tmp_table_size` [432]

  The maximum size of internal in-memory temporary tables. (The actual limit is determined as the minimum of `tmp_table_size` [432] and `max_heap_table_size` [419].) If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk `MyISAM` table. Increase the value of `tmp_table_size` [432] (and `max_heap_table_size` [419] if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory. This variable does not apply to user-created `MEMORY` tables.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` [450] and `Created_tmp_tables` [451] variables.

  See also Section 7.7.4, "How MySQL Uses Internal Temporary Tables".

- `tmpdir` [432]

  The directory used for temporary files and temporary tables. Starting from MySQL 4.1, this variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters ("`:`") on Unix and semicolon characters ("`;`") on Windows, NetWare, and OS/2.

  The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` [432] to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. However, if you are using MySQL 4.0.0 or later, you can set the slave's temporary directory using the `slave_load_tmpdir` [1180] variable. In that case, the slave will not use the general `tmpdir` [432] value and you can set `tmpdir` [432] to a nonpermanent location.

  This variable was added in MySQL 3.22.4.

- `transaction_alloc_block_size` [432]

  The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size` [432]. This variable was added in MySQL 4.0.16.

- `transaction_prealloc_size` [432]

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size` [432]. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` [432] bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` [432] bytes.

By making `transaction_prealloc_size` [432] sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls. This variable was added in MySQL 4.0.16.

- `tx_isolation` [433]

  The default transaction isolation level. This variable was added in MySQL 4.0.3.

  This variable is set by the `SET TRANSACTION ISOLATION LEVEL` statement. See Section 12.3.6, "`SET TRANSACTION` Syntax". If you set `tx_isolation` [433] directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

  Any unique prefix of a valid value may be used to set the value of this variable.

- `unique_checks` [433]

System Variable Name	`unique_checks` [433]	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`1`

  If set to 1 (the default), uniqueness checks for secondary indexes in `InnoDB` tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to `InnoDB`. This variable was added in MySQL 3.23.52.

  Note that setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- `version` [433]

  The version number for the server.

- `version_bdb` [433]

  The `BDB` storage engine version. This variable was added in MySQL 3.23.31 with the name `bdb_version` [407] and renamed to `version_bdb` [433] in MySQL 4.1.1.

- `version_comment` [433]

System Variable Name	`version_comment` [433]
Variable Scope	Global

Dynamic Variable	No	
	Permitted Values	
	Type	`string`

The `configure` script has a `--with-comment` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. This variable was added in MySQL 4.0.17.

- `version_compile_machine` [434]

System Variable Name	`version_compile_machine` [434]	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`string`

The type of machine or architecture on which MySQL was built. This variable was added in MySQL 4.1.1.

- `version_compile_os` [434]

  The type of operating system on which MySQL was built. This variable was added in MySQL 4.0.19.

- `wait_timeout` [434]

  The number of seconds the server waits for activity on a noninteractive connection before closing it. This timeout applies only to TCP/IP and Unix socket file connections, not to connections made using named pipes, or shared memory.

  On thread startup, the session `wait_timeout` [434] value is initialized from the global `wait_timeout` [434] value or from the global `interactive_timeout` [414] value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout` [414].

- `warning_count` [434]

  The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See Section 12.4.5.26, “`SHOW WARNINGS` Syntax”.

  This variable was added in MySQL 4.1.0.

5.1.4 Using System Variables

The MySQL server maintains many system variables that indicate how it is configured. Section 5.1.3, “Server System Variables”, describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. As of MySQL 4.0.3, most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

Beginning with MySQL 4.0.3, the server maintains two kinds of system variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes all global variables to their default values. These defaults can be changed by options specified on the command line or in an option file. (See Section 4.2.3, “Specifying Program Options”.)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, the client's SQL mode is controlled by the session `sql_mode` [429] value, which is initialized when the client connects to the value of the global `sql_mode` [429] value.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024^2 or 1024^3; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --query_cache_size=16M --max_allowed_packet=1G
```

Before MySQL 4.0.3, use this syntax instead:

```
mysqld --set-variable=query_cache_size=16M \
       --set-variable=max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

Or like this before MySQL 4.0.2:

```
[mysqld]
set-variable=query_cache_size=16M
set-variable=max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

If you want to restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, you can specify this maximum by using an option of the form `--maximum-`*`var_name`*`=`*`value`* at server startup. For example, to prevent the value of `query_cache_size` [424] from being increased to more than 32MB at runtime, use the option `--maximum-query_cache_size=32M`. This feature is available as of MySQL 4.0.2.

Many system variables are dynamic and can be changed while the server runs by using the `SET` statement. For a list, see Section 5.1.4.2, “Dynamic System Variables”. To change a system variable with `SET`, refer to it as *`var_name`*, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global.`. The `SUPER` [493] privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session.`, or `@@`. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session.`.
- If no modifier is present, `SET` changes the session variable.

A SET statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent GLOBAL or SESSION modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

The *@@var_name* syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the SET GLOBAL statement).

To prevent incorrect usage, MySQL produces an error if you use SET GLOBAL with a variable that can only be used with SET SESSION or if you do not specify GLOBAL (or @@global.) when setting a global variable.

To set a SESSION variable to the GLOBAL value or a GLOBAL value to the compiled-in MySQL default value, use the DEFAULT keyword. For example, the following two statements are identical in setting the session value of max_join_size [419] to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to DEFAULT. In such cases, use of DEFAULT results in an error.

You can refer to the values of specific global or sesson system variables in expressions by using one of the @@-modifiers. For example, you can retrieve values in a SELECT statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as *@@var_name* (that is, when you do not specify @@global. or @@session.), MySQL returns the session value if it exists and the global value otherwise. (This differs from SET *@@var_name = value*, which always refers to the session value.)

Note

Some variables displayed by SHOW VARIABLES may not be available using SELECT *@@var_name* syntax; an Unknown system variable occurs. As a workaround in such cases, you can use SHOW VARIABLES LIKE '*var_name*'.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with SET at runtime. On the other hand, with SET you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

Note

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` [410] works but `--delay_key_write=ON` [410] does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
+---------------------------------+-------------------------------------+
| Variable_name                   | Value                               |
+---------------------------------+-------------------------------------+
| back_log                        | 50                                  |
| basedir                         | /usr/local/mysql                    |
| bdb_cache_size                  | 8388600                             |
| bdb_home                        | /usr/local/mysql                    |

| bdb_logdir                      |                                     |
| bdb_max_lock                    | 10000                               |
| bdb_shared_data                 | OFF                                 |
| bdb_tmpdir                      | /tmp/                               |
| binlog_cache_size               | 32768                               |
| bulk_insert_buffer_size         | 8388608                             |
| character_set_client            | latin1                              |
| character_set_connection        | latin1                              |
| character_set_database          | latin1                              |
| character_set_results           | latin1                              |
| character_set_server            | latin1                              |
| character_set_system            | utf8                                |
| character_sets_dir              | /usr/local/mysql/share/charsets/    |
| collation_connection            | latin1_swedish_ci                   |
| collation_database              | latin1_swedish_ci                   |
| collation_server                | latin1_swedish_ci                   |
...
| innodb_additional_mem_pool_size | 1048576                             |
| innodb_autoextend_increment     | 8                                   |
| innodb_buffer_pool_awe_mem_mb   | 0                                   |
| innodb_buffer_pool_size         | 8388608                             |
| innodb_data_file_path           | ibdata1:10M:autoextend              |
| innodb_data_home_dir            |                                     |
...
| version                         | 4.1.18-max-log                      |
| version_comment                 | MySQL Community Edition - Max (GPL) |
| version_compile_machine         | i686                                |
| version_compile_os              | pc-linux-gnu                        |
| wait_timeout                    | 28800                               |
+---------------------------------+-------------------------------------+
```

With a `LIKE` [804] clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a `LIKE` [804] clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the "%" wildcard character in a LIKE [804] clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because "_" is a wildcard that matches any single character, you should escape it as "_" to match it literally. In practice, this is rarely necessary.

For SHOW VARIABLES, if you specify neither GLOBAL nor SESSION, MySQL returns SESSION values.

The reason for requiring the GLOBAL keyword when setting GLOBAL-only variables but not when retrieving them is to prevent problems in the future. If we were to remove a SESSION variable that has the same name as a GLOBAL variable, a client with the SUPER [493] privilege might accidentally change the GLOBAL variable rather than just the SESSION variable for its own connection. If we add a SESSION variable with the same name as a GLOBAL variable, a client that intends to change the GLOBAL variable might find only its own SESSION variable changed.

5.1.4.1 Structured System Variables

Structured system variables are supported beginning with MySQL 4.1.1. A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

In MySQL 4.1 (4.1.1 and above), MySQL supports one structured variable type. It specifies parameters that govern the operation of key caches. A key cache structured variable has these components:

- key_buffer_size [415]
- key_cache_block_size [416]
- key_cache_division_limit [416]
- key_cache_age_threshold [416]

The purpose of this section is to describe the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 7.5.1, "The MyISAM Key Cache".

To refer to a component of a structured variable instance, you can use a compound name in *instance_name.component_name* format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of default is always predefined. If you refer to a component of a structured variable without any instance name, the default instance is used. Thus, default.key_buffer_size and key_buffer_size [415] both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but `` `hot-cache` `` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@global.`*`var_name`* for referring to nonstructured system variables.

At the moment, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, it is permissible to refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with such an option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
         --extra_cache.key_buffer_size=128K \
         --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
         --hot_cache.key_buffer_size=2M \
         --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
```

```
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` [804] pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

5.1.4.2 Dynamic System Variables

Beginning with MySQL 4.0.3, many server system variables are dynamic and can be set at runtime using `SET GLOBAL` or `SET SESSION`. You can also select their values using `SELECT`. See Section 5.1.4, “Using System Variables”.

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether `GLOBAL` or `SESSION` (or both) apply. The table also lists session options that can be set with the `SET` statement. Section 5.1.3, “Server System Variables”, discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. (If you set them on the command line or in an option file, use the numeric values.) Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from `ENUM` columns, for which the first enumeration value corresponds to 1.

Table 5.3 Dynamic Variable Summary

Variable Name	Variable Type	Variable Scope
`autocommit` [406]	boolean	`SESSION`
`big_tables` [384]	boolean	`SESSION`
`binlog_cache_size` [407]	numeric	`GLOBAL`
`bulk_insert_buffer_size` [408]	numeric	`GLOBAL` | `SESSION`
`character_set_client` [408]	string	`GLOBAL` | `SESSION`
`character_set_connection` [408]	string	`GLOBAL` | `SESSION`
`character_set_database` [408]	string	`GLOBAL` | `SESSION`
`character_set_results` [408]	string	`GLOBAL` | `SESSION`
`character_set_server` [385]	string	`GLOBAL` | `SESSION`
`collation_connection` [409]	string	`GLOBAL` | `SESSION`
`collation_database` [409]	string	`GLOBAL` | `SESSION`
`collation_server` [385]	string	`GLOBAL` | `SESSION`
`concurrent_insert` [409]	boolean	`GLOBAL`
`connect_timeout` [409]	numeric	`GLOBAL`
`debug` [385]	string	`GLOBAL` | `SESSION`

Variable Name	Variable Type	Variable Scope
storage_engine [386]	enumeration	GLOBAL | SESSION
default_week_format [410]	numeric	GLOBAL | SESSION
delay_key_write [386]	enumeration	GLOBAL
delayed_insert_limit [410]	numeric	GLOBAL
delayed_insert_timeout [410]	numeric	GLOBAL
delayed_queue_size [410]	numeric	GLOBAL
expire_logs_days [411]	numeric	GLOBAL
flush [411]	boolean	GLOBAL
flush_time [411]	numeric	GLOBAL
foreign_key_checks [411]	boolean	SESSION
ft_boolean_syntax [411]	string	GLOBAL
group_concat_max_len [412]	numeric	GLOBAL | SESSION
identity [414]	numeric	SESSION
init_connect [414]	string	GLOBAL
init_slave [1180]	string	GLOBAL
innodb_autoextend_increment [1067]	numeric	GLOBAL
innodb_fast_shutdown [1068]	numeric	GLOBAL
innodb_flush_log_at_trx_commit [1068]	enumeration	GLOBAL
innodb_max_dirty_pages_pct [1071]	numeric	GLOBAL
innodb_max_purge_lag [1071]	numeric	GLOBAL
innodb_table_locks [1072]	boolean	GLOBAL | SESSION
innodb_thread_concurrency [1072]	numeric	GLOBAL
insert_id [414]	numeric	SESSION
interactive_timeout [414]	numeric	GLOBAL | SESSION
join_buffer_size [415]	numeric	GLOBAL | SESSION
key_buffer_size [415]	numeric	GLOBAL
key_cache_age_threshold [416]	numeric	GLOBAL
key_cache_block_size [416]	numeric	GLOBAL
key_cache_division_limit [416]	numeric	GLOBAL
last_insert_id [416]	numeric	SESSION
lc_time_names [417]	string	GLOBAL | SESSION
local_infile [417]	boolean	GLOBAL
log_queries_not_using_indexes [388]	boolean	GLOBAL
log_warnings [389]	numeric	GLOBAL | SESSION
long_query_time [417]	numeric	GLOBAL | SESSION
low_priority_updates [389]	boolean	GLOBAL | SESSION
max_allowed_packet [418]	numeric	GLOBAL
max_binlog_cache_size [1183]	numeric	GLOBAL

Variable Name	Variable Type	Variable Scope
max_binlog_size [1184]	numeric	GLOBAL
max_connect_errors [419]	numeric	GLOBAL
max_connections [419]	numeric	GLOBAL
max_delayed_threads [419]	numeric	GLOBAL | SESSION
max_error_count [419]	numeric	GLOBAL | SESSION
max_heap_table_size [419]	numeric	GLOBAL | SESSION
max_insert_delayed_threads [419]	numeric	GLOBAL | SESSION
max_join_size [419]	numeric	GLOBAL | SESSION
max_length_for_sort_data [420]	numeric	GLOBAL | SESSION
max_prepared_stmt_count [420]	numeric	GLOBAL
max_relay_log_size [420]	numeric	GLOBAL

5.1.5 Server Status Variables

The server maintains many status variables that provide information about its operation. You can view these variables and their values by using the SHOW STATUS statement (see Section 12.4.5.22, "SHOW STATUS Syntax").

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
...
```

The following table lists all available server status variables:

Table 5.4 Status Variable Summary

Variable Name	Variable Type
Aborted_clients [449]	numeric
Aborted_connects [449]	numeric
Binlog_cache_disk_use [449]	numeric
Binlog_cache_use [449]	numeric
Bytes_received [449]	numeric
Bytes_sent [450]	numeric
Com_admin_commands [450]	numeric
Com_alter_db [450]	numeric
Com_alter_table [450]	numeric
Com_analyze [450]	numeric
Com_backup_table [450]	numeric
Com_begin [450]	numeric
Com_change_db [450]	numeric

Variable Name	Variable Type
Com_change_master [450]	numeric
Com_check [450]	numeric
Com_checksum [450]	numeric
Com_commit [450]	numeric
Com_create_db [450]	numeric
Com_create_index [450]	numeric
Com_create_table [450]	numeric
Com_dealloc_sql [450]	numeric
Com_delete [450]	numeric
Com_delete_multi [450]	numeric
Com_do [450]	numeric
Com_drop_db [450]	numeric
Com_drop_index [450]	numeric
Com_drop_table [450]	numeric
Com_drop_user [450]	numeric
Com_execute_sql [450]	numeric
Com_flush [450]	numeric
Com_grant [450]	numeric
Com_ha_close [450]	numeric
Com_ha_open [450]	numeric
Com_ha_read [450]	numeric
Com_help [450]	numeric
Com_insert [450]	numeric
Com_insert_select [450]	numeric
Com_kill [450]	numeric
Com_load [450]	numeric

Com_show_slave_status [450]	numeric
Com_show_status [450]	numeric
Com_show_storage_engines [450]	numeric
Com_show_tables [450]	numeric
Com_show_variables [450]	numeric
Com_show_warnings [450]	numeric
Com_slave_start [450]	numeric

Variable Name	Variable Type
Com_slave_stop [450]	numeric
Com_stmt_close [450]	numeric
Com_stmt_execute [450]	numeric
Com_stmt_fetch [450]	numeric
Com_stmt_prepare [450]	numeric
Com_stmt_reset [450]	numeric
Com_stmt_send_long_data [450]	numeric
Com_truncate [450]	numeric
Com_unlock_tables [450]	numeric
Com_update [450]	numeric
Com_update_multi [450]	numeric
Created_tmp_disk_tables [450]	numeric
Created_tmp_files [451]	numeric
Created_tmp_tables [451]	numeric
Handler_commit [451]	numeric
Handler_delete [451]	numeric
Handler_discover [1306]	numeric
Handler_read_first [451]	numeric
Handler_read_key [451]	numeric
Handler_read_next [451]	numeric
Handler_read_prev [451]	numeric
Handler_read_rnd [452]	numeric
Handler_read_rnd_next [452]	numeric
Handler_rollback [452]	numeric
Handler_update [452]	numeric
Handler_write [452]	numeric
Key_blocks_not_flushed [452]	numeric
Key_blocks_unused [452]	numeric
Key_blocks_used [452]	numeric
Key_read_requests [452]	numeric
Key_reads [452]	numeric
Key_write_requests [452]	numeric
Key_writes [452]	numeric
Max_used_connections [453]	numeric
Not_flushed_delayed_rows	numeric
Open_files	numeric
Open_streams [453]	numeric
Open_tables [453]	numeric

Variable Name	Variable Type
Opened_tables [453]	numeric
Prepared_stmt_count [453]	numeric
Qcache_free_blocks [453]	numeric
Qcache_free_memory [453]	numeric
Qcache_hits [453]	numeric
Qcache_inserts [453]	numeric
Qcache_lowmem_prunes [453]	numeric
Qcache_not_cached [453]	numeric
Qcache_queries_in_cache [454]	numeric
Qcache_total_blocks [454]	numeric
Questions [454]	numeric
Select_full_join [454]	numeric
Select_full_range_join [454]	numeric
Select_range [454]	numeric
Select_range_check [454]	numeric
Select_scan [454]	numeric
Slave_open_temp_tables [454]	numeric
Slow_launch_threads [455]	numeric
Slow_queries [455]	numeric
Sort_merge_passes [455]	numeric
Sort_range [455]	numeric
Sort_rows [455]	numeric
Sort_scan [455]	numeric
Ssl_accept_renegotiates [455]	numeric
Ssl_accepts [455]	numeric
Ssl_callback_cache_hits [455]	numeric
Ssl_cipher [455]	string
Ssl_cipher_list [455]	string
Ssl_client_connects [455]	numeric
Ssl_connect_renegotiates [455]	numeric
Ssl_ctx_verify_depth [456]	numeric
Ssl_ctx_verify_mode [456]	numeric
Ssl_default_timeout [456]	numeric
Ssl_finished_accepts [456]	numeric
Ssl_finished_connects [456]	numeric
Ssl_session_cache_hits [456]	numeric
Ssl_session_cache_misses [456]	numeric
Ssl_session_cache_mode [456]	string

Variable Name	Variable Type
Ssl_session_cache_overflows [456]	numeric
Ssl_session_cache_size [456]	numeric
Ssl_session_cache_timeouts [456]	numeric
Ssl_sessions_reused [456]	numeric
Ssl_used_session_cache_entries [456]	numeric
Ssl_verify_depth [456]	numeric
Ssl_verify_mode [456]	numeric
Ssl_version [457]	string
Table_locks_immediate [457]	numeric
Table_locks_waited [457]	numeric
Threads_cached [457]	numeric
Threads_connected [457]	numeric
Threads_created [457]	numeric
Threads_running [457]	numeric
Uptime [457]	numeric

Many status variables are reset to 0 by the FLUSH STATUS statement.

The status variables have the following meanings. The Com_*xxx* statement counter variables were added beginning with MySQL 3.23.47. The Qcache_*xxx* query cache variables were added beginning with MySQL 4.0.1. Otherwise, variables with no version indicated have been present since at least MySQL 3.22.

For meanings of status variables specific to MySQL Cluster, see Section 15.3.4.4, “MySQL Cluster Status Variables”.

- Aborted_clients [449]

  The number of connections that were aborted because the client died without closing the connection properly. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

- Aborted_connects [449]

  The number of failed attempts to connect to the MySQL server. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

- Binlog_cache_disk_use [449]

  The number of transactions that used the temporary binary log cache but that exceeded the value of binlog_cache_size [407] and used a temporary file to store statements from the transaction. This variable was added in MySQL 4.1.2.

- Binlog_cache_use [449]

  The number of transactions that used the temporary binary log cache. This variable was added in MySQL 4.1.2.

- Bytes_received [449]

  The number of bytes received from all clients. This variable was added in MySQL 3.23.7.

- `Bytes_sent` [450]

  The number of bytes sent to all clients. This variable was added in MySQL 3.23.7.

- `Com_xxx`

  The `Com_xxx` statement counter variables were added beginning with MySQL 3.23.47. They indicate the number of times each *`xxx`* statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_insert` count `DELETE` and `INSERT` statements, respectively. However, if a query result is returned from query cache, the server increments the `Qcache_hits` [453] status variable, not `Com_select`. See Section 7.5.3.4, "Query Cache Status and Maintenance".

  New `Com_stmt_xxx` status variables have been added in MySQL 4.1.13:

  - `Com_stmt_prepare`
  - `Com_stmt_execute`
  - `Com_stmt_send_long_data`
  - `Com_stmt_reset`
  - `Com_stmt_close`

  Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older (available since MySQL 4.1.3) statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements.

  All of the `Com_stmt_xxx` variables are increased even if their argument (a prepared statement) is unknown or an error occurred during execution; in other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

- `Connections` [450]

  The number of connection attempts (successful or not) to the MySQL server.

- `Created_tmp_disk_tables` [450]

  The number of internal on-disk temporary tables created by the server while executing statements. This variable was added in MySQL 3.23.24.

  If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` [432] and `max_heap_table_size` [419] values. If `Created_tmp_disk_tables` [450] is large, you may want to increase the `tmp_table_size` [432] or `max_heap_table_size` [419] value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` [450] and `Created_tmp_tables` [451] variables.

See also Section 7.7.4, “How MySQL Uses Internal Temporary Tables”.

- `Created_tmp_files` [451]

  How many temporary files `mysqld` has created. This variable was added in MySQL 3.23.28.

- `Created_tmp_tables` [451]

  The number of internal temporary tables created by the server while executing statements.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` [450] and `Created_tmp_tables` [451] variables.

  See also Section 7.7.4, “How MySQL Uses Internal Temporary Tables”.

- `Delayed_errors` [451]

  The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).

- `Delayed_insert_threads` [451]

  The number of `INSERT DELAYED` handler threads in use.

- `Delayed_writes` [451]

  The number of `INSERT DELAYED` rows written.

- `Flush_commands` [451]

  The number of executed `FLUSH` statements.

- `Handler_commit` [451]

  The number of internal `COMMIT` statements. This variable was added in MySQL 4.0.2.

- `Handler_delete` [451]

  The number of times a row was deleted from a table.

- `Handler_read_first` [451]

  The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed.

- `Handler_read_key` [451]

  The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_next` [451]

  The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev` [451]

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`. This variable was added in MySQL 3.23.6.

- `Handler_read_rnd` [452]

  The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- `Handler_read_rnd_next` [452]

  The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback` [452]

  The number of internal `ROLLBACK` statements. This variable was added in MySQL 4.0.2.

- `Handler_update` [452]

  The number of requests to update a row in a table.

- `Handler_write` [452]

  The number of requests to insert a row in a table.

- `Key_blocks_not_flushed` [452]

  The number of key blocks in the key cache that have changed but have not yet been flushed to disk. This variable was added in MySQL 4.1.1. It used to be known as `Not_flushed_key_blocks` [453].

- `Key_blocks_unused` [452]

  The number of unused blocks in the key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` [415] in Section 5.1.3, “Server System Variables”. This variable was added in MySQL 4.1.2.

- `Key_blocks_used` [452]

  The number of used blocks in the key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- `Key_read_requests` [452]

  The number of requests to read a key block from the cache.

- `Key_reads` [452]

  The number of physical reads of a key block from disk. If `Key_reads` [452] is large, then your `key_buffer_size` [415] value is probably too small. The cache miss rate can be calculated as `Key_reads` [452]/`Key_read_requests` [452].

- `Key_write_requests` [452]

  The number of requests to write a key block to the cache.

- `Key_writes` [452]

The number of physical writes of a key block to disk.

- `Max_used_connections` [453]

  The maximum number of connections that have been in use simultaneously since the server started.

- `Not_flushed_delayed_rows`

  The number of rows waiting to be written in `INSERT DELAYED` queues.

- `Not_flushed_key_blocks` [453]

  The old name for `Key_blocks_not_flushed` [452] before MySQL 4.1.1.

- `Open_files`

  The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- `Open_streams` [453]

  The number of streams that are open (used mainly for logging).

- `Open_tables` [453]

  The number of tables that are open.

- `Opened_tables` [453]

  The number of tables that have been opened. If `Opened_tables` [453] is big, your `table_cache` [431] value is probably too small.

- `Prepared_stmt_count` [453]

  The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` [420] system variable.) This variable was added in MySQL 4.1.23.

- `Qcache_free_blocks` [453]

  The number of free memory blocks in the query cache.

- `Qcache_free_memory` [453]

  The amount of free memory for the query cache.

- `Qcache_hits` [453]

  The number of query cache hits.

- `Qcache_inserts` [453]

  The number of queries added to the query cache.

- `Qcache_lowmem_prunes` [453]

  The number of queries that were deleted from the query cache because of low memory.

- `Qcache_not_cached` [453]

The number of noncached queries (not cacheable, or not cached due to the `query_cache_type` [424] setting).

- `Qcache_queries_in_cache` [454]

  The number of queries registered in the query cache.

- `Qcache_total_blocks` [454]

  The total number of blocks in the query cache.

- `Questions` [454]

  The number of statements that clients have sent to the server.

- `Rpl_status` [454]

  The status of fail-safe replication (not implemented).

- `Select_full_join` [454]

  The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables. This variable was added in MySQL 3.23.25.

- `Select_full_range_join` [454]

  The number of joins that used a range search on a reference table. This variable was added in MySQL 3.23.25.

- `Select_range` [454]

  The number of joins that used ranges on the first table. This is normally not critical issue even if the value is quite large. This variable was added in MySQL 3.23.25.

- `Select_range_check` [454]

  The number of joins without keys that check for key usage after each row. (If this is not equal to `0`, you should very carefully check the indexes of your tables.) This variable was added in MySQL 3.23.25.

- `Select_scan` [454]

  The number of joins that did a full scan of the first table. This variable was added in MySQL 3.23.25.

- `Slave_open_temp_tables` [454]

  The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see Section 14.7.12, “Replication and Temporary Tables”. This variable was added in MySQL 3.23.29.

- `Slave_retried_transactions` [454]

  Total (since startup) number of times the replication slave SQL thread has retried transactions. This variable was added in MySQL 4.1.11.

- `Slave_running`

  This is `ON` if this server is a replication slave that is connected to a replication master, and both the I/O and SQL threads are running; otherwise, it is `OFF`.

This variable was added in MySQL 3.23.16.

- `Slow_launch_threads` [455]

  The number of threads that have taken more than `slow_launch_time` [427] seconds to create. This variable was added in MySQL 3.23.15.

- `Slow_queries` [455]

  The number of queries that have taken more than `long_query_time` [417] seconds. See Section 5.3.5, “The Slow Query Log”.

- `Sort_merge_passes` [455]

  The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` [427] system variable. This variable was added in MySQL 3.23.28.

- `Sort_range` [455]

  The number of sorts that were done with ranges. This variable was added in MySQL 3.23.25.

- `Sort_rows` [455]

  The number of sorted rows. This variable was added in MySQL 3.23.25.

- `Sort_scan` [455]

  The number of sorts that were done by scanning the table. This variable was added in MySQL 3.23.25.

- `Ssl_accept_renegotiates` [455]

  The number of negotiates needed to establish the connection. This variable was added in MySQL 4.0.0.

- `Ssl_accepts` [455]

  The number of accepted SSL connections. This variable was added in MySQL 4.0.0.

- `Ssl_callback_cache_hits` [455]

  The number of callback cache hits. This variable was added in MySQL 4.0.0.

- `Ssl_cipher` [455]

  The current SSL cipher (empty for non-SSL connections). This variable was added in MySQL 4.0.0.

- `Ssl_cipher_list` [455]

  The list of possible SSL ciphers. This variable was added in MySQL 4.0.0.

- `Ssl_client_connects` [455]

  The number of SSL connection attempts to an SSL-enabled master. This variable was added in MySQL 4.0.0.

- `Ssl_connect_renegotiates` [455]

  The number of negotiates needed to establish the connection to an SSL-enabled master. This variable was added in MySQL 4.0.0.

- `Ssl_ctx_verify_depth` [456]

  The SSL context verification depth (how many certificates in the chain are tested). This variable was added in MySQL 4.0.0.

- `Ssl_ctx_verify_mode` [456]

  The SSL context verification mode. This variable was added in MySQL 4.0.0.

- `Ssl_default_timeout` [456]

  The default SSL timeout. This variable was added in MySQL 4.0.0.

- `Ssl_finished_accepts` [456]

  The number of successful SSL connections to the server. This variable was added in MySQL 4.0.0.

- `Ssl_finished_connects` [456]

  The number of successful slave connections to an SSL-enabled master. This variable was added in MySQL 4.0.0.

- `Ssl_session_cache_hits` [456]

  The number of SSL session cache hits. This variable was added in MySQL 4.0.0.

- `Ssl_session_cache_misses` [456]

  The number of SSL session cache misses. This variable was added in MySQL 4.0.0.

- `Ssl_session_cache_mode` [456]

  The SSL session cache mode. This variable was added in MySQL 4.0.0.

- `Ssl_session_cache_overflows` [456]

  The number of SSL session cache overflows. This variable was added in MySQL 4.0.0.

- `Ssl_session_cache_size` [456]

  The SSL session cache size. This variable was added in MySQL 4.0.0.

- `Ssl_session_cache_timeouts` [456]

  The number of SSL session cache timeouts. This variable was added in MySQL 4.0.0.

- `Ssl_sessions_reused` [456]

  How many SSL connections were reused from the cache. This variable was added in MySQL 4.0.0.

- `Ssl_used_session_cache_entries` [456]

  How many SSL session cache entries were used. This variable was added in MySQL 4.0.0.

- `Ssl_verify_depth` [456]

  The verification depth for replication SSL connections. This variable was added in MySQL 4.0.0.

- `Ssl_verify_mode` [456]

The verification mode for replication SSL connections. This variable was added in MySQL 4.0.0.

- `Ssl_version` [457]

  The SSL version number. This variable was added in MySQL 4.0.0.

- `Table_locks_immediate` [457]

  The number of times that a request for a table lock could be granted immediately. This variable was added in MySQL 3.23.33.

- `Table_locks_waited` [457]

  The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication. This variable was added in MySQL 3.23.33.

- `Threads_cached` [457]

  The number of threads in the thread cache. This variable was added in MySQL 3.23.17.

- `Threads_connected` [457]

  The number of currently open connections.

- `Threads_created` [457]

  The number of threads created to handle connections. If `Threads_created` [457] is big, you may want to increase the `thread_cache_size` [431] value. The cache miss rate can be calculated as `Threads_created` [457] divided by `Connections` [450]. This variable was added in MySQL 3.23.31.

- `Threads_running` [457]

  The number of threads that are not sleeping.

- `Uptime` [457]

  The number of seconds that the server has been up.

5.1.6 Server SQL Modes

The MySQL server can operate in different SQL modes, and (as of MySQL 4.1) can apply these modes differentially for different clients. This capability enables each application to tailor the server's operating mode to its own requirements.

Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

You can set the default SQL mode by starting `mysqld` with the `--sql-mode="modes"` [394] option, or by using `sql-mode="modes"` [394] in `my.cnf` (Unix operating systems) or `my.ini` (Windows). *`modes`* is a list of different modes separated by comma (“`,`”) characters. The default value is empty (no modes set). The *`modes`* value also can be empty (`--sql-mode=""` [394] on the command line, or `sql-mode=""` [394] in `my.cnf` on Unix systems or in `my.ini` on Windows) if you want to clear it explicitly.

Beginning with MySQL 4.1, you can change the SQL mode at runtime by using a `SET [GLOBAL|SESSION] sql_mode='modes'` statement to set the `sql_mode` [429] system value. Setting the

GLOBAL variable requires the SUPER [493] privilege and affects the operation of all clients that connect from that time on. Setting the SESSION variable affects only the current client. Any client can change its own session sql_mode [429] value at any time.

You can retrieve the current global or session sql_mode [429] value with the following statements:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

This mode changes syntax and behavior to conform more closely to standard SQL, and is available beginning in MySQL 4.1.1.

The following list describes all supported modes:

- ANSI_QUOTES [458]

  Treat "!" as an identifier quote character (like the "`" quote character) and not as a string quote character. You can still use "`" to quote identifiers with this mode enabled. With ANSI_QUOTES [458] enabled, you cannot use double quotation marks to quote literal strings, because it is interpreted as an identifier. (Added in MySQL 4.0.0)

- IGNORE_SPACE [458]

  Permit spaces between a function name and the "(" character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 8.2, "Database, Table, Index, Column, and Alias Names". For example, because there is a COUNT() [882] function, the use of count as a table name in the following statement causes an error:

  ```
  mysql> CREATE TABLE count (i INT);
  ERROR 1064 (42000): You have an error in your SQL syntax
  ```

  The table name should be quoted:

  ```
  mysql> CREATE TABLE `count` (i INT);
  Query OK, 0 rows affected (0.00 sec)
  ```

  The IGNORE_SPACE [458] SQL mode applies to built-in functions, not to user-defined functions. It is always permissible to have spaces after a UDF name, regardless of whether IGNORE_SPACE [458] is enabled.

  For further discussion of IGNORE_SPACE [458], see Section 8.2.3, "Function Name Parsing and Resolution".

  (Added in MySQL 4.0.0)

- NO_AUTO_VALUE_ON_ZERO [458]

  NO_AUTO_VALUE_ON_ZERO [458] affects handling of AUTO_INCREMENT columns. Normally, you generate the next sequence number for the column by inserting either NULL or 0 into it. NO_AUTO_VALUE_ON_ZERO [458] suppresses this behavior for 0 so that only NULL generates the next sequence number. (Added in MySQL 4.1.1)

  This mode can be useful if 0 has been stored in a table's AUTO_INCREMENT column. (Storing 0 is not a recommended practice, by the way.) For example, if you dump the table with mysqldump and then reload it, MySQL normally generates new sequence numbers when it encounters the

`0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` [458] before reloading the dump file solves this problem. As of MySQL 4.1.1, `mysqldump` automatically includes a statement in the dump output that enables `NO_AUTO_VALUE_ON_ZERO` [458] to avoid this problem.

- `NO_DIR_IN_CREATE` [459]

  When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on slave replication servers. (Added in MySQL 4.0.15)

- `NO_FIELD_OPTIONS` [459]

  Do not print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode. (Added in MySQL 4.1.1)

- `NO_KEY_OPTIONS` [459]

  Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode. (Added in MySQL 4.1.1)

- `NO_TABLE_OPTIONS` [459]

  Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode. (Added in MySQL 4.1.1)

- `NO_UNSIGNED_SUBTRACTION` [459]

  By default, subtraction between integer operands produces an `UNSIGNED` result if any operand is`UNSIGNED`. When `NO_UNSIGNED_SUBTRACTION` [459] is enabled, the subtraction result is signed, *even if any operand is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-------+---------------------+------+-----+---------+-------+
| Field | Type                | Null | Key | Default | Extra |
+-------+---------------------+------+-----+---------+-------+
| c2    | bigint(21) unsigned |      |     | 0       |       |
+-------+---------------------+------+-----+---------+-------+

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| c2    | bigint(21) |      |     | 0       |       |
+-------+------------+------+-----+---------+-------+
```

Note that this means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See Section 11.10, “Cast Functions and Operators”. (Added in MySQL 4.0.2)

```
mysql> SET sql_mode = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+-------------------------+
|    18446744073709551615 |
```

```
+------------------------+

mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+------------------------+
|                     -1 |
+------------------------+
```

- `ONLY_FULL_GROUP_BY` [460]

  Do not permit queries for which the `SELECT` list refers to nonaggregated columns that are not named in the `GROUP BY` clause. (Added in MySQL 4.0.0) The following query is invalid with this mode enabled because `address` is not named in the `GROUP BY` clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

- `PIPES_AS_CONCAT` [460]

  Treat `||` [787] as a string concatenation operator (same as `CONCAT()` [795]) rather than as a synonym for `OR` [787]. (Added in MySQL 4.0.0)

- `REAL_AS_FLOAT` [460]

  Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`. (Added in MySQL 4.0.0)

The following special modes are provided as shorthand for combinations of mode values from the preceding list. All are available as of MySQL 4.1.1.

The descriptions include all mode values that are available in the most recent version of MySQL. For older versions, a combination mode does not include individual mode values that are not available except in newer versions.

- `ANSI` [460]

  Equivalent to `REAL_AS_FLOAT` [460], `PIPES_AS_CONCAT` [460], `ANSI_QUOTES` [458], `IGNORE_SPACE` [458]. Before MySQL 4.1.11, `ANSI` [460] also includes `ONLY_FULL_GROUP_BY` [460]. See Section 1.9.3, “Running MySQL in ANSI Mode”.

- `DB2` [460]

  Equivalent to `PIPES_AS_CONCAT` [460], `ANSI_QUOTES` [458], `IGNORE_SPACE` [458], `NO_KEY_OPTIONS` [459], `NO_TABLE_OPTIONS` [459], `NO_FIELD_OPTIONS` [459].

- `MAXDB` [460]

  Equivalent to `PIPES_AS_CONCAT` [460], `ANSI_QUOTES` [458], `IGNORE_SPACE` [458], `NO_KEY_OPTIONS` [459], `NO_TABLE_OPTIONS` [459], `NO_FIELD_OPTIONS` [459].

- `MSSQL` [460]

  Equivalent to `PIPES_AS_CONCAT` [460], `ANSI_QUOTES` [458], `IGNORE_SPACE` [458], `NO_KEY_OPTIONS` [459], `NO_TABLE_OPTIONS` [459], `NO_FIELD_OPTIONS` [459].

- `MYSQL323` [460]

  Equivalent to `NO_FIELD_OPTIONS` [459].

- `MYSQL40` [461]

  Equivalent to `NO_FIELD_OPTIONS` [459].

- `ORACLE` [461]

  Equivalent to `PIPES_AS_CONCAT` [460], `ANSI_QUOTES` [458], `IGNORE_SPACE` [458], `NO_KEY_OPTIONS` [459], `NO_TABLE_OPTIONS` [459], `NO_FIELD_OPTIONS` [459].

- `POSTGRESQL` [461]

  Equivalent to `PIPES_AS_CONCAT` [460], `ANSI_QUOTES` [458], `IGNORE_SPACE` [458], `NO_KEY_OPTIONS` [459], `NO_TABLE_OPTIONS` [459], `NO_FIELD_OPTIONS` [459].

5.1.7 Server-Side Help

As of MySQL 4.1, MySQL Server supports a `HELP` statement that returns online information from the MySQL Reference manual (see Section 12.7.3, “`HELP` Syntax”). The proper operation of this statement requires that the help tables in the `mysql` database be initialized with help topic information, which is done by processing the contents of the `fill_help_tables.sql` script.

If you install MySQL using a binary or source distribution on Unix, help table setup occurs when you run `mysql_install_db`. For an RPM distribution on Linux or binary distribution on Windows, help table setup occurs as part of the MySQL installation process.

If you upgrade MySQL using a binary distribution, the help tables are not upgraded automatically, but you can upgrade them manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

You can also obtain the latest `fill_help_tables.sql` at any time to upgrade your help tables. Download the proper file for your version of MySQL from http://dev.mysql.com/doc/index-other.html. After downloading and uncompressing the file, process it with `mysql` as described previously.

If you are working with Bazaar and a MySQL development source tree, you will need to download the `fill_help_tables.sql` file because the tree contains only a “stub” version.

5.1.8 Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- `SIGTERM` causes the server to shut down.

- `SIGHUP` causes the server to reload the grant tables and flush the logs (like `FLUSH PRIVILEGES` and `FLUSH LOGS`). It also writes a status report to the error log that has this format:

```
Status information:

Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:

Key caches:
default
Buffer_size:       8388600
Block_size:           1024
```

```
Division_limit:        100
Age_limit:             300
blocks used:             0
not flushed:             0
w_requests:              0
writes:                  0
r_requests:              0
reads:                   0

handler status:
read_key:            0
read_next:           0
read_rnd             0
read_first:          1
write:               0
delete               0
update:              0

Table status:
Opened tables:          5
Open tables:            0
Open files:             7
Open streams:           0

Alarm status:
Active alarms:   1
Max used alarms: 2
Next alarm time: 67
```

On some Mac OS X 10.3 versions, `mysqld` ignores `SIGHUP` and `SIGQUIT`.

5.1.9 The Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

   Server shutdown can be initiated several ways. For example, a user with the `SHUTDOWN` [492] privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to. (On Windows, a user with Administrator rights can also shut down the server using `NET STOP` *`service_name`*, where *`service_name`* is the name of the MySQL service. By default, this is `MySQL`.)

2. The server creates a shutdown thread if necessary.

   Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

   ```
   Error: Can't create thread to kill server
   ```

3. The server stops accepting new connections.

   To prevent new activity from being initiated during shutdown, the server stops accepting new client connections. It does this by closing the network connections to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

   For each thread that is associated with a client connection, the connection to the client is broken and the thread is marked as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see Section 12.4.6.3, “KILL Syntax”, in particular for the instructions about killed REPAIR TABLE or OPTIMIZE TABLE operations on MyISAM tables.

   For threads that have an open transaction, the transaction is rolled back. Note that if a thread is updating a nontransactional table, an operation such as a multiple-row UPDATE or INSERT may leave the table partially updated, because the operation can terminate before completion.

   If the server is a master replication server, threads associated with currently connected slaves are treated like other client threads. That is, each one is marked as killed and exits when it next checks its state.

   If the server is a slave replication server, the I/O and SQL threads, if active, are stopped before client threads are marked as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread was in the middle of a transaction at this point, the transaction is rolled back.

5. Storage engines are shut down or closed.

   At this stage, the table cache is flushed and all open tables are closed.

   Each storage engine performs any actions necessary for tables that it manages. For example, MyISAM flushes any pending index writes for a table. InnoDB flushes its buffer pool to disk, writes the current LSN to the tablespace, and terminates its own internal threads.

6. The server exits.

5.2 The mysqld-max Extended MySQL Server

A MySQL-Max server is a version of the mysqld MySQL server that has been built to include additional features. The MySQL-Max distribution to use depends on your platform:

- For Windows, MySQL binary distributions include both the standard server (mysqld.exe) and the MySQL-Max server (mysqld-max.exe), so no special distribution is needed. Just use a regular Windows distribution. See Section 2.3, “Installing MySQL on Microsoft Windows”.
- For Linux, if you install MySQL using RPM distributions, the MySQL-Max RPM presupposes that you have already installed the regular server RPM. Use the regular MySQL-server RPM first to install a standard server named mysqld, and then use the MySQL-Max RPM to install a server named mysqld-max. See Section 2.4, “Installing MySQL from RPM Packages on Linux”, for more information on the Linux RPM packages.
- All other MySQL-Max distributions contain a single server that is named mysqld but that has the additional features included.

You can find the MySQL-Max binaries on the MySQL Web site at http://dev.mysql.com/doc/.

We build the MySQL-Max servers by using the following configure options:

- --with-server-suffix=-max

  This option adds a -max suffix to the mysqld version string.

- `--with-innodb`

  This option enables support for the `InnoDB` storage engine. MySQL-Max servers always include `InnoDB` support, but this option actually is needed only for MySQL 3.23. From MySQL 4.0 onward, `InnoDB` is included by default in all binary distributions, so a MySQL-Max server is not needed to obtain `InnoDB` support.

- `--with-bdb`

  This option enables support for the Berkeley DB (`BDB`) storage engine on those platforms for which `BDB` is available. (See notes in the following discussion.)

- `--with-blackhole-storage-engine`

  This option enables support for the `BLACKHOLE` storage engine in MySQL 4.1.11 and newer.

- `--with-example-storage-engine`

  This option enables support for the `EXAMPLE` storage engine in MySQL 4.1.10 and newer.

- `--with-ndbcluster`

  As of MySQL 4.1.2, this option enables support for the `NDBCLUSTER` storage engine on those platforms for which Cluster is available. (See notes in the following discussion.)

- `USE_SYMDIR`

  This define is enabled to turn on database symbolic link support for Windows. This applies only before MySQL 4.0. From MySQL 4.0 onward, symbolic link support is enabled for all Windows servers, so a MySQL-Max server is not needed to take advantage of this feature.

MySQL-Max binary distributions are a convenience for those who wish to install precompiled programs. If you build MySQL using a source distribution, you can build your own Max-like server by enabling the same features at configuration time that the MySQL-Max binary distributions are built with.

MySQL-Max servers include the BerkeleyDB (`BDB`) storage engine whenever possible, but not all platforms support `BDB`.

The following table shows on which platforms MySQL-Max binaries include support for `BDB` and `NDB Cluster`:

As of MySQL 4.1.2, MySQL Cluster is supported on Linux (on most platforms), Solaris, Mac OS X, and HP-UX only. Some users have reported success in using MySQL Cluster built from source on BSD operating systems, but these are not officially supported at this time. Note that, even for servers compiled with Cluster support, the `NDBCLUSTER` storage engine is not enabled by default. You must start the server with the `--ndbcluster` [1301] option to use it as part of a MySQL Cluster. (For details, see Section 15.3, “MySQL Cluster Configuration”.)

The following table shows the platforms for which MySQL-Max binaries include support for `BDB` and `NDBCLUSTER`.

System	BDB Support	NDB Support
AIX 5.2	N	N
HP-UX	Y	Y
Linux-Alpha	N	N

System	BDB Support	NDB Support
Linux-IA-64	N	Y
Linux-Intel	Y	Y
Mac OS X	N	Y
NetWare	N	N
SCO 6	N	N
Solaris-SPARC	Y	Y
Solaris-Intel	N	Y
Solaris-AMD 64	Y	Y
Windows NT/2000/XP	Y	N

To find out which storage engines your server supports, use the `SHOW ENGINES` statement. (See Section 12.4.5.10, "`SHOW ENGINES` Syntax".) For example:

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
 Engine: MyISAM
Support: DEFAULT
Comment: Default engine as of MySQL 3.23 with great performance
*************************** 2. row ***************************
 Engine: HEAP
Support: YES
Comment: Alias for MEMORY
*************************** 3. row ***************************
 Engine: MEMORY
Support: YES
Comment: Hash based, stored in memory, useful for temporary tables
*************************** 4. row ***************************
 Engine: MERGE
Support: YES
Comment: Collection of identical MyISAM tables
...
```

Before MySQL 4.1.2, `SHOW ENGINES` is unavailable. Use the following statement instead and check the value of the variable for the storage engine in which you are interested:

```
mysql> SHOW VARIABLES LIKE 'have%';
+----------------------+-------+
| Variable_name        | Value |
+----------------------+-------+
| have_archive         | YES   |
| have_bdb             | YES   |
| have_blackhole_engine | YES   |
| have_compress        | YES   |
| have_crypt           | YES   |
| have_csv             | YES   |
| have_example_engine  | YES   |
| have_geometry        | YES   |
| have_innodb          | YES   |
| have_isam            | NO    |
| have_ndbcluster      | NO    |
| have_openssl         | YES   |
| have_query_cache     | YES   |
| have_raid            | NO    |
| have_rtree_keys      | YES   |
| have_symlink         | YES   |
+----------------------+-------+
```

```
16 rows in set (0.00 sec)
```

The precise output from these statements may vary according to the MySQL version used (and the features that are enabled). The values of the second column of the output indicate the server's level of support for each feature, as shown here:

Value	Meaning
YES	The feature is supported and is active.
NO	The feature is not supported.
DISABLED	The feature is supported but has been disabled.

A value of NO means that the server was compiled without support for the feature, so it cannot be activated at runtime.

A value of DISABLED occurs either because the server was started with an option that disables the feature, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See Section 5.3.1, “The Error Log”.

One situation in which you might see DISABLED occurs with MySQL 3.23 when the InnoDB storage engine is compiled in. In MySQL 3.23, you must supply at least the innodb_data_file_path [1067] option at runtime to set up the InnoDB tablespace. Without this option, InnoDB disables itself. See Section 13.2.2, “InnoDB in MySQL 3.23”. You can specify configuration options for the BDB storage engine, too, but BDB does not disable itself if you do not provide them. See Section 13.5.3, “BDB Startup Options”.

You might also see DISABLED for a storage engine if the server was compiled to support it, but was started with a --skip-*engine_name* option. For example, --skip-innodb [1066] disables the InnoDB engine. For the NDB Cluster storage engine, DISABLED means the server was compiled with support for MySQL Cluster, but was not started with the --ndb-cluster option.

As of version 3.23, all MySQL servers support MyISAM tables, because MyISAM is the default storage engine.

5.3 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

Log Type	Information Written to Log
Error log	Problems encountered starting, running, or stopping mysqld
ISAM log	Changes to the ISAM tables (used only for debugging the ISAM code)
General query log	Established client connections and statements received from clients
Update log	Statements that change data (this log is deprecated)
Binary log	Statements that change data (also used for replication)
Relay log	Data changes received from a replication master server
Slow query log	Queries that took more than long_query_time [417] seconds to execute

By default, all log files are created in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a FLUSH LOGS statement or execute a mysqladmin flush-logs, mysqladmin refresh,

`mysqldump --flush-logs`, or `mysqldump --master-data` command. See Section 12.4.6.2, "`FLUSH` Syntax", Section 4.5.2, "`mysqladmin` — Client for Administering a MySQL Server", and Section 4.5.4, "`mysqldump` — A Database Backup Program". In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` [1184] system variable.

The relay log is used only on slave replication servers, to hold data changes from the master server that must also be made on the slave. For discussion of relay log contents and configuration, see Section 14.3.2, "The Slave Relay Log".

For information about log maintenance operations such as expiration of old log files, see Section 5.3.6, "Server Log Maintenance".

See Section 5.4.2.1, "Administrator Guidelines for Password Security", for information about keeping logs secure.

5.3.1 The Error Log

The error log contains information indicating when `mysqld` was started and stopped and also any critical errors that occur while the server is running. If `mysqld` notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` dies. The trace can be used to determine where `mysqld` died. See Section 18.4, "Porting to Other Systems".

Beginning with MySQL 4.0.10, you can specify where `mysqld` writes the error log with the `--log-error[=file_name]` [388] option. If the option is given with no *`file_name`* value, `mysqld` uses the name *`host_name`*`.err` by default. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. (Prior to MySQL 4.0.10, the Windows error log name is `mysql.err`.) If you flush the logs using `FLUSH LOGS` or `mysqladmin flush-logs`, `mysqld` renames the current log file with the suffix `-old`, then creates a new empty log file. Be aware that a second log-flushing operation thus causes the original error log file to be lost unless you save it under a different name. For example, you can use the following commands to save the file:

```
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

No error log renaming occurs when the logs are flushed if the server is not writing to a named file.

In older MySQL versions on Unix, error log handling was done by `mysqld_safe` which redirected the error file to *`host_name`*`.err`. You could change this file name by specifying a `--err-log=`*`file_name`* [244] option to `mysqld_safe`.

If you do not specify `--log-error` [388], or (on Windows) if you use the `--console` [385] option, errors are written to `stderr`, the standard error output. Usually this is your terminal.

On Windows, error output is always written to the `.err` file if `--console` [385] is not given.

In addition, on Windows, events and error messages are written to the Windows Event Log within the Application log. Entries marked as `Warning` and `Note` are written to the Event Log, but informational messages (such as information statements from individual storage engines) are not copied to the Event Log. The log entries have a source of **MySQL**. You cannot disable writing information to the Windows Event Log.

The `--log-warnings` [389] option or `log_warnings` [417] system variable can be used to control warning logging to the error log. The default value is enabled (1) as of MySQL 4.0.19 and 4.1.2. Warning logging can be disabled using a value of 0. As of MySQL 4.0.21 and 4.1.3, the value can be greater than

1. If the value is greater than 1, aborted connections are written to the error log. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

If `mysqld_safe` is used to start `mysqld` and `mysqld` dies unexpectedly, `mysqld_safe` notices that it needs to restart `mysqld` and writes a `restarted mysqld` message to the error log.

5.3.2 The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

Older versions of the `mysql.server` script (from MySQL 3.23.4 to 3.23.8) pass a `--log` [388] option to `safe_mysqld` to enable the general query log. If you need better performance when you start using MySQL in a production environment, you can remove the `--log` [388] option from `mysql.server` or change it to `--log-bin` [1181]. See Section 5.3.4, “The Binary Log”.

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order contrasts to the update log and the binary log, which are written after the query is executed but before any locks are released. (Also, the query log contains all statements, whereas the update and binary logs do not contain statements that only select data.)

To enable the general query log, start `mysqld` with the `--log[=file_name]` [388] or `-l [file_name]` option.

If the general query log file is enabled but no name is specified, the default name is *`host_name`*`.log` and the server creates the file in the same directory where it creates the PID file. If a name is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). On Unix, you can rename the file and create a new one by using the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, you cannot rename the log file while the server has it open. You must stop the server, rename the file, and then restart the server to create a new log file.

To disable or enable general query logging for the current connection, set the session `sql_log_off` [429] variable to `ON` or `OFF`.

The general query log should be protected because logged statements might contain passwords. See Section 5.4.2.1, “Administrator Guidelines for Password Security”.

5.3.3 The Update Log

Note

The update log has been deprecated and replaced by the more useful, informative, and efficient binary log. See Section 5.3.4, “The Binary Log”.

When started with the `--log-update[=file_name]` [389] option, `mysqld` writes a log file containing all SQL statements that update data. If no *`file_name`* value is given, the default name is name of the host machine. If a file name is given, but it does not contain a leading path, the file is written in the data

directory. If `file_name` does not have an extension, `mysqld` creates log files with names of the form *`file_name.nnnnnn`*, where *`nnnnnn`* is a number that is incremented each time you start the server or flush the logs.

Note

For this naming scheme to work, you must not create your own files with the same names as those that might be used in the log file sequence.

Update logging is "smart" in that *it logs only statements that actually update data*. Thus, an `UPDATE` or `DELETE` with a `WHERE` clause that finds no rows is not written to the log. Update logging also skips `UPDATE` statements that merely set a column to its existing value.

The update logging is done immediately after a query completes but before any locks are released or any commit is done. This ensures that statements are logged in execution order.

If you want to update a database from update log files, you could do the following (assuming that your update logs have names of the form `file_name.nnnnnn`):

```
shell> ls -1 -t -r file_name.[0-9]* | xargs cat | mysql
```

`ls` is used to sort the update log file names into the right order.

This can be useful if you have to revert to backup files after a crash and you want to redo the updates that occurred between the time of the backup and the crash.

The update log should be protected because logged statements might contain passwords. See Section 5.4.2.1, "Administrator Guidelines for Password Security".

5.3.4 The Binary Log

The binary log contains "events" that describe database changes such as table creation operations or changes to table data. As of MySQL 4.1.3, it also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows). The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 14.2, "Replication Implementation Overview".
- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 6.5, "Point-in-Time (Incremental) Recovery Using the Binary Log".

Note

The binary log has replaced the old update log, which is no longer available as of MySQL 5.0. The binary log contains all information that is available in the update log in a more efficient format and in a manner that is transaction-safe. If you are using transactions, you must use the MySQL binary log for backups instead of the old update log.

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

For information about server options and variables affecting the operation of binary logging, see Section 14.8.4, “Binary Log Options and Variables”.

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. If you want to log all statements (for example, to identify a problem query), use the general query log. See Section 5.3.2, “The General Query Log”.

The binary log should be protected because logged statements might contain passwords. See Section 5.4.2.1, “Administrator Guidelines for Password Security”.

For detailed information about the format of the binary log, see MySQL Internals: The Binary Log.

To enable the binary log, start the server with the `--log-bin[=base_name]` [1181] option. If no *`base_name`* value is given, the default name is the value of the `pid-file` option (which by default is the name of host machine) followed by `-bin`. If the basename is given, the server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. It is recommended that you specify a basename; see Section B.5.8.4, “Open Issues in MySQL”, for the reason.

If you supply an extension in the log name (for example, `--log-bin=base_name.extension` [1181]), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log basename to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time it starts or flushes the logs. The server also creates a new binary log file automatically after the current log's size reaches `max_binlog_size` [1184]. A binary log file may become larger than `max_binlog_size` [1184] if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of all used binary log files. By default, this has the same basename as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` [1182] option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

The server evaluates the `--binlog-do-db` [1182] and `--binlog-ignore-db` [1182] options in the same way as it does the `--replicate-do-db` [1176] and `--replicate-ignore-db` [1176] options. For information about how this is done, see Section 14.9.1, “Evaluation of Database-Level Replication and Binary Logging Options”.

A replication slave server by default does not write to its own binary log any data modifications that are received from the replication master. To log these modifications, start the slave with the `--log-slave-updates` [1173] option in addition to the `--log-bin` [1181] option (see Section 14.8.3, “Replication Slave Options and Variables”). This is done when a slave is also to act as a master to other slaves in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See Section 12.4.6.5, “`RESET` Syntax”, and Section 12.5.1.1, “`PURGE BINARY LOGS` Syntax”.

If you are using replication, you should not delete old binary log files on the master until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the master and then remove any logs that are

more than three days old. You can remove the files manually, but it is preferable to use PURGE BINARY LOGS, which also safely updates the binary log index file for you (and which can take a date argument as of MySQL 4.1). See Section 12.5.1.1, “PURGE BINARY LOGS Syntax”.

A client that has the SUPER [493] privilege can disable binary logging of its own statements by using a SET sql_log_bin=0 statement. See Section 5.1.3, “Server System Variables”.

You can display the contents of binary log files with the mysqlbinlog utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

mysqlbinlog also can be used to display replication slave relay log file contents because they are written using the same format as binary log files. For more information on the mysqlbinlog utility and how to use it, see Section 4.6.6, “mysqlbinlog — Utility for Processing Binary Log Files”. For more information about the binary log and recovery operations, see Section 6.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

Binary logging is done immediately after a statement completes but before any locks are released or any commit is done. This ensures that the log is logged in execution order.

Updates to nontransactional tables are stored in the binary log immediately after execution. Within an uncommitted transaction, all updates (UPDATE, DELETE, or INSERT) that change transactional tables such as BDB or InnoDB tables are cached until a COMMIT statement is received by the server. At that point, mysqld writes the entire transaction to the binary log before the COMMIT is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that the modifications to those tables are replicated. This is true as of MySQL 4.0.15.

When a thread that handles the transaction starts, it allocates a buffer of binlog_cache_size [407] to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The Binlog_cache_use [449] status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The Binlog_cache_disk_use [449] status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning binlog_cache_size [407] to a large enough value that avoids the use of temporary files.

The max_binlog_cache_size [1183] system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the update log or binary log, concurrent inserts are converted to normal inserts for CREATE ... SELECT or INSERT ... SELECT statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation.

The binary log format has some known limitations that can affect recovery from backups, especially in old versions. These caveats, which also affect replication, are listed at Section 14.7, “Replication Features and Issues”. One caveat which does not affect replication but only recovery with mysqlbinlog: before MySQL 4.1, mysqlbinlog could not prepare output suitable for mysql if the binary log contained interlaced statements originating from different clients that used temporary tables of the same name. This is fixed in MySQL 4.1. However, the problem still existed for LOAD DATA INFILE statements until it was fixed in MySQL 4.1.8.

The binary log format differs between versions 3.23 and 4.0. (These format changes were required to implement enhancements to replication.) However, MySQL 4.1 has the same binary log format as 4.0. See Section 14.5, “Replication Compatibility Between MySQL Versions”.

Before MySQL 4.1.9, writes to a binary log file or binary log index file that failed due to a full disk or an exceeded quota resulted in corruption of the file. Starting from MySQL 4.1.9, writes to the binary log file and binary log index file are handled the same way as writes to `MyISAM` tables. See Section B.5.4.3, “How MySQL Handles a Full Disk”.

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, you can make the binary log be synchronized to disk after every *`N`* writes to the binary log, with the `sync_binlog` [1184] system variable. See Section 5.1.3, “Server System Variables”. 1 is the safest value for `sync_binlog` [1184], but also the slowest. Even with `sync_binlog` [1184] set to 1, there is still the chance of an inconsistency between the table content and binary log content in case of a crash. For example, if you are using `InnoDB` tables and the MySQL server processes a `COMMIT` statement, it writes the whole transaction to the binary log and then commits this transaction into `InnoDB`. If the server crashes between those two operations, the transaction is rolled back by `InnoDB` at restart but still exists in the binary log. This problem can be solved with the `--innodb-safe-binlog` [387] option (available starting from MySQL 4.1.3), which adds consistency between the content of `InnoDB` tables and the binary log.

For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the `InnoDB` logs to disk at every transaction. The `InnoDB` logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server cuts rolled back `InnoDB` transactions from the binary log. This ensures that the binary log reflects the exact data of `InnoDB` tables, and so, that the slave remains in synchrony with the master (not receiving a statement which has been rolled back).

Note that `--innodb-safe-binlog` [387] can be used even if the MySQL server updates other storage engines than `InnoDB`. Only statements and transactions that affect `InnoDB` tables are subject to removal from the binary log at `InnoDB`'s crash recovery. If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed `InnoDB` transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

5.3.5 The Slow Query Log

The slow query log consists of SQL statements that took more than `long_query_time` [417] seconds to execute. The minimum and default values of `long_query_time` [417] are 1 and 10, respectively.

The time to acquire the initial table locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

To enable the slow query log, start `mysqld` with the `--log-slow-queries[=`*`file_name`*`]` [388] option.

If the slow query log file is enabled but no name is specified, the default name is *`host_name`*`-slow.log` and the server creates the file in the same directory where it creates the PID file. If a name is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory.

Before MySQL 4.1, if you also use `--log-long-format` [388] when logging slow queries, queries that are not using indexes are logged as well. Starting with MySQL 4.1, logging of queries not using indexes for row lookups is enabled using the `--log-queries-not-using-indexes` [388] option instead. The `--log-long-format` [388] is deprecated as of MySQL 4.1, when `--log-short-format` [388] was introduced, which causes less information to be logged. (The long log format is the default setting since version 4.1.) See Section 5.1.2, “Server Command Options”.

In MySQL 4.0, slow administrative statements such as `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `ALTER TABLE` were written to the slow query log. This logging was disabled in MySQL 4.1 until 4.1.13, when the `--log-slow-admin-statements` [388] server option was added to specify logging of slow administrative statements.

The server does not write queries handled by the query cache to the slow query log, nor queries that would not benefit from the presence of an index because the table has zero rows or one row.

Replication slaves do not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. This is a known issue. (Bug #23300)

The slow query log should be protected because logged statements might contain passwords. See Section 5.4.2.1, “Administrator Guidelines for Password Security”.

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process a slow query log file using the `mysqldumpslow` command to summarize the queries that appear in the log. See Section 4.6.7, “`mysqldumpslow` — Summarize Slow Query Log Files”.

5.3.6 Server Log Maintenance

As described in Section 5.3, “MySQL Server Logs”, MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 6.2, “Database Backup Methods”.

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

For the binary log, you can set the `expire_logs_days` [411] system variable to expire binary log files automatically after a given number of days (see Section 5.1.3, “Server System Variables”). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see Section 12.5.1.1, “`PURGE BINARY LOGS` Syntax”).

You can force MySQL to start using new log files by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See Section 12.4.6.2, “`FLUSH` Syntax”, Section 4.5.2, “`mysqladmin` — Client for Administering a MySQL Server”, and Section 4.5.4, “`mysqldump` — A Database Backup Program”. In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` [1184] system variable.

A log-flushing operation does the following:

- If general query logging (`--log` [388]) or slow query logging (`--log-slow-queries` [388]) to a log file is enabled, the server closes and reopens the general query log file or slow query log file.
- If update logging (`--log-update` [389]) or binary logging (`--log-bin` [1181]) is used, the server closes the log and opens a new log file with a higher sequence number.
- If the server was started with the `--log-error` [388] option to cause the error log to be written to a file, it renames the current log file with the suffix `-old` and creates a new empty error log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current log files before flushing them. At flush time, the server opens new log files with the original names. For example, if the general and slow query log files are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.old` and `mysql-slow.old` and then remove them from disk.

On Windows, you cannot rename log files while the server has them open. You must stop the server and rename them, and then restart the server to create new logs. For the error log, you can rename the file without a restart as described in Section 5.3.1, “The Error Log”.

5.4 General Security Issues

This section describes some general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Section 5.5, “The MySQL Access Privilege System”.

5.4.1 General Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, we emphasize the necessity of fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines whenever possible:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` database!** This is critical, particularly before MySQL 4.1, when *the encrypted password is the real*

password in MySQL: Anyone who knows the password that is listed in the `mysql.user` table and who has access to the host listed for the account *can easily log in as that user*. In MySQL 4.1, the password hashing algorithm was changed so that this is no longer true.

- Learn the MySQL access privilege system. The `GRANT` and `REVOKE` statements are used for controlling access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

  Checklist:

  - Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See Section 2.10.3, “Securing the Initial MySQL Accounts”.

  - Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.

- Do not store any plaintext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `MD5()` [868], `SHA1()` [869], or some other one-way hashing function and store the hash value.

- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Mary had a little lamb” results in a password of “Mhall”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence.

- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

  Checklist:

  - Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. Another simple way to check whether or not your MySQL port is open is to try the following command from some remote machine, where *`server_host`* is the host name or IP address of the host on which your MySQL server runs:

    ```
    shell> telnet server_host 3306
    ```

    If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open. If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be.

- Do not trust any data entered by users of your applications. They can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like “`; DROP DATABASE mysql;`”. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

  A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table`

`WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Try to enter single and double quotation marks ("`'`" and "`"`") in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22` ("`"`"), `%23` ("`#`"), and `%27` ("`'`") to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

- Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:
  - MySQL C API: Use the `mysql_real_escape_string()` API call.
  - MySQL++: Use the `escape` and `quote` modifiers for query streams.
  - PHP: Use the `mysql_real_escape_string()` function (available as of PHP 4.3.0, prior to that PHP version use `mysql_escape_string()`, and prior to PHP 4.0.3, use `addslashes()`). Note that only `mysql_real_escape_string()` is character set-aware; the other functions can be "bypassed" when using (invalid) multi-byte character sets. In PHP 5 (and as of MySQL 4.1), you can use the `mysqli` extension, which supports the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders.
  - Perl DBI: Use placeholders or the `quote()` method.
  - Ruby DBI: Use placeholders or the `quote()` method.
  - Java JDBC: Use a `PreparedStatement` object and placeholders.

  Other programming interfaces might have similar capabilities.

- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections as of version 4.0. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.

- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

Warning

If you do not see plaintext data, this does not always mean that the information actually is encrypted. If you need high security, you should consult with a security expert.

5.4.2 Password Security in MySQL

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable administrators and end users to keep these passwords secure and avoid exposing them. There is also a discussion of how MySQL uses password hashing internally.

5.4.2.1 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` table. Access to this table should never be granted to any nonadministrative accounts. Passwords in the `user` table are stored in encrypted form, but in versions of MySQL earlier than 4.1, knowing the encrypted password for an account makes it possible to connect to the server using that account.

Passwords can appear as plain text in SQL statements such as `GRANT` and `SET PASSWORD`, or statements that invoke the `PASSWORD()` [868] function. If these statements are logged by the MySQL server, the passwords become available to anyone with access to the logs. This applies to the general query log, the slow query log, the update log, and the binary log (see Section 5.3, “MySQL Server Logs”). To guard against unwarranted exposure to log files, they should be located in a directory that restricts access to only the server and the database administrator.

Replication slaves store the password for the replication master in the `master.info` file. Access to this file should be restricted to the database adminstrator.

Database backups that include tables or log files containing passwords should be protected using a restricted access mode.

5.4.2.2 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use a `-p`*`your_pass`* or `--password=`*`your_pass`* option on the command line. For example:

```
shell> mysql -u francis -pfrank db_name
```

This is convenient *but insecure*, because your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically

overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `-p` or `--password` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
shell> mysql -u francis -p db_name
Enter password: ********
```

The "`*`" characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=your_pass
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
shell> chmod 600 .my.cnf
```

To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` [235] option, where `file_name` is the full path name to the file. For example:

```
shell> mysql --defaults-file=/home/francis/mysql-opts
```

Section 4.2.3.3, "Using Option Files", discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. See Section 2.13, "Environment Variables".

This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. If you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see Section 4.5.1.3, "`mysql` Logging"). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can appear as plain text in SQL statements such as `GRANT` and `SET PASSWORD`, so if you use

these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

5.4.2.3 Password Hashing in MySQL

MySQL user accounts are listed in the `user` table of the `mysql` database. Each MySQL account is assigned a password, although what is stored in the `Password` column of the `user` table is not the plaintext version of the password, but a hash value computed from it. Password hash values are computed by the `PASSWORD()` [868] function.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account that the client wants to use.
- After the client connects, it can (if it has sufficient privileges) set or change the password hashes for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` [868] function to generate a password hash, or by using the `GRANT` or `SET PASSWORD` statements.

In other words, the server *uses* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD()` [868] function or uses a `GRANT` or `SET PASSWORD` statement to set or change a password.

The password hashing mechanism was updated in MySQL 4.1 to provide better security and to reduce the risk of passwords being intercepted. However, this new mechanism is understood only by the 4.1 server and 4.1 clients, which can result in some compatibility problems. A 4.1 client can connect to a pre-4.1 server, because the client understands both the old and new password hashing mechanisms. However, a pre-4.1 client that attempts to connect to a 4.1 server may run into difficulties. For example, a 4.0 `mysql` client that attempts to connect to a 4.1 server may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

Another common example of this phenomenon occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or newer. (See Common Problems with MySQL and PHP.)

The following discussion describes the differences between the old and new password mechanisms, and what you should do if you upgrade your server to 4.1 but need to maintain backward compatibility with pre-4.1 clients. Additional information can be found in Section B.5.2.4, “`Client does not support authentication protocol`”. This information is of particular importance to PHP programmers migrating MySQL databases from version 4.0 or lower to version 4.1 or higher.

Note

This discussion contrasts 4.1 behavior with pre-4.1 behavior, but the 4.1 behavior described here actually begins with 4.1.1. MySQL 4.1.0 is an “odd” release because it has a slightly different mechanism than that implemented in 4.1.1 and up. Differences between 4.1.0 and more recent versions are described further in Section 5.4.2.5, “Password Hashing in MySQL 4.1.0”.

Prior to MySQL 4.1, password hashes computed by the `PASSWORD()` [868] function are 16 bytes long. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+-------------------+
| PASSWORD('mypass') |
+-------------------+
| 6f8c114b58f2ce9e   |
+-------------------+
```

The `Password` column of the `user` table (in which these hashes are stored) also is 16 bytes long before MySQL 4.1.

As of MySQL 4.1, the `PASSWORD()` [868] function has been modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-------------------------------------------+
| PASSWORD('mypass')                        |
+-------------------------------------------+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-------------------------------------------+
```

Accordingly, the `Password` column in the `user` table also must be 41 bytes long to store these values:

- If you perform a new installation of MySQL 4.1, the `Password` column is made 41 bytes long automatically.
- If you upgrade an older installation to 4.1, you should run the `mysql_fix_privilege_tables` script to increase the length of the `Password` column from 16 to 41 bytes. (The script does not change existing password values, which remain 16 bytes long.)

A widened `Password` column can store password hashes in both the old and new formats. The format of any given password hash value can be determined two ways:

- The obvious difference is the length (16 bytes versus 41 bytes).
- A second difference is that password hashes in the new format always begin with a "`*`" character, whereas passwords in the old format never do.

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
  - Pre-4.1 clients can connect, although because they know only about the old hashing mechanism, they can authenticate only using accounts that have short hashes.
  - 4.1 clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash

- 4.1 client authenticating with short password hash
- 4.1 client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `--old-passwords` [391] option. A 4.1 server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and the `--old-passwords` [391] option must not be given. These conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using `PASSWORD()` [868], `GRANT`, or `SET PASSWORD`. This is the behavior that occurs if you have upgraded to 4.1 but have not yet run the `mysql_fix_privilege_tables` script to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, `PASSWORD()` [868], `GRANT`, and `SET PASSWORD` generate long hashes unless the server was started with the `--old-passwords` [391] option. That option forces the server to generate short password hashes instead.

The purpose of the `--old-passwords` [391] option is to enable you to maintain backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option does not affect authentication (4.1 clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that to occur, the account no longer could be used by pre-4.1 clients. Without the `--old-passwords` [391] option, the following undesirable scenario is possible:

- An old client connects to an account that has a short password hash.
- The client changes its own password. Without `--old-passwords` [391], this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the new hashing mechanism during authentication. (Once an account has a long password hash in the user table, only 4.1 clients can authenticate for it, because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is dangerous to run a 4.1 server without using the `--old-passwords` [391] option. By running the server with `--old-passwords` [391], password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of the `--old-passwords` [391] option is that any passwords you create or change use short hashes, even for 4.1 clients. Thus, you lose the additional security provided by long password hashes. If you want to create an account that has a long hash (for example, for use by 4.1 clients), you must do so while running the server without `--old-passwords` [391].

The following scenarios are possible for running a 4.1 or later server:

Scenario 1: Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving `PASSWORD()` [868], `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

- The `--old-passwords` [391] option can be used but is superfluous because with a short `Password` column, the server generates only short password hashes anyway.

Scenario 2: Long `Password` column; server not started with `--old-passwords` [391] option:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving `PASSWORD()` [868], `GRANT`, or `SET PASSWORD` use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using `GRANT`, `PASSWORD()` [868], or `SET PASSWORD` results in the account being given a long password hash. From that point on, no pre-4.1 client can authenticate to that account until the client upgrades to 4.1.

To deal with this problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` [868] function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` [868] is useful for situations in which you explicitly want to generate a short hash.

Scenario 3: Long `Password` column; server started with `--old-passwords` [391] option:

- Short or long hashes can be stored in the `Password` column.
- 4.1 clients can authenticate for accounts that have short or long hashes (but note that it is possible to create long hashes only when the server is started without `--old-passwords` [391]).
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving `PASSWORD()` [868], `GRANT`, or `SET PASSWORD` use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, you cannot create accounts that have long password hashes, because the `--old-passwords` [391] option prevents generation of long hashes. Also, if you create an account with a long hash before using the `--old-passwords` [391] option, changing the account's password while `--old-passwords` [391] is in effect results in the account being given a short password, causing it to lose the security benefits of a longer hash.

The disadvantages for these scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()` [868].

In scenario 3, `--old-passwords` [391] prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes, and you cannot change them back to long hashes while `--old-passwords` [391] is in effect.

5.4.2.4 Implications of Password Hashing Changes in MySQL 4.1 for Application Programs

An upgrade to MySQL 4.1 can cause a compatibility issue for applications that use `PASSWORD()` [868] to generate passwords for their own purposes. Applications really should not do this, because `PASSWORD()` [868] should be used only to manage passwords for MySQL accounts. But some applications use `PASSWORD()` [868] for their own purposes anyway.

If you upgrade to 4.1 and run the server under conditions where it generates long password hashes, an application that uses `PASSWORD()` [868] for its own passwords breaks. The recommended course of action is to modify the application to use another function, such as `SHA1()` [869] or `MD5()` [868], to produce hashed values. If that is not possible, you can use the `OLD_PASSWORD()` [868] function, which is provided to generate short hashes in the old format. But note that `OLD_PASSWORD()` [868] may one day no longer be supported.

If the server is running under circumstances where it generates short hashes, `OLD_PASSWORD()` [868] is available but is equivalent to `PASSWORD()` [868].

PHP programmers migrating their MySQL databases from version 4.0 or lower to version 4.1 or higher should see MySQL and PHP.

5.4.2.5 Password Hashing in MySQL 4.1.0

Password hashing in MySQL 4.1.0 differs from hashing in 4.1.1 and up. The 4.1.0 differences are:

- Password hashes are 45 bytes long rather than 41 bytes.
- The `PASSWORD()` [868] function is nonrepeatable. That is, with a given argument *`X`*, successive calls to `PASSWORD(`*`X`*`)` [868] generate different results.

These differences make authentication in 4.1.0 incompatible with that of releases that follow it. If you have upgraded to MySQL 4.1.0, it is recommended that you upgrade to a newer version as soon as possible. After you do, reassign any long passwords in the `user` table so that they are compatible with the 41-byte format.

5.4.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See Section 5.4.2.3, “Password Hashing in MySQL”, for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol (in MySQL 3.22 and above) to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure in MySQL 4.0 and up. See Section 5.6.6, “Using SSL for Secure Connections”. Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at http://www.openssh.org/, and a commercial SSH client at http://www.ssh.com/.

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

  For a discussion of methods for setting passwords, see Section 5.6.5, “Assigning Account Passwords”.

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.

- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` [491] privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` [395] option.

  `mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

  ```
  [mysqld]
  user=mysql
  ```

  This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see Section 5.4.6, “How to Run MySQL as a Normal User”.

  Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts*.

- Do not grant the `PROCESS` [492] or `SUPER` [493] privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

  `mysqld` reserves an extra connection for users who have the `SUPER` [493] privilege (`PROCESS` [492] before MySQL 4.0.2), so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

  The `SUPER` [493] privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not grant the `FILE` [491] privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. To make this a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

  The `FILE` [491] privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the --skip-symbolic-links [393] option.) This is especially important if you run mysqld as root, because anyone that has write access to the server's data directory then could delete any file in the system! See Section 7.10.2, “Using Symbolic Links for Tables on Unix”.
- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.
- If you want to restrict the number of connections permitted to a single account, you can do so by setting the max_user_connections [420] variable in mysqld. The GRANT statement also supports resource control options for limiting the extent of server use permitted to an account. See Section 12.4.1.2, “GRANT Syntax”.
- If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using SELECT ... INTO DUMPFILE. This can be prevented by making plugin_dir [423] read only to the server.

5.4.4 Security-Related mysqld Options

The following mysqld options affect security:

Table 5.5 Security Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
allow-suspicious-udfs [384]	Yes	Yes				
chroot [385]	Yes	Yes				
des-key-file [386]	Yes	Yes				
local_infile [417]			Yes		Global	Yes
old_passwords [423]			Yes		Both	Yes
safe-show-database [391]	Yes	Yes	Yes		Global	Yes
safe-user-create [392]	Yes	Yes				
secure-auth [392]	Yes	Yes			Global	Yes
- *Variable*: secure_auth [426]			Yes		Global	Yes
skip-grant-tables [392]	Yes	Yes				
skip-name-resolve [393]	Yes	Yes			Global	No
- *Variable*: skip_name_resolve			Yes		Global	No
skip-networking [393]	Yes	Yes			Global	No
- *Variable*: skip_networking [427]			Yes		Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
skip-show-database [394]	Yes	Yes			Global	No
- *Variable*: skip_show_database [427]			Yes		Global	No

- `--allow-suspicious-udfs` [384]

  This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is turned off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. This option was added in MySQL 4.0.24 and 4.1.10a. See Section 18.2.2.6, “User-Defined Function Security Precautions”.

- `--local-infile[={0|1}]` [486]

  If you start the server with `--local-infile=0` [486], clients cannot use `LOCAL` in `LOAD DATA` statements. See Section 5.4.5, “Security Issues with `LOAD DATA LOCAL`”.

- `--old-passwords` [391]

  Force the server to generate short (pre-4.1) password hashes for new passwords. This is useful for compatibility when the server must support older client programs. See Section 5.4.2.3, “Password Hashing in MySQL”.

- `--safe-user-create` [392]

  If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` [492] privilege for the `mysql.user` table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

  ```
  GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
  ```

  This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth` [392]

  Disallow authentication for accounts that have old (pre-4.1) passwords. This option is available as of MySQL 4.1.1.

  The `mysql` client also has a `--secure-auth` [392] option, which prevents connections to a server if the server requires a password in old format for the client account.

- `--skip-grant-tables` [392]

  This option causes the server not to use the privilege system at all. This gives anyone with access to the server *unrestricted access* to *all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement. This option also suppresses loading of user-defined functions (UDFs).

- `--skip-name-resolve` [393]

Host names are not resolved. All Host column values in the grant tables must be IP addresses or localhost.

- --skip-networking [393]

  Do not permit TCP/IP connections over the network. All connections to mysqld must be made using Unix socket files. This option is unsuitable when using a MySQL version prior to 3.23.27 with the MIT-pthreads package, because Unix socket files were not supported by MIT-pthreads at that time.

- --skip-show-database [394]

  With this option, the SHOW DATABASES statement is permitted only to users who have the SHOW DATABASES [492] privilege, and the statement displays all database names. Without this option, SHOW DATABASES is permitted to all users, but displays each database name only if the user has the SHOW DATABASES [492] privilege or some privilege for the database. Note that any global privilege is a privilege for the database.

- --ssl*

  Options that begin with --ssl [521] specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See Section 5.6.6.3, “SSL Command Options”.

5.4.5 Security Issues with LOAD DATA LOCAL

The LOAD DATA statement can load a file that is located on the server host, or it can load a file that is located on the client host when the LOCAL keyword is specified.

There are two potential security issues with supporting the LOCAL version of LOAD DATA statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the LOAD DATA statement. Such a server could access any file on the client host to which the client user has read access.
- In a Web environment where the clients are connecting from a Web server, a user could use LOAD DATA LOCAL to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the remote program being run by the user who connects to the Web server.

To deal with these problems, we changed how LOAD DATA LOCAL is handled as of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows):

- By default, all MySQL clients and libraries in binary distributions are compiled with the --enable-local-infile option, to be compatible with MySQL 3.23.48 and before.
- If you build MySQL from source but do not invoke configure with the --enable-local-infile option, LOAD DATA LOCAL cannot be used by any client unless it is written explicitly to invoke mysql_options(... MYSQL_OPT_LOCAL_INFILE, 0). See Section 17.6.6.47, “mysql_options()”.
- You can disable all LOAD DATA LOCAL statements from the server side by starting mysqld with the --local-infile=0 [486] option.
- For the mysql command-line client, enable LOAD DATA LOCAL by specifying the --local-infile[=1] [261] option, or disable it with the --local-infile=0 [261] option. For mysqlimport,

local data file loading is off by default; enable it with the `--local` [304] or `-L` option. In any case, successful use of a local load operation requires that the server permits it.

- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add the `local-infile=1` option to that group. However, to keep this from causing problems for programs that do not understand `local-infile`, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=1
```

  The `loose-` prefix can be used as of MySQL 4.0.2.

- If `LOAD DATA LOCAL` is disabled, either in the server or the client, a client that attempts to issue such a statement receives the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

5.4.6 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account beginning with MySQL 4.0.17 and 4.1.2. (Older MySQL versions required you to have administrator rights. This was a bug introduced in MySQL 3.23.54.)

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user *`user_name`*, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).
2. Change the database directories and files so that *`user_name`* has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

   If you do not do this, the server will not be able to access databases or tables when it runs as *`user_name`*.

   If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.
3. Start the server as user *`user_name`*. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` [395] option. `mysqld` starts up, then switches to run as the Unix user *`user_name`* before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL `root` accounts in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` [265] option and perform any operation. (It is a good idea to assign passwords to

MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.10, “Postinstallation Setup and Testing”.

5.5 The MySQL Access Privilege System

The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as `LOAD DATA INFILE` and administrative operations.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database or table.

The user interface to the MySQL privilege system consists of SQL statements such as `GRANT` and `REVOKE`. See Section 12.4.1, “Account Management Statements”.

Internally, the server stores privilege information in the grant tables of the `mysql` database (that is, in the database named `mysql`). The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the user name you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by `joe` from `office.example.com`, and a different set of privileges for connections by `joe` from `home.example.com`. To see what privileges a given account has, use the `SHOW GRANTS` statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

MySQL access control involves two stages when you run a client program that connects to the server:

Stage 1: The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

Stage 2: Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the `SELECT` [492] privilege for the table or the `DROP` [491] privilege for the database.

For a more detailed description of what happens during each stage, see Section 5.5.4, “Access Control, Stage 1: Connection Verification”, and Section 5.5.5, “Access Control, Stage 2: Request Verification”.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see Section 5.5.6, “When Privilege Changes Take Effect”.

For general security-related advice, see Section 5.4, “General Security Issues”. For help in diagnosing privilege-related problems, see Section 5.5.7, “Causes of Access-Denied Errors”.

5.5.1 Privileges Provided by MySQL

MySQL provides privileges that apply in different contexts and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases).

Information about account privileges is stored in the `user`, `db`, `host`, `tables_priv`, and `columns_priv` tables in the `mysql` database (see Section 5.5.2, “Privilege System Grant Tables”). The MySQL server reads the contents of these tables into memory when it starts and reloads them under the circumstances indicated in Section 5.5.6, “When Privilege Changes Take Effect”. Access-control decisions are based on the in-memory copies of the grant tables.

Some releases of MySQL introduce changes to the structure of the grant tables to add new access privileges or features. Whenever you update to a new version of MySQL, you should update your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. See Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

The following table shows the privilege names used at the SQL level in the `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

Table 5.6 Permissible Privileges for `GRANT` and `REVOKE`

Privilege	Column	Context
`CREATE` [491]	`Create_priv`	databases, tables, or indexes
`DROP` [491]	`Drop_priv`	databases or tables
`GRANT OPTION` [491]	`Grant_priv`	databases, tables, or stored routines
`REFERENCES` [492]	`References_priv`	databases or tables
`ALTER` [491]	`Alter_priv`	tables
`DELETE` [491]	`Delete_priv`	tables
`INDEX` [491]	`Index_priv`	tables
`INSERT` [492]	`Insert_priv`	tables or columns
`SELECT` [492]	`Select_priv`	tables or columns
`UPDATE` [493]	`Update_priv`	tables or columns
`CREATE TEMPORARY TABLES` [491]	`Create_tmp_table_priv`	tables

Privilege	Column	Context
LOCK TABLES [492]	Lock_tables_priv	tables
FILE [491]	File_priv	file access on server host
PROCESS [492]	Process_priv	server administration
RELOAD [492]	Reload_priv	server administration
REPLICATION CLIENT [492]	Repl_client_priv	server administration
REPLICATION SLAVE [492]	Repl_slave_priv	server administration
SHOW DATABASES [492]	Show_db_priv	server administration
SHUTDOWN [492]	Shutdown_priv	server administration
SUPER [493]	Super_priv	server administration
ALL [PRIVILEGES] [491]		server administration
USAGE [493]		server administration

The following list provides a general description of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- The ALL [491] or ALL PRIVILEGES [491] privilege specifier is shorthand. It stands for “all privileges available at a given privilege level” (except GRANT OPTION [491]). For example, granting ALL [491] at the global or table level grants all global privileges or all table-level privileges.
- The ALTER [491] privilege enables use of ALTER TABLE to change the structure of or rename tables. (ALTER TABLE also requires the INSERT [492] and CREATE [491] privileges.)
- The CREATE [491] privilege enables creation of new databases and tables.
- The CREATE TEMPORARY TABLES [491] privilege enables the use of the keyword TEMPORARY in CREATE TABLE statements. This privilege was added in MySQL 4.0.2.
- The DELETE [491] privilege enables rows to be deleted from tables in a database.
- The DROP [491] privilege enables you to drop (remove) existing databases and tables. If you grant the DROP [491] privilege for the mysql database to a user, that user can drop the database in which the MySQL access privileges are stored!
- The EXECUTE [491] privilege was added in MySQL 4.0.2, but is not used until MySQL 5.0.
- The FILE [491] privilege gives you permission to read and write files on the server host using the LOAD DATA INFILE and SELECT ... INTO OUTFILE statements and the LOAD_FILE() [798] function. A user who has the FILE [491] privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The FILE [491] privilege also enables the user to create new files in any directory where the MySQL server has write access. This includes the server's data directory containing the files that implement the privilege tables. As a security measure, the server will not overwrite existing files.
- The GRANT OPTION [491] privilege enables you to give to other users or remove from other users those privileges that you yourself possess.
- The INDEX [491] privilege enables you to create or drop (remove) indexes. INDEX [491] applies to existing tables. If you have the CREATE [491] privilege for a table, you can include index definitions in the CREATE TABLE statement.

- The `INSERT` [492] privilege enables rows to be inserted into tables in a database. `INSERT` [492] is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.

- The `LOCK TABLES` [492] privilege enables the use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` [492] privilege. This includes the use of write locks, which prevents other sessions from reading the locked table. This privilege was added in MySQL 4.0.2.

- The `PROCESS` [492] privilege pertains to display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of `SHOW PROCESSLIST` or `mysqladmin processlist` to see threads belonging to other accounts; you can always see your own threads. Prior to MySQL 4.0.2, `PROCESS` [492] also enable the use of `KILL` to kill threads belonging to other accounts; you can always kill your own threads.

- The `REFERENCES` [492] privilege currently is unused.

- The `RELOAD` [492] privilege enables use of the `FLUSH` statement. It also enables `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

  The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-`*`xxx`* commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

- The `REPLICATION CLIENT` [492] privilege enables the use of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. This privilege was added in MySQL 4.0.2.

- The `REPLICATION SLAVE` [492] privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server. This privilege was added in MySQL 4.0.2.

- The `SELECT` [492] privilege enables you to select rows from tables in a database. `SELECT` statements require the `SELECT` [492] privilege only if they actually retrieve rows from a table. Some `SELECT` statements do not access tables and can be executed without permission for any database. For example, you can use `SELECT` as a simple calculator to evaluate expressions that make no reference to tables:

  ```
  SELECT 1+1;
  SELECT PI()*2;
  ```

  The `SELECT` [492] privilege is also needed for other statements that read column values. For example, `SELECT` [492] is needed for columns referenced on the right hand side of *`col_name`*=*`expr`* assignment in `UPDATE` statements or for columns named in the `WHERE` clause of `DELETE` or `UPDATE` statements.

- The `SHOW DATABASES` [492] privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` [394] option. Note that *any* global privilege is a privilege for the database. `SHOW DATABASES` [492] was added in MySQL 4.0.2.

- The `SHUTDOWN` [492] privilege enables use of the `mysqladmin shutdown` command. There is no corresponding SQL statement.

- The SUPER [493] privilege enables an account to use CHANGE MASTER TO, KILL or mysqladmin kill to kill threads belonging to other accounts (you can always kill your own threads), PURGE BINARY LOGS, configuration changes using SET GLOBAL to modify global system variables, the mysqladmin debug command, enabling or disabling logging, performing updates even if the read_only [425] system variable is enabled, starting and stopping replication on slave servers, and enables you to connect (once) even if the connection limit controlled by the max_connections [419] system variable is reached. This privilege was added in MySQL 4.0.2. Prior to MySQL 4.0.2, the PROCESS [492] privilege controls the ability to terminate threads for other accounts.
- The UPDATE [493] privilege enables rows to be updated in tables in a database.
- The USAGE [493] privilege specifier stands for “no privileges.” It is used at the global level with GRANT to modify account attributes such as resource limits or SSL characteristics without affecting existing account privileges.

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the FILE [491] and administrative privileges:

- The FILE [491] privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using SELECT to transfer its contents to the client host.
- The GRANT OPTION [491] privilege enables users to give their privileges to other users. Two users that have different privileges and with the GRANT OPTION [491] privilege are able to combine privileges.
- The ALTER [491] privilege may be used to subvert the privilege system by renaming tables.
- The SHUTDOWN [492] privilege can be abused to deny service to other users entirely by terminating the server.
- The PROCESS [492] privilege can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- The SUPER [493] privilege can be used to terminate other sessions or change how the server operates.
- Privileges granted for the mysql database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the user table Password column can change an account's password, and then connect to the MySQL server using that account.

5.5.2 Privilege System Grant Tables

Normally, you manipulate the contents of the grant tables in the mysql database indirectly by using statements such as GRANT and REVOKE to set up accounts and control the privileges available to each one. See Section 12.4.1, “Account Management Statements”. The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

These mysql database tables contain grant information:

- user: Contains user accounts, global privileges, and other non-privilege columns.
- db: Contains database-level privileges.
- host: Obsolete.

- `tables_priv`: Contains table-level privileges.
- `columns_priv`: Contains column-level privileges.

Other tables in the `mysql` database do not hold grant information and are discussed elsewhere:

- `func`: Contains information about user-defined functions: See Section 18.2, “Adding New Functions to MySQL”.
- `help_xxx`: These tables are used for server-side help: See Section 5.1.7, “Server-Side Help”.
- `time_zone_xxx`: These tables contain time zone information: See Section 9.7, “MySQL Server Time Zone Support”.

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row (entry) in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of `'thomas.loc.gov'` and `'bob'` would be used for authenticating connections made to the server from the host `thomas.loc.gov` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of `'thomas.loc.gov'`, `'bob'` and `'reports'` would be used when `bob` connects from the host `thomas.loc.gov` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies.
- Privilege columns indicate which privileges are granted by a table row; that is, what operations can be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. Section 5.5.5, “Access Control, Stage 2: Request Verification”, describes the rules that are used to do this.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user's global privileges. Any privilege granted in this table applies to *all* databases on the server.

Note

Because any global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with `SHOW DATABASES`.

- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine which operations are permitted. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.
- The `host` table is used in conjunction with the `db` table when you want a given `db` table row to apply to several hosts. For example, if you want a user to be able to use a database from several hosts in your network, leave the `Host` value empty in the user's `db` table row, then populate the `host` table with a row for each of those hosts. This mechanism is described more detail in Section 5.5.5, “Access Control, Stage 2: Request Verification”.

Note

The `host` table must be modified directly with statements such as `INSERT`, `UPDATE`, and `DELETE`. It is not affected by statements such as `GRANT` and `REVOKE` that modify the grant tables indirectly. Most MySQL installations need not use this table at all.

- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

The server uses the `user`, `db`, and `host` tables in the `mysql` database at both the first and second stages of access control (see Section 5.5, "The MySQL Access Privilege System"). The columns in the `user` and `db` tables are shown here. The `host` table is similar to the `db` table but has a specialized use as described in Section 5.5.5, "Access Control, Stage 2: Request Verification".

Table 5.7 `user` and `db` Table Columns

Table Name	`user`	`db`
Scope columns	`Host`	`Host`
	`User`	`Db`
	`Password`	`User`
Privilege columns	`Select_priv`	`Select_priv`
	`Insert_priv`	`Insert_priv`
	`Update_priv`	`Update_priv`
	`Delete_priv`	`Delete_priv`
	`Index_priv`	`Index_priv`
	`Alter_priv`	`Alter_priv`
	`Create_priv`	`Create_priv`
	`Drop_priv`	`Drop_priv`
	`Grant_priv`	`Grant_priv`
	`References_priv`	`References_priv`
	`Execute_priv`	
	`Reload_priv`	
	`Shutdown_priv`	
	`Process_priv`	
	`File_priv`	
	`Show_db_priv`	
	`Super_priv`	
	`Create_tmp_table_priv`	`Create_tmp_table_priv`
	`Lock_tables_priv`	`Lock_tables_priv`
	`Repl_slave_priv`	
	`Repl_client_priv`	
Security columns	`ssl_type`	
	`ssl_cipher`	
	`x509_issuer`	
	`x509_subject`	
Resource control columns	`max_questions`	
	`max_updates`	

Table Name	user	db
	max_connections	
	max_user_connections	

The ssl_type, ssl_cipher, x509_issuer, and x509_subject columns were added in MySQL 4.0.0.

The Create_tmp_table_priv, Execute_priv, Lock_tables_priv, Repl_client_priv, Repl_slave_priv, Show_db_priv, Super_priv, max_questions, max_updates, and max_connections columns were added in MySQL 4.0.2. Execute_priv is not operational through MySQL 4.1.

During the second stage of access control, the server performs request verification to make sure that each client has sufficient privileges for each request that it issues. In addition to the user, db, and host grant tables, the server may also consult the tables_priv and columns_priv tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

Table 5.8 tables_priv and columns_priv Table Columns

Table Name	tables_priv	columns_priv
Scope columns	Host	Host
	Db	Db
	User	User
	Table_name	Table_name
		Column_name
Privilege columns	Table_priv	Column_priv
	Column_priv	
Other columns	Timestamp	Timestamp
	Grantor	

The Timestamp and Grantor columns are set to the current timestamp and the CURRENT_USER [872] value, respectively. However, they are unused and are discussed no further here.

Scope columns in the grant tables contain strings. They are declared as shown here; the default value for each is the empty string.

Table 5.9 Grant Table Scope Column Types

Column Name	Type
Column Name	**Type**
Host	CHAR(60)
User	CHAR(16)
Password	CHAR(41)
Db	CHAR(64)
Table_name	CHAR(64)
Column_name	CHAR(64)
Routine_name	CHAR(64)

Before MySQL 3.23, the `Db` column is `CHAR(32)` in some tables and `CHAR(60)` in others.

For access-checking purposes, comparisons of `User`, `Password`, `Db`, and `Table_name` values are case sensitive. Comparisons of `Host` values are not case sensitive. Comparisons of `Column_name` values are not case sensitive as of MySQL 3.22.12.

In the `user`, `db`, and `host` tables, each privilege is listed in a separate column that is declared as `ENUM('N','Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

In the `tables_priv` and `columns_priv` tables, the privilege columns are declared as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

Table 5.10 Set-Type Privilege Column Values

Table Name	Column Name	Possible Set Elements
Table Name	**Column Name**	**Possible Set Elements**
`tables_priv`	`Table_priv`	`'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter'`
`tables_priv`	`Column_priv`	`'Select', 'Insert', 'Update', 'References'`
`columns_priv`	`Column_priv`	`'Select', 'Insert', 'Update', 'References'`

Administrative privileges (such as `RELOAD` [492] or `SHUTDOWN` [492]) are specified only in the `user` table. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, to determine whether you can perform an administrative operation, the server need consult only the `user` table.

The `FILE` [491] privilege also is specified only in the `user` table. It is not an administrative privilege as such, but your ability to read or write files on the server host is independent of the database you are accessing.

The `mysqld` server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in Section 5.5.6, “When Privilege Changes Take Effect”.

When you modify an account's privileges, it is a good idea to verify that the changes set up privileges the way you want. To check the privileges for a given account, use the `SHOW GRANTS` statement (see Section 12.4.5.12, “`SHOW GRANTS` Syntax”). For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

5.5.3 Specifying Account Names

MySQL account names consist of a user name and a host name. This enables creation of accounts for users with the same name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

In SQL statements such as `GRANT` and `SET PASSWORD`, write account names using the following rules:

- Syntax for account names is *'user_name'@'host_name'*.
- An account name consisting only of a user name is equivalent to *'user_name'@'%'*. For example, 'me' is equivalent to 'me'@'%'.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a *user_name* string containing special characters (such as "-"), or a *host_name* string containing special characters or wildcard characters (such as "%"); for example, 'test-user'@'%.com'.
- Quote user names and host names as identifiers or as strings, using either backticks ("`"), single quotation marks ("'"), or double quotation marks ("").
- The user name and host name parts, if quoted, must be quoted separately. That is, write 'me'@'localhost', not 'me@localhost'; the latter is interpreted as 'me@localhost'@'%'.

MySQL stores account names in grant tables in the mysql database using separate columns for the user name and host name parts:

- The user table contains one row for each account. The User and Host columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have User and Host columns to store the account name. Each row in these tables associates with the account in the user table that has the same User and Host values.

For additional detail about grant table structure, see Section 5.5.2, "Privilege System Grant Tables".

User names and host names have certain special values or wildcard conventions, as described following.

A user name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as ''@'localhost'.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address. The name 'localhost' indicates the local host. The IP address '127.0.0.1' indicates the loopback interface.
- You can use the wildcard characters "%" and "_" in host values. These have the same meaning as for pattern-matching operations performed with the LIKE [804] operator. For example, a host value of '%' matches any host name, whereas a value of '%.mysql.com' matches any host in the mysql.com domain. '192.168.1.%' matches any host in the 192.168.1 class C network.

  Because you can use IP wildcard values in host values (for example, '192.168.1.%' to match every host on a subnet), someone could try to exploit this capability by naming a host 192.168.1.somewhere.com. To foil such attempts, MySQL disallows matching on host names that start with digits and a dot. Thus, if you have a host named something like 1.2.example.com, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.
- For a host value specified as an IP address, you can specify a netmask indicating how many address bits to use for the network number. The syntax is *host_ip/netmask*. For example:

```
GRANT ALL PRIVILEGES ON db.* TO 'david'@'192.58.197.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP address *`client_ip`* for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `GRANT` statement just shown:

```
client_ip & 255.255.255.0 = 192.58.197.0
```

IP addresses that satisfy this condition and can connect to the MySQL server are those in the range from `192.58.197.0` to `192.58.197.255`.

The netmask can only be used to tell the server to use 8, 16, 24, or 32 bits of the address. Examples:

- `192.0.0.0/255.0.0.0`: Any host on the 192 class A network
- `192.168.0.0/255.255.0.0`: Any host on the 192.168 class B network
- `192.168.1.0/255.255.255.0`: Any host on the 192.168.1 class C network
- `192.168.1.1`: Only the host with this specific IP address

The following netmask will not work because it masks 28 bits, and 28 is not a multiple of 8:

```
192.168.0.1/255.255.255.240
```

5.5.4 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the server denies access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name
- A reference to the `CURRENT_USER()` [872] (or `CURRENT_USER` [872]) function is equivalent to specifying the current user's name and host name literally.

Identity checking is performed using the three `user` table scope columns (`Host`, `User`, and `Password`). The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name and the client supplies the password specified in that row. The rules for permissible `Host` and `User` values are given in Section 5.5.3, “Specifying Account Names”.

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `Password` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password.

Nonblank `Password` values in the `user` table represent encrypted passwords. MySQL does not store passwords in plaintext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the `PASSWORD()` [868] function). The encrypted password then is used during the connection process when checking whether the password is correct. (This is done without the encrypted password ever traveling over the connection.) See Section 5.6.1, “User Names and Passwords”.

From MySQL's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give nonadministrative users read access to tables in the `mysql` database*.

The following table shows how various combinations of `Host` and `User` values in the `user` table apply to incoming connections.

`Host` Value	**`User` Value**	**Permissible Connections**
`'thomas.loc.gov'`	`'fred'`	`fred`, connecting from `thomas.loc.gov`
`'thomas.loc.gov'`	`''`	Any user, connecting from `thomas.loc.gov`
`'%'`	`'fred'`	`fred`, connecting from any host
`'%'`	`''`	Any user, connecting from any host
`'%.loc.gov'`	`'fred'`	`fred`, connecting from any host in the `loc.gov` domain
`'x.y.%'`	`'fred'`	`fred`, connecting from `x.y.net`, `x.y.com`, `x.y.edu`, and so on; this is probably not useful
`'144.155.166.177'`	`'fred'`	`fred`, connecting from the host with IP address `144.155.166.177`
`'144.155.166.%'`	`'fred'`	`fred`, connecting from any host in the `144.155.166` class C subnet
`'144.155.166.0/255.255.255.0"fred'`		Same as previous example

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `thomas.loc.gov` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

To see how this works, suppose that the `user` table looks like this:

```
+-----------+----------+-
| Host      | User     | ...
+-----------+----------+-
| %         | root     | ...
| %         | jeffrey  | ...
| localhost | root     | ...
| localhost |          | ...
+-----------+----------+-
```

When the server reads the table into memory, it orders the rows with the most-specific `Host` values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so `192.168.1.13` and `192.168.1.0/255.255.255.0` are considered equally specific.) The pattern `'%'` means “any host” and is least specific. Rows with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means “any user” and is least specific). For the `user` table just shown, the result after sorting looks like this:

```
+-----------+----------+-
| Host      | User     | ...
+-----------+----------+-
| localhost | root     | ...
| localhost |          | ...
| %         | jeffrey  | ...
| %         | root     | ...
+-----------+----------+-
```

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of `'localhost'` and `''`, and the one with values of `'%'` and `'jeffrey'`. The `'localhost'` row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

```
+----------------+----------+-
| Host           | User     | ...
+----------------+----------+-
| %              | jeffrey  | ...
| thomas.loc.gov |          | ...
+----------------+----------+-
```

The sorted table looks like this:

```
+----------------+----------+-
| Host           | User     | ...
+----------------+----------+-
| thomas.loc.gov |          | ...
| %              | jeffrey  | ...
+----------------+----------+-
```

A connection by `jeffrey` from `thomas.loc.gov` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

Note

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `thomas.loc.gov` by `jeffrey` is first matched not by the row containing `'jeffrey'` as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` [872] function. (See Section 11.13, “Information Functions”.) It returns a value in *`user_name@host_name`* format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| @localhost     |
+----------------+
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

The `CURRENT_USER()` [872] function is available as of MySQL 4.0.6. See Section 11.13, "Information Functions". Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

5.5.5 Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `host`, `tables_priv`, or `columns_priv` tables. (You may find it helpful to refer to Section 5.5.2, "Privilege System Grant Tables", which lists the columns present in each of the grant tables.)

The `user` table grants privileges that are assigned to you on a global basis and that apply no matter what the default database is. For example, if the `user` table grants you the `DELETE` [491] privilege, you can delete rows from any table in any database on the server host! It is wise to grant privileges in the `user` table only to people who need them, such as database administrators. For other users, you should leave all privileges in the `user` table set to `'N'` and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, or columns.

The `db` and `host` tables grant database-specific privileges. Values in the scope columns of these tables can take the following forms:

- A blank `User` value in the `db` table matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters "`%`" and "`_`" can be used in the `Host` and `Db` columns of either table. These have the same meaning as for pattern-matching operations performed with the `LIKE` [804] operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include "`_`" character as part of a database name, specify it as "`\_`" in the `GRANT` statement.
- A `'%'` `Host` value in the `db` table means "any host." A blank `Host` value in the `db` table means "consult the `host` table for further information" (a process that is described later in this section).
- A `'%'` or blank `Host` value in the `host` table means "any host."
- A `'%'` or blank `Db` value in either table means "any database."

The server reads the `db` and `host` tables into memory and sorts them at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns, and sorts the `host` table based on the `Host` and `Db` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching entries, it uses the first match that it finds.

The `tables_priv` and `columns_priv` tables grant table-specific and column-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters “`%`” and “`_`” can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` [804] operator.
- A `'%'` or blank `Host` value means “any host.”
- The `Db`, `Table_name`, and `Column_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv` and `columns_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` [492] or `RELOAD` [492], the server checks only the `user` table row because that is the only table that specifies administrative privileges. The server grants access if the row permits the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row does not grant the `SHUTDOWN` [492] privilege to you, the server denies access without even checking the `db` or `host` tables. (They contain no `Shutdown_priv` column, so there is no need to do so.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global privileges by looking in the `user` table row. If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges by checking the `db` and `host` tables:

1. The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.
2. If there is a matching `db` table row and its `Host` column is not blank, that row defines the user's database-specific privileges.
3. If the matching `db` table row's `Host` column is blank, it signifies that the `host` table enumerates which hosts should be permitted access to the database. In this case, a further lookup is done in the `host` table to find a match on the `Host` and `Db` columns. If no `host` table row matches, access is denied. If there is a match, the user's database-specific privileges are computed as the intersection (*not* the union!) of the privileges in the `db` and `host` table entries; that is, the privileges that are `'Y'` in both entries. (This way you can grant general privileges in the `db` table row and then selectively restrict them on a host-by-host basis using the `host` table entries.)

After determining the database-specific privileges granted by the `db` and `host` table entries, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies access based on the result.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
```

It may not be apparent why, if the global `user` row privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute

an `INSERT INTO ... SELECT` statement, you need both the `INSERT` [492] and the `SELECT` [492] privileges. Your privileges might be such that the `user` table row grants one privilege and the `db` table row grants the other. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either table by itself; the privileges granted by the entries in both tables must be combined.

The `host` table is not affected by the `GRANT` or `REVOKE` statements, so it is unused in most MySQL installations. If you modify it directly, you can use it for some specialized purposes, such as to maintain a list of secure servers on the local network that are granted all privileges.

You can also use the `host` table to indicate hosts that are *not* secure. Suppose that you have a machine `public.your.domain` that is located in a public area that you do not consider secure. You can enable access to all hosts on your network except that machine by using `host` table entries like this:

```
+--------------------+----+-
| Host               | Db | ...
+--------------------+----+-
| public.your.domain | %  | ... (all privileges set to 'N')
| %.your.domain      | %  | ... (all privileges set to 'Y')
+--------------------+----+-
```

5.5.6 When Privilege Changes Take Effect

When `mysqld` starts, it reads all grant table contents into memory. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using account-management statements such as `GRANT`, `REVOKE`, or `SET PASSWORD`, the server notices these changes and loads the grant tables into memory again immediately.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE`, your changes have no effect on privilege checking until you either restart the server or tell it to reload the tables. If you change the grant tables directly but forget to reload them, your changes have *no effect* until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client connection as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

Note

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database or flushing the privileges.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only for subsequent connections.

If the server is started with the `--skip-grant-tables` [392] option, it does not read the grant tables or implement any access control. Anyone can connect and do anything, *which is insecure.* To cause a server thus started to read the tables and enable access checking, flush the privileges.

5.5.7 Causes of Access-Denied Errors

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` [226] option to indicate the proper port number, or a `--socket` [227] option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
shell> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking` [393], it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1` [384], it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.

- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.

- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the `mysql` database containing the grant tables. For distributions that do not do this, you must initialize the grant tables manually by running the `mysql_install_db` script. For details, see Section 2.10.2, “Unix Postinstallation Procedures”.

  To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, execute the `mysql_install_db` script. After running this script and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root test
```

  The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect because the MySQL `root` user has no password initially. That is also a security risk, so setting the password for the `root` accounts is something you should do while you're setting up your other MySQL accounts. For instructions on setting the initial passwords, see Section 2.10.3, “Securing the Initial MySQL Accounts”.

- If you have updated an existing MySQL installation to a newer version, did you run the `mysql_fix_privilege_tables` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

  For information on how to deal with this, see Section 5.4.2.3, “Password Hashing in MySQL”, and Section B.5.2.4, “`Client does not support authentication protocol`”.

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

  You can suppress the use of option files by a client program by invoking it with the `--no-defaults` [235] option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

  The option files that clients use are listed in Section 4.2.3.3, “Using Option Files”. Environment variables are listed in Section 2.13, “Environment Variables”.

- If you get the following error, it means that you are using an incorrect `root` password:

```
shell> mysqladmin -u root -pxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```

  If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` [235] option as described in the previous item.

  For information on changing passwords, see Section 5.6.5, “Assigning Account Passwords”.

  If you have lost or forgotten the `root` password, see Section B.5.4.1, “How to Reset the Root Password”.

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` [868] function. If you do not use `PASSWORD()` [868] for these statements, the password will not work. For example, the following statement assigns a password, but fails to encrypt it, so the user is not able to connect afterward:

```
```

```
SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The `PASSWORD()` [868] function is unnecessary when you specify a password using the `GRANT` statement or the `mysqladmin password` command. Each of those automatically uses `PASSWORD()` [868] to encrypt the password. See Section 5.6.5, “Assigning Account Passwords”.

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly. However, connections to `localhost` on Unix systems do not work if you are using a MySQL version older than 3.23.27 that uses MIT-pthreads: `localhost` connections are made using Unix socket files, which were not supported by MIT-pthreads at that time.

  To avoid this problem on such systems, you can use a `--host=127.0.0.1` [226] option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` [226] option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.

- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

  ```
  SELECT * FROM user;
  ```

  The result should include a row with the `Host` and `User` columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

  ```
  Host ... is not allowed to connect to this MySQL server
  ```

  You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

  If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with `'%'` as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the `'%'` in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

  (Note that if you are running a version of MySQL older than 3.23.11, the output from `USER()` [876] does not include the host name. In this case, you must restart the server with the `--log` [388] option, then obtain the host name from the log.)

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

```
shell> mysqladmin -u root -pxxxx -h some_hostname ver
Access denied for user 'root'@'' (using password: YES)
```

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host name cache. See Section 7.8.5, “How MySQL Uses DNS”.

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `--skip-name-resolve` [393] option.
- Start `mysqld` with the `--skip-host-cache` [392] option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. Unix connections to `localhost` use a Unix socket file rather than TCP/IP.
- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name `.` (period). Connections to `.` use a named pipe rather than TCP/IP.

- If `mysql -u root test` works but `mysql -h your_hostname -u root test` results in `Access denied` (where *`your_hostname`* is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have an entry with host `'pluto'` in the `user` table, but your DNS tells MySQL that your host name is `'pluto.example.com'`, the entry does not work. Try adding an entry to the `user` table that contains the IP address of your host as the `Host` column value. (Alternatively, you could add an entry to the `user` table with a `Host` value that contains a wildcard; for example, `'pluto.%'`. However, use of `Host` values ending with “`%`” is *insecure* and is *not* recommended!)

- If `mysql -u user_name test` works but `mysql -u user_name other_db` does not, you have not granted access to the given user for the database named *`other_db`*.

- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.

- If you cannot figure out why you get `Access denied`, remove from the `user` table all entries that have `Host` values containing wildcards (entries that contain `'%'` or `'_'` characters). A very common error is to insert a new entry with `Host='%'` and `User='some_user'`, thinking that this enables you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include an entry with `Host='localhost'` and `User=''`. Because that entry has a `Host` value `'localhost'` that is more specific than `'%'`, it is used in preference to the new entry when connecting from `localhost`! The correct procedure is to insert a second entry with `Host='localhost'` and `User='some_user'`, or to delete the entry with `Host='localhost'` and `User=''`. After deleting the entry, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also Section 5.5.4, “Access Control, Stage 1: Connection Verification”.

- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA INFILE` statement, your entry in the `user` table does not have the `FILE` [491] privilege enabled.

- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!

- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 5.5.6, “When Privilege Changes Take Effect”.

- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -pyour_pass db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass` [226] syntax to specify the password. If you use the `-p` or `--password` [226] option with no password value, MySQL prompts you for the password.)

- For testing purposes, start the `mysqld` server with the `--skip-grant-tables` [392] option. Then you can change the MySQL grant tables and use the `mysqlaccess` script to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.

- If you get the following error, you may have a problem with the `db` or `host` table:

  ```
  Access to database denied
  ```

  If the entry selected from the `db` table has an empty value in the `Host` column, make sure that there are one or more corresponding entries in the `host` table specifying which hosts the `db` table entry applies to. This problem occurs infrequently because the `host` table is rarely used.

- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query` [385]). This prints host and user information about attempted connections, as well as information about each command issued. See Section 18.4.3, “The DBUG Package”.

- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at Section 1.8, "How to Report Bugs or Problems". In some cases, you may need to restart `mysqld` with `--skip-grant-tables` [392] to run `mysqldump`.

5.6 MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system
- How to set up new accounts and remove existing accounts
- How to change passwords
- Guidelines for using passwords securely
- How to use secure connections with SSL

See also Section 12.4.1, "Account Management Statements", which describes the syntax and use for all user-management SQL statements.

5.6.1 User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. The account may also have a password. For information about account representation in the `user` table, see Section 5.5.2, "Privilege System Grant Tables".

There are several distinctions between the way user names and passwords are used by MySQL and the way they are used by your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. Because this means that anyone can attempt to connect to the server using any user name, you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password is able to connect successfully to the server.
- MySQL user names can be up to 16 characters long. Operating system user names, because they are completely unrelated to MySQL user names, may be of a different maximum length. For example, Unix user names typically are limited to eight characters.

Warning

The limit on MySQL user name length is hard-coded in the MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.

You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure prescribed that is described in Section 4.4.5, "`mysql_fix_privilege_tables` — Upgrade MySQL System

> Tables”. Attempting to redefine MySQL's system tables in any other fashion results in undefined (and unsupported!) behavior.

- MySQL user names can be up to 16 characters long. *Changing the maximum length is not supported*. If you try to change it, for example by changing the length of the `User` column in the `mysql` database tables, this will result in unpredictable behavior. (Altering privilege tables is not supported in any case.) Operating system user names might have a different maximum length. For example, Unix user names typically are limited to eight characters.
- It is best to use only ASCII characters for user names and passwords.
- The server uses MySQL passwords stored in the `user` table to authenticate client connections using MySQL built-in authentication. These passwords have nothing to do with passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.
- MySQL encrypts passwords stored in the `user` table using its own algorithm. This encryption is the same as that implemented by the `PASSWORD()` [868] SQL function but differs from that used during the Unix login process. Unix password encryption is the same as that implemented by the `ENCRYPT()` [867] SQL function. See the descriptions of the `PASSWORD()` [868] and `ENCRYPT()` [867] functions in Section 11.12, “Encryption and Compression Functions”.

  From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. (In earlier versions, even though passwords are stored in encrypted form in the `user` table, knowledge of the encrypted password value could be used to connect to the MySQL server.) Section 5.4.2.3, “Password Hashing in MySQL”, discusses password encryption further.

When you install MySQL, the grant tables are populated with an initial set of accounts. The names and access privileges for these accounts are described in Section 2.10.3, “Securing the Initial MySQL Accounts”, which also discusses how to assign passwords to them. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `GRANT` and `REVOKE`. See Section 12.4.1, “Account Management Statements”.

When you connect to a MySQL server with a command-line client, specify the user name and password as necessary for the account that you want to use:

```
shell> mysql --user=monty --password=password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u monty -ppassword db_name
```

There must be *no space* between the `-p` option and the following password value.

If you omit the *`password`* value following the `--password` [226] or `-p` option on the command line, the client prompts for one.

Specifying a password on the command line should be considered insecure. See Section 5.4.2.2, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

For additional information about specifying user names, passwords, and other connection parameters, see Section 4.2.2, “Connecting to the MySQL Server”.

5.6.2 Adding User Accounts

You can create MySQL accounts in two ways:

- By using `GRANT` statements. These statements cause the server to make appropriate modifications to the grant tables.
- By manipulating the MySQL grant tables directly with statements such as `INSERT`, `UPDATE`, or `DELETE`.

The preferred method is to use `GRANT` statements, because they are more concise and less error-prone than manipulating the grant tables directly. `GRANT` is described in Section 12.4.1.2, “`GRANT` Syntax”.

Another option for creating accounts is to use one of several available third-party programs that offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that privileges have been set up according to the defaults described in Section 2.10.3, “Securing the Initial MySQL Accounts”. This means that to make changes, you must connect to the MySQL server as the MySQL `root` user, and the `root` account must have the `INSERT` [492] privilege for the `mysql` database and the `RELOAD` [492] administrative privilege.

First, use the `mysql` program to connect to the server as the MySQL `root` user:

```
shell> mysql --user=root mysql
```

If you have assigned a password to the `root` account, you also need to supply a `--password` or `-p` option, both for this `mysql` command and for those later in this section.

After connecting to the server as `root`, you can add new accounts. The following statements use `GRANT` to set up four new accounts:

```
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'localhost'
    ->     IDENTIFIED BY 'some_pass' WITH GRANT OPTION;
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'%'
    ->     IDENTIFIED BY 'some_pass' WITH GRANT OPTION;
mysql> GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
mysql> GRANT USAGE ON *.* TO 'dummy'@'localhost';
```

The accounts created by these statements have the following properties:

- Two of the accounts have a user name of `monty` and a password of `some_pass`. Both accounts are superuser accounts with full privileges to do anything. The `'monty'@'localhost'` account can be used only when connecting from the local host. The `'monty'@'%'` account uses the `'%'` wildcard for the host part, so it can be used to connect from any host.

  It is necessary to have both accounts for `monty` to be able to connect from anywhere as `monty`. Without the `localhost` account, the anonymous-user account for `localhost` that is created by `mysql_install_db` would take precedence when `monty` connects from the local host. As a result, `monty` would be treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'monty'@'%'` account and thus comes earlier in the `user` table sort order. (`user` table sorting is discussed in Section 5.5.4, “Access Control, Stage 1: Connection Verification”.)

- The `'admin'@'localhost'` account has no password. This account can be used only by `admin` to connect from the local host. It is granted the `RELOAD` [492] and `PROCESS` [492] administrative privileges. These privileges enable the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist` . No

privileges are granted for accessing any databases. You could add such privileges later by issuing other GRANT statements.

- The 'dummy'@'localhost' account has no password. This account can be used only to connect from the local host. No privileges are granted. The USAGE [493] privilege in the GRANT statement enables you to create an account without giving it any privileges. It has the effect of setting all the global privileges to 'N'. It is assumed that you will grant specific privileges to the account later.

To check the privileges for an account, use SHOW GRANTS:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----------------------------------------------------+
| Grants for admin@localhost                          |
+-----------------------------------------------------+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----------------------------------------------------+
```

As an alternative to GRANT, you can create the same accounts directly by issuing INSERT statements and then telling the server to reload the grant tables:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user
    ->     VALUES('localhost','monty',PASSWORD('some_pass'),
    ->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user
    ->     VALUES('%','monty',PASSWORD('some_pass'),
    ->     'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user SET Host='localhost',User='admin',
    ->     Reload_priv='Y', Process_priv='Y';
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('localhost','dummy','');
mysql> FLUSH PRIVILEGES;
```

When you create accounts with INSERT, it is necessary to use FLUSH PRIVILEGES to tell the server to reload the grant tables. Otherwise, the changes go unnoticed until you restart the server. With GRANT, FLUSH PRIVILEGES is unnecessary.

The reason for using the PASSWORD() [868] function with INSERT is to encrypt the password. The GRANT statement encrypts the password for you, so PASSWORD() [868] is unnecessary.

The 'Y' values enable privileges for the accounts. Depending on your MySQL version, you may have to use a different number of 'Y' values in the first two INSERT statements. (Versions prior to 3.22.11 have fewer privilege columns, and versions from 4.0.2 on have more.) The INSERT statement for the admin account employs the more readable extended INSERT syntax using SET that is available starting with MySQL 3.22.11 is used.

In the INSERT statement for the dummy account, only the Host, User, and Password columns in the user table row are assigned values. None of the privilege columns are set explicitly, so MySQL assigns them all the default value of 'N'. This is equivalent to what GRANT USAGE does.

To set up a superuser account, it is necessary only to insert a user table row with all privilege columns set to 'Y'. The user table privileges are global, so no entries in any of the other grant tables are needed.

The next examples create three accounts and give them access to specific databases. Each of them has a user name of custom and password of obscure.

To create the accounts with GRANT, use the following statements:

```
shell> mysql --user=root mysql
```

```
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON bankaccount.*
    ->     TO 'custom'@'localhost'
    ->     IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON expenses.*
    ->     TO 'custom'@'host47.example.com'
    ->     IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ->     ON customer.*
    ->     TO 'custom'@'server.domain'
    ->     IDENTIFIED BY 'obscure';
```

The three accounts can be used as follows:

- The first account can access the `bankaccount` database, but only from the local host.
- The second account can access the `expenses` database, but only from the host `host47.example.com`.
- The third account can access the `customer` database, but only from the host `server.domain`.

To set up the `custom` accounts without `GRANT`, use `INSERT` statements as follows to modify the grant tables directly:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('localhost','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('host47.example.com','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
    ->     VALUES('server.domain','custom',PASSWORD('obscure'));
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('localhost','bankaccount','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('host47.example.com','expenses','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
    ->     (Host,Db,User,Select_priv,Insert_priv,
    ->     Update_priv,Delete_priv,Create_priv,Drop_priv)
    ->     VALUES('server.domain','customer','custom',
    ->     'Y','Y','Y','Y','Y','Y');
mysql> FLUSH PRIVILEGES;
```

The first three `INSERT` statements add `user` table entries that permit the user `custom` to connect from the various hosts with the given password, but grant no global privileges (all privileges are set to the default value of `'N'`). The next three `INSERT` statements add `db` table entries that grant privileges to `custom` for the `bankaccount`, `expenses`, and `customer` databases, but only when accessed from the proper hosts. As usual when you modify the grant tables directly, you must tell the server to reload them with `FLUSH PRIVILEGES` so that the privilege changes take effect.

To create a user who has access from all machines in a given domain (for example, `mydomain.com`), you can use the "`%`" wildcard character in the host part of the account name:

```
mysql> GRANT ...
    ->     ON *.*
    ->     TO 'myname'@'%.mydomain.com'
    ->     IDENTIFIED BY 'mypass';
```

To do the same thing by modifying the grant tables directly, do this:

```
mysql> INSERT INTO user (Host,User,Password,...)
    ->     VALUES('%.mydomain.com','myname',PASSWORD('mypass'),...);
mysql> FLUSH PRIVILEGES;
```

5.6.3 Removing User Accounts

To remove an account, use the `DROP USER` statement, which was added in MySQL 4.1.1. For older versions of MySQL, use `DELETE` instead. The account removal procedure is described in Section 12.4.1.1, “`DROP USER` Syntax”.

5.6.4 Setting Account Resource Limits

Before MySQL 4.0.2, the only means of limiting use of MySQL server resources is to set the global `max_user_connections` [420] system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, this method is strictly global, and does not enable management of individual accounts. Both types of control are of interest to many MySQL administrators, particularly those working for Internet Service Providers.

Starting from MySQL 4.0.2, you can limit access to the following server resources for individual accounts:

- The number of queries that an account can issue per hour
- The number of updates that an account can issue per hour
- The number of times an account can connect to the server per hour

Any statement that a client can issue counts against the query limit (unless its results are served from the query cache). Only statements that modify databases or tables count against the update limit.

An “account” in this context is assessed against the actual host from which a user connects. Suppose that there is a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. If `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

The server limits account resources based on the resource-related columns of the `user` table in the `mysql` database: `max_questions`, `max_updates`, `max_connections`, and `max_user_connections`. If your `user` table does not have these columns, it must be upgraded; see Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

To set resource limits for an account, use the `GRANT` statement (see Section 12.4.1.2, “`GRANT` Syntax”). Provide a `WITH` clause that names each resource to be limited. For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue this statement:

```
mysql> GRANT ALL ON customer.* TO 'francis'@'localhost'
    ->     IDENTIFIED BY 'frank'
    ->     WITH MAX_QUERIES_PER_HOUR 20
    ->          MAX_UPDATES_PER_HOUR 10
    ->          MAX_CONNECTIONS_PER_HOUR 5;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. If the `GRANT` statement has no `WITH` clause, the limits are each set to the default value of zero (that is, no limit).

To modify existing limits for an account, use a `GRANT USAGE` statement at the global level (`ON *.*`). The following statement changes the query limit for `francis` to 100:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
    ->     WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
    ->     WITH MAX_CONNECTIONS_PER_HOUR 0;
```

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits. (See Section 5.5.2, “Privilege System Grant Tables”.)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, further connections for the account are rejected until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, further queries or updates are rejected until the hour is up. In all such cases, an appropriate error message is issued.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be set to zero by re-granting it any of its limits. To do this, use `GRANT USAGE` as described earlier and specify a limit value equal to the value that the account currently has.

All counts begin at zero when the server starts; counts are not carried over through a restart.

5.6.5 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts.

To assign a password when you create a new account with `GRANT`, include an `IDENTIFIED BY` clause:

```
mysql> GRANT ALL ON db.* TO 'jeffrey'@'localhost'
    -> IDENTIFIED BY 'mypass';
```

To assign or change a password for an existing account, one way is to issue a `SET PASSWORD` statement:

```
mysql> SET PASSWORD FOR
    -> 'jeffrey'@'localhost' = PASSWORD('mypass');
```

MySQL stores passwords in the `user` table in the `mysql` database. Only users such as `root` that have update access to the `mysql` database can change the password for other users. If you are not connected as an anonymous user, you can change your own password by omitting the `FOR` clause:

```
mysql> SET PASSWORD = PASSWORD('mypass');
```

You can also use a `GRANT USAGE` statement at the global level (`ON *.*`) to assign a password to an account without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost'
    -> IDENTIFIED BY 'mypass';
```

To assign a password from the command line, use the `mysqladmin` command:

```
shell> mysqladmin -u user_name -h host_name password "newpwd"
```

The account for which this command sets the password is the one with a `user` table row that matches *`user_name`* in the `User` column and the client host *from which you connect* in the `Host` column.

It is preferable to assign passwords using one of the preceding methods, but it is also possible to modify the `user` table directly. In this case, you must also use `FLUSH PRIVILEGES` to cause the server to reread the grant tables. Otherwise, the change remains unnoticed by the server until you restart it.

- To establish a password for a new account, provide a value for the `Password` column:

  ```
  mysql> INSERT INTO mysql.user (Host,User,Password)
      -> VALUES('localhost','jeffrey',PASSWORD('mypass'));
  mysql> FLUSH PRIVILEGES;
  ```

- To change the password for an existing account, use `UPDATE` to set the `Password` column value:

  ```
  mysql> UPDATE mysql.user SET Password = PASSWORD('bagel')
      -> WHERE Host = 'localhost' AND User = 'francis';
  mysql> FLUSH PRIVILEGES;
  ```

During authentication when a client connects to the server, MySQL treats the password in the `user` table as an encrypted hash value (the value that `PASSWORD()` [868] would return for the password). When assigning a password to an account, it is important to store an encrypted value, not the plaintext password. Use the following guidelines:

- When you assign a password using `GRANT` with an `IDENTIFIED BY` clause or with the `mysqladmin password` command, they encrypt the password for you. Specify the literal plaintext password:

  ```
  mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost'
      -> IDENTIFIED BY 'mypass';
  ```

- For `GRANT`, you can avoid sending the plaintext password if you know the hashed value that `PASSWORD()` [868] would return for the password. Specify the hashed value preceded by the keyword `PASSWORD`:

  ```
  mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost'
      -> IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
  ```

- When you assign an account a nonempty password using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must use the `PASSWORD()` [868] function to encrypt the password, otherwise the password is stored as plaintext. Suppose that you assign a password like this:

```
mysql> SET PASSWORD FOR
    -> 'jeffrey'@'localhost' = 'mypass';
```

The result is that the literal value `'mypass'` is stored as the password in the `user` table, not the encrypted value. When `jeffrey` attempts to connect to the server using this password, the value is encrypted and compared to the value stored in the `user` table. However, the stored value is the literal string `'mypass'`, so the comparison fails and the server rejects the connection with an `Access denied` error.

Note

`PASSWORD()` [868] encryption differs from Unix password encryption. See Section 5.6.1, “User Names and Passwords”.

5.6.6 Using SSL for Secure Connections

Beginning with version 4.0.0, MySQL has support for secure (encrypted) connections between MySQL clients and the server using the Secure Sockets Layer (SSL) protocol. This section discusses how to use SSL connections. For information on how to require users to use SSL connections, see the discussion of the `REQUIRE` clause of the `GRANT` statement in Section 12.4.1.2, “`GRANT` Syntax”.

The standard configuration of MySQL is intended to be as fast as possible, so encrypted connections are not used by default. Doing so would make the client/server protocol much slower. Encrypting data is a CPU-intensive operation that requires the computer to do additional work and can delay other MySQL tasks. For applications that require the security provided by encrypted connections, the extra computation is warranted.

MySQL enables encryption on a per-connection basis. You can choose a normal unencrypted connection or a secure encrypted SSL connection according the requirements of individual applications.

Secure connections are based on the OpenSSL API and are available through the MySQL C API. Replication uses the C API, so secure connections can be used between master and slave servers.

Another way to connect securely is from within an SSH connection to the MySQL server host. For an example, see Section 5.6.7, “Connecting to MySQL Remotely from Windows with SSH”.

5.6.6.1 Basic SSL Concepts

To understand how MySQL uses SSL, it is necessary to explain some basic SSL and X509 concepts. People who are familiar with these can skip this part of the discussion.

By default, MySQL uses unencrypted connections between the client and the server. This means that someone with access to the network could watch all your traffic and look at the data being sent or received. They could even change the data while it is in transit between client and server. To improve security a little, you can compress client/server traffic by using the `--compress` option when invoking client programs. However, this does not foil a determined attacker.

When you need to move information over a network in a secure fashion, an unencrypted connection is unacceptable. Encryption is the way to make any kind of data unreadable. In fact, today's practice requires many additional security elements from encryption algorithms. They should resist many kind of known attacks such as changing the order of encrypted messages or replaying data twice.

SSL is a protocol that uses different encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect any data change, loss, or replay. SSL also incorporates algorithms that provide identity verification using the X509 standard.

X509 makes it possible to identify someone on the Internet. It is most commonly used in e-commerce applications. In basic terms, there should be some company called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can show the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted with this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

If you need more information about SSL, X509, or encryption, use your favorite Internet search engine to search for the keywords in which you are interested.

5.6.6.2 Using SSL Connections

To use SSL connections between the MySQL server and client programs, your system must support OpenSSL and your version of MySQL must be 4.0.0 or newer and built with SSL support.

To get secure connections to work with MySQL and SSL, you must do the following:

1. Install the OpenSSL library if it has not already been installed. We have tested MySQL with OpenSSL 0.9.6. To obtain OpenSSL, visit http://www.openssl.org.

   Building MySQL using OpenSSL requires a shared OpenSSL library, otherwise linker errors occur.

2. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, configure a MySQL source distribution to use SSL. When you configure MySQL, invoke the `configure` script with the `--with-vio` and `--with-openssl` options:

   ```
   shell> ./configure --with-vio --with-openssl
   ```

3. Make sure that the `user` in the `mysql` database includes the SSL-related columns (beginning with `ssl_` and `x509_`). If your `user` table does not have these columns, it must be upgraded; see Section 4.4.5, “`mysql_fix_privilege_tables` — Upgrade MySQL System Tables”.

4. To check whether a server binary is compiled with SSL support, invoke it with the `--ssl` [521] option. An error will occur if the server does not support SSL:

   ```
   shell> mysqld --ssl --help
   060525 14:18:52 [ERROR] mysqld: unknown option '--ssl'
   ```

   To check whether a running `mysqld` server supports SSL, examine the value of the `have_openssl` [413] system variable:

   ```
   mysql> SHOW VARIABLES LIKE 'have_openssl';
   +---------------+-------+
   | Variable_name | Value |
   +---------------+-------+
   | have_openssl  | YES   |
   +---------------+-------+
   ```

   If the value is `YES`, the server supports OpenSSL connections.

To enable SSL connections, the proper SSL-related options must be used (see Section 5.6.6.3, “SSL Command Options”).

To start the MySQL server so that it permits clients to connect using SSL, use the options that identify the key and certificate files the server needs when establishing a secure connection:

```
shell> mysqld --ssl-ca=ca-cert.pem \
       --ssl-cert=server-cert.pem \
       --ssl-key=server-key.pem
```

- `--ssl-ca` [522] identifies the Certificate Authority (CA) certificate.
- `--ssl-cert` [522] identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key` [522] identifies the server private key.

To establish a secure connection to a MySQL server with SSL support, the options that a client must specify depend on the SSL requirements of the user account that the client uses. (See the discussion of the `REQUIRE` clause in Section 12.4.1.2, “`GRANT` Syntax”.)

If the account has no special SSL requirements or was created using a `GRANT` statement that includes the `REQUIRE SSL` option, a client can connect securely by using just the `--ssl-ca` [522] option:

```
shell> mysql --ssl-ca=ca-cert.pem
```

To require that a client certificate also be specified, create the account using the `REQUIRE X509` option. Then the client must also specify the proper client key and certificate files or the server will reject the connection:

```
shell> mysql --ssl-ca=ca-cert.pem \
       --ssl-cert=client-cert.pem \
       --ssl-key=client-key.pem
```

In other words, the options are similar to those used for the server. Note that the Certificate Authority certificate has to be the same.

A client can determine whether the current connection with the server uses SSL by checking the value of the `Ssl_cipher` [455] status variable. The value of `Ssl_cipher` [455] is nonempty if SSL is used, and empty otherwise. For example:

```
mysql> SHOW STATUS LIKE 'Ssl_cipher';
+---------------+--------------------+
| Variable_name | Value              |
+---------------+--------------------+
| Ssl_cipher    | DHE-RSA-AES256-SHA |
+---------------+--------------------+
```

For the `mysql` client, you can use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
...
SSL:                    Not in use
...
```

Or:

```
mysql> \s
...
SSL:                    Cipher in use is DHE-RSA-AES256-SHA
...
```

To establish a secure connection from within an application program, use the `mysql_ssl_set()` C API function to set the appropriate certificate options before calling `mysql_real_connect()`. See Section 17.6.6.65, “`mysql_ssl_set()`”.

5.6.6.3 SSL Command Options

The following list describes options that are used for specifying the use of SSL, certificate files, and key files. These options are available beginning with MySQL 4.0. They can be given on the command line or in an option file. These options are not available unless MySQL has been built with SSL support. See Section 5.6.6.2, “Using SSL Connections”. (There are also `--master-ssl*` options that can be used for setting up a secure connection from a slave replication server to a master server; see Section 14.8, “Replication and Binary Logging Options and Variables”.)

Table 5.11 SSL Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
have_openssl [413]			Yes		Global	No
skip-ssl [521]	Yes	Yes				
ssl [521]	Yes	Yes				
ssl-ca [522]	Yes	Yes			Global	No
- *Variable*: ssl_ca			Yes		Global	No
ssl-capath [522]	Yes	Yes			Global	No
- *Variable*: ssl_capath			Yes		Global	No
ssl-cert [522]	Yes	Yes			Global	No
- *Variable*: ssl_cert			Yes		Global	No
ssl-cipher [522]	Yes	Yes			Global	No
- *Variable*: ssl_cipher			Yes		Global	No
ssl-key [522]	Yes	Yes			Global	No
- *Variable*: ssl_key			Yes		Global	No

- `--ssl` [521]

  For the server, this option specifies that the server permits SSL connections. For a client program, it permits the client to connect to the server using SSL. This option is not sufficient in itself to cause an SSL connection to be used. You must also specify the `--ssl-ca` [522] option, and possibly the `--ssl-cert` [522] and `--ssl-key` [522] options.

  This option is more often used in its opposite form to override any other SSL options and indicate that SSL should *not* be used. To do this, specify the option as `--skip-ssl` [521] or `--ssl=0` [521].

  Note that use of `--ssl` [521] does not *require* an SSL connection. For example, if the server or client is compiled without SSL support, a normal unencrypted connection is used.

  The secure way to require use of an SSL connection is to create an account on the server that includes a `REQUIRE SSL` clause in the `GRANT` statement. Then use that account to connect to the server, where both the server and the client have SSL support enabled.

  The `REQUIRE` clause permits other SSL-related restrictions as well. The description of `REQUIRE` in Section 12.4.1.2, “`GRANT` Syntax”, provides additional detail about which SSL command options may or must be specified by clients that connect using accounts that are created using the various `REQUIRE` options.

- `--ssl-ca=file_name` [522]

  The path to a file that contains a list of trusted SSL CAs.

- `--ssl-capath=directory_name` [522]

  The path to a directory that contains trusted SSL CA certificates in PEM format.

- `--ssl-cert=file_name` [522]

  The name of the SSL certificate file to use for establishing a secure connection.

- `--ssl-cipher=cipher_list` [522]

  A list of permissible ciphers to use for SSL encryption. For greatest portability, `cipher_list` should be a list of one or more cipher names, separated by colons. Examples:

```
--ssl-cipher=AES128-SHA
--ssl-cipher=DHE-RSA-AES256-SHA:AES128-SHA
```

  This format is understood both by OpenSSL and yaSSL. OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at http://www.openssl.org/docs/apps/ciphers.html. However, this extended syntax will fail if used with a MySQL installation compiled against yaSSL (which may be the case for MySQL 5.0 and up).

  If no cipher in the list is supported, SSL connections will not work.

- `--ssl-key=file_name` [522]

  The name of the SSL key file to use for establishing a secure connection.

5.6.6.4 Setting Up SSL Certificates for MySQL

This section demonstrates how to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

Following the third example, instructions are given for using the files to test SSL connections. You can also use the files as described in Section 5.6.6.2, “Using SSL Connections”.

Example 1: Creating SSL files from the command line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the `openssl` commands. For testing, you can press Enter to all prompts. For production use, you should provide nonempty responses.

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts

# Create CA certificate
shell> openssl genrsa 2048 > ca-key.pem
shell> openssl req -new -x509 -nodes -days 1000 \
         -key ca-key.pem > ca-cert.pem

# Create server certificate
shell> openssl req -newkey rsa:2048 -days 1000 \
```

```
        -nodes -keyout server-key.pem > server-req.pem
shell> openssl x509 -req -in server-req.pem -days 1000 \
        -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 > server-cert.pem

# Create client certificate
shell> openssl req -newkey rsa:2048 -days 1000 \
        -nodes -keyout client-key.pem > client-req.pem
shell> openssl x509 -req -in client-req.pem -days 1000 \
        -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 > client-cert.pem
```

Example 2: Creating SSL files using a script on Unix

Here is an example script that shows how to set up SSL certificates for MySQL:

```
DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
# Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca-cert.pem \
    -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# ................++++++
# .........++++++
# writing new private key to '/home/monty/openssl/private/cakey.pem'
# Enter PEM pass phrase:
# Verifying password - Enter PEM pass phrase:

```

Example 3: Creating SSL files on Windows

Download OpenSSL for Windows. An overview of available packages can be seen here: http://www.slproweb.com/products/Win32OpenSSL.html

Choose of the following packages, depending on your architecture (32-bit or 64-bit):

- Win32 OpenSSL v0.9.8l Light, available at: http://www.slproweb.com/download/Win32OpenSSL_Light-0_9_8l.exe
- Win64 OpenSSL v0.9.8l Light, available at: http://www.slproweb.com/download/Win64OpenSSL_Light-0_9_8l.exe

if a message occurs during setup indicating `'...critical component is missing: Microsoft Visual C++ 2008 Redistributables'`, cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at: http://www.microsoft.com/downloads/details.aspx?familyid=9B2DA534-3E03-4391-8A4D-074B9F2BC1BF“isplaylang=en
- Visual C++ 2008 Redistributables (x64), available at: http://www.microsoft.com/downloads/details.aspx?familyid=bd2a6171-e2d6-4230-b809-9a8d7548c1b6“isplaylang=en

After installing the additional package, restart the OpenSSL setup.

During installation, leave the default `C:\OpenSSL` as the install path, and also leave the default option `'Copy OpenSSL DLL files to the Windows system directory'` selected.

When the installation has finished, add `C:\OpenSSL\bin` to the Windows System Path variable of your server:

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
3. Under **System Variables**, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.
4. Add `';C:\OpenSSL\bin'` to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \

C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

Depending on your version of Windows, the preceding instructions might be slightly different.

After OpenSSL has been installed, use the instructions from Example 1 (shown earlier in this section), with the following changes:

- Change the follow Unix commands:

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts
```

  On Windows, use these commands instead:

```
# Create clean environment
shell> md c:\newcerts
shell> cd c:\newcerts
```

- When a `'\'` character is shown at the end of a command line, this `'\'` character must be removed and the command lines entered all on a single line.
- For references to `my.cnf` option files, substitute `my.ini` instead.

Testing SSL connections

To test SSL connections, start the server as follows, where `$DIR` is the path name to the directory where the sample `my.cnf` option file is located:

```
shell> mysqld --defaults-file=$DIR/my.cnf &
```

Then invoke a client program using the same option file:

```
shell> mysql --defaults-file=$DIR/my.cnf
```

If you have a MySQL source distribution, you can also test your setup by modifying the preceding `my.cnf` file to refer to the demonstration certificate and key files in the `SSL` directory of the distribution.

5.6.7 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get a secure connection to a remote MySQL server with SSH. The information was provided by David Carlson `<dcarlson@mplcomm.com>`.

1. Install an SSH client on your Windows machine. As a user, the best nonfree one I have found is from `SecureCRT` from http://www.vandyke.com/. Another option is `f-secure` from http://www.f-secure.com/. You can also find some free ones on `Google` at http://directory.google.com/Top/Computers/Internet/Protocols/SSH/Clients/Windows/.
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.

6. On your Windows machine, start some ODBC application (such as Access).
7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not *`yourmysqlservername`*.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

5.6.8 Auditing MySQL Account Activity

Applications can use the following guidelines to perform auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the *`'user_name'@'host_name'`* format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` [872] function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

To determine the invoking user, you can also call the `USER()` [876] function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` [876] value never contains wildcards, whereas account values (as returned by `CURRENT_USER()` [872]) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `''@'localhost'` enables clients to connect as an anonymous user from the local host with any user name. If this case, if a client connects as `user1` from the local host, `USER()` [876] and `CURRENT_USER()` [872] return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+----------------+----------------+
| USER()         | CURRENT_USER() |
+----------------+----------------+
| user1@localhost | @localhost     |
+----------------+----------------+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%'` or `'_'` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` [872] value will not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` [876] and `CURRENT_USER()` [872] return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-------------------------+---------------------+
| USER()                  | CURRENT_USER()      |
+-------------------------+---------------------+
| user2@remote.example.com | user2@%.example.com |
+-------------------------+---------------------+
```

If an application invokes `USER()` [876] for user auditing, but must also be able to associate the `USER()` [876] value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the `''@'localhost'` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```
RENAME USER ''@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` [872] or `USER()` [876] value, use the `SUBSTRING()` [802] function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',1);
+--------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',1) |
+--------------------------------------+
| user1                                |
+--------------------------------------+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',-1);
+---------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',-1) |
+---------------------------------------+
| localhost                             |
+---------------------------------------+
```

5.7 Running Multiple MySQL Servers on the Same Machine

In some cases, you might want to run multiple `mysqld` servers on the same machine. You might want to test a new MySQL release while leaving your existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

To run multiple servers on a single machine, each server must have unique values for several operating parameters. These can be set on the command line or in option files. See Section 4.2.3, “Specifying Program Options”.

At least the following options must be different for each server:

- `--port=`*`port_num`* [391]

  `--port` [391] controls the port number for TCP/IP connections. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` [384] to cause different servers to listen to different interfaces.)

- `--socket=`*`path`* [394]

  `--socket` [394] controls the Unix socket file path on Unix and the name of the named pipe on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers that support named-pipe connections.

- `--shared-memory-base-name=`*`name`* [392]

  The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive. This option was added in MySQL 4.1.

- `--pid-file=file_name` [391]

  This option is used only on Unix. It indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, they must be different for each server:

- `--log[=file_name]` [388]
- `--log-bin[=file_name]` [1181]
- `--log-update[=file_name]` [389]
- `--log-error[=file_name]` [388]
- `--log-isam=file_name` [388]
- `--bdb-logdir=file_name` [1138]

Section 5.3.6, “Server Log Maintenance”, discusses the log file options further.

For better performance, you can specify the following options differently for each server, to spread the load between several physical disks:

- `--tmpdir=path` [394]
- `--bdb-tmpdir=path` [1138]

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

With very limited exceptions, each server should use a different data directory, which is specified using the `--datadir=path` [385] option.

Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files. Please note that this kind of setup only works with `ISAM`, `MyISAM` and `MERGE` tables, and not with any of the other storage engines.

The warning against sharing a data directory among servers also applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a *very bad idea*.

- The primary problem is that NFS is the speed bottleneck. It is not meant for such use.
- Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

Make it easy for yourself: Forget about sharing a data directory among servers over NFS. A better solution is to have one computer that contains several CPUs and use an operating system that handles threads efficiently.

If you have multiple MySQL installations in different locations, you can specify the base installation directory for each server with the `--basedir=path` [384] option to cause each server to use a different

data directory, log files, and PID file. (The defaults for all these values are determined relative to the base directory). In that case, the only other options you need to specify are the `--socket` [394] and `--port` [391] options. Suppose that you install different versions of MySQL using tarfile binary distributions. These install in different locations, so you can start the server for each installation using `bin/mysqld_safe` under its own corresponding base directory. `mysqld_safe` determines the proper `--basedir` [384] option to pass to `mysqld`, and you need specify only the `--socket` [245] and `--port` [245] options to `mysqld_safe`. (For versions of MySQL older than 4.0, use `safe_mysqld` rather than `mysqld_safe`.)

As discussed in the following sections, it is possible to start additional servers by setting environment variables or by specifying appropriate command-line options. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` [235] option is useful for this purpose.

5.7.1 Running Multiple Servers on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters. On Windows NT-based systems, you also have the option of installing several servers as Windows services and running them that way. General instructions for running MySQL servers from the command line or as services are given in Section 2.3, “Installing MySQL on Microsoft Windows”. This section describes how to make sure that you start each server with different values for those startup options that must be unique per server, such as the data directory. These options are described in Section 5.7, “Running Multiple MySQL Servers on the Same Machine”.

5.7.1.1 Starting Multiple Windows Servers at the Command Line

To start multiple servers manually from the command line, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` [235] option when you run it.

Suppose that you want to run `mysqld` on port 3307 with a data directory of `C:\mydata1`, and `mysqld-max` on port 3308 with a data directory of `C:\mydata2`. (To do this, make sure that before you start the servers, each data directory exists and has its own copy of the `mysql` database that contains the grant tables.) Then create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

Then start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld-max --defaults-file=C:\my-opts2.cnf
```

On NT, each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, you must connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, use the `mysqld-nt` or `mysqld-max-nt` servers and specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Then start the server this way:

```
C:\> C:\mysql\bin\mysqld-nt --defaults-file=C:\my-opts1.cnf
```

Modify `C:\my-opts2.cnf` similarly for use by the second server.

A similar procedure applies for servers that you want to support shared-memory connections. Enable such connections with the `--shared-memory` [392] option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` [392] option.

5.7.1.2 Starting Multiple Windows Servers as Services

On NT-based systems, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.11, “Starting MySQL as a Windows Service”.

As of MySQL 4.0.2, you can install multiple servers as services. In this case, you must make sure that each server uses a different service name in addition to all the other parameters that must be unique per server.

For the following instructions, assume that you want to run the `mysqld-nt` server from two different versions of MySQL that are installed at `C:\mysql-4.0.8` and `C:\mysql-4.0.17`, respectively. (This might be the case if you are running 4.0.8 as your production server, but want to test 4.0.17 before upgrading to it.)

The following principles apply when installing a MySQL service with the `--install` or `--install-manual` option:

- If you specify no service name, the server uses the default service name of `MySQL` and the server reads options from the `[mysqld]` group in the standard option files.
- If you specify a service name after the `--install` option, the server ignores the `[mysqld]` option group and instead reads options from the group that has the same name as the service. The server reads options from the standard option files.
- If you specify a `--defaults-file` [235] option after the service name, the server ignores the standard option files and reads options only from the `[mysqld]` group of the named file.

Note

Before MySQL 4.0.17, only a server installed using the default service name (`MySQL`) or one installed explicitly with a service name of `mysqld` will read the

> `[mysqld]` group in the standard option files. As of 4.0.17, all servers read the `[mysqld]` group if they read the standard option files, even if they are installed using another service name. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group named after each service for use by the server installed with that service name.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, be sure that you shut down and remove any existing MySQL services first.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 4.0.8 `mysqld-nt` using the service name of `mysqld1` and the 4.0.17 `mysqld-nt` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 4.0.8 and the `[mysqld2]` group for 4.0.17. For example, you can set up `C:\my.cnf` like this:

  ```
  # options for mysqld1 service
  [mysqld1]
  basedir = C:/mysql-4.0.8
  port = 3307
  enable-named-pipe
  socket = mypipe1

  # options for mysqld2 service
  [mysqld2]
  basedir = C:/mysql-4.0.17
  port = 3308
  enable-named-pipe
  socket = mypipe2
  ```

  Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

  ```
  C:\> C:\mysql-4.0.8\bin\mysqld-nt --install mysqld1
  C:\> C:\mysql-4.0.17\bin\mysqld-nt --install mysqld2
  ```

  To start the services, use the services manager, or use `NET START` with the appropriate service names:

  ```
  C:\> NET START mysqld1
  C:\> NET START mysqld2
  ```

  To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

  ```
  C:\> NET STOP mysqld1
  C:\> NET STOP mysqld2
  ```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` [235] when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

  With this approach, to specify options for the 4.0.8 `mysqld-nt`, create a file `C:\my-opts1.cnf` that looks like this:

  ```
  [mysqld]
  basedir = C:/mysql-4.0.8
  port = 3307
  enable-named-pipe
  ```

```
socket = mypipe1
```

For the 4.0.17 `mysqld-nt`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-4.0.17
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-4.0.8\bin\mysqld-nt --install mysqld1
           --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-4.0.17\bin\mysqld-nt --install mysqld2
           --defaults-file=C:\my-opts2.cnf
```

To use a `--defaults-file` [235] option when you install a MySQL server as a service, you must precede the option with the service name.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (`MySQL`), you can omit it.

5.7.2 Running Multiple Servers on Unix

The easiest way is to run multiple servers on Unix is to compile them with different TCP/IP ports and Unix socket files so that each one is listening on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new server to have different operating parameters, use a `configure` command something like this:

```
shell> ./configure --with-tcp-port=port_number \
            --with-unix-socket-path=file_name \
            --prefix=/usr/local/mysql-4.0.17
```

Here, *`port_number`* and *`file_name`* must be different from the default TCP/IP port number and Unix socket file path name, and the `--prefix` [95] value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

Note that if you specify `localhost` as a host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. In MySQL 4.1, you can explicitly specify the connection protocol to use by using the `--protocol={TCP|SOCKET|PIPE|MEMORY}` [226] option.

You do not have to compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` [394] and `--port` [391] option values, and pass a `--datadir=path` [385] option to `mysqld_safe` so that the server uses a different data directory.

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

Section 2.13, “Environment Variables”, includes a list of other environment variables you can use to affect `mysqld`.

For automatic server execution, the startup script that is executed at boot time should run the following command once for each server with an appropriate option file path for each command:

```
shell> mysqld_safe --defaults-file=file_name
```

Each option file should contain option values specific to a given server.

On Unix, the `mysqld_multi` script is another way to start multiple servers. See Section 4.3.4, “`mysqld_multi` — Manage Multiple MySQL Servers”.

5.7.3 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name` [226] `--port=port_number` [226] to connect using TCP/IP to a remote server, with `--host=127.0.0.1` [226] `--port=port_number` [226] to connect using TCP/IP to a local server, or with `--host=localhost` [226] `--socket=file_name` [227] to connect to a local server using a Unix socket file or a Windows named pipe.

- As of MySQL 4.1, start the client with `--protocol=TCP` [226] to connect using TCP/IP, `--protocol=SOCKET` [226] to connect using a Unix socket file, `--protocol=PIPE` [226] to connect using a named pipe, or `--protocol=MEMORY` [226] to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` [226] and `--port` [226] options. For the other types of connections, you may need to specify a `--socket` [227] option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` [226] option to specify the shared-memory name. Shared-memory connections are supported only on Windows.

- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific

socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Section 2.13, “Environment Variables”.

- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 4.2.3.3, “Using Option Files”.

- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See Section 17.6.6, “C API Function Descriptions”.

- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
       . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

  See Section 17.8, “MySQL Perl API”.

  Other programming interfaces may provide similar capabilities for reading option files.

Chapter 6 Backup and Recovery

Table of Contents

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replication slave servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

- Types of backups: Logical versus physical, full versus incremental, and so forth
- Methods for creating backups
- Recovery methods, including point-in-time recovery
- Backup scheduling, compression, and encryption
- Table maintenance, to enable recovery of corrupt tables

Additional Resources

Resources related to backup or to maintaining data availability include the following:

- A forum dedicated to backup issues is available at http://forums.mysql.com/list.php?28.
- Details for `mysqldump`, `mysqlhotcopy`, and other MySQL backup programs can be found in Chapter 4, *MySQL Programs*.

- The syntax of the SQL statements described here is given in Chapter 12, *SQL Statement Syntax*.
- For additional information about `InnoDB` backup procedures, see Section 13.2.7, “Backing Up and Recovering an `InnoDB` Database”.
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the master by using a slave server. See Chapter 14, *Replication*.
- MySQL Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See Chapter 15, *MySQL Cluster*. For information specifically about MySQL Cluster backup, see Section 15.5.3, “Online Backup of MySQL Cluster”.

6.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

Logical Versus Physical (Raw) Backups

Logical backups save information represented as logical database structure (`CREATE DATABASE`, `CREATE TABLE` statements) and content (`INSERT` statements or delimited-text files). Physical backups consist of raw copies of the directories and files that store database contents.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even `MEMORY`.
- To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA INFILE` statement or the `mysqlimport` client.

Physical backup methods have these characteristics:

- The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory. Data from `MEMORY` tables cannot be backed up this way because their contents are not stored on disk.
- Physical backup methods are faster than logical because they involve only file copying without conversion.

- Output is more compact than for logical backup.
- Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. (Each `MyISAM` table corresponds uniquely to a set of files, but an `InnoDB` table shares file storage with other `InnoDB` tables.)
- In addition to databases, the backup can include any related files such as log or configuration files.
- Backups are portable only to other machines that have identical or similar hardware characteristics.
- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup.
- Physical backup tools include file system-level commands (such as `cp`, `scp`, `tar`, `rsync`), `mysqlhotcopy` for `MyISAM` tables, `ibbackup` for `InnoDB` tables, or `START BACKUP` for `NDB` tables.
- For restore, files copied at the file system level or with `mysqlhotcopy` can be copied back to their original locations with file system commands; `ibbackup` restores `InnoDB` tables, and `ndb_restore` restores `NDB` tables.

Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

- The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
- Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity.

Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup.
- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely that clients will be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server. host.

- `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` [299] option), data files are created on the server host.

- `mysqlhotcopy` performs only local backups: It connects to the server to lock it against data modifications and then copies local table files.
- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.
- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

Table Maintenance

Data integrity can be compromised if tables become corrupt. MySQL provides programs for checking `MyISAM` and `ISAM` tables and repairing them should problems be found. See Section 6.6, “`MyISAM` Table Maintenance and Crash Recovery”.

Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. `ibbackup` can compress `InnoDB` backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

6.2 Database Backup Methods

This section summarizes some general methods for making backups.

Making Backups by Copying Table Files

For storage engines that represent each table using its own files, tables can be backed up by copying those files. For example, `MyISAM` tables are stored as files, so it is easy to do a backup by copying files (`*.frm`, `*.MYD`, and `*.MYI` files). To get a consistent backup, stop the server or do a `LOCK TABLES` on the relevant tables followed by `FLUSH TABLES` for the tables. See Section 12.3.5, "`LOCK TABLES` and `UNLOCK TABLES` Syntax", and Section 12.4.6.2, "`FLUSH` Syntax". You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The `FLUSH TABLES` statement is needed to ensure that the all active index pages are written to disk before you start the backup.

You can also create a binary backup simply by copying all table files, as long as the server isn't updating anything. The `mysqlhotcopy` script uses this method. (But note that table file copying methods do not work if your database contains `InnoDB` tables. `mysqlhotcopy` does not work for `InnoDB` tables because `InnoDB` does not necessarily store table contents in database directories. Also, even if the server is not actively updating data, `InnoDB` may still have modified data cached in memory and not flushed to disk.

Making Delimited-Text File Backups

To create a text file containing a table's data, you can use `SELECT * INTO OUTFILE '`*`file_name`*`' FROM `*`tbl_name`*. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See Section 12.2.7, "`SELECT` Syntax". This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing `CREATE TABLE` statements for the backed up tables) is to use `mysqldump` with the `--tab` [299] option. See Section 6.4.3, "Dumping Data in Delimited-Text Format with `mysqldump`".

To reload a delimited-text data file, use `LOAD DATA INFILE` or `mysqlimport`.

Making Backups with `mysqldump` or `mysqlhotcopy`

The `mysqldump` program and the `mysqlhotcopy` script can make backups. `mysqldump` is more general because it can back up all kinds of tables. `mysqlhotcopy` works only with some storage engines. (See Section 6.4, "Using `mysqldump` for Backups", and Section 4.6.8, "`mysqlhotcopy` — A Database Backup Program".)

For `InnoDB` tables, it is possible to perform an online backup that takes no locks on tables using the `--single-transaction` [298] option to `mysqldump`. See Section 6.3.1, "Establishing a Backup Policy".

Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the `--log-bin` [1181] option to enable binary logging; see Section 5.3.4, "The Binary Log". The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in Section 6.5, "Point-in-Time (Incremental) Recovery Using the Binary Log". The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS`, `mysqldump --flush-logs`, or `mysqlhotcopy --flushlog`. See Section 4.5.4, "`mysqldump` — A Database Backup Program", and Section 4.6.8, "`mysqlhotcopy` — A Database Backup Program".

Making Backups Using Replication Slaves

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See Using Replication for Backups.

If you are backing up a slave replication server, you should back up its `master.info` and `relay-log.info` files when you back up the slave's databases, regardless of the backup method you choose. These information files are always needed to resume replication after you restore the slave's data. If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` [1179] option. If the server was not started with that option, the directory location is the value of the `tmpdir` [432] system variable.

Recovering Corrupt Tables

If you have to restore `MyISAM` tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see Section 6.6, "`MyISAM` Table Maintenance and Crash Recovery".

Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

6.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The following instructions assume a minimum version of MySQL 4.1.8, because some `mysqldump` options used here are not available in earlier versions.

The example commands do not include options such as `--user` [227] and `--password` [226] for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the InnoDB storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The InnoDB data files might not contain consistent data due to the crash, but InnoDB reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. InnoDB automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

6.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, InnoDB Hot Backup provides online nonblocking physical backup of the InnoDB data files, and mysqldump provides online logical backup. This discussion uses mysqldump.

Assume that we make a full backup of all our InnoDB tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

The resulting .sql file produced by mysqldump contains a set of SQL INSERT statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using FLUSH TABLES WITH READ LOCK). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the FLUSH statement is issued, the

backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are `InnoDB` tables, so `--single-transaction` [298] uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to `InnoDB` tables are not seen by the `mysqldump` process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the `MyISAM` tables in the `mysql` database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` [1181] option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the `--log-bin` [1181] option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem  guilhem   1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem  guilhem         4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem  guilhem        79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem  guilhem       508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem  guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem  guilhem    998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem  guilhem       361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
         --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` [294] option causes the server to flush its logs. The `--master-data` [296] option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or newer.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or newer.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
         --all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

Note

Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See Section 12.5.1.1, “PURGE BINARY LOGS Syntax”.

6.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` [1181] option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
```

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see Section 6.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

6.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` [1181] option, or even `--log-bin=log_name` [1181], where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in Section 6.3.1, “Establishing a Backup Policy”, that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

6.4 Using `mysqldump` for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replication slaves.
- As a source of data for experimentation:
  - To make a copy of a database that you can use without changing the original data.
  - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` [299] option is given:

- Without `--tab` [299], `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements.
- With `--tab` [299], `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named *`tbl_name`*`.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named *`tbl_name`*`.sql` in the output directory.

6.4.1 Dumping Data in SQL Format with `mysqldump`

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see Section 6.4.2, “Reloading SQL-Format Backups”.

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
```

```
shell> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` [293] option:

```
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` [294] option:

```
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` [294] option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` [293] or `--databases` [294], `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` [292] option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` [294] option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases` [294], the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output will contain no `CREATE DATABASE` statement, the `--add-drop-database` [292] option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

6.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` [293] or `--databases` [294] option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
shell> mysql < dump.sql
```

Alternatively, from within mysql, use a source command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing CREATE DATABASE and USE statements, create the database first (if necessary):

```
shell> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
shell> mysql db1 < dump.sql
```

Alternatively, from within mysql, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

6.4.3 Dumping Data in Delimited-Text Format with mysqldump

This section describes how to use mysqldump to create delimited-text dump files. For information about reloading such dump files, see Section 6.4.4, “Reloading Delimited-Text Format Backups”.

If you invoke mysqldump with the --tab=*dir_name* [299] option, it uses *dir_name* as the output directory and dumps tables individually in that directory using two files for each table. The table name is the basename for these files. For a table named t1, the files are named t1.sql and t1.txt. The .sql file contains a CREATE TABLE statement for the table. The .txt file contains the table data, one line per table row.

The following command dumps the contents of the db1 database to files in the /tmp database:

```
shell> mysqldump --tab=/tmp db1
```

The .txt files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses SELECT ... INTO OUTFILE to write the files, so you must have the FILE [491] privilege to perform this operation, and an error occurs if a given .txt file already exists.

The server sends the CREATE definitions for dumped tables to mysqldump, which writes them to .sql files. These files therefore are owned by the user who executes mysqldump.

It is best that --tab [299] be used only for dumping a local server. If you use it with a remote server, the --tab [299] directory must exist on both the local and remote hosts, and the .txt files will be written by the server in the remote directory (on the server host), whereas the .sql files will be written by mysqldump in the local directory (on the client host).

For mysqldump --tab, the server by default writes table data to .txt files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for SELECT ... INTO OUTFILE.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=`*`str`* [294]

  The string for separating column values (default: tab).

- `--fields-enclosed-by=`*`char`* [294]

  The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=`*`char`* [294]

  The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=`*`char`* [294]

  The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=`*`str`* [295]

  The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` [294] option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,
         --fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

6.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using mysqlimport to load the data file is to use the LOAD DATA INFILE statement from within the mysql client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with mysqldump when you initially dumped the table, you must use the same options with mysqlimport or LOAD DATA INFILE to ensure proper interpretation of the data file contents:

```
shell> mysqlimport --fields-terminated-by=,
         --fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
    -> FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY '"'
    -> LINES TERMINATED BY '\r\n';
```

6.4.5 mysqldump Tips

This section surveys techniques that enable you to use mysqldump to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump definitions and data separately

6.4.5.1 Making a Copy of a Database

```
shell> mysqldump db1 > dump.sql
shell> mysqladmin create db2
shell> mysql db2 < dump.sql
```

Do not use --databases [294] on the mysqldump command line because that causes USE db1 to be included in the dump file, which overrides the effect of naming db2 on the mysql command line.

6.4.5.2 Copy a Database from one Server to Another

On Server 1:

```
shell> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
shell> mysql < dump.sql
```

Use of --databases [294] with the mysqldump command line causes the dump file to include CREATE DATABASE and USE statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` [294] from the `mysqldump` command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
shell> mysqldump db1 > dump.sql
```

On Server 2:

```
shell> mysqladmin create db1
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` [294] from the `mysqldump` command enables you to dump data from one database and load it into another.

6.4.5.3 Dumping Table Definitions and Content Separately

The `--no-data` [297] option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` [297] option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

6.4.5.4 Using `mysqldump` to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

6.5 Point-in-Time (Incremental) Recovery Using the Binary Log

Point-in-time recovery refers to recovery of data changes made since a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in Section 6.2, “Database Backup Methods”.) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

Point-in-time recovery is based on these principles:

- The source of information for point-in-time recovery is the set of incremental backups represented by the binary log files generated subsequent to the full backup operation. Therefore, the server must be started with the `--log-bin` [1181] option to enable binary logging (see Section 5.3.4, “The Binary Log”).

  To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` [1181] option to place the files in a different location. Section 5.3.4, “The Binary Log”.

  To see a listing of all binary log files, use this statement:

  ```
  mysql> SHOW BINARY LOGS;
  ```

  To determine the name of the current binary log file, issue the following statement:

  ```
  mysql> SHOW MASTER STATUS;
  ```

- The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be executed or viewed. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See Section 4.6.6, “`mysqlbinlog` — Utility for Processing Binary Log Files”.

- Executing events from the binary log causes the data modifications they represent to be redone. This enables recovery of data changes for a given span of time. To execute events from the binary log, process `mysqlbinlog` output using the `mysql` client:

  ```
  shell> mysqlbinlog binlog_files | mysql -u root -p
  ```

- Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

  ```
  shell> mysqlbinlog binlog_files | more
  ```

  Alternatively, save the output in a file and view the file in a text editor:

  ```
  shell> mysqlbinlog binlog_files > tmpfile
  shell> ... edit tmpfile ...
  ```

- Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP DATABASE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, execute the contents as follows:

```
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 >  /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

6.5.1 Point-in-Time Recovery Using Event Times

To indicate the start and end times for recovery, specify the `--start-datetime` [341] and `--stop-datetime` [342] options for `mysqlbinlog`, in `DATETIME` format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
        /var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the `--stop-datetime` [342] option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
        /var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on.

To use this method of point-in-time recovery, you should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
```

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the `/tmp/mysql_restore.sql` file with a text editor to examine it.

Excluding specific changes by specifying times for `mysqlbinlog` does not work well if multiple statements executed at the same time as the one to be excluded.

6.5.2 Point-in-Time Recovery Using Event Positions

Instead of specifying dates and times, the `--start-position` [342] and `--stop-position` [342] options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \
        --stop-datetime="2005-04-20 10:05:00" \
        /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you do not want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position=368312 /var/log/mysql/bin.123456 \
        | mysql -u root -p

shell> mysqlbinlog --start-position=368315 /var/log/mysql/bin.123456 \
        | mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

6.6 `MyISAM` Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair `MyISAM` tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). The same concepts apply to using `isamchk` to check or repair `ISAM` tables (tables that have `.ISD` and `.ISM` files for storing data and indexes). For general `myisamchk` or `isamchk` background, see Section 4.6.2, “`myisamchk` — MyISAM Table-Maintenance Utility”. Other table-repair information can be found at Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see Section 4.6.2.5, “Obtaining Table Information with `myisamchk`”.

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

myisamchk operations that affect indexes can cause FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in Section 4.6.2.1, “myisamchk General Options”.

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what myisamchk can do:

- To check MyISAM tables, use CHECK TABLE.
- To repair MyISAM tables, use REPAIR TABLE.
- To optimize MyISAM tables, use OPTIMIZE TABLE.
- To analyze MyISAM tables, use ANALYZE TABLE.

For additional information about these statements, see Section 12.4.2, “Table Maintenance Statements”.

These statements were introduced in different versions, but all are available from MySQL 3.23.14 on. These statements can be used directly or by means of the mysqlcheck client program. One advantage of these statements over myisamchk is that the server does all the work. With myisamchk, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between myisamchk and the server.

6.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See Section B.5.4.2, “What to Do If MySQL Keeps Crashing”.

For an explanation of how MyISAM tables can become corrupted, see Section 13.1.4, “MyISAM Table Problems”.

If you run mysqld with external locking disabled (which is the default as of MySQL 4.0), you cannot reliably use myisamchk to check a table when mysqld is using the same table. If you can be certain that no one will access the tables through mysqld while you run myisamchk, you only have to execute mysqladmin flush-tables before you start checking the tables. If you cannot guarantee this, you must stop mysqld while you check the tables. If you run myisamchk to check tables that mysqld is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use myisamchk to check tables at any time. In this case, if the server tries to update a table that myisamchk is using, the server will wait for myisamchk to finish before it continues.

If you use myisamchk to repair or optimize tables, you *must* always ensure that the mysqld server is not using the table (this also applies if external locking is disabled). If you do not stop mysqld, you should at least do a mysqladmin flush-tables before you run myisamchk. Your tables *may become corrupted* if the server and myisamchk access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table *tbl_name* in a database corresponds to the three files in the database directory shown in the following table.

File	Purpose
tbl_name.frm	Definition (format) file
tbl_name.MYD	Data file
tbl_name.MYI	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

myisamchk works by creating a copy of the .MYD data file row by row. It ends the repair stage by removing the old .MYD file and renaming the new file to the original file name. If you use --quick [317], myisamchk does not create a temporary .MYD file, but instead assumes that the .MYD file is correct and generates only a new index file without touching the .MYD file. This is safe, because myisamchk automatically detects whether the .MYD file is corrupt and aborts the repair if it is. You can also specify the --quick [317] option twice to myisamchk. In this case, myisamchk does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the .MYD file. Normally the use of two --quick [317] options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running myisamchk.

6.6.2 How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:

- myisamchk *tbl_name*

  This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run myisamchk without options or with the -s (silent) option.

- myisamchk -m *tbl_name*

  This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- myisamchk -e *tbl_name*

  This does a complete and thorough check of all data (-e means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, myisamchk stops after the first error it finds. If you want to obtain more information, you can add the -v (verbose) option. This causes myisamchk to keep going, up through a maximum of 20 errors.

- myisamchk -e -i *tbl_name*

  This is like the previous command, but the -i option tells myisamchk to print additional statistical information.

In most cases, a simple myisamchk command with no arguments other than the table name is sufficient to check a table.

6.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use myisamchk on MyISAM tables (extensions .MYI and .MYD). If you are using ISAM tables (extensions .ISM and .ISD), you should use isamchk instead; the concepts are similar.

You can also use the CHECK TABLE and REPAIR TABLE statements to check and repair MyISAM tables. See Section 12.4.2.3, “CHECK TABLE Syntax”, and Section 12.4.2.6, “REPAIR TABLE Syntax”.

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- *tbl_name*.frm is locked against change
- Can't find file *tbl_name*.MYI (Errcode: *nnn*)
- Unexpected end of file
- Record file is crashed
- Got error *nnn* from table handler

To get more information about the error, run perror *nnn*, where *nnn* is the error number. The following example shows how to use perror to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> perror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use ALTER TABLE to increase the MAX_ROWS and AVG_ROW_LENGTH table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use SHOW CREATE TABLE.

For the other errors, you must repair your tables. myisamchk can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that mysqld runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in Section 6.6.2, “How to Check MyISAM Tables for Errors”), or you want to use the extended features that myisamchk provides.

The options that you can use for table maintenance with myisamchk and isamchk are described in Section 4.6.2, “myisamchk — MyISAM Table-Maintenance Utility”. myisamchk also has variables that you can set to control memory allocation that may improve performance. See Section 4.6.2.6, “myisamchk Memory Usage”.

If you are going to repair a table from the command line, you must first stop the mysqld server. Note that when you do mysqladmin shutdown on a remote server, the mysqld server is still available for a while after mysqladmin returns, until all statement-processing has stopped and all index changes have been flushed to disk.

Stage 1: Checking your tables

Run myisamchk *.MYI or myisamchk -e *.MYI if you have more time. Use the -s (silent) option to suppress unnecessary information.

If the mysqld server is stopped, you should use the --update-state [316] option to tell myisamchk to mark the table as “checked.”

You have to repair only those tables for which myisamchk announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as out of memory errors), or if myisamchk crashes, go to Stage 3.

Stage 2: Easy safe repair

First, try myisamchk -r -q *tbl_name* (-r -q means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use myisamchk -r *tbl_name* (-r means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use myisamchk --safe-recover *tbl_name*. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

Note

If you want a repair operation to go much faster, you should set the values of the sort_buffer_size [427] and key_buffer_size [415] variables each to about 25% of your available memory when running myisamchk.

If you get unexpected errors when repairing (such as out of memory errors), or if myisamchk crashes, go to Stage 3.

Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
mysql> quit
```

   If your version of MySQL does not have TRUNCATE TABLE, use DELETE FROM *tbl_name* instead.

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

Important

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

As of MySQL 4.0.2, you can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See Section 12.4.2.6, "`REPAIR TABLE` Syntax".

Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.

2. If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

6.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See Section 12.4.2.5, "`OPTIMIZE TABLE` Syntax".

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` [318] or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
- `--sort-index` [319] or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num` [319] or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see Section 4.6.2, "`myisamchk` — MyISAM Table-Maintenance Utility".

6.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair `MyISAM` tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. These are available starting with MySQL 3.23.16. See Section 12.4.2, "Table Maintenance Statements".

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent` [314]) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to check tables when the server starts. For example, whenever the machine has done a restart in the middle of an update, you usually need to check all the tables that could have been affected. (These are “expected” crashed tables.) To cause the server to check MyISAM tables automatically, start it with the --myisam-recover [390] option, available as of MySQL 3.23.25. If your server is too old to support this option, you could add a test to mysqld_safe that runs myisamchk to check all tables that have been modified during the last 24 hours if there is an old .pid (process ID) file left after a restart. (The .pid file is created by mysqld when it starts and removed when it terminates normally. The presence of a .pid file at system startup time indicates that mysqld terminated abnormally.)

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To check MyISAM tables automatically, start the server with the --myisam-recover [390] option, available as of MySQL 3.23.25. See Section 5.1.2, “Server Command Options”. If your server is too old to support this option, you could add a test to mysqld_safe that runs myisamchk to check all tables that have been modified during the last 24 hours if there is an old .pid (process ID) file left after a restart. (The .pid file is created by mysqld when it starts and removed when it terminates normally. The presence of a .pid file at system startup time indicates that mysqld terminated abnormally.)

You should also check your tables regularly during normal system operation. For example, you can run a cron job to check important tables once a week, using a line like this in a crontab file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute myisamchk -s each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with VARCHAR, BLOB, or TEXT columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using OPTIMIZE TABLE on the tables in question. Alternatively, if you can stop the mysqld server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --sort_buffer_size=16M */*.MYI
```

For ISAM tables, the command is similar:

```
shell> isamchk -r -s --sort-index -O sort_buffer_size=16M */*.ISM
```

Chapter 7 Optimization

Table of Contents

This chapter explains different ways to optimize MySQL and provides examples. Optimization is a complex task because ultimately it requires understanding of the entire system to be optimized. Although it may be possible to perform some local optimizations with little knowledge of your system or application, the more optimal you want your system to become, the more you must know about it.

7.1 Optimization Overview

The most important factor in making a system fast is its basic design. You must also know what kinds of processing your system is doing, and what its bottlenecks are. In most cases, system bottlenecks arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.
- Disk reading and writing. When the disk is at the correct position, we need to read the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When we have the data in main memory, we need to process it to get our result. Having small tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

7.1.1 MySQL Design Limitations and Tradeoffs

When using the `MyISAM` storage engine, MySQL uses extremely fast table locking that permits multiple readers or a single writer. The biggest problem with this storage engine occurs when you have a steady stream of mixed updates and slow selects on a single table. If this is a problem for certain tables, you can use another storage engine for them. See Chapter 13, *Storage Engines*.

MySQL can work with both transactional and nontransactional tables. To make it easier to work smoothly with nontransactional tables (which cannot roll back if something goes wrong), MySQL has the following rules. Note that these rules apply *only* when you use the `IGNORE` specifier for `INSERT` or `UPDATE`.

- All columns have default values.
- If you insert an inappropriate or out-of-range value into a column, MySQL sets the column to the “best possible value” instead of reporting an error. For numeric values, this is 0, the smallest possible value or the largest possible value. For strings, this is either the empty string or as much of the string as can be stored in the column.
- All calculated expressions return a value that can be used instead of signaling an error condition. For example, 1/0 returns `NULL`.

To change the preceding behaviors, you can enable stricter data handling by setting the server SQL mode appropriately. For more information about data handling, see Section 1.9.6, “How MySQL Deals with Constraints”, Section 5.1.6, “Server SQL Modes”, and Section 12.2.4, “`INSERT` Syntax”.

7.1.2 Designing Applications for Portability

Because all SQL servers implement different parts of standard SQL, it takes work to write portable database applications. It is very easy to achieve portability for very simple selects and inserts, but becomes more difficult the more capabilities you require. If you want an application that is fast with many database systems, it becomes even more difficult.

All database systems have some weak points. That is, they have different design compromises that lead to different behavior.

To make a complex application portable, you need to determine which SQL servers it must work with, and then determine what features those servers support. You can use the MySQL `crash-me` program to find functions, types, and limits that you can use with a selection of database servers. `crash-me` does not check for every possible feature, but it is still reasonably comprehensive, performing about 450 tests. An example of the type of information `crash-me` can provide is that you should not use column names that are longer than 18 characters if you want to be able to use Informix or DB2.

The `crash-me` program and the MySQL benchmarks are all very database independent. By taking a look at how they are written, you can get a feeling for what you must do to make your own applications database independent. The programs can be found in the `sql-bench` directory of MySQL source distributions. They are written in Perl and use the DBI database interface. Use of DBI in itself solves part of the portability problem because it provides database-independent access methods. See Section 7.1.3, “The MySQL Benchmark Suite”.

If you strive for database independence, you need to get a good feeling for each SQL server's bottlenecks. For example, MySQL is very fast in retrieving and updating rows for `MyISAM` tables, but has a problem in mixing slow readers and writers on the same table. Transactional database systems in general are not very good at generating summary tables from log tables, because in this case row locking is almost useless.

To make your application *really* database independent, you should define an easily extendable interface through which you manipulate your data. For example, C++ is available on most systems, so it makes sense to use a C++ class-based interface to the databases.

If you use some feature that is specific to a given database system (such as the `REPLACE` statement, which is specific to MySQL), you should implement the same feature for other SQL servers by coding an alternative method. Although the alternative might be slower, it enables the other servers to perform the same tasks.

With MySQL, you can use the `/*! */` syntax to add MySQL-specific keywords to a statement. The code inside `/* */` is treated as a comment (and ignored) by most other SQL servers. For information about writing comments, see Section 8.6, “Comment Syntax”.

If high performance is more important than exactness, as for some Web applications, it is possible to create an application layer that caches all results to give you even higher performance. By letting old results expire after a while, you can keep the cache reasonably fresh. This provides a method to handle high load spikes, in which case you can dynamically increase the cache size and set the expiration timeout higher until things get back to normal.

In this case, the table creation information should contain information about the initial cache size and how often the table should normally be refreshed.

An attractive alternative to implementing an application cache is to use the MySQL query cache. By enabling the query cache, the server handles the details of determining whether a query result can be reused. This simplifies your application. See Section 7.5.3, “The MySQL Query Cache”.

7.1.3 The MySQL Benchmark Suite

This benchmark suite is meant to tell any user what operations a given SQL implementation performs well or poorly. You can get a good idea for how the benchmarks work by looking at the code and results in the `sql-bench` directory in any MySQL source distribution.

Note that this benchmark is single-threaded, so it measures the minimum time for the operations performed. We plan to add multi-threaded tests to the benchmark suite in the future.

To use the benchmark suite, the following requirements must be satisfied:

- The benchmark suite is provided with MySQL source distributions. You can either download a released distribution from http://dev.mysql.com/downloads/, or use the current development source tree. (See Section 2.9.2, “Installing MySQL from a Development Source Tree”.)
- The benchmark scripts are written in Perl and use the Perl DBI module to access database servers, so DBI must be installed. You also need the server-specific DBD drivers for each of the servers you want to test. For example, to test MySQL, PostgreSQL, and DB2, you must have the `DBD::mysql`, `DBD::Pg`, and `DBD::DB2` modules installed. See Section 2.14, “Perl Installation Notes”.

After you obtain a MySQL source distribution, you can find the benchmark suite located in its `sql-bench` directory. To run the benchmark tests, build MySQL, and then change location into the `sql-bench` directory and execute the `run-all-tests` script:

```
shell> cd sql-bench
shell> perl run-all-tests --server=server_name
```

`server_name` should be the name of one of the supported servers. To get a list of all options and supported servers, invoke this command:

```
shell> perl run-all-tests --help
```

The `crash-me` script also is located in the `sql-bench` directory. `crash-me` tries to determine what features a database system supports and what its capabilities and limitations are by actually running queries. For example, it determines:

- What data types are supported
- How many indexes are supported
- What functions are supported
- How big a query can be
- How big a `VARCHAR` column can be

For more information about benchmark results, visit http://www.mysql.com/why-mysql/benchmarks/.

7.1.4 Using Your Own Benchmarks

You should definitely benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

For examples of portable benchmark programs, look at those in the MySQL benchmark suite. See Section 7.1.3, “The MySQL Benchmark Suite”. You can take any program from this suite and modify it

for your own needs. By doing this, you can try different solutions to your problem and test which really is fastest for you.

Another free benchmark suite is the Open Source Database Benchmark, available at http://osdb.sourceforge.net/.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, you should put some effort into benchmarking your whole application under the worst possible load. You can use Super Smack, available at http://jeremy.zawodny.com/mysql/super-smack/. As suggested by its name, it can bring a system to its knees, so make sure to use it only on your development systems.

7.2 Obtaining Query Execution Plan Information

7.2.1 Optimizing Queries with `EXPLAIN`

The `EXPLAIN` statement can be used either as a synonym for `DESCRIBE` or as a way to obtain information about how MySQL executes a `SELECT` statement:

- `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` or `SHOW COLUMNS FROM tbl_name`:

```
EXPLAIN tbl_name
```

- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the query execution plan. That is, MySQL explains how it would process the `SELECT`, including information about how tables are joined and in which order:

```
EXPLAIN [EXTENDED] SELECT select_options
```

This section describes the second use of `EXPLAIN` for obtaining query execution plan information. See also Section 12.7.2, “`EXPLAIN` Syntax”. For a description of the `DESCRIBE` and `SHOW COLUMNS` statements, see Section 12.7.1, “`DESCRIBE` Syntax”, and Section 12.4.5.5, “`SHOW COLUMNS` Syntax”.

With the help of `EXPLAIN`, you can see where you should add indexes to tables to get a faster `SELECT` that uses indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in the `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See Section 12.2.7, “`SELECT` Syntax”.)

If you have a problem with indexes not being used when you believe that they should be, you should run `ANALYZE TABLE` to update table statistics such as cardinality of keys, that can affect the choices the optimizer makes. See Section 12.4.2.1, “`ANALYZE TABLE` Syntax”.

7.2.2 `EXPLAIN` Output Format

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. The tables are listed in the output in the order that MySQL would read them while processing the query. MySQL resolves all joins using a nested-loop join method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

In MySQL version 4.1, the EXPLAIN output format was changed to work better with constructs such as UNION statements, subqueries, and derived tables. Most notable is the addition of two new columns: id and select_type. You do not see these columns when using servers older than MySQL 4.1. EXPLAIN syntax also was augmented to permit the EXTENDED keyword. When this keyword is used, EXPLAIN produces extra information that can be viewed by issuing a SHOW WARNINGS statement following the EXPLAIN statement. This information displays how the optimizer qualifies table and column names in the SELECT statement, what the SELECT looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

Each output row from EXPLAIN provides information about one table, and each row contains the following columns:

- id

  The SELECT identifier. This is the sequential number of the SELECT within the query.

- select_type

  The type of SELECT, which can be any of those shown in the following table.

select_type Value	Meaning
SIMPLE	Simple SELECT (not using UNION or subqueries)
PRIMARY	Outermost SELECT
UNION	Second or later SELECT statement in a UNION
DEPENDENT UNION	Second or later SELECT statement in a UNION, dependent on outer query
UNION RESULT	Result of a UNION.
SUBQUERY	First SELECT in subquery
DEPENDENT SUBQUERY	First SELECT in subquery, dependent on outer query
DERIVED	Derived table SELECT (subquery in FROM clause)
UNCACHEABLE SUBQUERY	A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query

  DEPENDENT typically signifies the use of a correlated subquery. See Section 12.2.8.7, “Correlated Subqueries”.

  DEPENDENT SUBQUERY evaluation differs from UNCACHEABLE SUBQUERY evaluation. For DEPENDENT SUBQUERY, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For UNCACHEABLE SUBQUERY, the subquery is re-evaluated for each row of the outer context. Cacheability of subqueries is subject to the restrictions detailed in Section 7.5.3.1, “How the Query Cache Operates”. For example, referring to user variables makes a subquery uncacheable.

- table

  The table to which the row of output refers.

- type

  The join type. The different join types are listed here, ordered from the best type to the worst:

  - system [566]

    The table has only one row (= system table). This is a special case of the const [567] join type.

- `const` [567]

  The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` [567] tables are very fast because they are read only once.

  `const` [567] is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, *`tbl_name`* can be used as a `const` [567] table:

  ```
  SELECT * FROM tbl_name WHERE primary_key=1;

  SELECT * FROM tbl_name
    WHERE primary_key_part1=1 AND primary_key_part2=2;
  ```

- `eq_ref` [567]

  One row is read from this table for each combination of rows from the previous tables. Other than the `system` [566] and `const` [567] types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE NOT NULL` index.

  `eq_ref` [567] can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` [567] join to process *`ref_table`*:

  ```
  SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column=other_table.column;

  SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column_part1=other_table.column
    AND ref_table.key_column_part2=1;
  ```

- `ref` [567]

  All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` [567] is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

  `ref` [567] can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` [567] join to process *`ref_table`*:

  ```
  SELECT * FROM ref_table WHERE key_column=expr;

  SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column=other_table.column;

  SELECT * FROM ref_table,other_table
    WHERE ref_table.key_column_part1=other_table.column
    AND ref_table.key_column_part2=1;
  ```

- `fulltext` [567]

  The join is performed using a `FULLTEXT` index.

- `ref_or_null` [567]

This join type is like ref [567], but with the addition that MySQL does an extra search for rows that contain NULL values. This join type optimization was added for MySQL 4.1.1 and is used mostly when resolving subqueries. In the following examples, MySQL can use a ref_or_null [567] join to process *ref_table*:

```
SELECT * FROM ref_table
  WHERE key_column=expr OR key_column IS NULL;
```

See Section 7.3.1.4, “IS NULL Optimization”.

- unique_subquery [568]

  This type replaces ref [567] for some IN subqueries of the following form:

  ```
  value IN (SELECT primary_key FROM single_table WHERE some_expr)
  ```

  unique_subquery [568] is just an index lookup function that replaces the subquery completely for better efficiency.

- index_subquery [568]

  This join type is similar to unique_subquery [568]. It replaces IN subqueries, but it works for nonunique indexes in subqueries of the following form:

  ```
  value IN (SELECT key_column FROM single_table WHERE some_expr)
  ```

- range [568]

  Only rows that are in a given range are retrieved, using an index to select the rows. The key column in the output row indicates which index is used. The key_len contains the longest key part that was used. The ref column is NULL for this type.

  range [568] can be used when a key column is compared to a constant using any of the = [782], <> [782], > [783], >= [782], < [782], <= [782], IS NULL [783], <=> [782], BETWEEN [783], or IN() [784] operators:

  ```
  SELECT * FROM tbl_name
    WHERE key_column = 10;

  SELECT * FROM tbl_name
    WHERE key_column BETWEEN 10 and 20;

  SELECT * FROM tbl_name
    WHERE key_column IN (10,20,30);

  SELECT * FROM tbl_name
    WHERE key_part1= 10 AND key_part2 IN (10,20,30);
  ```

- index [568]

  This join type is the same as ALL, except that only the index tree is scanned. This usually is faster than ALL because the index file usually is smaller than the data file.

  MySQL can use this join type when the query uses only columns that are part of a single index.

- ALL

  A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked const [567], and usually *very* bad in all other cases. Normally, you can avoid ALL by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

- possible_keys

  The possible_keys column indicates which indexes MySQL can choose from use to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from EXPLAIN. That means that some of the keys in possible_keys might not be usable in practice with the generated table order.

  If this column is NULL, there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the WHERE clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with EXPLAIN again. See Section 12.1.2, “ALTER TABLE Syntax”.

  To see what indexes a table has, use SHOW INDEX FROM *tbl_name*.

- key

  The key column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the possible_keys indexes to look up rows, that index is listed as the key value.

  It is possible that key will name an index that is not present in the possible_keys value. This can happen if none of the possible_keys indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

  For InnoDB, a secondary index might cover the selected columns even if the query also selects the primary key because InnoDB stores the primary key value with each secondary index. If key is NULL, MySQL found no index to use for executing the query more efficiently.

  To force MySQL to use or ignore an index listed in the possible_keys column, use FORCE INDEX, USE INDEX, or IGNORE INDEX in your query. See Section 12.2.7.2, “Index Hint Syntax”.

  For MyISAM and BDB tables, running ANALYZE TABLE helps the optimizer choose better indexes. For MyISAM tables, myisamchk --analyze does the same. See Section 12.4.2.1, “ANALYZE TABLE Syntax”, and Section 6.6, “MyISAM Table Maintenance and Crash Recovery”.

- key_len

  The key_len column indicates the length of the key that MySQL decided to use. The length is NULL if the key column says NULL. Note that the value of key_len enables you to determine how many parts of a multiple-part key MySQL actually uses.

- ref

  The ref column shows which columns or constants are compared to the index named in the key column to select rows from the table.

- rows

The rows column indicates the number of rows MySQL believes it must examine to execute the query.

For InnoDB tables, this number is an estimate, and may not always be exact.

- Extra

  This column contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. If you want to make your queries as fast as possible, you should look out for Extra values of Using filesort and Using temporary.

  - const row not found

    For a query such as SELECT ... FROM *tbl_name*, the table was empty.

  - Distinct

    MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

  - Impossible HAVING

    The HAVING clause is always false and cannot select any rows.

  - Impossible WHERE

    The WHERE clause is always false and cannot select any rows.

  - Impossible WHERE noticed after reading const tables

    MySQL has read all const [567] (and system [566]) tables and notice that the WHERE clause is always false.

  - No matching min/max row

    No row satisfies the condition for a query such as SELECT MIN(...) FROM ... WHERE *condition*.

  - no matching row in const table

    For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

  - No tables used

    The query has no FROM clause, or has a FROM DUAL clause.

  - Not exists

    MySQL was able to do a LEFT JOIN optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the LEFT JOIN criteria. Here is an example of the type of query that can be optimized this way:

    ```
    SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
      WHERE t2.id IS NULL;
    ```

Assume that t2.id is defined as NOT NULL. In this case, MySQL scans t1 and looks up the rows in t2 using the values of t1.id. If MySQL finds a matching row in t2, it knows that t2.id can never be NULL, and does not scan through the rest of the rows in t2 that have the same id value. In other words, for each row in t1, MySQL needs to do only a single lookup in t2, regardless of how many rows actually match in t2.

- Range checked for each record (index map: *N*)

  MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a range [568] access method to retrieve rows. The applicability criteria are as described in Section 7.3.1.3, "Range Optimization", with the exception that all column values for the preceding table are known and considered to be constants.

  This is not very fast, but is faster than performing a join with no index at all.

  Indexes are numbered beginning with 1, in the same order as shown by SHOW INDEX for the table. The index map value *N* is a bitmask value that indicates which indexes are candidates. For example, a value of 0x19 (binary 11001) means that indexes 1, 4, and 5 will be considered.

- Select tables optimized away

  The query contained only aggregate functions (MIN() [884], MAX() [884]) that were all resolved using an index, or COUNT(*) [882] for MyISAM, and no GROUP BY clause. The optimizer determined that only one row should be returned.

- unique row not found

  For a query such as SELECT ... FROM *tbl_name*, no rows satisfy the condition for a UNIQUE index or PRIMARY KEY on the table.

- Using filesort

  MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the WHERE clause. The keys then are sorted and the rows are retrieved in sorted order. See Section 7.3.1.7, "ORDER BY Optimization".

- Using index

  The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

- Using index for group-by

  Similar to the Using index table access method, Using index for group-by indicates that MySQL found an index that can be used to retrieve all columns of a GROUP BY or DISTINCT query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see Section 7.3.1.8, "GROUP BY Optimization".

- Using temporary

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- `Using where`

  A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index` [568]. Even if you are using an index for all parts of a `WHERE` clause, you may see `Using where` if the column can be `NULL`.

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the `EXPLAIN` output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` [419] system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See Section 7.8.2, “Tuning Server Parameters”.

The following example shows how a multiple-table join can be optimized progressively based on the information provided by `EXPLAIN`.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using `EXPLAIN`:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
               tt.ProjectReference, tt.EstimatedShipDate,
               tt.ActualShipDate, tt.ClientID,
               tt.ServiceCodes, tt.RepetitiveID,
               tt.CurrentProcess, tt.CurrentDPPerson,
               tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
               et_1.COUNTRY, do.CUSTNAME
        FROM tt, et, et AS et_1, do
        WHERE tt.SubmitTime IS NULL
          AND tt.ActualPC = et.EMPLOYID
          AND tt.AssignedPC = et_1.EMPLOYID
          AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

Table	Column	Data Type
`tt`	`ActualPC`	`CHAR(10)`
`tt`	`AssignedPC`	`CHAR(10)`
`tt`	`ClientID`	`CHAR(10)`
`et`	`EMPLOYID`	`CHAR(15)`
`do`	`CUSTNMBR`	`CHAR(15)`

- The tables have the following indexes.

Table	Index
`tt`	`ActualPC`
`tt`	`AssignedPC`
`tt`	`ClientID`
`et`	`EMPLOYID` (primary key)

Table	Index
do	CUSTNMBR (primary key)

- The tt.ActualPC values are not evenly distributed.

Initially, before any optimizations have been performed, the EXPLAIN statement produces the following information:

```
table type possible_keys key  key_len ref  rows  Extra
et    ALL  PRIMARY       NULL NULL    NULL 74
do    ALL  PRIMARY       NULL NULL    NULL 2135
et_1  ALL  PRIMARY       NULL NULL    NULL 74
tt    ALL  AssignedPC,   NULL NULL    NULL 3872
           ClientID,
           ActualPC
      Range checked for each record (index map: 0x23)
```

Because type is ALL for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is 74 × 2135 × 74 × 3872 = 45,268,558,720 rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. (For ISAM tables, indexes may not be used at all unless the columns are declared the same.) In this context, VARCHAR and CHAR are considered the same if they are declared as the same size. tt.ActualPC is declared as CHAR(10) and et.EMPLOYID is CHAR(15), so there is a length mismatch.

To fix this disparity between column lengths, use ALTER TABLE to lengthen ActualPC from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now tt.ActualPC and et.EMPLOYID are both VARCHAR(15). Executing the EXPLAIN statement again produces this result:

```
table type   possible_keys key     key_len ref         rows    Extra
tt    ALL    AssignedPC,   NULL    NULL    NULL        3872    Using
             ClientID,                                         where
             ActualPC
do    ALL    PRIMARY       NULL    NULL    NULL        2135
      Range checked for each record (index map: 0x1)
et_1  ALL    PRIMARY       NULL    NULL    NULL        74
      Range checked for each record (index map: 0x1)
et    eq_ref PRIMARY       PRIMARY 15      tt.ActualPC 1
```

This is not perfect, but is much better: The product of the rows values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the tt.AssignedPC = et_1.EMPLOYID and tt.ClientID = do.CUSTNMBR comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
    ->                MODIFY ClientID   VARCHAR(15);
```

After that modification, EXPLAIN produces the output shown here:

```
table type   possible_keys key      key_len ref           rows Extra
et    ALL    PRIMARY       NULL     NULL    NULL          74
tt    ref    AssignedPC,   ActualPC 15      et.EMPLOYID   52   Using
             ClientID,                                        where
             ActualPC
et_1  eq_ref PRIMARY       PRIMARY  15      tt.AssignedPC 1
do    eq_ref PRIMARY       PRIMARY  15      tt.ClientID   1
```

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

```
table type   possible_keys key     key_len ref           rows Extra
tt    ALL    AssignedPC    NULL    NULL    NULL          3872 Using
             ClientID,                                        where
             ActualPC
et    eq_ref PRIMARY       PRIMARY 15      tt.ActualPC   1
et_1  eq_ref PRIMARY       PRIMARY 15      tt.AssignedPC 1
do    eq_ref PRIMARY       PRIMARY 15      tt.ClientID   1
```

Note that the `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. You should check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause.

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see Section 12.2.8.8, “Subqueries in the `FROM` Clause”.

7.2.3 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row: `log(row_count) / log(index_block_length / 3 * 2 / (index_length + data_pointer_length)) + 1`.

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates `log(500,000)/log(1024/3*2/(3+4)) + 1` = `4` seeks.

This index would require storage of about 500,000 * 7 * 3/2 = 5.2MB (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

Note that the preceding discussion does not mean that your application performance slowly degenerates by log N. As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are only bound by disk-seeks (which increase by log *N*). To avoid this, increase

the key cache size as the data grows. For MyISAM tables, the key cache size is controlled by the key_buffer_size [415] system variable. See Section 7.8.2, “Tuning Server Parameters”.

7.3 Optimizing SQL Statements

7.3.1 Optimizing SELECT Statements

First, one factor affects all statements: The more complex your permissions setup, the more overhead you have. Using simpler permissions when you issue GRANT statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the tables_priv and columns_priv tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, it may be worth the time to use a simplified grant structure to reduce permission-checking overhead.

If your problem is with a specific MySQL expression or function, you can perform a timing test by invoking the BENCHMARK() [870] function using the mysql client program. Its syntax is BENCHMARK(*loop_count*,*expression*) [870]. The return value is always zero, but mysql prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+------------------------+
| BENCHMARK(1000000,1+1) |
+------------------------+
|                      0 |
+------------------------+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

All MySQL functions should be highly optimized, but there may be some exceptions. BENCHMARK() [870] is an excellent tool for finding out if some function is a problem for your queries.

7.3.1.1 Speed of SELECT Statements

In general, when you want to make a slow SELECT ... WHERE query faster, the first thing to check is whether you can add an index. All references between different tables should usually be done with indexes. You can use the EXPLAIN statement to determine which indexes are used for a SELECT. See Section 7.2.1, “Optimizing Queries with EXPLAIN”, and Section 7.4.3, “How MySQL Uses Indexes”.

Some general tips for speeding up queries on MyISAM tables:

- To help MySQL better optimize queries, use ANALYZE TABLE or run myisamchk --analyze on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using SHOW INDEX FROM *tbl_name* and examining the Cardinality value. myisamchk --description --verbose shows index distribution information.
- To sort an index and data according to an index, use myisamchk --sort-index --sort-records=1 (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.

7.3.1.2 WHERE Clause Optimization

This section discusses optimizations that can be made for processing WHERE clauses. The examples use SELECT statements, but the same optimizations apply for WHERE clauses in DELETE and UPDATE statements.

Work on the MySQL optimizer is ongoing, so this section is incomplete. MySQL performs a great many optimizations, not all of which are documented here.

Some of the optimizations performed by MySQL follow:

- Removal of unnecessary parentheses:

```
   ((a AND b) AND c OR (((a AND b) AND (c AND d))))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
   (a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal (needed because of constant folding):

```
   (B>=5 AND B=5) OR (B=6 AND 5=5) OR (B=7 AND 5=6)
-> B=5 OR B=6
```

- Constant expressions used by indexes are evaluated only once.
- COUNT(*) [882] on a single table without a WHERE is retrieved directly from the table information for MyISAM and MEMORY (HASH) tables. This is also done for any NOT NULL expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some SELECT statements are impossible and returns no rows.
- HAVING is merged with WHERE if you do not use GROUP BY or aggregate functions (COUNT() [882], MIN() [884], and so on).
- For each table in a join, a simpler WHERE is constructed to get a fast WHERE evaluation for the table and also to skip rows as soon as possible.
- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a WHERE clause on a PRIMARY KEY or a UNIQUE index, where all index parts are compared to constant expressions and are defined as NOT NULL.

  All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
  WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in ORDER BY and GROUP BY clauses come from the same table, that table is preferred first when joining.

- If there is an ORDER BY clause and a different GROUP BY clause, or if the ORDER BY or GROUP BY contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the SQL_SMALL_RESULT option, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the HAVING clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
  WHERE key_part1=constant;

SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
  WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... ;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

7.3.1.3 Range Optimization

The range [568] access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections give a detailed description of how intervals are extracted from the WHERE clause.

The Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the WHERE clause, so we speak of *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both BTREE and HASH indexes, comparison of a key part with a constant value is a range condition when using the = [782], <=> [782], IN() [784], IS NULL [783], or IS NOT NULL [783] operators.
- Additionally, for BTREE indexes, comparison of a key part with a constant value is a range condition when using the > [783], < [782], >= [782], <= [782], BETWEEN [783], != [782], or <> [782] operators, or LIKE [804] comparisons if the argument to LIKE [804] is a constant string that does not start with a wildcard character.
- For all types of indexes, multiple range conditions combined with OR [787] or AND [787] form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a const [567] or system [566] table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the WHERE clause:

```
SELECT * FROM t1
  WHERE key_col > 1
  AND key_col < 10;

SELECT * FROM t1
  WHERE key_col = 1
  OR key_col IN (15,18,20);

SELECT * FROM t1
  WHERE key_col LIKE 'ab%'
  OR key_col BETWEEN 'bar' AND 'foo';
```

Note that some nonconstant values may be converted to constants during the constant propagation phase.

MySQL tries to extract range conditions from the WHERE clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where key1 is an indexed column and nonkey is not indexed:

```
SELECT * FROM t1 WHERE
  (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
  (key1 < 'bar' AND nonkey = 4) OR
  (key1 < 'uux' AND key1 > 'z');
```

The extraction process for key key1 is as follows:

1. Start with original WHERE clause:

   ```
   (key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
   (key1 < 'bar' AND nonkey = 4) OR
   ```

```
(key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Having replaced them with `TRUE`, we get:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

   - `(key1 LIKE 'abcde%' OR TRUE)` is always true
   - `(key1 < 'uux' AND key1 > 'z')` is always false

   Replacing these conditions with constants, we get:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

   Removing unnecessary `TRUE` and `FALSE` constants, we obtain:

```
(key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
(key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND` [787]/`OR` [787] constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

The Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

```
key_part1  key_part2  key_part3
  NULL       1          'abc'
  NULL       1          'xyz'
  NULL       2          'foo'
   1         1          'abc'
   1         1          'xyz'
   1         2          'abc'
   2         1          'aaa'
```

The condition `key_part1 = 1` defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition `key_part3 = 'abc'` does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For HASH indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

  ```
      key_part1 cmp const1
  AND key_part2 cmp const2
  AND ...
  AND key_partN cmp constN;
  ```

  Here, `const1`, `const2`, ... are constants, `cmp` is one of the = [782], <=> [782], or IS NULL [783] comparison operators, and the conditions cover all index parts. (That is, there are `N` conditions, one for each part of an `N`-part index.) For example, the following is a range condition for a three-part HASH index:

  ```
  key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
  ```

  For the definition of what is considered to be a constant, see The Range Access Method for Single-Part Indexes.

- For a BTREE index, an interval might be usable for conditions combined with AND [787], where each condition compares a key part with a constant value using = [782], <=> [782], IS NULL [783], > [783], < [782], >= [782], <= [782], != [782], <> [782], BETWEEN [783], or LIKE `'pattern'` [804] (where `'pattern'` does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if <> [782] or != [782] is used). For example, for this condition:

  ```
  key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
  ```

  The single interval is:

  ```
  ('foo',10,10) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)
  ```

  It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value `('foo', 11, 0)`, which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with OR [787], they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with AND [787], they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

  ```
  (key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
  ```

  The intervals are:

  ```
  (1,-inf) < (key_part1,key_part2) < (1,2)
  (5,-inf) < (key_part1,key_part2)
  ```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The key_len column in the EXPLAIN output indicates the maximum length of the key prefix used.

In some cases, key_len may indicate that a key part was used, but that might be not what you would expect. Suppose that key_part1 and key_part2 can be NULL. Then the key_len column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

The Range Access Method for Single-Part Indexes, describes how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index. Analogous steps are performed for range conditions on multiple-part indexes.

7.3.1.4 IS NULL Optimization

MySQL can perform the same optimization on col_name IS NULL [783] that it can use for col_name = constant_value. For example, MySQL can use indexes and ranges to search for NULL with IS NULL [783].

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;

SELECT * FROM tbl_name WHERE key_col <=> NULL;

SELECT * FROM tbl_name
  WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a WHERE clause includes a col_name IS NULL [783] condition for a column that is declared as NOT NULL, that expression is optimized away. This optimization does not occur in cases when the column might produce NULL anyway; for example, if it comes from a table on the right side of a LEFT JOIN.

MySQL 4.1.1 and up can also optimize the combination col_name = expr OR col_name IS NULL, a form that is common in resolved subqueries. EXPLAIN shows ref_or_null [567] when this optimization is used.

This optimization can handle one IS NULL [783] for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns a and b of table t2:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;

SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;

SELECT * FROM t1, t2
  WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;

SELECT * FROM t1, t2
  WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);
```

```
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
  OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

ref_or_null [567] works by first doing a read on the reference key, and then a separate search for rows with a NULL key value.

Note that the optimization can handle only one IS NULL [783] level. In the following query, MySQL uses key lookups only on the expression (t1.a=t2.a AND t2.a IS NULL) and is not able to use the key part on b:

```
SELECT * FROM t1, t2
  WHERE (t1.a=t2.a AND t2.a IS NULL)
  OR (t1.b=t2.b AND t2.b IS NULL);
```

7.3.1.5 LEFT JOIN and RIGHT JOIN Optimization

MySQL implements a *A* LEFT JOIN *B* join_condition as follows:

- Table *B* is set to depend on table *A* and all tables on which *A* depends.
- Table *A* is set to depend on all tables (except *B*) that are used in the LEFT JOIN condition.
- The LEFT JOIN condition is used to decide how to retrieve rows from table *B*. (In other words, any condition in the WHERE clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependence, MySQL issues an error.
- All standard WHERE optimizations are performed.
- If there is a row in *A* that matches the WHERE clause, but there is no row in *B* that matches the ON condition, an extra *B* row is generated with all columns set to NULL.
- If you use LEFT JOIN to find rows that do not exist in some table and you have the following test: *col_name* IS NULL in the WHERE part, where *col_name* is a column that is declared as NOT NULL, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the LEFT JOIN condition.

The implementation of RIGHT JOIN is analogous to that of LEFT JOIN with the roles of the tables reversed.

The join optimizer calculates the order in which tables should be joined. The table read order forced by LEFT JOIN or STRAIGHT_JOIN helps the join optimizer do its work much more quickly, because there are fewer table permutations to check. Note that this means that if you do a query of the following type, MySQL does a full scan on b because the LEFT JOIN forces it to be read before d:

```
SELECT *
  FROM a JOIN b LEFT JOIN c ON (c.key=a.key) LEFT JOIN d ON (d.key=a.key)
  WHERE b.key=d.key;
```

The fix in this case is reverse the order in which a and b are listed in the FROM clause:

```
SELECT *
  FROM b JOIN a LEFT JOIN c ON (c.key=a.key) LEFT JOIN d ON (d.key=a.key)
```

```
  WHERE b.key=d.key;
```

Starting from 4.0.14, for a LEFT JOIN , if the WHERE condition is always false for the generated NULL row, the LEFT JOIN is changed to a normal join. For example, the WHERE clause would be false in the following query if t2.column1 were NULL:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to a normal join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

This can be made faster because MySQL can use table t2 before table t1 if doing so would result in a better query plan. To provide a hint about the table join order, use STRAIGHT_JOIN. (See Section 12.2.7, “SELECT Syntax”.)

7.3.1.6 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables t1, t2, and t3 is to be executed using the following join types:

```
Table   Join Type
t1      range
t2      ref
t3      ALL
```

If a simple NLJ algorithm is used, the join would be processed like this:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    for each row in t3 {
      if row satisfies join conditions,
      send to client
    }
  }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, tables processed in the inner loops typically are read many times.

Block Nested-Loop Join Algorithm

A Block Nested-Loop (BNL) Join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. The reduces the number of times the inner table must be read by an order of magnitude.

MySQL uses join buffering under these conditions:

- The join_buffer_size [415] system variable determines the size of each join buffer.

- Join buffering can be used when the join is of type ALL [569] or index [568] (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or range [568].
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.
- A join buffer is never allocated for the first nonconst table, even if it would be of type ALL [569] or index [568].
- A join buffer is allocated prior to executing the join and freed after the query is done.
- Only columns of interest to the join are stored in the join buffer, not whole rows.

For the example join described previously for the NLJ algorithm (without buffering), the join would be done as follow using join buffering:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    store used columns from t1, t2 in join buffer
    if buffer is full {
      for each row in t3 {
        for each t1, t2 combination in join buffer {
          if row satisfies join conditions,
          send to client
        }
      }
      empty buffer
    }
  }
}

if buffer is not empty {
  for each row in t3 {
    for each t1, t2 combination in join buffer {
      if row satisfies join conditions,
      send to client
    }
  }
}
```

If *S* is the size of each stored t1, t2 combination is the join buffer and *C* is the number of combinations in the buffer, the number of times table t3 is scanned is:

```
(S * C)/join_buffer_size + 1
```

One implication is that the number of t3 scans decreases as the value of join_buffer_size [415] increases, up to the point when join_buffer_size [415] is large enough to hold all previous row combinations. At that point, there is no speed to be gained by making it larger.

7.3.1.7 ORDER BY Optimization

In some cases, MySQL can use an index to satisfy an ORDER BY clause without doing any extra sorting.

The index can also be used even if the ORDER BY does not match the index exactly, as long as all of the unused portions of the index and all the extra ORDER BY columns are constants in the WHERE clause. The following queries use the index to resolve the ORDER BY part:

```
SELECT * FROM t1
  ORDER BY key_part1,key_part2,... ;

SELECT * FROM t1
  WHERE key_part1=constant
  ORDER BY key_part2;

SELECT * FROM t1
  ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
  WHERE key_part1=1
  ORDER BY key_part1 DESC, key_part2 DESC;
```

In some cases, MySQL *cannot* use indexes to resolve the ORDER BY, although it still uses indexes to find the rows that match the WHERE clause. These cases include the following:

- You use ORDER BY on different keys:

  ```
  SELECT * FROM t1 ORDER BY key1, key2;
  ```

- You use ORDER BY on nonconsecutive parts of a key:

  ```
  SELECT * FROM t1 WHERE key2=constant ORDER BY key_part2;
  ```

- You mix ASC and DESC:

  ```
  SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;
  ```

- The key used to fetch the rows is not the same as the one used in the ORDER BY:

  ```
  SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
  ```

- You use ORDER BY with an expression that includes terms other than the key column name:

  ```
  SELECT * FROM t1 ORDER BY ABS(key);
  SELECT * FROM t1 ORDER BY -key;
  ```

- You are joining many tables, and the columns in the ORDER BY are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the EXPLAIN output that does not have a const [567] join type.)

- You have different ORDER BY and GROUP BY expressions.

- You index only a prefix of a column named in the ORDER BY clause. In this case, the index cannot be used to fully resolve the sort order. For example, if you have a CHAR(20) column, but index only the first 10 bytes, the index cannot distinguish values past the 10th byte and a filesort will be needed.

- The type of table index used does not store rows in order. For example, this is true for a HASH index in a MEMORY table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column t1.a is indexed. In this statement, the name of the column in the select list is a. It refers to t1.a, so for the reference to a in the ORDER BY, the index can be used:

```
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also a, but it is the alias name. It refers to ABS(a), so for the reference to a in the ORDER BY, the index cannot be used:

```
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the ORDER BY refers to a name that is not the name of a column in the select list. But there is a column in t1 named a, so the ORDER BY uses that, and the index can be used. (The resulting sort order may be completely different from the order for ABS(a), of course.)

```
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

By default, MySQL sorts all GROUP BY *col1, col2, ...* queries as if you specified ORDER BY *col1, col2, ...* in the query as well. If you include an explicit ORDER BY clause that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs. If a query includes GROUP BY but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying ORDER BY NULL. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```

With EXPLAIN SELECT ... ORDER BY, you can check whether MySQL can use indexes to resolve the query. It cannot if you see Using filesort in the Extra column. See Section 7.2.1, “Optimizing Queries with EXPLAIN”.

MySQL has two filesort algorithms for sorting and retrieving results. The original method uses only the ORDER BY columns. The modified method uses not just the ORDER BY columns, but all the columns used in the query.

The optimizer selects which filesort algorithm to use. Prior to MySQL 4.1, it uses the original algorithm. As of MySQL 4.1, it normally uses the modified algorithm except when BLOB or TEXT columns are involved, in which case it uses the original algorithm.

The original filesort algorithm works as follows:

1. Read all rows according to key or by table scanning. Rows that do not match the WHERE clause are skipped.
2. For each row, store a pair of values in a buffer (the sort key and the row pointer). The size of the buffer is the value of the sort_buffer_size [427] system variable.
3. When the buffer gets full, run a qsort (quicksort) on it and store the result in a temporary file. Save a pointer to the sorted block. (If all pairs fit into the sort buffer, no temporary file is created.)
4. Repeat the preceding steps until all rows have been read.
5. Do a multi-merge of up to MERGEBUFF (7) regions to one block in another temporary file. Repeat until all blocks from the first file are in the second file.
6. Repeat the following until there are fewer than MERGEBUFF2 (15) blocks left.
7. On the last multi-merge, only the pointer to the row (the last part of the sort key) is written to a result file.
8. Read the rows in sorted order by using the row pointers in the result file. To optimize this, we read in a big block of row pointers, sort them, and use them to read the rows in sorted order into a row buffer.

The size of the buffer is the value of the read_rnd_buffer_size [426] system variable. The code for this step is in the sql/records.cc source file.

One problem with this approach is that it reads rows twice: One time when evaluating the WHERE clause, and again after sorting the pair values. And even if the rows were accessed successively the first time (for example, if a table scan is done), the second time they are accessed randomly. (The sort keys are ordered, but the row positions are not.)

The modified filesort algorithm incorporates an optimization such that it records not only the sort key value and row position, but also the columns required for the query. This avoids reading the rows twice. The modified filesort algorithm works like this:

1. Read the rows that match the WHERE clause.
2. For each row, record a tuple of values consisting of the sort key value and row position, and also the columns required for the query.
3. Sort the tuples by sort key value
4. Retrieve the rows in sorted order, but read the required columns directly from the sorted tuples rather than by accessing the table a second time.

Using the modified filesort algorithm, the tuples are longer than the pairs used in the original method, and fewer of them fit in the sort buffer (the size of which is given by sort_buffer_size [427]). As a result, it is possible for the extra I/O to make the modified approach slower, not faster. To avoid a slowdown, the optimization is used only if the total size of the extra columns in the sort tuple does not exceed the value of the max_length_for_sort_data [420] system variable. (A symptom of setting the value of this variable too high is that you should see high disk activity and low CPU activity.)

For slow queries for which filesort is not used, you might try lowering max_length_for_sort_data [420] to a value that is appropriate to trigger a filesort.

If you want to increase ORDER BY speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, you can try the following strategies:

- Increase the size of the sort_buffer_size [427] variable.
- Increase the size of the read_rnd_buffer_size [426] variable.
- Use less RAM per row by declaring columns only as large as they need to be to hold the values stored in them. For example, CHAR(16) is better than CHAR(200) if values never exceed 16 characters.
- Change tmpdir [432] to point to a dedicated file system with large amounts of free space. Also, if you use MySQL 4.1 or later, this option accepts several paths that are used in round-robin fashion, so you you can use this feature to spread the load across several directories. Paths should be separated by colon characters (“:”) on Unix and semicolon characters (“;”) on Windows, NetWare, and OS/2. The paths should be for directories in file systems that are located on different *physical* disks, not different partitions on the same disk.

7.3.1.8 GROUP BY Optimization

The most general way to satisfy a GROUP BY clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and to avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for GROUP BY are that all GROUP BY columns reference attributes from the same index, and that the index stores its keys in order (for example, this is a

BTREE index, and not a HASH index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

The following section details how a GROUP BY query can be executed through index access. The method first performs a range scan, and then groups the resulting tuples.

In MySQL, GROUP BY is used for sorting, so the server may also apply ORDER BY optimizations to grouping. See Section 7.3.1.7, “ORDER BY Optimization”.

Tight Index Scan

A tight index scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a loose index scan are not met, it still may be possible to avoid creation of temporary tables for GROUP BY queries. If there are range conditions in the WHERE clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the WHERE clause, or scans the whole index if there are no range conditions, we term it a *tight index scan*. With a tight index scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there is a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the GROUP BY key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If we require sorting of the GROUP BY result, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index idx(c1,c2,c3) on table t1(c1,c2,c3,c4). The following queries do not work with the loose index scan access method described earlier, but still work with the tight index scan access method.

- There is a gap in the GROUP BY, but it is covered by the condition c2 = 'a':

```
SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
```

- The GROUP BY does not begin with the first part of the key, but there is a condition that provides a constant for that part:

```
SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
```

7.3.1.9 DISTINCT Optimization

DISTINCT combined with ORDER BY needs a temporary table in many cases.

Because DISTINCT may use GROUP BY, you should be aware of how MySQL works with columns in ORDER BY or HAVING clauses that are not part of the selected columns. See Section 11.15.3, “GROUP BY and HAVING with Hidden Columns”.

In most cases, a DISTINCT clause can be considered as a special case of GROUP BY. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;
```

```
SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to GROUP BY queries can be also applied to queries with a DISTINCT clause. Thus, for more details on the optimization possibilities for DISTINCT queries, see Section 7.3.1.8, "GROUP BY Optimization".

When combining LIMIT *row_count* with DISTINCT, MySQL stops as soon as it finds *row_count* unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that t1 is used before t2 (which you can check with EXPLAIN), MySQL stops reading from t2 (for any particular row in t1) when it finds the first row in t2:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

7.3.1.10 LIMIT Optimization

In some cases, MySQL handles a query differently when you are using LIMIT *row_count* and not using HAVING:

- If you are selecting only a few rows with LIMIT, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.
- If you use LIMIT *row_count* with ORDER BY, MySQL ends the sorting as soon as it has found the first *row_count* rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the LIMIT clause must be selected, and most or all of them must be sorted, before it can be ascertained that the first *row_count* rows have been found. In either case, after the initial rows have been found, there is no need to sort any remainder of the result set, and MySQL does not do so.
- When combining LIMIT *row_count* with DISTINCT, MySQL stops as soon as it finds *row_count* unique rows.
- In some cases, a GROUP BY can be resolved by reading the key in order (or doing a sort on the key) and then calculating summaries until the key value changes. In this case, LIMIT *row_count* does not calculate any unnecessary GROUP BY values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using SQL_CALC_FOUND_ROWS.
- LIMIT 0 quickly returns an empty set. This can be useful for checking the validity of a query. When using one of the MySQL APIs, it can also be employed for obtaining the types of the result columns. (This trick does not work in the MySQL Monitor (the mysql program), which merely displays Empty set in such cases; you should instead use SHOW COLUMNS or DESCRIBE for this purpose.)
- When the server uses temporary tables to resolve the query, it uses the LIMIT *row_count* clause to calculate how much space is required.

7.3.1.11 How to Avoid Table Scans

The output from EXPLAIN shows ALL in the type column when MySQL uses a table scan to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.

- There are no usable restrictions in the ON or WHERE clause for indexed columns.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See Section 7.3.1.2, “WHERE Clause Optimization”.
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use ANALYZE TABLE *tbl_name* to update the key distributions for the scanned table. See Section 12.4.2.1, “ANALYZE TABLE Syntax”.
- Use FORCE INDEX for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
  WHERE t1.col_name=t2.col_name;
```

  See Section 12.2.7.2, “Index Hint Syntax”.
- Start mysqld with the --max-seeks-for-key=1000 [420] option or use SET max_seeks_for_key=1000 to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.3, “Server System Variables”.

7.3.2 Optimizing Non-SELECT Statements

7.3.2.1 Speed of INSERT Statements

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)
- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by log *N*, assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use INSERT statements with multiple VALUES lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row INSERT statements. If you are adding data to a nonempty

table, you can tune the bulk_insert_buffer_size [408] variable to make data insertion even faster. See Section 5.1.3, “Server System Variables”.

- If multiple clients are inserting a lot of rows, you can get higher speed by using the INSERT DELAYED statement. See Section 12.2.4.2, “INSERT DELAYED Syntax”.
- For a MyISAM table, you can use concurrent inserts to add rows at the same time that SELECT statements are running, if there are no deleted rows in middle of the data file. See Section 7.6.3, “Concurrent Inserts”.
- When loading a table from a text file, use LOAD DATA INFILE. This is usually 20 times faster than using INSERT statements. See Section 12.2.5, “LOAD DATA INFILE Syntax”.
- With some extra work, it is possible to make LOAD DATA INFILE run even faster for a MyISAM table when the table has many indexes. Use the following procedure:

  1. Optionally create the table with CREATE TABLE.
  2. Execute a FLUSH TABLES statement or a mysqladmin flush-tables command.
  3. Use myisamchk --keys-used=0 -rq */path/to/db/tbl_name*. This removes all use of indexes for the table.
  4. Insert data into the table with LOAD DATA INFILE. This does not update any indexes and therefore is very fast.
  5. If you intend only to read from the table in the future, use myisampack to compress it. See Section 13.1.3.3, “Compressed Table Characteristics”.
  6. Re-create the indexes with myisamchk -rq */path/to/db/tbl_name*. This creates the index tree in memory before writing it to disk, which is much faster that updating the index during LOAD DATA INFILE because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
  7. Execute a FLUSH TABLES statement or a mysqladmin flush-tables command.

  LOAD DATA INFILE performs the preceding optimization automatically if the MyISAM table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let myisamchk allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the LOAD DATA INFILE statement.

  As of MySQL 4.0, you can also disable or enable the nonunique indexes for a MyISAM table by using the following statements rather than myisamchk. If you use these statements, you can skip the FLUSH TABLE operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up INSERT operations that are performed with multiple statements for nontransactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all INSERT statements have completed. Normally, there would be as many index buffer flushes as there are INSERT statements. Explicit locking statements are not needed if you can insert all rows with a single INSERT.

To obtain faster insertions for transactional tables, you should use START TRANSACTION and COMMIT instead of LOCK TABLES.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert
- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

INSERT, UPDATE, and DELETE operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a LOCK TABLES followed by an UNLOCK TABLES once in a while (each 1,000 rows or so) to permit other threads to access the table. This would still result in a nice performance gain.

INSERT is still much slower for loading data than LOAD DATA INFILE, even when using the strategies just outlined.

- To increase performance for MyISAM tables, for both LOAD DATA INFILE and INSERT, enlarge the key cache by increasing the key_buffer_size [415] system variable. See Section 7.8.2, “Tuning Server Parameters”.

7.3.2.2 Speed of UPDATE Statements

An update statement is optimized like a SELECT query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a MyISAM table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use OPTIMIZE TABLE occasionally. See Section 12.4.2.5, “OPTIMIZE TABLE Syntax”.

7.3.2.3 Speed of DELETE Statements

The time required to delete individual rows is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the key_buffer_size [415] system variable. See Section 7.8.2, “Tuning Server Parameters”.

To delete all rows from a table, TRUNCATE TABLE *tbl_name* is faster than than DELETE FROM *tbl_name*. Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See Section 12.1.10, “TRUNCATE TABLE Syntax”.

7.3.2.4 Speed of REPAIR TABLE Statements

REPAIR TABLE for MyISAM tables is similar to using myisamchk for repair operations, and some of the same performance optimizations apply:

- myisamchck has variables that control memory allocation. You may be able to its improve performance by setting these variables, as described in Section 4.6.2.6, “myisamchk Memory Usage”.
- For REPAIR TABLE, the same principle applies, but because the repair is done by the server, you set server system variables instead of myisamchk variables. Also, In addition to setting memory-allocation variables, increasing the myisam_max_sort_file_size [421] system variable increases the likelihood that the repair will use the faster filesort method and avoid the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a myisamchk table-repair operation is done using the following options to set its memory-allocation variables:

```
--key_buffer_size=128M --sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those myisamchk variables correspond to server system variables:

myisamchk Variable	System Variable
key_buffer_size	key_buffer_size [415]
sort_buffer_size	myisam_sort_buffer_size [421]
read_buffer_size	read_buffer_size [425]
write_buffer_size	none

Each of the server system variables can be set at runtime, and some of them (myisam_sort_buffer_size [421], read_buffer_size [425]) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (key_buffer_size [415], myisam_max_sort_file_size [421]) affects other users as well. For key_buffer_size [415], you must take into account that the buffer is shared with those users. For example, if you set the myisamchk key_buffer_size variable to 128MB, you could set the corresponding key_buffer_size [415] system variable larger than that (if it is not already set larger), to allow for key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See Section 7.5.1.2, “Multiple Key Caches”.

Based on the preceding remarks, a REPAIR TABLE operation can be done as follows to use settings similar to the myisamchk command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
REPAIR TABLE tbl_name ;
```

```
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a `REPAIR TABLE` operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```
SET @old_myisam_sort_buffer_size = @@global.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE tbl_name ;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```

The system variables that affect `REPAIR TABLE` can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server `my.cnf` file:

```
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include `read_buffer_size` [425]. Setting `read_buffer_size` [425] globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.

7.3.3 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- Use persistent connections to the database to avoid connection overhead. If you cannot use persistent connections and you are initiating many new connections to the database, you may want to change the value of the `thread_cache_size` [431] variable. See Section 7.8.2, “Tuning Server Parameters”.
- Always check whether all your queries really use the indexes that you have created in the tables. In MySQL, you can do this with the `EXPLAIN` statement. See Section 7.2.1, “Optimizing Queries with `EXPLAIN`”.
- Try to avoid complex `SELECT` queries on `MyISAM` tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.
- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, you should consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. See Section 7.6.3, “Concurrent Inserts”.
- To fix any compression issues that may have occurred with `ARCHIVE` tables, you can use `OPTIMIZE TABLE`. See Section 13.7, “The `ARCHIVE` Storage Engine”.
- Use `ALTER TABLE ... ORDER BY` *`expr1, expr2, ...`* if you usually retrieve rows in *`expr1, expr2, ...`* order. By using this option after extensive changes to the table, you may be able to get higher performance.
- In some cases, it may make sense to introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it may be much faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
  WHERE hash_col=MD5(CONCAT(col1,col2))
```

```
  AND col1='constant' AND col2='constant';
```

- For MyISAM tables that change frequently, you should try to avoid all variable-length columns (VARCHAR, BLOB, and TEXT). The table uses dynamic row format if it includes even a single variable-length column. See Chapter 13, *Storage Engines*.

- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a MyISAM table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See Chapter 13, *Storage Engines*.

- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

  ```
  UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
  ```

  This is very important when you use MySQL storage engines such as MyISAM and ISAM that have only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- If you need to collect statistics from large log tables, use summary tables instead of scanning the entire log table. Maintaining the summaries should be much faster than trying to calculate statistics “live.” Regenerating new summary tables from the logs when things change (depending on business decisions) is faster than changing the running application.

- If possible, you should classify reports as “live” or as “statistical,” where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.

- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.

- In some cases, it is convenient to pack and store data into a BLOB column. In this case, you must provide code in your application to pack and unpack information, but this may save a lot of accesses at some stage. This is practical when you have data that does not conform well to a rows-and-columns table structure.

- Normally, you should try to keep all data nonredundant (observing what is referred to in database theory as *third normal form*). However, there may be situations in which it can be advantageous to duplicate information or create summary tables to gain more speed.

- UDFs (user-defined functions) may be a good way to get more performance for some tasks. See Section 18.2, “Adding New Functions to MySQL”, for more information.

- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. If your database system supports table locks, this should help to ensure that the index cache is only flushed once after all updates. You can also take advantage of MySQL's query cache to achieve similar results; see Section 7.5.3, “The MySQL Query Cache”.

- Use INSERT DELAYED when you do not need to know when your data is written. This reduces the overall insertion impact because many rows can be written with a single disk write.

- Use INSERT LOW_PRIORITY when you want to give SELECT statements higher priority than your inserts.

Use `SELECT HIGH_PRIORITY` to get retrievals that jump the queue. That is, the `SELECT` is executed even if there is another client waiting to do a write.

`LOW_PRIORITY` and `HIGH_PRIORITY` have an effect only for storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- Use multiple-row `INSERT` statements to store many rows with one SQL statement. Many SQL servers support this, including MySQL.
- Use `LOAD DATA INFILE` to load large amounts of data. This is faster than using `INSERT` statements.
- Use `AUTO_INCREMENT` columns so that each row in a table can be identified by a single unique value. unique values.
- Use `OPTIMIZE TABLE` once in a while to avoid fragmentation with dynamic-format `MyISAM` tables. See Section 13.1.3, “`MyISAM` Table Storage Formats”.
- Use `MEMORY` (`HEAP`) tables when possible to get more speed. See Section 13.4, “The `MEMORY` (`HEAP`) Storage Engine”. `MEMORY` tables are useful for noncritical data that is accessed often, such as information about the last displayed banner for users who don't have cookies enabled in their Web browser. User sessions are another alternative available in many Web application environments for handling volatile state data.
- With Web servers, images and other binary assets should normally be stored as files. That is, store only a reference to the file rather than the file itself in the database. Most Web servers are better at caching files than database contents, so using files is generally faster.
- Columns with identical information in different tables should be declared to have identical data types so that joins based on the corresponding columns will be faster. Before MySQL 3.23, you get slow joins otherwise.

  Try to keep column names simple. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, you should keep them shorter than 18 characters.
- If you need really high speed, you should take a look at the low-level interfaces for data storage that the different SQL servers support. For example, by accessing the MySQL `MyISAM` storage engine directly, you could get a speed increase of two to five times compared to using the SQL interface. To be able to do this, the data must be on the same server as the application, and usually it should only be accessed by one process (because external file locking is really slow). One could eliminate these problems by introducing low-level `MyISAM` commands in the MySQL server (this could be one easy way to get more performance if needed). By carefully designing the database interface, it should be quite easy to support this type of optimization.
- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you need not parse your text files to find line and column boundaries.
- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See Chapter 14, *Replication*.
- Declaring a `MyISAM` table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you should ensure that the table is okay by running the server

with the `--myisam-recover` [390] option, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

7.4 Optimization and Indexes

7.4.1 Column Indexes

All MySQL data types can be indexed. Use of indexes on the relevant columns is the best way to improve the performance of `SELECT` operations.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See Chapter 13, *Storage Engines*. All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

The `MyISAM` and (as of MySQL 4.0.14) `InnoDB` storage engines also support indexing on `BLOB` and `TEXT` columns. When indexing a `BLOB` or `TEXT` column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for `InnoDB` tables). (Before MySQL 4.1.2, the limit is 255 bytes for all tables.) Note that prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE` statements is interpreted as number of characters. *Be sure to take this into account when specifying a prefix length for a column that uses a multi-byte character set*.

As of MySQL 3.23.23, you can also create `FULLTEXT` indexes. They are used for full-text searches. Only the `MyISAM` storage engine supports `FULLTEXT` indexes and only for `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see Section 11.9, “Full-Text Search Functions”.

As of MySQL 4.1.0, you can create indexes on spatial data types. Spatial indexes use R-trees. Currently, only `MyISAM` supports indexes on spatial types.

The `MEMORY` (`HEAP`) storage engine uses `HASH` indexes by default. It also supports `BTREE` indexes as of MySQL 4.1.0.

7.4.2 Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see Section 7.4.1, “Column Indexes”).

A multiple-column index can be considered a sorted array containing values that are created by concatenating the values of the indexed columns.

MySQL uses multiple-column indexes in such a way that queries are fast when you specify a known quantity for the first column of the index in a `WHERE` clause, even if you do not specify values for the other columns.

Suppose that a table has the following specification:

```
CREATE TABLE test (
```

```
    id         INT NOT NULL,
    last_name  CHAR(30) NOT NULL,
    first_name CHAR(30) NOT NULL,
    PRIMARY KEY (id),
    INDEX name (last_name,first_name)
);
```

The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for queries that specify values in a known range for `last_name`, or for both `last_name` and `first_name`. Therefore, the `name` index is used in the following queries:

```
SELECT * FROM test WHERE last_name='Widenius';

SELECT * FROM test
  WHERE last_name='Widenius' AND first_name='Michael';

SELECT * FROM test
  WHERE last_name='Widenius'
  AND (first_name='Michael' OR first_name='Monty');

SELECT * FROM test
  WHERE last_name='Widenius'
  AND first_name >='M' AND first_name < 'N';
```

However, the `name` index is *not* used in the following queries:

```
SELECT * FROM test WHERE first_name='Michael';

SELECT * FROM test
  WHERE last_name='Widenius' OR first_name='Michael';
```

The manner in which MySQL uses indexes to improve query performance is discussed further in Section 7.4.3, “How MySQL Uses Indexes”.

7.4.3 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. If a table has 1,000 rows, this is at least 100 times faster than reading sequentially. If you need to access most of the rows, it is faster to read sequentially, because this minimizes disk seeks.

Most MySQL indexes (`PRIMARY KEY`, `UNIQUE`, `INDEX`, and `FULLTEXT`) are stored in B-trees. Exceptions are that indexes on spatial data types use R-trees, and that `MEMORY` (`HEAP`) tables support hash indexes.

Strings are automatically prefix- and end-space compressed. See Section 12.1.4, “`CREATE INDEX` Syntax”.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in `MEMORY` tables) are described at the end of this section.

MySQL uses indexes for these operations:

- To find the rows matching a `WHERE` clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows.

- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. For example, `VARCHAR(10)` and `CHAR(10)` are the same size, but `VARCHAR(10)` and `CHAR(15)` are not.

  Comparison of dissimilar columns may prevent use of indexes if values cannot be compared directly without conversion. Suppose that a numeric column is compared to a string column. For a given value such as `1` in the numeric column, it might compare equal to any number of values in the string column such as `'1'`, `' 1'`, `'00001'`, or `'01.e1'`. This rules out use of any indexes for the string column.

- To find the `MIN()` [884] or `MAX()` [884] value for a specific indexed column *`key_col`*. This is optimized by a preprocessor that checks whether you are using `WHERE key_part_N = constant` on all key parts that occur before *`key_col`* in the index. In this case, MySQL does a single key lookup for each `MIN()` [884] or `MAX()` [884] expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```
SELECT MIN(key_part2),MAX(key_part2)
  FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable key (for example, `ORDER BY key_part1, key_part2`). If all key parts are followed by `DESC`, the key is read in reverse order. See Section 7.3.1.7, “`ORDER BY` Optimization”, and Section 7.3.1.8, “`GROUP BY` Optimization”.

- In some cases, a query can be optimized to retrieve values without consulting the data rows. If a query uses only columns from a table that are numeric and that form a leftmost prefix for some key, the selected values may be retrieved from the index tree for greater speed:

```
SELECT key_part3 FROM tbl_name
  WHERE key_part1=1
```

Suppose that you issue the following `SELECT` statement:

```
mysql> SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer tries to find the most restrictive index by deciding which index finds fewer rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to find rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`.

MySQL cannot use an index if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;

SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve indexed columns, but `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)`.

B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the = [782], > [783], >= [782], < [782], <= [782], or BETWEEN [783] operators. The index also can be used for LIKE [804] comparisons if the argument to LIKE [804] is a constant string that does not start with a wildcard character. For example, the following SELECT statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%_ck%';
```

In the first statement, only rows with `'Patrick' <= key_col < 'Patricl'` are considered. In the second statement, only rows with `'Pat' <= key_col < 'Pau'` are considered.

The following SELECT statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the LIKE [804] value begins with a wildcard character. In the second statement, the LIKE [804] value is not a constant.

MySQL 4.0 and later versions perform an additional LIKE [804] optimization. If you use `... LIKE '%string%'` and *`string`* is longer than three characters, MySQL uses the *Turbo Boyer-Moore algorithm* to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using *`col_name`* `IS NULL` employs indexes if *`col_name`* is indexed.

Any index that does not span all AND [787] levels in the WHERE clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every AND [787] group.

The following WHERE clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3
    /* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2
    /* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5
    /* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These WHERE clauses do *not* use indexes:

```
    /* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2

    /*  Index is not used in both parts of the WHERE clause  */
... WHERE index=1 OR A=10

    /* No index spans all rows  */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses LIMIT to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the = or <=> operators (but are *very* fast). They are not used for comparison operators such as < that find a range of values.
- The optimizer cannot use a hash index to speed up ORDER BY operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a MyISAM table to a hash-indexed MEMORY table.
- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

7.4.4 MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how may rows must be read for each ref [567] access
- To estimate how many row a partial join will produce; that is, the number of rows that an operation of this form will produce:

```
(...) JOIN tbl_name ON tbl_name.key = expr
```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The SHOW INDEX statement displays a cardinality value based on *N*/*S*, where *N* is the number of rows in the table and *S* is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the <=> comparison operator, NULL is not treated differently from any other value: NULL <=> NULL, just as *N* <=> *N* for any other *N*.

However, for a join based on the = operator, NULL is different from non-NULL values: *expr1* = *expr2* is not true when *expr1* or *expr2* (or both) are NULL. This affects ref [567] accesses for comparisons of the form *tbl_name.key* = *expr*: MySQL will not access the table if the current value of *expr* is NULL, because the comparison cannot be true.

For = comparisons, it does not matter how many NULL values are in the table. For optimization purposes, the relevant value is the average size of the non-NULL value groups. However, MySQL does not currently enable that average size to be collected or used.

For MyISAM tables, you have some control over collection of table statistics by means of the myisam_stats_method [422] system variable. This variable has three possible values, which differ as follows:

- When myisam_stats_method [422] is nulls_equal, all NULL values are treated as identical (that is, they all form a single value group).

  If the NULL value group size is much higher than the average non-NULL value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-NULL values. Consequently, the nulls_equal method may cause the optimizer not to use the index for ref [567] accesses when it should.

- When myisam_stats_method [422] is nulls_unequal, NULL values are not considered the same. Instead, each NULL value forms a separate value group of size 1.

  If you have many NULL values, this method skews the average value group size downward. If the average non-NULL value group size is large, counting NULL values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-NULL values. Consequently, the nulls_unequal method may cause the optimizer to use this index for ref [567] lookups when other methods may be better.

- When myisam_stats_method [422] is nulls_ignored, NULL values are ignored.

If you tend to use many joins that use <=> rather than =, NULL values are not special in comparisons and one NULL is equal to another. In this case, nulls_equal is the appropriate statistics method.

The myisam_stats_method [422] system variable has global and session values. Setting the global value affects MyISAM statistics collection for all MyISAM tables. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table's statistics to be regenerated with a given method without affecting other clients by setting the session value of myisam_stats_method [422].

To regenerate table statistics, you can use any of the following methods:

- Set myisam_stats_method [422], and then issue a CHECK TABLE statement
- Execute myisamchk --stats_method=*method_name* --analyze
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set myisam_stats_method [422] and issue an ANALYZE TABLE statement

Some caveats regarding the use of myisam_stats_method [422]:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some ALTER TABLE statements, for example.) If this happens, the statistics are collected using whatever value myisam_stats_method [422] has at the time. Thus, if you collect statistics using one method, but myisam_stats_method [422] is set to the other method when a table's statistics are collected automatically later, the other method will be used.
- There is no way to tell which method was used to generate statistics for a given MyISAM table.
- myisam_stats_method [422] applies only to MyISAM tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the nulls_equal method.

7.5 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

7.5.1 The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses changes made in MySQL 4.1 that improve key cache performance and that enable you to better control cache operation:

- Access to the key cache no longer is serialized among threads. Multiple sessions can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

The key cache mechanism also is used for ISAM tables. However, the significance of this fact is on the wane. ISAM table use has been decreasing since MySQL 3.23 when MyISAM was introduced. MySQL 4.1 carries this trend further; the ISAM storage engine is disabled by default. (Subsequent MySQL release series have no support at all for ISAM.)

To control the size of the key cache, use the key_buffer_size [415] system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the key_buffer_size [415] value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an *LRU (Least Recently Used)* strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (*LRU chain*) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The InnoDB storage engine also uses an LRU algorithm, to manage its buffer pool. See Section 7.5.2, “The InnoDB Buffer Pool”.

7.5.1.1 Shared Key Cache Access

Prior to MySQL 4.1, access to the key cache is serialized: No two threads can access key cache buffers simultaneously. The server processes a request for an index block only after it has finished processing the previous request. As a result, a request for an index block not present in any key cache buffer blocks access by other threads while a buffer is being updated to contain the requested index block.

Starting from version 4.1.0, the server supports shared access to the key cache:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

7.5.1.2 Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL 4.1.1 also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given `MyISAM` table. By default, all `MyISAM` table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the `CACHE INDEX` statement (see Section 12.4.6.1, “`CACHE INDEX` Syntax”). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+---------+--------------------+----------+----------+
| Table   | Op                 | Msg_type | Msg_text |
+---------+--------------------+----------+----------+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+---------+--------------------+----------+----------+
```

Note

If the server has been built with the `ISAM` storage engine enabled, `ISAM` tables use the key cache mechanism. However, `ISAM` indexes use only the default key cache and cannot be reassigned to a different cache.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a `SET GLOBAL` parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

Note that you cannot destroy the default key cache. Any attempt to do this will be ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----------------+---------+
| Variable_name   | Value   |
+-----------------+---------+
| key_buffer_size | 8384512 |
+-----------------+---------+
```

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size` [415] is the cache component. See Section 5.1.4.1, “Structured System Variables”, for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read in from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The `CACHE INDEX` statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init-file` option that names a file containing `CACHE INDEX` statements to be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql
```

The statements in mysqld_init.sql are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to hot_cache and cold_cache:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

7.5.1.3 Midpoint Insertion Strategy

By default, the key cache management system of MySQL 4.1 uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the *midpoint insertion strategy*.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not "too short," always containing at least key_cache_division_limit [416] percent of the key cache blocks. key_cache_division_limit [416] is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the key_cache_age_threshold [416] component of the key cache.

The threshold value prescribes that, for a key cache containing *N* blocks, the block at the beginning of the hot sublist not accessed within the last `N * key_cache_age_threshold / 100` hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the key_cache_division_limit [416] value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the key_cache_division_limit [416] set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

7.5.1.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the LOAD INDEX INTO CACHE statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables t1 and t2:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+---------+--------------+----------+----------+
```

The IGNORE LEAVES modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from t1, but only blocks for the nonleaf nodes from t2.

If an index has been assigned to a key cache using a CACHE INDEX statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

7.5.1.5 Key Cache Block Size

MySQL 4.1 introduces a new key_cache_block_size [416] variable on a per-key cache basis. This variable specifies the size of the block buffers for a key cache. It is intended to enable tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the .MYI index file of MyISAM tables, use the --myisam-block-size [390] option at server startup.

7.5.1.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the key_buffer_size [415] or key_cache_block_size [416] key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

7.5.2 The InnoDB Buffer Pool

InnoDB maintains a buffer pool for caching data and indexes in memory. InnoDB manages the pool as a list, using a least recently used (LRU) algorithm incorporating a midpoint insertion strategy. When room is needed to add a new block to the pool, InnoDB evicts the least recently used block and adds the new

block to the middle of the list. The midpoint insertion strategy in effect causes the list to be treated as two sublists:

- At the head, a sublist of “new” (or “young”) blocks that have been recently used.
- At the tail, a sublist of “old” blocks that are less recently used.

As a result of the algorithm, the new sublist contains blocks that are heavily used by queries. The old sublist contains less-used blocks, and candidates for eviction are taken from this sublist.

The LRU algorithm operates as follows by default:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When `InnoDB` reads a block into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A block can be read in as a result of two types of read requests: Because it is required (for example, to satisfy query execution), or as part of read-ahead performed in anticipation that it will be required.
- The first access to a block in the old sublist makes it “young”, causing it to move to the head of the buffer pool (the head of the new sublist). If the block was read in because it was required, the first access occurs immediately and the block is made young. If the block was read in due to read-ahead, the first access does not occur immediately (and might not occur at all before the block is evicted).
- As long as no accesses occur for a block in the pool, it “ages” by moving toward the tail of the list. Blocks in both the new and old sublists age as other blocks are made new. Blocks in the old sublist also age as blocks are inserted at the midpoint. Eventually, a block that remains unused for long enough reaches the tail of the old sublist and is evicted.

In the default operation of the buffer pool, a block when read in is loaded at the midpoint and then moved immediately to the head of the new sublist as soon as an access occurs. In the case of a table scan (such as performed for a `mysqldump` operation), each block read by the scan ends up moving to the head of the new sublist because multiple rows are accessed from each block. This occurs even for a one-time scan, where the blocks are not otherwise used by other queries. Blocks may also be loaded by the read-ahead background thread and then moved to the head of the new sublist by a single access. These effects can be disadvantageous because they push blocks that are in heavy use by other queries out of the new sublist to the old sublist where they become subject to eviction.

The `innodb_buffer_pool_size` [1067] system variable specifies the size of the buffer pool. If your buffer pool is small and you have sufficient memory, making the pool larger can improve performance by reducing the amount of disk I/O needed as queries access `InnoDB` tables.

The `MyISAM` storage engine also uses an LRU algorithm, to manage its key cache. See Section 7.5.1, “The `MyISAM` Key Cache”.

7.5.3 The MySQL Query Cache

From version 4.0.1 on, MySQL Server features a query cache. When in use, the query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again. The query cache is shared among sessions, so a result set generated by one client can be sent in response to the same query issued by another client.

The query cache can be useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content.

The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

Note

The query cache does not work in an environment where you have multiple `mysqld` servers updating the same `MyISAM` tables.

Note

The query cache is not used for prepared statements. If you are using prepared statements, consider that these statements will not be satisfied by the query cache. See Section 17.6.7, “C API Prepared Statements”.

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2×500MHz system with 2GB RAM and a 64MB query cache.

- If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.
- Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` [424] system variable to 0. By disabling the query cache code, there is no noticeable overhead. If you build MySQL from source, query cache capabilities can be excluded from the server entirely by invoking `configure` with the `--without-query-cache` option.

The query cache offers the potential for substantial performance improvement, but you should not assume that it will do so under all circumstances. With some query cache configurations or server workloads, you might actually see a performance decrease:

- Be cautious about sizing the query cache excessively large, which increases the overhead required to maintain the cache, possibly beyond the benefit of enabling it. Sizes in tens of megabytes are usually beneficial. Sizes in the hundreds of megabytes might not be.
- Server workload has a significant effect on query cache efficiency. A query mix consisting almost entirely of a fixed set of `SELECT` statements is much more likely to benefit from enabling the cache than a mix in which frequent `INSERT` statements cause continual invalidation of results in the cache. In some cases, a workaround is to use the `SQL_NO_CACHE` option to prevent results from even entering the cache for `SELECT` statements that use frequently modified tables. (See Section 7.5.3.2, “Query Cache `SELECT` Options”.)

To verify that enabling the query cache is beneficial, test the operation of your MySQL server with the cache enabled and disabled. Then retest periodically because query cache efficiency may change as server workload changes.

7.5.3.1 How the Query Cache Operates

This section describes how the query cache works when it is operational. Section 7.5.3.3, “Query Cache Configuration”, describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be *exactly* the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

Because comparison of a query against those in the cache occurs before parsing, the cache is not used for queries of the following types:

- Prepared statements
- Queries that are a subquery of an outer query

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` [453] status variable, not `Com_select`. See Section 7.5.3.4, “Query Cache Status and Maintenance”.

If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

In MySQL 4.0, the query cache is disabled within transactions (it does not return results). Beginning with MySQL 4.1.1, the query cache also works within transactions when using `InnoDB` tables.

A query that begins with a leading comment may be cached, but cannot be fetched from the cache.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS ...` queries and stores a value that is returned by a following `SELECT FOUND_ROWS()` query. `FOUND_ROWS()` [872] returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache. The `SELECT FOUND_ROWS()` query itself cannot be cached.

A query cannot be cached if it contains any of the functions shown in the following table.

`BENCHMARK()` [870]	`CONNECTION_ID()` [872]	`CONVERT_TZ()` [828]
`CURDATE()` [828]	`CURRENT_DATE()` [829]	`CURRENT_TIME()` [829]
`CURRENT_TIMESTAMP()` [829]	`CURTIME()` [829]	`DATABASE()` [872]
`ENCRYPT()` [867] with one parameter	`FOUND_ROWS()` [872]	`GET_LOCK()` [877]
`LAST_INSERT_ID()` [874]	`LOAD_FILE()` [798]	`MASTER_POS_WAIT()` [879]
`NOW()` [837]	`RAND()` [822]	`RELEASE_LOCK()` [879]
`SYSDATE()` [840]	`UNIX_TIMESTAMP()` [841] with no parameters	`USER()` [876]
`UUID()` [879]		

A query also is not cached under these conditions:

- It refers to user-defined functions (UDFs).

- It refers to user variables.
- It refers to tables in the `mysql` system database.
- It is of any of the following forms:

```
SELECT ... LOCK IN SHARE MODE
SELECT ... FOR UPDATE
SELECT ... INTO OUTFILE ...
SELECT ... INTO DUMPFILE ...
SELECT * FROM ... WHERE autoincrement_col IS NULL
```

  The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See the MyODBC section of Chapter 17, *Connectors and APIs*.

  Statements within transactions that use `SERIALIZABLE` [976] isolation level also cannot be cached because they use `LOCK IN SHARE MODE` locking.

- It was issued as a prepared statement, even if no placeholders were employed. For example, the query used here is not cached:

```
char *my_sql_stmt = "SELECT a, b FROM table_c";
/* ... */
mysql_stmt_prepare(stmt, my_sql_stmt, strlen(my_sql_stmt));
```

  See Section 17.6.7, “C API Prepared Statements”.

- It uses `TEMPORARY` tables.
- It does not use any tables.
- It generates warnings.
- The user has a column-level privilege for any of the involved tables.

7.5.3.2 Query Cache `SELECT` Options

Two query cache-related options may be specified in `SELECT` statements:

- `SQL_CACHE`

  The query result is cached if it is cacheable and the value of the `query_cache_type` [424] system variable is `ON` or `DEMAND`.

- `SQL_NO_CACHE`

  The query result is not cached.

Examples:

```
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

7.5.3.3 Query Cache Configuration

The `have_query_cache` [413] server system variable indicates whether the query cache is available:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting `mysqld`. The query cache system variables all have names that begin with `query_cache_`. They are described briefly in Section 5.1.3, “Server System Variables”, with additional configuration information given here.

To set the size of the query cache, set the `query_cache_size` [424] system variable. Setting it to 0 disables the query cache. The default size is 0, so the query cache is disabled by default.

Note

When using the Windows Configuration Wizard to install or configure MySQL, the default value for `query_cache_size` [424] will be configured automatically for you based on the different configuration types available. When using the Windows Configuration Wizard, the query cache may be enabled (that is, set to a nonzero value) due to the selected configuration. The query cache is also controlled by the setting of the `query_cache_type` [424] variable. You should check the values of these variables as set in your `my.ini` file after configuration has taken place.

When you set `query_cache_size` [424] to a nonzero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
  Level: Warning
   Code: 1282
Message: Query cache failed to set size 39936;
         new query cache size is 0

mysql> SET GLOBAL query_cache_size = 41984;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+-------+
| Variable_name    | Value |
+------------------+-------+
| query_cache_size | 41984 |
+------------------+-------+
```

For the query cache to actually be able to hold any query results, its size must be set larger:

```
mysql> SET GLOBAL query_cache_size = 1000000;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+--------+
| Variable_name    | Value  |
+------------------+--------+
| query_cache_size | 999424 |
+------------------+--------+
1 row in set (0.00 sec)
```

The query_cache_size [424] value is aligned to the nearest 1024 byte block. The value reported may therefore be different from the value that you assign.

If the query cache size is greater than 0, the query_cache_type [424] variable influences how it works. This variable can be set to the following values:

- A value of 0 or OFF prevents caching or retrieval of cached results.
- A value of 1 or ON enables caching except of those statements that begin with SELECT SQL_NO_CACHE.
- A value of 2 or DEMAND causes caching of only those statements that begin with SELECT SQL_CACHE.

Setting the GLOBAL query_cache_type [424] value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the SESSION query_cache_type [424] value. For example, a client can disable use of the query cache for its own queries like this:

```
mysql> SET SESSION query_cache_type = OFF;
```

If you set query_cache_type [424] at server startup (rather than at runtime with a SET statement), only the numeric values are permitted.

To control the maximum size of individual query results that can be cached, set the query_cache_limit [424] system variable. The default value is 1MB.

When a query is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated. Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the query_cache_min_res_unit [424] system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed. Depending on the types of queries your server executes, you might find it helpful to tune the value of query_cache_min_res_unit [424]:

- The default value of query_cache_min_res_unit [424] is 4KB. This should be adequate for most cases.
- If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, you should decrease the value of query_cache_min_res_unit [424]. The number of free blocks and queries removed due to pruning are given by the values of the Qcache_free_blocks [453] and Qcache_lowmem_prunes [453] status variables.
- If most of your queries have large results (check the Qcache_total_blocks [454] and Qcache_queries_in_cache [454] status variables), you can increase performance by increasing query_cache_min_res_unit [424]. However, be careful to not make it too large (see the previous item).

query_cache_min_res_unit [424] is present as of MySQL 4.1.

7.5.3.4 Query Cache Status and Maintenance

To check whether the query cache is present in your MySQL server, use the following statement:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
```

```
| Variable_name    | Value |
+------------------+-------+
| have_query_cache | YES   |
+------------------+-------+
```

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
+-------------------------+--------+
| Variable_name           | Value  |
+-------------------------+--------+
| Qcache_free_blocks      | 36     |
| Qcache_free_memory      | 138488 |
| Qcache_hits             | 79570  |
| Qcache_inserts          | 27087  |
| Qcache_lowmem_prunes    | 3114   |
| Qcache_not_cached       | 22989  |
| Qcache_queries_in_cache | 415    |
| Qcache_total_blocks     | 912    |
+-------------------------+--------+
```

Descriptions of each of these variables are given in Section 5.1.5, “Server Status Variables”. Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

```
  Com_select
+ Qcache_hits
+ queries with errors found by parser
```

The `Com_select` value is given by this formula:

```
  Qcache_inserts
+ Qcache_not_cached
+ queries with errors found during the column-privileges check
```

The query cache uses variable-length blocks, so `Qcache_total_blocks` [454] and `Qcache_free_blocks` [453] may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` [453] status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in Section 7.5.3.3, “Query Cache Configuration”.

7.6 Locking Issues

MySQL manages contention for table contents using locking:

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See Section 7.6.1, “Internal Locking Methods”.
- External locking occurs when the server and other programs lock table files to coordinate among themselves which program can access the tables at which time. See Section 7.6.4, “External Locking”.

7.6.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. External locking occurs when the server and other programs lock table files to coordinate among themselves which program can access the tables at which time. See Section 7.6.4, “External Locking”.

MySQL uses table-level locking for `ISAM`, `MyISAM`, `MEMORY` (`HEAP`), and `MERGE` tables, page-level locking for `BDB` tables, and row-level locking for `InnoDB` tables.

In many cases, you can make an educated guess about which locking type is best for an application, but generally it is difficult to say that a given lock type is better than another. Everything depends on the application and different parts of an application may require different lock types.

To decide whether you want to use a storage engine with row-level locking, you should look at what your application does and what mix of select and update statements it uses. For example, most Web applications perform many selects, relatively few deletes, updates based mainly on key values, and inserts into a few specific tables. The base MySQL `MyISAM` setup is very well tuned for this.

Table locking in MySQL is deadlock-free for storage engines that use table-level locking. Deadlock avoidance is managed by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even if there is heavy `SELECT` activity for the table. However, if you have many updates for a table, `SELECT` statements wait until there are no more updates.

For information on altering the priority of reads and writes, see Section 7.6.2, “Table Locking Issues”.

Starting in MySQL 3.23.33, you can analyze the table lock contention on your system by checking the `Table_locks_immediate` [457] and `Table_locks_waited` [457] status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----------------------+---------+
```

```
| Variable_name         | Value   |
+-----------------------+---------+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324   |
+-----------------------+---------+
```

As of MySQL 3.23.7 (3.23.25 for Windows), the MyISAM storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a MyISAM table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent INSERT and SELECT statements for a MyISAM table without locks. That is, you can insert rows into a MyISAM table at the same time other clients are reading from it. (Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data.)

If you acquire a table lock explicitly with LOCK TABLES, you can request a READ LOCAL lock rather than a READ lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many INSERT and SELECT operations on a table real_table when concurrent inserts are not possible, you can insert rows into a temporary table temp_table and update the real table with the rows from the temporary table periodically. This can be done with the following code:

```
mysql> LOCK TABLES real_table WRITE, temp_table WRITE;
mysql> INSERT INTO real_table SELECT * FROM temp_table;
mysql> DELETE FROM temp_table;
mysql> UNLOCK TABLES;
```

InnoDB uses row locks and BDB uses page locks. Deadlocks are possible for these storage engines because they automatically acquire locks during the processing of SQL statements, not at the start of the transaction.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows
- Fewer changes for rollbacks
- Possible to lock a single row for a long time

Disadvantages of row-level locking:

- Requires more memory than page-level or table-level locks
- Slower than page-level or table-level locks when used on a large part of the table because you must acquire many more locks
- Slower than other locks if you often do GROUP BY operations on a large part of the data or if you must scan the entire table frequently

Generally, table locks are superior to page-level or row-level locks in the following cases:

- Most statements for the table are reads
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

```
UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
DELETE FROM tbl_name WHERE unique_key_col=key_value;
```

- `SELECT` combined with concurrent `INSERT` statements, and very few `UPDATE` or `DELETE` statements
- Many scans or `GROUP BY` operations on the entire table without any writers

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level or page-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”
- Copy on demand is in many cases superior to page-level or row-level locking. However, in the worst case, it can use much more memory than using normal locks.
- Instead of using row-level locks, you can employ application-level locks, such as those provided by `GET_LOCK()` [877] and `RELEASE_LOCK()` [879] in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See Section 11.14, “Miscellaneous Functions”.

7.6.2 Table Locking Issues

To achieve a very high lock speed, MySQL uses table locking (instead of page, row, or column locking) for all storage engines except `InnoDB`, `BDB`, and `NDBCLUSTER`.

For `InnoDB` and `BDB` tables, MySQL uses table locking only if you explicitly lock the table with `LOCK TABLES`. For these storage engines, avoid using `LOCK TABLES` at all, because `InnoDB` uses automatic row-level locking and `BDB` uses page-level locking to ensure transaction isolation.

For large tables, table locking is often better than row locking, but there are some disadvantages:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access. During the update, all other sessions that want to access this particular table must wait until the update is done.
- Table locking causes problems in cases such as when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.

Table locking is also disadvantageous under the following scenario:

- A session issues a `SELECT` that takes a long time to run.
- Another session then issues an `UPDATE` on the same table. This session waits until the `SELECT` is finished.
- Another session issues another `SELECT` statement on the same table. Because `UPDATE` has higher priority than `SELECT`, this `SELECT` waits for the `UPDATE` to finish, *after* waiting for the first `SELECT` to finish.

The following items describe some ways to avoid or reduce contention caused by table locking:

- Try to get the `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.
- Start `mysqld` with `--low-priority-updates` [389]. For storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`), this gives all statements that update (modify) a table

lower priority than SELECT statements. In this case, the second SELECT statement in the preceding scenario would execute before the UPDATE statement, and would not need to wait for the first SELECT to finish.

- To specify that all updates issued in a specific connection should be done with low priority, set the low_priority_updates [418] server system variable equal to 1.
- To give a specific INSERT, UPDATE, or DELETE statement lower priority, use the LOW_PRIORITY attribute.
- To give a specific SELECT statement higher priority, use the HIGH_PRIORITY attribute. See Section 12.2.7, “SELECT Syntax”.
- Starting from MySQL 3.23.7, you can start mysqld with a low value for the max_write_lock_count [421] system variable to force MySQL to temporarily elevate the priority of all SELECT statements that are waiting for a table after a specific number of inserts to the table occur. This permits READ locks after a certain number of WRITE locks.
- If you have problems with INSERT combined with SELECT, consider switching to MyISAM tables, which support concurrent SELECT and INSERT statements. (See Section 7.6.3, “Concurrent Inserts”.)
- If you mix inserts and deletes on the same table, INSERT DELAYED may be of great help. See Section 12.2.4.2, “INSERT DELAYED Syntax”.
- If you have problems with mixed SELECT and DELETE statements, the LIMIT option to DELETE may help. See Section 12.2.1, “DELETE Syntax”.
- Using SQL_BUFFER_RESULT with SELECT statements can help to make the duration of table locks shorter. See Section 12.2.7, “SELECT Syntax”.
- You could change the locking code in mysys/thr_lock.c to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

Here are some tips concerning table locks in MySQL:

- Concurrent users are not a problem if you do not mix updates with selects that need to examine many rows in the same table.
- You can use LOCK TABLES to increase speed, because many updates within a single lock is much faster than updating without locks. Splitting table contents into separate tables may also help.
- If you encounter speed problems with table locks in MySQL, you may be able to improve performance by converting some of your tables to InnoDB or BDB tables. See Section 13.2, “The InnoDB Storage Engine”, and Section 13.5, “The BDB (BerkeleyDB) Storage Engine”.

7.6.3 Concurrent Inserts

As of MySQL 3.23.7 (3.23.25 for Windows), the MyISAM storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a MyISAM table has no holes in the data file (deleted rows in the middle), an INSERT statement can be executed to add rows to the end of the table at the same time that SELECT statements are reading rows from the table. If there are multiple INSERT statements, they are queued and performed in sequence, concurrently with the SELECT statements. The results of a concurrent INSERT may not be visible immediately.

Concurrent inserts are enabled by default, but can be disabled by setting the concurrent_insert [409] system variable to 0.

Under circumstances where concurrent inserts can be used, there is seldom any need to use the `DELAYED` modifier for `INSERT` statements. See Section 12.2.4.2, “`INSERT DELAYED` Syntax”.

If you are using the update log or binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See Section 5.3.4, “The Binary Log”. In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA INFILE`, if you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` [389] option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

7.6.4 External Locking

External locking is the use of file system locking to manage contention for database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.
- If you use `myisamchk` to perform table maintenance operations on `MyISAM` tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `myisampack` to pack `MyISAM` tables.

  If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such a checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

  If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `myisampack` to pack tables, you *must* always ensure that the `mysqld` server is not using the table. If you don't stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is

running. If you only *read* tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. (See Section 7.8.1, “System Factors and Startup Parameter Tuning”.) To avoid this requirement as of MySQL 3.23, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables.

For `mysqld`, external locking is controlled by the value of the `skip_external_locking` [427] system variable. (Before MySQL 4.0.3, this variable is named `skip_locking`.) When this variable is enabled, external locking is disabled, and vice versa. From MySQL 4.0 on, external locking is disabled by default. Before MySQL 4.0, external locking is enabled by default on Linux or when MySQL is configured to use MIT-pthreads.

Use of external locking can be controlled at server startup by using the `--external-locking` [387] or `--skip-external-locking` [392] option. (Before MySQL 4.0.3, these options are named `--enable-locking` and `--skip-locking`.)

If you do use external locking option to enable updates to `MyISAM` tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- You should not use the query cache for queries that use tables that are updated by another process.
- You should not start the server with the `--delay-key-write=ALL` [386] option or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy these conditions is to always use `--external-locking` [387] together with `--delay-key-write=OFF` [386] and `--query-cache-size=0` [424]. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

7.7 Optimizing Database Structure

7.7.1 Make Your Data as Small as Possible

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application may give you a big performance gain. See Chapter 13, *Storage Engines*.

You can get better performance for a table and minimize storage space by using the techniques listed here:

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.
- Declare columns to be `NOT NULL` if possible. It makes everything faster and you save one bit per column. If you really need `NULL` in your application, you should definitely use it. Just avoid having it on all columns by default.
- For `MyISAM` tables, if you do not have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size row format is used. This is faster but unfortunately may waste some space. See

Section 13.1.3, “MyISAM Table Storage Formats”. You can hint that you want to have fixed length rows even if you have VARCHAR columns with the CREATE TABLE option ROW_FORMAT=FIXED.

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient.
- Create only the indexes that you really need. Indexes are good for retrieval but bad when you need to store data quickly. If you access a table mostly by searching on a combination of columns, create an index on them. The first part of the index should be the column most used. If you *always* use many columns when selecting from the table, the first column in the index should be the one with the most duplicates to obtain better compression of the index.
- If it is very likely that a string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see Section 12.1.4, “CREATE INDEX Syntax”). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See Section 7.8.2, “Tuning Server Parameters”.
- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.

7.7.2 How MySQL Opens and Closes Tables

When you execute a mysqladmin status command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The Open tables value of 12 can be somewhat puzzling if you have only six tables.

MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With MyISAM tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The table_cache [431], max_connections [419], and max_tmp_tables [420] system variables affect the maximum number of files the server keeps open. If you increase one or more of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

table_cache [431] is related to max_connections [419]. For example, for 200 concurrent running connections, you should have a table cache size of at least 200 * *N*, where *N* is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the table_cache [431] setting. If table_cache [431] is set too high, MySQL may run out of file descriptors and refuse connections, fail to perform queries, and be very unreliable. You also have to take into account that the MyISAM storage engine needs two file descriptors for each unique open table. You can increase the number of file descriptors available to MySQL using the --open-files-limit [391] startup option to mysqld. See Section B.5.2.18, “'*File*' Not Found and Similar Errors”.

The cache of open tables is kept at a level of `table_cache` [431] entries. The default value is 64; this can be changed with the `--table_cache` [431] option to `mysqld`. Note that MySQL may temporarily open more tables than this to execute queries.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_cache` [431] entries and a table in the cache is no longer being used by any threads.
- When a table flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables that are not currently in use are released, beginning with the table least recently used.
- If a new table needs to be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A `MyISAM` table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any `MyISAM` table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER *tbl_name* OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER *tbl_name* CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See Section 12.2.3, “HANDLER Syntax”.

You can determine whether your table cache is too small by checking the `mysqld` status variable `Opened_tables` [453], which indicates the number of table-opening operations since the server started:

```
mysql> SHOW STATUS LIKE 'Opened_tables';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Opened_tables | 2741  |
+---------------+-------+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, you should increase the table cache size. See Section 5.1.3, “Server System Variables”, and Section 5.1.5, “Server Status Variables”.

7.7.3 Disadvantages of Creating Many Tables in the Same Database

If you have many `MyISAM` or `ISAM` tables in a database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

7.7.4 How MySQL Uses Internal Temporary Tables

In some cases, the server creates internal temporary tables while processing queries. Such a table can be held in memory and processed by the `MEMORY` storage engine, or stored on disk and processed by the `MyISAM` storage engine. The server may create a temporary table initially as an in-memory table, then convert it to an on-disk table if it becomes too large. Users have no direct control over when the server creates an internal temporary table or which storage engine the server uses to manage it.

Temporary tables can be created under conditions such as these:

- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.
- `DISTINCT` combined with `ORDER BY` may require a temporary table.
- If you use the `SQL_SMALL_RESULT` option, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.

To determine whether a query requires a temporary table, use `EXPLAIN` and check the `Extra` column to see whether it says `Using temporary` (see Section 7.2.1, “Optimizing Queries with `EXPLAIN`”).

Some conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a `BLOB` or `TEXT` column in the table
- Presence of any column in a `GROUP BY` or `DISTINCT` clause larger than 512 bytes
- Presence of any column larger than 512 bytes in the `SELECT` list, if `UNION` or `UNION ALL` is used

If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` [432] and `max_heap_table_size` [419] values. This differs from `MEMORY` tables explicitly created with `CREATE TABLE`: For such tables, only the `max_heap_table_size` [419] system variable determines how large the table is permitted to grow and there is no conversion to on-disk format.

When the server creates an internal temporary table (either in memory or on disk), it increments the `Created_tmp_tables` [451] status variable. If the server creates the table on disk (either initially or by converting an in-memory table) it increments the `Created_tmp_disk_tables` [450] status variable.

7.8 Optimizing the MySQL Server

7.8.1 System Factors and Startup Parameter Tuning

We start with system-level factors, because some of these decisions must be made very early to achieve large performance gains. In other cases, a quick look at this section may suffice. However, it is always nice to have a sense of how much can be gained by changing factors that apply at this level.

The operating system to use is very important. To get the best use of multiple-CPU machines, you should use Solaris (because its threads implementation works well) or Linux (because the 2.4 and later kernels have good SMP support). Note that older Linux kernels have a 2GB filesize limit by default. If you have such a kernel and a need for files larger than 2GB, you should get the Large File Support (LFS) patch for the ext2 file system. Other file systems such as ReiserFS and XFS do not have this 2GB limitation.

Before using MySQL in production, we advise you to test it on your intended platform.

Other tips:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.
- Use the `--skip-external-locking` [392] MySQL option to avoid external locking. This option is turned on by default as of MySQL 4.0. Before that, it is on by default when compiling with MIT-pthreads, because `flock()` is not fully supported by MIT-pthreads on all platforms. It is also on by default for Linux because Linux file locking is not yet safe.

  Note that disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems it is mandatory to disable external locking because it does not work, anyway.

  The only case in which you cannot disable external locking is when you run multiple MySQL *servers* (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally *not* recommended, except when using MySQL Cluster.

  The `LOCK TABLES` and `UNLOCK TABLES` statements use internal locking, so you can use them even if external locking is disabled.

7.8.2 Tuning Server Parameters

You can determine the default buffer sizes used by the `mysqld` server with this command (prior to MySQL 4.1, omit `--verbose` [395]):

```
shell> mysqld --verbose --help
```

This command produces a list of all `mysqld` options and configurable system variables. The output includes the default variable values and looks something like this:

```
back_log                current value: 5
bdb_cache_size          current value: 1048540
binlog_cache_size       current value: 32768
connect_timeout         current value: 5
delayed_insert_limit    current value: 100
delayed_insert_timeout  current value: 300
delayed_queue_size      current value: 1000
flush_time              current value: 0
interactive_timeout     current value: 28800
join_buffer_size        current value: 131072
key_buffer_size         current value: 1048540
long_query_time         current value: 10
lower_case_table_names  current value: 0
max_allowed_packet      current value: 1048576
max_binlog_cache_size   current value: 4294967295
max_connect_errors      current value: 10
max_connections         current value: 100
max_delayed_threads     current value: 20
max_heap_table_size     current value: 16777216
max_join_size           current value: 4294967295
max_sort_length         current value: 1024
max_tmp_tables          current value: 32
max_write_lock_count    current value: 4294967295
myisam_sort_buffer_size current value: 8388608
net_buffer_length       current value: 16384
net_read_timeout        current value: 30
net_retry_count         current value: 10
net_write_timeout       current value: 60
```

```
read_buffer_size          current value: 131072
read_rnd_buffer_size      current value: 262144
slow_launch_time          current value: 2
sort_buffer               current value: 2097116
table_cache               current value: 64
thread_concurrency        current value: 10
thread_stack              current value: 131072
tmp_table_size            current value: 1048576
wait_timeout              current value: 28800
```

For a `mysqld` server that is currently running, you can see the current values of its system variables by connecting to it and issuing this statement:

```
mysql> SHOW VARIABLES;
```

You can also see some statistical and status indicators for a running server by issuing this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also can be obtained using `mysqladmin`:

```
shell> mysqladmin variables
shell> mysqladmin extended-status
```

For a full description of all system and status variables, see Section 5.1.3, “Server System Variables”, and Section 5.1.5, “Server Status Variables”.

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally you get better performance by giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` [415] and `table_cache` [431]. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations. The examples use the `mysqld_safe` script and use `--var_name=value` syntax to set the variable *`var_name`* to the value *`value`*. This syntax is available as of MySQL 4.0. For older versions of MySQL, take the following differences into account:

- Use `safe_mysqld` rather than `mysqld_safe`.
- Set variables using `--set-variable=var_name=value` or `-O var_name=value` syntax.
- For variable names that end in `_size`, you may need to specify them without `_size`. For example, the old name for `sort_buffer_size` [427] is `sort_buffer`. The old name for `read_buffer_size` [425] is `record_buffer`. To see which variables your version of the server recognizes, use `mysqld --help`.

If you have at least 256MB of memory and many tables and want maximum performance with a moderate number of clients, you should use something like this:

```
shell> mysqld_safe --key_buffer_size=64M --table_cache=256 \
          --sort_buffer_size=4M --read_buffer_size=1M &
```

If you have only 128MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:

```
shell> mysqld_safe --key_buffer_size=16M --sort_buffer_size=1M
```

If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

With little memory and lots of connections, use something like this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K \
           --read_buffer_size=100K &
```

Or even this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K \
           --table_cache=32 --read_buffer_size=8K \
           --net_buffer_length=1K &
```

If you are performing `GROUP BY` or `ORDER BY` operations on tables that are much larger than your available memory, you should increase the value of `read_rnd_buffer_size` [426] to speed up the reading of rows following sorting operations.

You can make use of the example option files included with your MySQL distribution; see Preconfigured Option Files.

If you specify an option on the command line for `mysqld` or `mysqld_safe`, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file.

To see the effects of a parameter change, do something like this (prior to MySQL 4.1, omit `--verbose` [395]):

```
shell> mysqld --key_buffer_size=32M --verbose --help
```

The variable values are listed near the end of the output. Make sure that the `--verbose` [395] and `--help` [384] options are last. Otherwise, the effect of any options listed after them on the command line are not reflected in the output.

For information on tuning the `InnoDB` storage engine, see Section 13.2.14.1, “`InnoDB` Performance Tuning Tips”.

7.8.3 How MySQL Uses Threads for Client Connections

Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See Section 5.1.3, “Server System Variables”, and Section 5.1.5, “Server Status Variables”.)

The thread cache has a size determined by the `thread_cache_size` [431] system variable. The default value is 0 (no caching), which causes a thread to be set up for each new connection and disposed of when the connection terminates. Set `thread_cache_size` [431] to *`N`* to enable *`N`* inactive connection threads to be cached. `thread_cache_size` [431] can be set at server startup or changed while the server runs. A connection thread becomes inactive when the client connection with which it was associated terminates.

To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, monitor the `Threads_cached` [457] and `Threads_created` [457] status variables.

You can set `max_connections` [419] at server startup or at runtime to control the maximum number of clients that can connect simultaneously.

When the thread stack is too small, this limits the complexity of the SQL statements which the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of *`N`* bytes for each thread, start the server with `--thread_stack=`*`N`* [431].

7.8.4 How MySQL Uses Memory

The following list indicates some of the ways that the `mysqld` server uses memory. Where applicable, the name of the system variable relevant to the memory use is given:

- All threads share the `MyISAM` key buffer; its size is determined by the `key_buffer_size` [415] variable. Other buffers used by the server are allocated as needed. See Section 7.8.2, “Tuning Server Parameters”.
- Each thread that is used to manage client connections uses some thread-specific space. The following list indicates these and which variables control their size:
  - A stack (variable `thread_stack` [431])
  - A connection buffer (variable `net_buffer_length` [422])
  - A result buffer (variable `net_buffer_length` [422])

  The connection buffer and result buffer each begin with a size equal to `net_buffer_length` [422] bytes, but are dynamically enlarged up to `max_allowed_packet` [418] bytes as needed. The result buffer shrinks to `net_buffer_length` [422] bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.
- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.

- Only compressed `ISAM` and `MyISAM` tables are memory mapped. This is because the 32-bit memory space of 4GB is not large enough for most big tables. When systems with a 64-bit address space become more common, we may add general support for memory mapping.
- Each request that performs a sequential scan of a table allocates a *read buffer* (variable `read_buffer_size` [425]).
- When reading rows in an arbitrary sequence (for example, following a sort), a *random-read buffer* (variable `read_rnd_buffer_size` [426]) may be allocated to avoid disk seeks.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain `BLOB` columns are stored on disk.

  One problem before MySQL 3.23.2 is that if an internal in-memory temporary table becomes too large, the error `The table tbl_name is full` occurs. From 3.23.2 on, MySQL handles this automatically by changing the table from in-memory to on-disk format, to be handled by the `MyISAM` storage engine. To work around this problem for older servers, you can increase the temporary table size by setting the `tmp_table_size` [432] option to `mysqld`, or by setting the SQL option `sql_big_tables` in the client program. See Section 7.7.4, “How MySQL Uses Internal Temporary Tables”, and Section 5.1.3, “Server System Variables”.

  In MySQL 3.20, the maximum size of the temporary table is `record_buffer*16`; if you are using this version, you have to increase the value of `record_buffer`. You can also start `mysqld` with the `--big-tables` [384] option to always store temporary tables on disk. However, this affects the speed of many complicated queries.
- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section B.5.4.4, “Where MySQL Stores Temporary Files”.
- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, so the normal slow memory allocation and freeing is avoided. Memory is allocated only for unexpectedly large strings.
- For each `MyISAM` or `ISAM` table that is opened, the index file is opened once and the data file is opened once for each concurrently running thread. For each concurrent thread, a table structure, column structures for each column, and a buffer of size `3 * N` are allocated (where `N` is the maximum row length, not counting `BLOB` columns). A `BLOB` column requires five to eight bytes plus the length of the `BLOB` data. The `MyISAM` and `ISAM` storage engines maintain one extra row buffer for internal use.
- For each table having `BLOB` columns, a buffer is enlarged dynamically to read in larger `BLOB` values. If you scan a table, a buffer as large as the largest `BLOB` value is allocated.
- Handler structures for all in-use tables are saved in a cache and managed as a FIFO. The initial cache size is taken from the value of the `table_cache` [431] system variable. If a table has been used by two running threads at the same time, the cache contains two entries for the table. See Section 7.7.2, “How MySQL Opens and Closes Tables”.
- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.
- The server caches information in memory as a result of `GRANT` statements. This memory is not released by the corresponding `REVOKE` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

7.8.5 How MySQL Uses DNS

When a new client connects to `mysqld`, `mysqld` spawns a new thread to handle the request. This thread first checks whether the host name is in the host name cache. If not, the thread attempts to resolve the host name:

- The thread takes the IP address and resolves it to a host name (using `gethostbyaddr()`). It then takes that host name and resolves it back to the IP address (using `gethostbyname()`) and compares to ensure it is the original IP address.
- If the operating system supports the thread-safe `gethostbyaddr_r()` and `gethostbyname_r()` calls, the thread uses them to perform host name resolution.
- If the operating system does not support the thread-safe calls, the thread locks a mutex and calls `gethostbyaddr()` and `gethostbyname()` instead. In this case, no other thread can resolve host names that are not in the host name cache until the first thread unlocks the mutex.

You can disable DNS host name lookups by starting `mysqld` with the `--skip-name-resolve` [393] option. However, in this case, you can use only IP addresses in the MySQL grant tables.

If you have a very slow DNS and many hosts, you can get more performance by either disabling DNS lookups with `--skip-name-resolve` [393] or by increasing the `HOST_CACHE_SIZE` define (default value: 128) and recompiling `mysqld`.

You can disable the host name cache by starting the server with the `--skip-host-cache` [392] option. To clear the host name cache, issue a `FLUSH HOSTS` statement or execute the `mysqladmin flush-hosts` command.

To disallow TCP/IP connections entirely, start `mysqld` with the `--skip-networking` [393] option.

7.9 Disk Issues

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.
- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
  - Using symbolic links

    This means that, for `MyISAM` tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 7.10, “Using Symbolic Links”.
  - Striping

    Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the *`N`*-th block on the (*`N MOD number_of_disks`*) disk, and so on. This

means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 7.1.4, “Using Your Own Benchmarks”.

The speed difference for striping is *very* dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need 2 × *N* drives to hold *N* drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.
- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID *N* disk. RAID *N* can be a problem if you have many writes, due to the time required to update the parity bits.
- On Linux, you can get much more performance by using `hdparm` to configure your disk's interface. (Up to 100% under load is not uncommon.) The following `hdparm` options should be quite good for MySQL, and probably for many other applications:

  ```
  hdparm -m 16 -d 1
  ```

  Note that performance and reliability when using this command depend on your hardware, so we strongly suggest that you test your system thoroughly after using `hdparm`. Please consult the `hdparm` manual page for more information. If `hdparm` is not used wisely, file system corruption may result, so back up everything before experimenting!
- You can also set the parameters for the file system that the database uses:

  If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

  On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you more performance without sacrificing too much reliability. (This flag is on by default on Linux.)

7.10 Using Symbolic Links

You can move tables and databases from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disk.

The recommended way to do this is simply to symlink databases to a different disk. Symlink tables only as a last resort.

7.10.1 Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a symlink to it from the MySQL data directory.

```
shell> mkdir /dr1/databases/test
```

```
shell> ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
shell> cd /path/to/datadir
shell> ln -s db1 db2
```

The result is that, or any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

If you really need to do this, you can change one of the source files. The file to modify depends on your version of MySQL. For MySQL 4.0 and up, look for the following statement in the `mysys/my_symlink.c` file:

```
if (!(MyFlags & MY_RESOLVE_LINK) ||
    (!lstat(filename,&stat_buff) && S_ISLNK(stat_buff.st_mode)))
```

Before MySQL 4.0, look for this statement in the `mysys/mf_format.c` file:

```
if (flag & 32 || (!lstat(to,&stat_buff) && S_ISLNK(stat_buff.st_mode)))
```

Change the statement to this:

```
if (1)
```

7.10.2 Using Symbolic Links for Tables on Unix

Before MySQL 4.0, you should not symlink tables unless you are *very* careful with them. The problem is that if you run `ALTER TABLE`, `REPAIR TABLE`, or `OPTIMIZE TABLE` on a symlinked table, the symlinks are removed and replaced by the original files. This happens because these statements work by creating a temporary file in the database directory and replacing the original file with the temporary file when the statement operation is complete.

You should not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). You can check whether your system supports symbolic links by issuing a `SHOW VARIABLES LIKE 'have_symlink'` statement.

In MySQL 4.0, symlinks are fully supported only for `MyISAM` tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links.

The handling of symbolic links for `MyISAM` tables in MySQL 4.0 works the following way:

- In the data directory, you always have the table format (`.frm`) file, the data (`.MYD`) file, and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.
- You can symlink the data file and the index file independently to different directories.
- You can instruct a running MySQL server to perform the symlinking by using the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See Section 12.1.5, “`CREATE TABLE` Syntax”. Alternatively, symlinking can be accomplished manually from the command line using `ln -s` if `mysqld` is not running.

Note

Beginning with MySQL 4.1.24, the path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL `data` directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

- 

  Note

  When you drop a table that is using symlinks, *both the symlink and the file to which the symlink points are dropped*. This is an extremely good reason why you should *not* run `mysqld` as the system `root` or permit system users to have write access to MySQL database directories.

- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you are not using symlinks, you should use the `--skip-symbolic-links` [393] option to `mysqld` to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

`SHOW CREATE TABLE` does not report if a table has symbolic links prior to MySQL 4.0.15. This is also true for `mysqldump`, which uses `SHOW CREATE TABLE` to generate `CREATE TABLE` statements.

Table symlink operations that are not supported up through MySQL 4.1:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

- `BACKUP TABLE` and `RESTORE TABLE` do not respect symbolic links.

- The `.frm` file must *never* be a symbolic link (as indicated previously, only the data and index files can be symbolic links). Attempting to do this (for example, to make synonyms) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

  ```
  shell> cd /path/to/datadir/db1
  shell> ln -s tbl1.frm tbl2.frm
  shell> ln -s tbl1.MYD tbl2.MYD
  shell> ln -s tbl1.MYI tbl2.MYI
  ```

  Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

  - The query cache is “fooled” (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).

  - `ALTER` statements on `tbl2` fail.

7.10.3 Using Symbolic Links for Databases on Windows

Beginning with MySQL 3.23.16, the `mysqld-max` and `mysql-max-nt` servers for Windows are compiled with the `-DUSE_SYMDIR` option. This enables you to put a database directory on a different disk by setting up a symbolic link to it. This is similar to the way that symbolic links work on Unix, although the procedure for setting up the link is different.

It is necessary to define `USE_SYMDIR` explicitly only before MySQL 4.0; for `mysqld-max` and `mysql-max-nt`, you can enable symbolic links by using the `--symbolic-links` [393] option. As of MySQL 4.0, symbolic links are enabled by default for all Windows servers. If you do not need them, you can disable them with the `--skip-symbolic-links` [393] option.

On Windows, create a symbolic link to a MySQL database by creating a file in the data directory that contains the path to the destination directory. The file should be named *`db_name`*`.sym`, where *`db_name`* is the database name.

Suppose that the MySQL data directory is `C:\mysql\data` and you want to have database `foo` located at `D:\data\foo`. Set up a symlink using this procedure:

1. Make sure that the `D:\data\foo` directory exists by creating it if necessary. If you already have a database directory named `foo` in the data directory, you should move it to `D:\data`. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.
2. Create a text file `C:\mysql\data\foo.sym` that contains the path name `D:\data\foo\`.

Note

The path name to the new database and tables should be absolute. If you specify a relative path, the location will be relative to the `foo.sym` file.

After this, all tables created in the database `foo` are created in `D:\data\foo`.

The following limitations apply to the use of `.sym` files for database symbolic linking on Windows:

- The symbolic link is not used if a directory with the same name as the database exists in the MySQL data directory.
- The `--innodb_file_per_table` [1068] option cannot be used.
- If you run `mysqld` as a service, you cannot use a mapped drive to a remote server as the destination of the symbolic link. As a workaround, you can use the full path (`\\servername\path\`).

7.11 Examining Thread Information

When you are attempting to ascertain what your MySQL server is doing, it can be helpful to examine the process list, which is the set of threads currently executing within the server. Process list information is available from these sources:

- The `SHOW [FULL] PROCESSLIST` statement: Section 12.4.5.19, “`SHOW PROCESSLIST` Syntax”
- The `mysqladmin processlist` command: Section 4.5.2, “`mysqladmin` — Client for Administering a MySQL Server”

You can always view information about your own threads. To view information about threads being executed for other accounts, you must have the `PROCESS` [492] privilege.

Each process list entry contains several pieces of information:

- `Id` is the connection identifier for the client associated with the thread.

- `User` and `Host` indicate the account associated with the thread.
- `db` is the default database for the thread, or `NULL` if none is selected.
- `Command` and `State` indicate what the thread is doing.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.
- `Time` indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a thread running on a slave that is processing events from the master, the thread time is set to the time found in the events and thus reflects current time on the master and not the slave.
- `Info` contains the text of the statement being executed by the thread, or `NULL` if it is not executing one. By default, this value contains only the first 100 characters of the statement. To see the complete statements, use `SHOW FULL PROCESSLIST`.

The following sections list the possible `Command` values, and `State` values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

7.11.1 Thread Command Values

A thread can have any of the following `Command` values:

- `Binlog Dump`

  This is a thread on a master server for sending binary log contents to a slave server.
- `Change user`

  The thread is executing a change-user operation.
- `Close stmt`

  The thread is closing a prepared statement.
- `Connect`

  A replication slave is connected to its master.
- `Connect Out`

  A replication slave is connecting to its master.
- `Create DB`

  The thread is executing a create-database operation.
- `Daemon`

  This thread is internal to the server, not a thread that services a client connection.
- `Debug`

  The thread is generating debugging information.
- `Delayed insert`

The thread is a delayed-insert handler.

- `Drop DB`

  The thread is executing a drop-database operation.

- `Error`

- `Execute`

  The thread is executing a prepared statement.

- `Fetch`

  The thread is fetching the results from executing a prepared statement.

- `Field List`

  The thread is retrieving information for table columns.

- `Init DB`

  The thread is selecting a default database.

- `Kill`

  The thread is killing another thread.

- `Long Data`

  The thread is retrieving long data in the result of executing a prepared statement.

- `Ping`

  The thread is handling a server-ping request.

- `Prepare`

  The thread is preparing a prepared statement.

- `Processlist`

  The thread is producing information about server threads.

- `Query`

  The thread is executing a statement.

- `Quit`

  The thread is terminating.

- `Refresh`

  The thread is flushing table, logs, or caches, or resetting status variable or replication server information.

- `Register Slave`

  The thread is registering a slave server.

- `Reset stmt`

  The thread is resetting a prepared statement.

- `Set option`

  The thread is setting or resetting a client statement-execution option.

- `Shutdown`

  The thread is shutting down the server.

- `Sleep`

  The thread is waiting for the client to send a new statement to it.

- `Statistics`

  The thread is producing server-status information.

- `Table Dump`

  The thread is sending table contents to a slave server.

- `Time`

  Unused.

7.11.2 General Thread States

The following list describes thread `State` values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- `After create`

  This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- `Analyzing`

  The thread is calculating a `MyISAM` table key distributions (for example, for `ANALYZE TABLE`).

- `Checking table`

  The thread is performing a table check operation.

- `cleaning up`

  The thread has processed one command and is preparing to free memory and reset certain state variables.

- `closing tables`

  The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, you should verify that you do not have a full disk and that the disk is not in very heavy use.

- `converting HEAP to MyISAM`

  The thread is converting an internal temporary table from a `MEMORY` table to an on-disk `MyISAM` table.

- `copy to tmp table`

  The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

- `Copying to group table`

  If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- `Copying to tmp table`

  The server is copying to a temporary table in memory.

- `Copying to tmp table on disk`

  The server is copying to a temporary table on disk. The temporary result set has become too large (see Section 7.7.4, “How MySQL Uses Internal Temporary Tables”). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- `Creating index`

  The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- `Creating sort index`

  The thread is processing a `SELECT` that is resolved using an internal temporary table.

- `creating table`

  The thread is creating a table. This includes creation of temporary tables.

- `Creating tmp table`

  The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation will be `Copying to tmp table on disk`.

- `deleting from main table`

  The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- `deleting from reference tables`

  The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `discard_or_import_tablespace`

  The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- `end`

This occurs at the end but before the cleanup of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

- `executing`

  The thread has begun executing a statement.

- `Execution of init_command`

  The thread is executing statements in the value of the `init_command` system variable.

- `freeing items`

  The thread has executed a command. Some freeing of items done during this state involves the query cache. This state is usually followed by `cleaning up`.

- `Flushing tables`

  The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables.

- `FULLTEXT initialization`

  The server is preparing to perform a natural-language full-text search.

- `init`

  This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log, the `InnoDB` log, and some query cache cleanup operations.

  For the `end` state, the following operations could be happening:

  - Removing query cache entries after data in a table is changed
  - Writing an event to the binary log
  - Freeing memory buffers, including for blobs

- `Killed`

  Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- `Locked`

  The query is locked by another query.

- `logging slow query`

  The thread is writing a statement to the slow-query log.

- `NULL`

  This state is used for the `SHOW PROCESSLIST` state.

- `login`

The initial state for a connection thread until the client has been authenticated successfully.

- `Opening tables`, `Opening table`

  The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_cache` [431] value is large enough.

- `optimizing`

  The server is performing initial optimizations for a query.

- `preparing`

  This state occurs during query optimization.

- `Purging old relay logs`

  The thread is removing unneeded relay log files.

- `query end`

  This state occurs after processing a query but before the `freeing items` state.

- `Reading from net`

  The server is reading a packet from the network.

- `Removing duplicates`

  The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `removing tmp table`

  The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- `rename`

  The thread is renaming a table.

- `rename result table`

  The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- `Reopen tables`

  The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

  The repair code is using a sort to create indexes.

- `Repair done`

The thread has completed a multi-threaded repair for a `MyISAM` table.

- `Repair with keycache`

  The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Rolling back`

  The thread is rolling back a transaction.

- `Saving state`

  For `MyISAM` table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- `Searching rows for update`

  The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- `Sending data`

  The thread is processing rows for a `SELECT` statement and also is sending data to the client.

- `setup`

  The thread is beginning an `ALTER TABLE` operation.

- `Sorting for group`

  The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

  The thread is doing a sort to satisfy a `ORDER BY`.

- `Sorting index`

  The thread is sorting index pages for more efficient access during a `MyISAM` table optimization operation.

- `Sorting result`

  For a `SELECT` statement, this is similar to `Creating sort index`, but for nontemporary tables.

- `statistics`

  The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

- `System lock`

  The thread is going to request or is waiting for an internal or external system lock for the table. If this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same tables, you can disable external system locks with the `--skip-external-locking` [392] option. However, external locking has been disabled by default since MySQL 4.0, so it is likely that this option will have no effect.

- `Table lock`

  The next thread state after `System lock`. The thread has acquired an external lock and is going to request an internal table lock.

- `update`

  The thread is getting ready to start updating the table.

- `Updating`

  The thread is searching for rows to update and is updating them.

- `updating main table`

  The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- `updating reference tables`

  The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- `User lock`

  The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` [877] call.

- `Waiting for release of readlock`

  The thread is waiting for a global read lock obtained by another thread (with `FLUSH TABLES WITH READ LOCK`) to be released.

- `Waiting for tables`, `Waiting for table`

  The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

  This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES` *`tbl_name`*, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting on cond`

  A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- `Waiting to get readlock`

  The thread has issued a `FLUSH TABLES WITH READ LOCK` statement to obtain a global read lock and is waiting to obtain the lock.

- `Writing to net`

  The server is writing a packet to the network.

7.11.3 Delayed-Insert Thread States

These thread states are associated with processing for `DELAYED` inserts (see Section 12.2.4.2, “`INSERT DELAYED` Syntax”). Some states are associated with connection threads that process `INSERT DELAYED` statements from clients. Other states are associated with delayed-insert handler threads that insert the rows. There is a delayed-insert handler thread for each table for which `INSERT DELAYED` statements are issued.

States associated with a connection thread that processes an `INSERT DELAYED` statement from the client:

- `allocating local table`

  The thread is preparing to feed rows to the delayed-insert handler thread.

- `Creating delayed handler`

  The thread is creating a handler for `DELAYED` inserts.

- `got handler lock`

  This occurs before the `allocating local table` state and after the `waiting for handler lock` state, when the connection thread gets access to the delayed-insert handler thread.

- `got old table`

  This occurs after the `waiting for handler open` state. The delayed-insert handler thread has signaled that it has ended its initialization phase, which includes opening the table for delayed inserts.

- `storing row into queue`

  The thread is adding a new row to the list of rows that the delayed-insert handler thread must insert.

- `waiting for delay_list`

  This occurs during the initialization phase when the thread is trying to find the delayed-insert handler thread for the table, and before attempting to gain access to the list of delayed-insert threads.

- `waiting for handler insert`

  An `INSERT DELAYED` handler has processed all pending inserts and is waiting for new ones.

- `waiting for handler lock`

  This occurs before the `allocating local table` state when the connection thread waits for access to the delayed-insert handler thread.

- `waiting for handler open`

  This occurs after the `Creating delayed handler` state and before the `got old table` state. The delayed-insert handler thread has just been started, and the connection thread is waiting for it to initialize.

States associated with a delayed-insert handler thread that inserts the rows:

- `insert`

  The state that occurs just before inserting rows into the table.

- `reschedule`

After inserting a number of rows, the delayed-insert thread sleeps to let other threads do work.

- `upgrading lock`

  A delayed-insert handler is trying to get a lock for the table to insert rows.

- `Waiting for INSERT`

  A delayed-insert handler is waiting for a connection thread to add rows to the queue (see `storing row into queue`).

7.11.4 Replication Master Thread States

The following list shows the most common states you may see in the `State` column for the master's `Binlog Dump` thread. If you see no `Binlog Dump` threads on a master server, this means that replication is not running—that is, that no slaves are currently connected.

- `Sending binlog event to slave`

  Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.

- `Finished reading one binlog; switching to next binlog`

  The thread has finished reading a binary log file and is opening the next one to send to the slave.

- `Has sent all binlog to slave; waiting for binlog to be updated`

  The thread has read all outstanding updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.

- `Waiting to finalize termination`

  A very brief state that occurs as the thread is stopping.

7.11.5 Replication Slave I/O Thread States

The following list shows the most common states you see in the `State` column for a slave server I/O thread. Beginning with MySQL 4.1.1, this state also appears in the `Slave_IO_State` column displayed by `SHOW SLAVE STATUS`, so you can get a good view of what is happening by using that statement.

- `Waiting for master update`

  The initial state before `Connecting to master`.

- `Connecting to master`

  The thread is attempting to connect to the master.

- `Checking master version`

  A state that occurs very briefly, after the connection to the master is established.

- `Registering slave on master`

  A state that occurs very briefly after the connection to the master is established.

- `Requesting binlog dump`

  A state that occurs very briefly, after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log file name and position.

- `Waiting to reconnect after a failed binlog dump request`

  If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement or the `--master-connect-retry` [1173] option.

- `Reconnecting after a failed binlog dump request`

  The thread is trying to reconnect to the master.

- `Waiting for master to send event`

  The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_net_timeout` [1181] seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- `Queueing master event to the relay log`

  The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Waiting to reconnect after a failed master event read`

  An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement or `--master-connect-retry` [1173] option (default 60) before attempting to reconnect.

- `Reconnecting after a failed master event read`

  The thread is trying to reconnect to the master. When connection is established again, the state becomes `Waiting for master to send event`.

- `Waiting for the slave SQL thread to free enough relay log space`

  You are using a nonzero `relay_log_space_limit` [426] value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- `Waiting for slave mutex on exit`

  A state that occurs briefly as the thread is stopping.

7.11.6 Replication Slave SQL Thread States

The following list shows the most common states you may see in the `State` column for a slave server SQL thread:

- `Waiting for the next event in relay log`

  The initial state before `Reading event from the relay log`.

- `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

- `Has read all relay log; waiting for the slave I/O thread to update it`

  The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- `Making temp file`

  The thread is executing a `LOAD DATA INFILE` statement and is creating a temporary file containing the data from which the slave will read rows.

- `Waiting for slave mutex on exit`

  A very brief state that occurs as the thread is stopping.

The `State` column for the I/O thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and is executing it.

7.11.7 Replication Slave Connection Thread States

These thread states occur on a replication slave but are associated with connection threads, not with the I/O or SQL threads.

- `Changing master`

  The thread is processing a `CHANGE MASTER TO` statement.

- `Creating table from master dump`

  The slave is creating a table using the `CREATE TABLE` statement contained in the dump from the master. Used for `LOAD TABLE FROM MASTER` and `LOAD DATA FROM MASTER`.

- `Killing slave`

  The thread is processing a `SLAVE STOP` statement.

- `Opening master dump table`

  This state occurs after `Creating table from master dump`.

- `Reading master dump table data`

  This state occurs after `Opening master dump table`.

- `Rebuilding the index on master dump table`

  This state occurs after `Reading master dump table data`.

- `starting slave`

  The thread is starting the slave threads after processing a successful `LOAD DATA FROM MASTER` load operation.

7.11.8 MySQL Cluster Thread States

- `Committing events to binlog`

- `Opening mysql.ndb_apply_status`
- `Processing events`

  The thread is processing events for binary logging.

- `Processing events from schema table`

  The thread is doing the work of schema replication.

- `Shutting down`
- `Syncing ndb table schema operation and binlog`

  This is used to have a correct binary log of schema operations for NDB.

- `Waiting for event from ndbcluster`

  The server is acting as an SQL node in a MySQL Cluster, and is connected to a cluster management node.

- `Waiting for first event from ndbcluster`
- `Waiting for ndbcluster binlog update to reach current position`
- `Waiting for ndbcluster to start`
- `Waiting for schema epoch`

  The thread is waiting for a schema epoch (that is, a global checkpoint).

Chapter 8 Language Structure

Table of Contents

This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Reserved words
- User-defined and system variables
- Comments

8.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal values, boolean values, and NULL. The section also covers the various nuances and “gotchas” that you may run into when dealing with these basic types in MySQL.

8.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote (“'”) or double quote (“"”) characters. Examples:

```
'a string'
"another string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
```

If the ANSI_QUOTES [458] SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

As of MySQL 4.1.1, a *binary string* is a string of bytes that has no character set or collation. A *nonbinary string* is a string of characters that has a character set and collation. For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte. For nonbinary strings the unit is the character and some character sets support multi-byte characters. Character value ordering is a function of the string collation.

Also as of MySQL 4.1.1, string literals may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For more information about these forms of string syntax, see Section 9.1.3.5, “Character String Literal Character Set and Collation”, and Section 9.1.3.6, “National Character Set”.

Within a string, certain sequences have special meaning. Each of these sequences begins with a backslash (“`\`”), known as the *escape character*. MySQL recognizes the following escape sequences.

Character	Escape Sequence
`\0`	An ASCII NUL (`0x00`) character.
`\'`	A single quote (“`'`”) character.
`\"`	A double quote (“`"`”) character.
`\b`	A backspace character.
`\n`	A newline (linefeed) character.
`\r`	A carriage return character.
`\t`	A tab character.
`\Z`	ASCII 26 (Control-Z). See note following the table.
`\\`	A backslash (“`\`”) character.
`\%`	A “`%`” character. See note following the table.
`\_`	A “`_`” character. See note following the table.

For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, “`\x`” is just “`x`”.

These sequences are case sensitive. For example, “`\b`” is interpreted as a backspace, but “`\B`” is interpreted as “`B`”.

The ASCII 26 character can be encoded as “`\Z`” to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

Escape processing is done according to the character set indicated by the `character_set_connection` [408] system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in Section 9.1.3.5, “Character String Literal Character Set and Collation”.

The “`\%`” and “`\_`” sequences are used to search for literal instances of “`%`” and “`_`” in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the `LIKE` [804] operator in Section 11.5.1, “String Comparison Functions”. If you use “`\%`” or “`\_`” outside of pattern-matching contexts, they evaluate to the strings “`\%`” and “`\_`”, not to “`%`” and “`_`”.

There are several ways to include quote characters within a string:

- A “`'`” inside a string quoted with “`'`” may be written as “`''`”.
- A “`"`” inside a string quoted with “`"`” may be written as “`""`”.
- Precede the quote character by an escape character (“`\`”).
- A “`'`” inside a string quoted with “`"`” needs no special treatment and need not be doubled or escaped. In the same way, “`"`” inside a string quoted with “`'`” needs no special treatment.

The following `SELECT` statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', '"hello"', '""hello""', 'hel''lo', '\'hello';
+-------+---------+-----------+--------+--------+
| hello | "hello" | ""hello"" | hel'lo | 'hello |
+-------+---------+-----------+--------+--------+

mysql> SELECT "hello", "'hello'", "''hello''", "hel""lo", "\"hello";
+-------+---------+-----------+--------+--------+
| hello | 'hello' | ''hello'' | hel"lo | "hello |
+-------+---------+-----------+--------+--------+

mysql> SELECT 'This\nIs\nFour\nLines';
+--------------------+
| This
Is
Four
Lines |
+--------------------+

mysql> SELECT 'disappearing\ backslash';
+------------------------+
| disappearing backslash |
+------------------------+
```

If you want to insert binary data into a string column (such as a `BLOB` column), the following characters must be represented by escape sequences.

Character	Escape Sequence
`NUL`	`NUL` byte (`0x00`). Represent this character by “`\0`” (a backslash followed by an ASCII “`0`” character).
`\`	Backslash (ASCII 92). Represent this character by “`\\`”.
`'`	Single quote (ASCII 39). Represent this character by “`\'`”.
`"`	Double quote (ASCII 34). Represent this character by “`\"`”.

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string()` C API function to escape characters. See Section 17.6.6.51, “`mysql_real_escape_string()`”. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See Section 17.8, “MySQL Perl API”. Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

8.1.2 Number Literals

Integers are represented as a sequence of digits. Floats use “`.`” as a decimal separator. Either type of number may be preceded by “`-`” or “`+`” to indicate a negative or positive value, respectively

Examples of valid integers:

```
1221
0
-32
```

Examples of valid floating-point numbers:

```
294.42
-32032.6809e+10
148.00
```

An integer may be used in a floating-point context; it is interpreted as the equivalent floating-point number.

8.1.3 Date and Time Literals

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of `'2015-07-21'`, `'20150721'`, and `20150721` as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, consult these sections:

- Section 10.1.2, “Date and Time Type Overview”
- Section 10.3, “Date and Time Types”

Standard SQL and ODBC Date and Time Literals

Standard SQL permits temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes those constructions and also the corresponding ODBC syntax:

```
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

However, MySQL ignores the type keyword and each of the preceding constructions produces the string value `'str'`, with a type of `VARCHAR`.

String and Numeric Literals in Date and Time Context

MySQL recognizes `DATE` values in these formats:

- As a string in either `'YYYY-MM-DD'` or `'YY-MM-DD'` format. A “relaxed” syntax is permitted: Any punctuation character may be used as the delimiter between date parts. For example, `'2012-12-31'`, `'2012/12/31'`, `'2012^12^31'`, and `'2012@12@31'` are equivalent.
- As a string with no delimiters in either `'YYYYMMDD'` or `'YYMMDD'` format, provided that the string makes sense as a date. For example, `'20070523'` and `'070523'` are interpreted as `'2007-05-23'`, but `'071332'` is illegal (it has nonsensical month and day parts) and becomes `'0000-00-00'`.
- As a number in either `YYYYMMDD` or `YYMMDD` format, provided that the number makes sense as a date. For example, `19830905` and `830905` are interpreted as `'1983-09-05'`.

MySQL recognizes `DATETIME` and `TIMESTAMP` values in these formats:

- As a string in either `'YYYY-MM-DD HH:MM:SS'` or `'YY-MM-DD HH:MM:SS'` format. A “relaxed” syntax is permitted here, too: Any punctuation character may be used as the delimiter between date parts or time parts. For example, `'2012-12-31 11:30:45'`, `'2012^12^31 11+30+45'`, `'2012/12/31 11*30*45'`, and `'2012@12@31 11^30^45'` are equivalent.
- As a string with no delimiters in either `'YYYYMMDDHHMMSS'` or `'YYMMDDHHMMSS'` format, provided that the string makes sense as a date. For example, `'20070523091528'` and `'070523091528'` are interpreted as `'2007-05-23 09:15:28'`, but `'071122129015'` is illegal (it has a nonsensical minute part) and becomes `'0000-00-00 00:00:00'`.
- As a number in either `YYYYMMDDHHMMSS` or `YYMMDDHHMMSS` format, provided that the number makes sense as a date. For example, `19830905132800` and `830905132800` are interpreted as `'1983-09-05 13:28:00'`.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into `DATETIME` or `TIMESTAMP` columns. For information about fractional seconds support in MySQL, see Section 10.3.4, “Fractional Seconds in Time Values”.

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

- Year values in the range `70-99` are converted to `1970-1999`.
- Year values in the range `00-69` are converted to `2000-2069`.

See also Section 10.3.6, “Two-Digit Years in Dates”.

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than `10`. `'2015-6-9'` is the same as `'2015-06-09'`. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than `10`. `'2015-10-30 1:2:3'` is the same as `'2015-10-30 01:02:03'`.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYMMDD` or `YYYYMMDDHHMMSS` format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in `YYMMDD` or `YYMMDDHHMMSS` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify `'9903'`, thinking that represents March, 1999, MySQL converts it to the “zero” date value. This occurs because the year and month values are `99` and `03`, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value `'1999-03-00'`, use `'990300'`.

MySQL recognizes `TIME` values in these formats:

- As a string in `'D HH:MM:SS'` format. You can also use one of the following “relaxed” syntaxes: `'HH:MM:SS'`, `'HH:MM'`, `'D HH:MM'`, `'D HH'`, or `'SS'`. Here `D` represents days and can have a value from 0 to 34.
- As a string with no delimiters in `'HHMMSS'` format, provided that it makes sense as a time. For example, `'101112'` is understood as `'10:11:12'`, but `'109712'` is illegal (it has a nonsensical minute part) and becomes `'00:00:00'`.
- As a number in `HHMMSS` format, provided that it makes sense as a time. For example, `101112` is understood as `'10:11:12'`. The following alternative formats are also understood: `SS`, `MMSS`, or `HHMMSS`.

A trailing fractional seconds part is recognized in the `'D HH:MM:SS.fraction'`, `'HH:MM:SS.fraction'`, `'HHMMSS.fraction'`, and `HHMMSS.fraction` time formats, where `fraction` is the fractional part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into `TIME` columns. For information about fractional seconds support in MySQL, see Section 10.3.4, “Fractional Seconds in Time Values”.

For `TIME` values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than `10`. `'8:3:2'` is the same as `'08:03:02'`.

8.1.4 Hexadecimal Literals

MySQL supports hexadecimal values, written using `X'val'`, `x'val'`, or `0xval` format, where *`val`* contains hexadecimal digits (`0..9`, `A..F`). Lettercase of the digits does not matter. For values written using `X'val'` or `x'val'` format, *`val`* must contain an even number of digits. For values written using `0xval` syntax, values that contain an odd number of digits are treated as having an extra leading `0`. For example, `0x0a` and `0xaaa` are interpreted as `0x0a` and `0x0aaa`.

In numeric contexts, hexadecimal values act like integers (64-bit precision). In string contexts, they act like binary strings, where each pair of hex digits is converted to a character:

```
mysql> SELECT X'4D7953514C';
        -> 'MySQL'
mysql> SELECT 0x0a+0;
        -> 10
mysql> SELECT 0x5061756c;
        -> 'Paul'
```

In MySQL 4.1 (and in MySQL 4.0 when using the `--new` option), the default type of a hexadecimal value is a string. If you want to ensure that the value is treated as a number, you can use `CAST(... AS UNSIGNED)` [859]:

```
mysql> SELECT 0x41, CAST(0x41 AS UNSIGNED);
        -> 'A', 65
```

The `X'hexstring'` syntax is new in 4.0 and is based on standard SQL. The `0x` syntax is based on ODBC. Hexadecimal strings are often used by ODBC to supply values for `BLOB` columns.

Beginning with MySQL 4.0.1, you can convert a string or a number to a string in hexadecimal format with the `HEX()` [796] function:

```
mysql> SELECT HEX('cat');
        -> '636174'
mysql> SELECT 0x636174;
        -> 'cat'
```

8.1.5 Boolean Literals

Beginning with MySQL 4.1, The constants `TRUE` and `FALSE` evaluate to `1` and `0`, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
        -> 1, 1, 0, 0
```

8.1.6 `NULL` Values

The `NULL` value means “no data.” `NULL` can be written in any lettercase. A synonym is `\N` (case sensitive).

For text file import or export operations performed with `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See Section 12.2.5, “`LOAD DATA INFILE` Syntax”.

Be aware that the `NULL` value is different from values such as `0` for numeric types or the empty string for string types. For more information, see Section B.5.5.3, “Problems with `NULL` Values”.

8.2 Database, Table, Index, Column, and Alias Names

Database, table, index, column, and alias names are identifiers. This section describes the permissible syntax for identifiers in MySQL. Section 8.2.2, “Identifier Case Sensitivity”, describes which types of identifiers are case sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you *must* quote it whenever you refer to it. The set of alphanumeric characters from the current character set, “_”, and “$” are not special. Reserved words are listed at Section 8.3, “Reserved Words”. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.)

The identifier quote character is the backtick (“`”):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the `ANSI_QUOTES` [458] SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
```

```
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The ANSI_QUOTES [458] mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in Section 5.1.6, “Server SQL Modes”.

As of MySQL 4.1, identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, double the character. The following statement creates a table named a`b that contains a column named c"d:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
| one | two |
+-----+-----+
|   1 |   2 |
+-----+-----+
```

Identifier quoting was introduced in MySQL 3.23.6 to permit use of identifiers that contain special characters or are reserved words. Before 3.23.6, you cannot use identifiers that require quotation marks, so the only legal characters are the set of alphanumeric characters from the current character set, “_”, and “$”.

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

Identifiers may begin with a digit but unless quoted may not consist solely of digits.

It is recommended that you do not use names that begin with *Me* or *MeN*, where *M* and *N* are integers. For example, avoid using 1e as an identifier, because an expression such as 1e+3 is ambiguous. Depending on context, it might be interpreted as the expression 1e + 3 or as the number 1e+3.

Be careful when using MD5() [868] to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See Section 8.4, “User-Defined Variables”, for more information and examples of workarounds.

There are some restrictions on the characters that may appear in identifiers:

- No identifier can contain ASCII NUL (0x00) or a byte with a value of 255.
- Before MySQL 4.1, identifier quote characters should not be used in identifiers.
- Database, table, and column names should not end with space characters.
- Database and table names cannot contain “/”, “\”, “.”, or characters that are not permitted in file names.

The following table describes the maximum length for each type of identifier. Before MySQL 4.1.5, the maximum-length restrictions on identifiers are measured in bytes, not characters. Until that version, if you

use multi-byte characters in your identifier names, the maximum length will depend on the byte count of all the characters used.

Identifier	Maximum Length
Database	64
Table	64
Column	64
Index	64
Constraint	64
Alias	256

Beginning with MySQL 4.1, identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that are stored in `.frm` files and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multi-byte characters without reducing the number of characters permitted for values stored in these columns, something not true prior to MySQL 4.1. The permissible Unicode characters are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted.

8.2.1 Identifier Qualifiers

MySQL permits names that consist of a single identifier or multiple identifiers. The components of a multiple-part name must be separated by period (“`.`”) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which the final identifier is interpreted.

In MySQL, you can refer to a table column using any of the following forms.

Column Reference	Meaning
`col_name`	The column *`col_name`* from whichever table used in the statement contains a column of that name.
`tbl_name.col_name`	The column *`col_name`* from table *`tbl_name`* of the default database.
`db_name.tbl_name.col_name`	The column *`col_name`* from table *`tbl_name`* of the database *`db_name`*. This syntax is unavailable before MySQL 3.22.

If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write `` `my-table`.`my-column` ``, not `` `my-table.my-column` ``.

A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

You need not specify a *`tbl_name`* or *`db_name.tbl_name`* prefix for a column reference in a statement unless the reference would be ambiguous. Suppose that tables `t1` and `t2` each contain a column `c`, and you retrieve `c` in a `SELECT` statement that uses both `t1` and `t2`. In this case, `c` is ambiguous because it is not unique among the tables used in the statement. You must qualify it with a table name as `t1.c` or `t2.c` to indicate which table you mean. Similarly, to retrieve from a table `t` in database `db1` and from a table `t` in database `db2` in the same statement, you must refer to columns in those tables as `db1.t.`*`col_name`* and `db2.t.`*`col_name`*.

The syntax `.`*`tbl_name`* means the table *`tbl_name`* in the default database. This syntax is accepted for ODBC compatibility because some ODBC programs prefix table names with a “`.`” character.

8.2.2 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database and table names. This means database and table names are not case sensitive in Windows, and case sensitive in most varieties of Unix. One notable exception is Mac OS X, which is Unix-based but uses a default file system type (HFS+) that is not case sensitive. However, Mac OS X also supports UFS volumes, which are case sensitive just as on any Unix. See Section 1.9.4, "MySQL Extensions to Standard SQL". The `lower_case_table_names` [418] system variable also affects how the server handles identifier case sensitivity, as described later in this section.

Note

Although database and table names are not case sensitive on some platforms, you should not refer to a given database or table using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column and index names are not case sensitive on any platform, nor are column aliases.

Table aliases are case sensitive before MySQL 4.1.1. The following query would not work because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
    -> WHERE a.col_name = 1 OR A.col_name = 2;
```

If you have trouble remembering the permissible lettercase for database and table names, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` [418] system variable, which you can set when starting `mysqld`. `lower_case_table_names` [418] can take the values shown in the following table. On Unix, the default value of `lower_case_table_names` [418] is 0. On Windows, the default value is 1. On Mac OS X, the default is 1 before MySQL 4.0.18 and 2 as of 4.0.18.

Value	Meaning
`0`	Table and database names are stored on disk using the lettercase specified in the `CREATE TABLE` or `CREATE DATABASE` statement. Name comparisons are case sensitive. You should *not* set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or Mac OS X). If you force this variable to 0 with `--lower-case-table-names=0` [418] on a case-insensitive file system and access `MyISAM` tablenames using different lettercases, this may lead to index corruption.
`1`	Table names are stored in lowercase on disk and name comparisons are not case sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names as of MySQL 4.0.2, and to table aliases as of 4.1.1.
`2`	Table and database names are stored on disk using the lettercase specified in the `CREATE TABLE` or `CREATE DATABASE` statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. This works *only* on file systems that are not case sensitive! `InnoDB` table names are stored in lowercase, as for `lower_case_table_names=1`. Setting `lower_case_table_names` [418] to `2` can be done as of MySQL 4.0.18.

If you are using MySQL on only one platform, you do not normally have to change the `lower_case_table_names` [418] variable from its default value. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows those names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- Use `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.
- Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

  Exception: If you are using `InnoDB` tables and you are trying to avoid these data transfer problems, you should set `lower_case_table_names` [418] to 1 on all platforms to force names to be converted to lowercase.

If you plan to set the `lower_case_table_names` [418] system variable to 1 on Unix, you must first convert your old database and table names to lowercase before stopping `mysqld` and restarting it with the new variable setting.

8.2.3 Function Name Parsing and Resolution

MySQL 4.1 supports built-in (native) functions and user-defined functions (UDFs). This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

Built-In Function Name Parsing

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` [458] SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following "`(`" parenthesis character.

- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such name. The exact list of function names for which following whitespace determines their interpretation are those listed in the `sql_functions[]` array of the `sql/lex.h` source file. Before MySQL 5.1, they are rather numerous (about 200), so you may find it easiest to treat the no-whitespace requirement as applying to all function calls. In MySQL 5.1, parser improvements reduce to about 30 the number of affected function names.

For functions not listed in the `sql_functions[]`) array, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. `ASCII` is one such name. However, for these nonaffected function names, interpretation may vary in expression context: *`func_name ()`* is interpreted as a built-in function if there is one with the given name; if not, *`func_name ()`* is interpreted as a user-defined function if one exists with that name.

The `IGNORE_SPACE` [458] SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- With `IGNORE_SPACE` [458] disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'
```

  To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```
CREATE TABLE count (i INT);
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

- With `IGNORE_SPACE` [458] enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```
SELECT COUNT(*) FROM mytable;
SELECT COUNT (*) FROM mytable;
```

  However, enabling `IGNORE_SPACE` [458] also has the side effect that the parser treats the affected function names as reserved words (see Section 8.3, “Reserved Words”). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with `IGNORE_SPACE` [458] enabled, both of the following statements fail with a syntax error because the parser interprets `count` as a reserved word:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

  To use the function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

To enable the IGNORE_SPACE [458] SQL mode, use this statement:

```
SET sql_mode = 'IGNORE_SPACE';
```

IGNORE_SPACE [458] is also enabled by certain other composite modes such as ANSI [460] that include it in their value:

```
SET sql_mode = 'ANSI';
```

Check Section 5.1.6, “Server SQL Modes”, to see which composite modes enable IGNORE_SPACE [458].

To minimize the dependency of SQL code on the IGNORE_SPACE [458] setting, use these guidelines:

- Avoid creating UDFs that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use count (one of the affected function names affected by IGNORE_SPACE [458]), so they fail with or without whitespace following the name if IGNORE_SPACE [458] is enabled:

  ```
  CREATE TABLE count(i INT);
  CREATE TABLE count (i INT);
  ```

  If you must use a function name in nonexpression context, write it as a quoted identifier:

  ```
  CREATE TABLE `count`(i INT);
  CREATE TABLE `count` (i INT);
  ```

Function Name Resolution

The server resolves references to function names for function creation and invocation as follows: A UDF can be created with the same name as a built-in function but the UDF cannot be invoked because the parser resolves invocations of the function to refer to the built-in function. For example, if you create a UDF named ABS, references to ABS() [817] invoke the built-in function.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions. If you have already created a user-defined function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use DROP FUNCTION to drop the UDF, and then use CREATE FUNCTION to re-create the UDF with a different nonconflicting name.

8.3 Reserved Words

Certain words such as SELECT, DELETE, or BIGINT are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Reserved words are permitted as identifiers if you quote them as described in Section 8.2, “Database, Table, Index, Column, and Alias Names”:

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'

mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following "`(`" character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further detail on recognition of function names, see Section 8.2.3, "Function Name Parsing and Resolution".

The words in the following table are explicitly reserved in MySQL 4.1. At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the words in the table are forbidden by standard SQL as column or table names (for example, `GROUP`). A few are reserved because MySQL needs them and uses a `yacc` parser. A reserved word can be used as an identifier if you quote it.

ADD	ALL	ALTER
ANALYZE	AND	AS
ASC	BEFORE	BETWEEN
BIGINT	BINARY	BLOB
BOTH	BY	CASCADE
CASE	CHANGE	CHAR
CHARACTER	CHECK	COLLATE
COLUMN	COLUMNS	CONSTRAINT
CONVERT	CREATE	CROSS

TRAILING	TRUE	UNION
UNIQUE	UNLOCK	UNSIGNED
UPDATE	USAGE	USE
USING	UTC_DATE	UTC_TIME
UTC_TIMESTAMP	VALUES	VARBINARY
VARCHAR	VARCHARACTER	VARYING
WHEN	WHERE	WITH
WRITE	XOR	YEAR_MONTH
ZEROFILL		

The following are new reserved words in MySQL 4.0:

CHECK	FORCE	LOCALTIME
LOCALTIMESTAMP	REQUIRE	SQL_CALC_FOUND_ROWS
SSL	XOR	

The following are new reserved words in MySQL 4.1:

BEFORE	COLLATE	CONVERT
CURRENT_USER	DAY_MICROSECOND	DIV
DUAL	FALSE	HOUR_MICROSECOND
MINUTE_MICROSECOND	MOD	NO_WRITE_TO_BINLOG
SECOND_MICROSECOND	SEPARATOR	SPATIAL
TRUE	UTC_DATE	UTC_TIME
UTC_TIMESTAMP	VARCHARACTER	

MySQL permits some keywords to be used as unquoted identifiers because many people previously used them. Examples are those in the following list:

- ACTION
- BIT
- DATE
- ENUM
- NO
- TEXT
- TIME
- TIMESTAMP

8.4 User-Defined Variables

MySQL supports user variables as of version 3.23.6. You can store a value in a user-defined variable in one statement and then refer to it later in another statement. This enables you to pass values from one statement to another. *User-defined variables are connection-specific*. That is, a user variable defined by one client cannot be seen or used by other clients. All variables for a given client connection are automatically freed when that client exits.

User variables are written as `@var_name`, where the variable name *`var_name`* consists of alphanumeric characters from the current character set, “.”, “_”, and “$”. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `` @`my-var` ``). The default character set is `latin1` (cp1252 West European). This can be changed with the `--default-character-set` [385] option to `mysqld`. See Section 9.6, “Character Set Configuration”.

User variable names are not case sensitive in MySQL 5.0 and up, but are case sensitive before MySQL 5.0.

One way to set a user-defined variable is by issuing a `SET` statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For SET, either = [789] or := [788] can be used as the assignment operator.

You can also assign a value to a user variable in statements other than SET. In this case, the assignment operator must be := [788] and not = [789] because the latter is treated as the comparison operator = [782] in non-SET statements:

```
mysql> SET @t1=1, @t2=2, @t3:=4;
mysql> SELECT @t1, @t2, @t3, @t4 := @t1+@t2+@t3;
+------+------+------+--------------------+
| @t1  | @t2  | @t3  | @t4 := @t1+@t2+@t3 |
+------+------+------+--------------------+
|    1 |    2 |    4 |                  7 |
+------+------+------+--------------------+
```

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or NULL value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string.

Beginning with MySQL 4.1.1, if a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is “implicit” as of MySQL 4.1.11 and 5.0.3. (This is the same coercibility as table column values.)

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of NULL and a type of string.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the LIMIT clause of a SELECT statement, or the IGNORE *N* LINES clause of a LOAD DATA statement.

As a general rule, you should never assign a value to a user variable and read the value within the same statement. You might get the results you expect, but this is not guaranteed. The order of evaluation for expressions involving user variables is undefined and may change based on the elements contained within a given statement. In SELECT @a, @a:=@a+1, ..., you might think that MySQL will evaluate @a first and then do an assignment second. However, changing the statement (for example, by adding a GROUP BY, HAVING, or ORDER BY clause) may cause MySQL to select an execution plan with a different order of evaluation.

Another issue with assigning a value to a variable and reading the value within the same statement is that the default result type of a variable is based on its type at the start of the statement. The following example illustrates this:

```
mysql> SET @a='test';
mysql> SELECT @a,(@a:=20) FROM tbl_name;
```

For this SELECT statement, MySQL reports to the client that column one is a string and converts all accesses of @a to strings, even though @a is set to a number for the second row. After the SELECT statement executes, @a is regarded as a number for the next statement.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to 0, 0.0, or '' to define its type before you use it.

In a SELECT statement, each select expression is evaluated only when sent to the client. This means that in a HAVING, GROUP BY, or ORDER BY clause, referring to a variable that is assigned a value in the select expression list does *not* work as expected:

```
mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
```

The reference to b in the HAVING clause refers to an alias for an expression in the select list that uses @aa. This does not work as expected: @aa contains the value of id from the previous selected row, not from the current row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as SELECT. This is true even if the variable is quoted, as shown in the following example:

```
mysql> SELECT c1 FROM t;
+----+
| c1 |
+----+
|  0 |
+----+
|  1 |
+----+
2 rows in set (0.00 sec)

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+------+
| @col |
+------+
| c1   |
+------+
1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "`c1`";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+------+
| @col |
+------+
| `c1` |
+------+
1 row in set (0.00 sec)
```

An exception to this principle that user variables cannot be used to provide identifiers is that if you are constructing a string for use as a prepared statement to be executed later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

```
mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
```

```
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+----+
| c1 |
+----+
|  0 |
+----+
|  1 |
+----+
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)
```

See Section 12.6, “SQL Syntax for Prepared Statements”, for more information.

PREPARE is available as of MySQL 4.1. Before MySQL 4.1, you must assemble a string for the query in application code, as shown here using PHP 5:

```
<?php
  $mysqli = new mysqli("localhost", "user", "pass", "test");

  if( mysqli_connect_errno() )
    die("Connection failed: %s\n", mysqli_connect_error());

  $col = "c1";

  $query = "SELECT $col FROM t";

  $result = $mysqli->query($query);

  while($row = $result->fetch_assoc())
  {
    echo "<p>" . $row["$col"] . "</p>\n";
  }

  $result->close();

  $mysqli->close();
?>
```

Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

8.5 Expression Syntax

The following rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. See the notes after the grammar for additional information about some of the terms. Operator precedence is given in Section 11.3.1, “Operator Precedence”.

```
expr:
    expr OR expr
  | expr || expr
  | expr XOR expr
  | expr AND expr
  | expr && expr
  | NOT expr
  | ! expr
  | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
  | boolean_primary
```

```
boolean_primary:
    boolean_primary IS [NOT] NULL
  | boolean_primary <=> predicate
  | boolean_primary comparison_operator predicate
  | boolean_primary comparison_operator {ALL | ANY} (subquery)
  | predicate

comparison_operator: = | >= | > | <= | < | <> | !=

predicate:
    bit_expr [NOT] IN (subquery)
  | bit_expr [NOT] IN (expr [, expr] ...)
  | bit_expr [NOT] BETWEEN bit_expr AND predicate
  | bit_expr SOUNDS LIKE bit_expr
  | bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]
  | bit_expr [NOT] REGEXP bit_expr
  | bit_expr

bit_expr:
    bit_expr | bit_expr
  | bit_expr & bit_expr
  | bit_expr << bit_expr
  | bit_expr >> bit_expr
  | bit_expr + bit_expr
  | bit_expr - bit_expr
  | bit_expr * bit_expr
  | bit_expr / bit_expr
  | bit_expr DIV bit_expr
  | bit_expr MOD bit_expr
  | bit_expr % bit_expr
  | bit_expr ^ bit_expr
  | bit_expr + interval_expr
  | bit_expr - interval_expr
  | simple_expr

simple_expr:
    literal
  | identifier
  | function_call
  | simple_expr COLLATE collation_name
  | param_marker
  | variable
  | simple_expr || simple_expr
  | + simple_expr
  | - simple_expr
  | ~ simple_expr
  | ! simple_expr
  | BINARY simple_expr
  | (expr [, expr] ...)
  | ROW (expr, expr [, expr] ...)
  | (subquery)
  | EXISTS (subquery)
  | {identifier expr}
  | match_expr
  | case_expr
  | interval_expr
```

Notes:

For literal value syntax, see Section 8.1, “Literal Values”.

For identifier syntax, see Section 8.2, “Database, Table, Index, Column, and Alias Names”.

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: Section 8.4, “User-Defined Variables”

- System variables: Section 5.1.4, “Using System Variables”
- Local variables: Local Variable DECLARE Syntax
- Parameters: CREATE PROCEDURE and CREATE FUNCTION Syntax

param_marker is '?' as used in prepared statements for placeholders. See Section 12.6.1, “PREPARE Syntax”.

(*subquery*) indicates a subquery that returns a single value; that is, a scalar subquery. See Section 12.2.8.1, “The Subquery as Scalar Operand”.

{*identifier expr*} is ODBC escape syntax and is accepted for ODBC compatibility. The value is *expr*. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

match_expr indicates a MATCH [845] expression. See Section 11.9, “Full-Text Search Functions”.

case_expr indicates a CASE [790] expression. See Section 11.4, “Control Flow Functions”.

interval_expr represents a time interval. The syntax is INTERVAL *expr unit*, where *unit* is a specifier such as HOUR, DAY, or WEEK. For the full list of *unit* specifiers, see the description of the DATE_ADD() [829] function in Section 11.7, “Date and Time Functions”.

The meaning of the || [787] operator depends on the SQL mode. By default, || [787] is a logical OR [787] operator. With PIPES_AS_CONCAT [460] enabled, || [787] is string concatenation, with a precedence between ^ [863] and the unary operators. See Section 5.1.6, “Server SQL Modes”.

8.6 Comment Syntax

MySQL Server supports three comment styles:

- From a “#” character to the end of the line.
- From a “-- ” sequence to the end of the line. This style is supported as of MySQL 3.23.3. In MySQL, the “-- ” (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.9.5.8, “'--' as the Start of a Comment”.
- From a /* sequence to the following */ sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```
mysql> SELECT 1+1;     # This comment continues to the end of line
mysql> SELECT 1+1;     -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;
```

Nested comments are not supported.

MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the "`!`" character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.) However, there are some limitations on the way that `mysql` parses `/* ... */` comments:

- A semicolon within the comment is taken to indicate the end of the current SQL statement and anything following it to indicate the beginning of the next statement. This problem was fixed in MySQL 4.0.13.
- A single quote, double quote, or backtick character is taken to indicate the beginning of a quoted string or identifier, even within a comment. If the quote is not matched by a second quote within the comment, the parser doesn't realize the comment has ended. If you are running `mysql` interactively, you can tell that it has gotten confused like this because the prompt changes from `mysql>` to `'>`, `">`, or `` `> ``. This problem was fixed in MySQL 4.1.1.
- The use of short-form commands such as `\C` within multi-line `/* ... */` comments is not supported.

Comments in this format, `/*!12345 ... */`, are not stored on the server. If this format is used to comment stored routines, the comments will not be retained on the server.

For affected versions of MySQL, these limitations apply both when you run `mysql` interactively and when you put commands in a file and use `mysql` in batch mode to process the file with `mysql < file_name`.

Chapter 9 Internationalization and Localization

Table of Contents

This chapter covers issues of internationalization (MySQL's capabilities for adapting to local use) and localization (selecting particular local conventions):

- MySQL support for character sets in SQL statements.
- How to configure the server to support different character sets.
- Selecting the language for error messages.
- How to set the server's time zone and enable per-connection time zone support.
- Selecting the locale for day and month names.

9.1 Character Set Support

Improved support for character set handling was added to MySQL in version 4.1. This support enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. You can specify character sets at the server, database, table, and column level. MySQL supports the use of character sets for the `MyISAM`, `MEMORY`, and (as of MySQL 4.1.2) `InnoDB` storage engines. The `ISAM`

storage engine does not include character set support; there are no plans to change this, because `ISAM` is deprecated.

Note

The `NDBCLUSTER` storage engine in MySQL 4.1 (available beginning with MySQL 4.1.3-Max) provides limited character set and collation support; see Section 15.1.4, “Known Limitations of MySQL Cluster”.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment
- Syntax for specifying character sets and collations
- Affected functions and operations
- Unicode support
- The character sets and collations that are available, with notes

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see Section 9.1.5, “Configuring the Character Set and Collation for Applications”, and Section 9.1.4, “Connection Character Sets and Collations”.

9.1.1 Character Sets and Collations in General

A *character set* is a set of symbols and encodings. A *collation* is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: “A”, “B”, “a”, “b”. We give each letter a number: “A” = 0, “B” = 1, “a” = 2, “b” = 3. The letter “A” is a symbol, the number 0 is the **encoding** for “A”, and the combination of all four letters and their encodings is a **character set**.

Suppose that we want to compare two string values, “A” and “B”. The simplest way to do this is to look at the encodings: 0 for “A” and 1 for “B”. Because 0 is less than 1, we say “A” is less than “B”. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a *binary* collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters “a” and “b” as equivalent to “A” and “B”; (2) then compare the encodings. We call this a *case-insensitive* collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just “A” and “B” but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether

to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German “Ö”), and for multiple-character mappings (such as the rule that “Ö” = “OE” in one of the two German collations).

MySQL 4.1 can do these things for you:

- Store strings using a variety of character sets
- Compare strings using a variety of collations
- Mix strings with different character sets or collations in the same server, the same database, or even the same table
- Enable specification of character set and collation at any level

In these respects, not only is MySQL 4.1 far more flexible than MySQL 4.0, it also is far ahead of most other database management systems. However, to use these features effectively, you need to know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

9.1.2 Character Sets and Collations in MySQL

The MySQL server can support multiple character sets. To list the available character sets, use the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see Section 9.1.12, “Character Sets and Collations That MySQL Supports”.

```
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     |      2 |
| dec8     | DEC West European           | dec8_swedish_ci     |      1 |
| cp850    | DOS West European           | cp850_general_ci    |      1 |
| hp8      | HP West European            | hp8_english_ci      |      1 |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |      1 |
| latin1   | cp1252 West European        | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   |      1 |
| swe7     | 7bit Swedish                | swe7_swedish_ci     |      1 |
| ascii    | US ASCII                    | ascii_general_ci    |      1 |
| ujis     | EUC-JP Japanese             | ujis_japanese_ci    |      3 |
| sjis     | Shift-JIS Japanese          | sjis_japanese_ci    |      2 |
| hebrew   | ISO 8859-8 Hebrew           | hebrew_general_ci   |      1 |
| tis620   | TIS620 Thai                 | tis620_thai_ci      |      1 |
| euckr    | EUC-KR Korean               | euckr_korean_ci     |      2 |
| koi8u    | KOI8-U Ukrainian            | koi8u_general_ci    |      1 |
| gb2312   | GB2312 Simplified Chinese   | gb2312_chinese_ci   |      2 |
| greek    | ISO 8859-7 Greek            | greek_general_ci    |      1 |
| cp1250   | Windows Central European    | cp1250_general_ci   |      1 |
| gbk      | GBK Simplified Chinese      | gbk_chinese_ci      |      2 |
| latin5   | ISO 8859-9 Turkish          | latin5_turkish_ci   |      1 |
...
```

Any given character set always has at least one collation. It may have several collations. To list the collations for a character set, use the `SHOW COLLATION` statement. For example, to see the collations for the `latin1` (cp1252 West European) character set, use this statement to find those collation names that begin with `latin1`:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-------------------+---------+----+---------+----------+---------+
```

```
| Collation           | Charset | Id | Default | Compiled | Sortlen |
+---------------------+---------+----+---------+----------+---------+
| latin1_german1_ci   | latin1  |  5 |         |          |       0 |
| latin1_swedish_ci   | latin1  |  8 | Yes     | Yes      |       1 |
| latin1_danish_ci    | latin1  | 15 |         |          |       0 |
| latin1_german2_ci   | latin1  | 31 |         | Yes      |       2 |
| latin1_bin          | latin1  | 47 |         | Yes      |       1 |
| latin1_general_ci   | latin1  | 48 |         |          |       0 |
| latin1_general_cs   | latin1  | 49 |         |          |       0 |
| latin1_spanish_ci   | latin1  | 94 |         |          |       0 |
+---------------------+---------+----+---------+----------+---------+
```

The `latin1` collations have the following meanings.

Collation	Meaning
`latin1_german1_ci`	German DIN-1
`latin1_swedish_ci`	Swedish/Finnish
`latin1_danish_ci`	Danish/Norwegian
`latin1_german2_ci`	German DIN-2
`latin1_bin`	Binary according to `latin1` encoding
`latin1_general_ci`	Multilingual (Western European)
`latin1_general_cs`	Multilingual (ISO Western European), case sensitive
`latin1_spanish_ci`	Modern Spanish

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has one collation that is the *default collation*. For example, the default collation for `latin1` is `latin1_swedish_ci`. The output for `SHOW CHARACTER SET` indicates which collation is the default for each displayed character set.
- There is a convention for collation names: They start with the name of the character set with which they are associated, they usually include a language name, and they end with `_ci` (case insensitive), `_cs` (case sensitive), or `_bin` (binary).

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

Collation-Charts.Org is a useful site for information that shows how one collation compares to another.

9.1.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character

set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see Section 9.1.4, “Connection Character Sets and Collations”.

9.1.3.1 Server Character Set and Collation

MySQL Server has a server character set and a server collation. These can be set at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` [385] for the character set. Along with it, you can add `--collation-server` [385] for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=latin1` [385]. If you specify only a character set (for example, `latin1`) but not a collation, that is the same as saying `--character-set-server=latin1` [385] `--collation-server=latin1_swedish_ci` [385] because `latin1_swedish_ci` is the default collation for `latin1`. Therefore, the following three commands all have the same effect:

```
shell> mysqld
shell> mysqld --character-set-server=latin1
shell> mysqld --character-set-server=latin1 \
          --collation-server=latin1_swedish_ci
```

One way to change the settings is by recompiling. If you want to change the default server character set and collation when building from sources, use: `--with-charset` [97] and `--with-collation` [97] as arguments for `configure`. For example:

```
shell> ./configure --with-charset=latin1
```

Or:

```
shell> ./configure --with-charset=latin1 \
          --with-collation=latin1_german1_ci
```

Both `mysqld` and `configure` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in `CREATE DATABASE` statements. They have no other purpose.

The current server character set and collation can be determined from the values of the `character_set_server` [408] and `collation_server` [409] system variables. These variables can be changed at runtime.

9.1.3.2 Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
```

```
CREATE DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]
```

All database options are stored in a text file named `db.opt` that can be found in the database directory.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set *X* and collation *Y* are used.
- If `CHARACTER SET X` is specified without `COLLATE`, character set *X* and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with *Y* and collation *Y* are used.
- Otherwise, the server character set and server collation are used.

The database character set and collation are used as default values for table definitions if the table character set and collation are not specified in `CREATE TABLE` statements. They have no other purpose.

The character set and collation for the default database can be determined from the values of the `character_set_database` [408] and `collation_database` [409] system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` [408] and `collation_server` [409].

9.1.3.3 Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
    [[DEFAULT] CHARACTER SET charset_name]
    [COLLATE collation_name]]

ALTER TABLE tbl_name
    [[DEFAULT] CHARACTER SET charset_name]
    [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set *X* and collation *Y* are used.
- If `CHARACTER SET X` is specified without `COLLATE`, character set *X* and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with *Y* and collation *Y* are used.
- Otherwise, the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

9.1.3.4 Column Character Set and Collation

Every “character” column (that is, a column of type `CHAR`, `VARCHAR`, or `TEXT`) has a column character set and a column collation. Column definition syntax for `CREATE TABLE` and `ALTER TABLE` has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
    [CHARACTER SET charset_name]
    [COLLATE collation_name]
```

These clauses can also be used for `ENUM` and `SET` columns:

```
col_name {ENUM | SET} (val_list)
    [CHARACTER SET charset_name]
    [COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
(
    col1 VARCHAR(5)
      CHARACTER SET latin1
      COLLATE latin1_german1_ci
);

ALTER TABLE t1 MODIFY
    col1 VARCHAR(5)
      CHARACTER SET latin1
      COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set *X* and collation *Y* are used.

  ```
  CREATE TABLE t1
  (
      col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
  ) CHARACTER SET latin1 COLLATE latin1_bin;
  ```

  The character set and collation are specified for the column, so they are used. The column has character set `utf8` and collation `utf8_unicode_ci`.

- If `CHARACTER SET X` is specified without `COLLATE`, character set *X* and its default collation are used.

```
CREATE TABLE t1
(
    col1 CHAR(10) CHARACTER SET utf8
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set `utf8` and the default collation for `utf8`, which is `utf8_general_ci`. To see the default collation for each character set, use the `SHOW COLLATION` statement.

- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with *`Y`* and collation *`Y`* are used.

```
CREATE TABLE t1
(
    col1 CHAR(10) COLLATE utf8_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation `utf8_polish_ci` and the character set is the one associated with the collation, which is `utf8`.

- Otherwise, the table character set and collation are used.

```
CREATE TABLE t1
(
    col1 CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation are specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

9.1.3.5 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

A character string literal may have an optional character set introducer and `COLLATE` clause:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT 'string';
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

For the simple statement `SELECT 'string'`, the string has the character set and collation defined by the `character_set_connection` [408] and `collation_connection` [409] system variables.

The *`_charset_name`* expression is formally called an *introducer*. It tells the parser, “the string that is about to follow uses character set *`X`*.” Because this has confused people in the past, we emphasize that

an introducer does not change the string to the introducer character set like `CONVERT()` [859] would do. It does not change the string's value, although padding may occur. The introducer is just a signal. An introducer is also legal before standard hex literal and numeric hex literal notation (`x'literal'` and `0xnnnn`).

Examples:

```
SELECT _latin1 x'AABBCC';
SELECT _latin1 0xAABBCC;
```

MySQL determines a literal's character set and collation in the following manner:

- If both `_X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.
- If `_X` is specified but `COLLATE` is not specified, character set `X` and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- Otherwise, the character set and collation given by the `character_set_connection` [408] and `collation_connection` [409] system variables are used.

Examples:

- A string with `latin1` character set and `latin1_german1_ci` collation:

  ```
  SELECT _latin1'Müller' COLLATE latin1_german1_ci;
  ```

- A string with `latin1` character set and its default collation (that is, `latin1_swedish_ci`):

  ```
  SELECT _latin1'Müller';
  ```

- A string with the connection default character set and collation:

  ```
  SELECT 'Müller';
  ```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

An introducer indicates the character set for the following string, but does not change now how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection` [408].

The following examples show that escape processing occurs using `character_set_connection` [408] even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection` [408], as discussed in Section 9.1.4, “Connection Character Sets and Collations”), and display the resulting strings using the `HEX()` [796] function so that the exact string contents can be seen.

Example 1:

```
mysql> SET NAMES latin1;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+------------+-----------------+
| HEX('à\n') | HEX(_sjis'à\n') |
```

```
+------------+-----------------+
| E00A       | E00A            |
+------------+-----------------+
1 row in set (0.00 sec)
```

Here, “à” (hex value E0) is followed by “\n”, the escape sequence for newline. The escape sequence is interpreted using the character_set_connection [408] value of latin1 to produce a literal newline (hex value 0A). This happens even for the second string. That is, the introducer of _sjis does not affect the parser's escape processing.

Example 2:

```
mysql> SET NAMES sjis;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
+------------+-------------------+
| HEX('à\n') | HEX(_latin1'à\n') |
+------------+-------------------+
| E05C6E     | E05C6E            |
+------------+-------------------+
1 row in set (0.04 sec)
```

Here, character_set_connection [408] is sjis, a character set in which the sequence of “à” followed by “\” (hex values 05 and 5C) is a valid multi-byte character. Hence, the first two bytes of the string are interpreted as a single sjis character, and the “\” is not interpreted as an escape character. The following “n” (hex value 6E) is not interpreted as part of an escape sequence. This is true even for the second string; the introducer of _latin1 does not affect escape processing.

9.1.3.6 National Character Set

Before MySQL 4.1, NCHAR and CHAR were synonymous. Standard SQL defines NCHAR or NATIONAL CHAR as a way to indicate that a CHAR column should use some predefined character set. MySQL 4.1 and up uses utf8 as that predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use N'*literal*' (or n'*literal*') to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

9.1.3.7 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

Example 1: Table and Column Definition

```
CREATE TABLE t1
(
    c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

Example 2: Table and Column Definition

```
CREATE TABLE t1
(
    c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

Example 3: Table and Column Definition

```
CREATE TABLE t1
(
    c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

Example 4: Database, Table, and Column Definition

```
CREATE DATABASE d1
    DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
    c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

9.1.3.8 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

9.1.4 Connection Character Sets and Collations

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The server character set and collation can be determined from the values of the `character_set_server` [408] and `collation_server` [409] system variables.
- The character set and collation of the default database can be determined from the values of the `character_set_database` [408] and `collation_database` [409] system variables.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has connection-related character set and collation system variables.

Consider what a “connection” is: It is what you make when you connect to the server. The client sends SQL statements, such as queries, over the connection to the server. The server sends responses, such as result sets or error messages, over the connection back to the client. This leads to several questions about character set and collation handling for client connections, each of which can be answered in terms of system variables:

- What character set is the statement in when it leaves the client?

  The server takes the `character_set_client` [408] system variable to be the character set in which statements are sent by the client.

- What character set should the server translate a statement to after receiving it?

  For this, the server uses the `character_set_connection` [408] and `collation_connection` [409] system variables. It converts statements sent by the client from `character_set_client` [408] to `character_set_connection` [408] (except for string literals that have an introducer such as `_latin1` or `_utf8`). `collation_connection` [409] is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` [409] does not matter because columns have their own collation, which has a higher collation precedence.

- What character set should the server translate to before shipping result sets back to the client?

  The `character_set_results` [408] system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, and result metadata such as column names.

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings *for each connection to the server.*

There are two statements that affect the connection-related character set variables as a group:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

  `SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement.)

  A `SET NAMES 'x'` statement is equivalent to these three statements:

```
SET character_set_client = x;
SET character_set_results = x;
SET character_set_connection = x;
```

Setting each of these character set variables also sets its corresponding collation variable to the default correlation for the character set. For example, setting `character_set_connection` [408] to *x* also sets `collation_connection` [409] to the default collation for *x*. It is not necessary to set that collation explicitly. To specify a particular collation for the character sets, use the optional `COLLATE` clause:

```
SET NAMES 'charset_name' COLLATE 'collation_name'
```

- `SET CHARACTER SET charset_name`

  `SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` [408] and `collation_connection` [409] to `character_set_database` [408] and `collation_database` [409]. A `SET CHARACTER SET x` statement is equivalent to these three statements:

```
SET character_set_client = x;
SET character_set_results = x;
SET collation_connection = @@collation_database;
```

  Setting `collation_connection` [409] also sets `character_set_connection` [408] to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is not necessary to set `character_set_connection` [408] explicitly.

Note

`ucs2` cannot be used as a client character set, which means that it does not work for `SET NAMES` or `SET CHARACTER SET`.

The MySQL client programs `mysql`, `mysqladmin`, `mysqlcheck`, `mysqlimport`, and `mysqlshow` determine the default character set to use as follows:

- In the absence of other information, the programs use the compiled-in default character set, usually `latin1`.
- The programs support a `--default-character-set` [260] option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

When a client connects to the server, it sends the name of the character set that it wants to use. The server uses the name to set the `character_set_client` [408], `character_set_results` [408], and `character_set_connection` [408] system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

With the `mysql` client, if you want to use a character set different from the default, you could explicitly execute `SET NAMES` every time you start up. However, to accomplish the same result more easily, you can add the `--default-character-set` [260] option setting to your `mysql` command line or in your option file. For example, the following option file setting changes the three connection-related character set variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET latin1` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy if there are characters that are not in both character sets.

If you do not want the server to perform any conversion of result sets or error messages, set `character_set_results` [408] to `NULL` or `binary`:

```
SET character_set_results = NULL;
```

To see the values of the character set and collation system variables that apply to your connection, use these statements:

```
SHOW VARIABLES LIKE 'character_set%';
SHOW VARIABLES LIKE 'collation%';
```

You must also consider the environment within which your MySQL applications execute. See Section 9.1.5, “Configuring the Character Set and Collation for Applications”.

For more information about character sets and error messages, see Section 9.1.6, “Character Set for Error Messages”.

9.1.5 Configuring the Character Set and Collation for Applications

For applications that store data using the default MySQL character set and collation (`latin1`, `latin1_swedish_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might require `utf8`, whereas applications that use another database might require `sjis`.
- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.
- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the `utf8` character set and `utf8_general_ci` collation.

Specify character settings per database. To create a database such that its tables will use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```
CREATE DATABASE mydb
  DEFAULT CHARACTER SET utf8
```

```
  DEFAULT COLLATE utf8_general_ci;
```

Tables created in the database will use `utf8` and `utf8_general_ci` by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'utf8'` statement after connecting. The statement can be used regardless of connection method: The `mysql` client, PHP scripts, and so forth.

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, for connections made using `mysql`, you can specify the `--default-character-set=utf8` [260] command-line option to achieve the same effect as `SET NAMES 'utf8'`.

For more information about configuring client connections, see Section 9.1.4, “Connection Character Sets and Collations”.

Specify character settings at server startup. To select a character set and collation at server startup, use the `--character-set-server` [385] and `--collation-server` [385] options. For example, to specify the options in an option file, include these lines:

```
[mysqld]
character-set-server=utf8
collation-server=utf8_general_ci
```

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'utf8'"` [414] option to cause `SET NAMES` to be executed automatically for each client that connects. However, this will yield inconsistent results because the `init_connect` [414] value is not executed for users who have the `SUPER` [493] privilege.

Specify character settings at MySQL configuration time. To select a character set and collation when you configure and build MySQL from source, use the `--with-charset` [97] and `--with-collation` [97] options:

```
shell> ./configure --with-charset=utf8 --with-collation=utf8_general_ci
```

The resulting server uses `utf8` and `utf8_general_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` [385] and `--collation-server` [385] to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. If you will send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
```

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

9.1.6 Character Set for Error Messages

This section describes how the server uses character sets for constructing error messages and returning them to clients. For information about the language of error messages (rather than the character set), see Section 9.3, “Setting the Error Message Language”.

In MySQL 4.1, the server constructs error messages and returns them to clients as follows:

- The message template has the character set associated with the error message language. For example, English, Korean, and Russian messages use `latin1`, `euckr`, and `koi8r`, respectively.
- Parameters in the message template are replaced with values that apply to a specific error occurrence. These parameters use their own character set. Identifiers such as table or column names use UTF-8. Data values retain their character set. For example, in the following duplicate-key message, `'xxx'` has the character set of the table column associated with key 1:

```
Duplicate entry 'xxx' for key1
```

The preceding method of error-message construction can result in messages that contain a mix of character sets unless all items involved contain only ASCII characters. This issue is resolved in MySQL 5.5, in which error messages are constructed internally within the server using UTF-8 and returned to the client in the character set specified by the `character_set_results` [408] system variable.

9.1.7 Collation Issues

The following sections discuss various aspects of character set collations.

9.1.7.1 Collation Names

MySQL collation names follow these rules:

- A name ending in `_ci` indicates a case-insensitive collation.
- A name ending in `_cs` indicates a case-sensitive collation.
- A name ending in `_bin` indicates a binary collation. Character comparisons are based on character binary code values.

9.1.7.2 Using `COLLATE` in SQL Statements

With the `COLLATE` clause, you can override whatever the default collation is for a comparison. `COLLATE` may be used in various parts of SQL statements. Here are some examples:

- With `ORDER BY`:

```
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With `AS`:

```
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
```

```
ORDER BY k1;
```

- With `GROUP BY`:

```
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With `DISTINCT`:

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With `WHERE`:

```
    SELECT *
    FROM t1
    WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```
    SELECT *
    FROM t1
    WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With `HAVING`:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

9.1.7.3 `COLLATE` Clause Precedence

The `COLLATE` clause has high precedence (higher than `||` [787]), so the following two expressions are equivalent:

```
x || y COLLATE z
x || (y COLLATE z)
```

9.1.7.4 Collations Must Be for the Right Character Set

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

In some cases, expressions that worked before MySQL 4.1 fail in early versions of MySQL 4.1 if you do not take character set and collation into account. For example, before 4.1, this statement works as is:

```
mysql> SELECT SUBSTRING_INDEX(USER(),'@',1);
+-----------------------------+
| SUBSTRING_INDEX(USER(),'@',1) |
+-----------------------------+
| root                        |
+-----------------------------+
```

The statement also works as is in MySQL 4.1 as of 4.1.8: In MySQL 4.1, user names are stored using the `utf8` character set (see Section 9.1.10, “UTF-8 for Metadata”). The literal string `'@'` has the server character set (`latin1` by default). Although the character sets are different, MySQL can coerce the `latin1` string to the character set (and collation) of `USER()` [876] without data loss. It does so, performs the substring operation, and returns a result that has a character set of `utf8`.

However, in versions of MySQL 4.1 before 4.1.8, the statement fails:

```
mysql> SELECT SUBSTRING_INDEX(USER(),'@',1);
ERROR 1267 (HY000): Illegal mix of collations
(utf8_general_ci,IMPLICIT) and (latin1_swedish_ci,COERCIBLE)
for operation 'substr_index'
```

This happens because the automatic character set conversion of `'@'` does not occur and the string operands have different character sets (and thus different collations):

```
mysql> SELECT COLLATION(USER()), COLLATION('@');
+-------------------+-------------------+
| COLLATION(USER()) | COLLATION('@')    |
+-------------------+-------------------+
| utf8_general_ci   | latin1_swedish_ci |
+-------------------+-------------------+
```

One way to deal with this is to upgrade to MySQL 4.1.8 or later. If that is not possible, you can tell MySQL to interpret the literal string as `utf8`:

```
mysql> SELECT SUBSTRING_INDEX(USER(),_utf8'@',1);
+-----------------------------------+
| SUBSTRING_INDEX(USER(),_utf8'@',1) |
+-----------------------------------+
| root                              |
+-----------------------------------+
```

Another way is to change the connection character set and collation to `utf8`. You can do that with `SET NAMES 'utf8'` or by setting the `character_set_connection` [408] and `collation_connection` [409] system variables directly.

9.1.7.5 Collation of Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `x`:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, with multiple operands, there can be ambiguity. For example:

```
SELECT x FROM T WHERE x = 'Y';
```

Should the comparison use the collation of the column `x`, or of the string literal `'Y'`? Both `x` and `'Y'` have collations, so which collation takes precedence?

Standard SQL resolves such questions using what used to be called “coercibility” rules. MySQL assigns coercibility values as follows:

- An explicit `COLLATE` clause has a coercibility of 0. (Not coercible at all.)
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` [876] or `VERSION()` [876]) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 5.

The preceding coercibility values are current as of MySQL 4.1.11. Before MySQL 4.1.11, there is no system constant or `NULL` coercibility. Functions such as `USER()` [876] have a coercibility of 2 rather than 3, and literals have a coercibility of 3 rather than 4.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:

    ```
    SELECT CONCAT(utf8_column, latin1_column) FROM t1;
    ```

    It returns a result that has a character set of `utf8` and the same collation as `utf8_column`. Values of `latin1_column` are automatically converted to `utf8` before concatenating.
  - For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, except that it is for collations rather than data types.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

Examples:

Comparison	Collation Used
`column1 = 'A'`	Use collation of `column1`

Comparison	Collation Used
`column1 = 'A' COLLATE x`	Use collation of `'A' COLLATE x`
`column1 COLLATE x = 'A' COLLATE y`	Error

The `COERCIBILITY()` [871] function can be used to determine the coercibility of a string expression:

```
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
        -> 0
mysql> SELECT COERCIBILITY(VERSION());
        -> 3
mysql> SELECT COERCIBILITY('A');
        -> 4
```

See Section 11.13, “Information Functions”.

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument `1` in the expression `CONCAT(1, 'abc')` [795], the result is a binary string for which the character set and collation are `binary`. See Section 11.2, “Type Conversion in Expression Evaluation”.

9.1.7.6 The `_bin` and `binary` Collations

This section describes how `_bin` collations for nonbinary strings differ from the `binary` “collation” for binary strings.

Nonbinary strings (as stored in the `CHAR`, `VARCHAR`, and `TEXT` data types) have a character set and collation. A given character set can have several collations, each of which defines a particular sorting and comparison order for the characters in the set. One of these is the binary collation for the character set, indicated by a `_bin` suffix in the collation name. For example, `latin1` and `utf8` have binary collations named `latin1_bin` and `utf8_bin`.

Binary strings (as stored in the `BINARY`, `VARBINARY`, and `BLOB` data types) have no character set or collation in the sense that nonbinary strings do. (Applied to a binary string, the `CHARSET()` and `COLLATION()` functions both return a value of `binary`.) Binary strings are sequences of bytes and the numeric values of those bytes determine sort order.

The `_bin` collations differ from the `binary` collation in several respects.

The unit for sorting and comparison. Binary strings are sequences of bytes. Sorting and comparison is always based on numeric byte values. Nonbinary strings are sequences of characters, which might be multi-byte. Collations for nonbinary strings define an ordering of the character values for sorting and comparison. For the `_bin` collation, this ordering is based solely on binary code values of the characters (which is similar to ordering for binary strings except that a `_bin` collation must take into account that a character might contain multiple bytes). For other collations, character ordering might take additional factors such as lettercase into account.

Character set conversion. A nonbinary string has a character set and is converted to another character set in many cases, even when the string has a `_bin` collation:

- When assigning column values from another column that has a different character set:

```
UPDATE t1 SET utf8_bin_column=latin1_column;
INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
```

- When assigning column values for `INSERT` or `UPDATE` using a string literal:

```
SET NAMES latin1;
INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
```

- When sending results from the server to a client:

```
SET NAMES latin1;
SELECT utf8_bin_column FROM t2;
```

For binary string columns, no conversion occurs. For the preceding cases, the string value is copied byte-wise.

Lettercase conversion. Collations provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for `_bin` collations that ignore lettercase for ordering:

```
mysql> SET NAMES latin1 COLLATE latin1_bin;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT LOWER('aA'), UPPER('zZ');
+-------------+-------------+
| LOWER('aA') | UPPER('zZ') |
+-------------+-------------+
| aa          | ZZ          |
+-------------+-------------+
1 row in set (0.13 sec)
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must be converted to a nonbinary string:

```
mysql> SET NAMES binary;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING latin1));
+-------------+-----------------------------------+
| LOWER('aA') | LOWER(CONVERT('aA' USING latin1)) |
+-------------+-----------------------------------+
| aA          | aa                                |
+-------------+-----------------------------------+
1 row in set (0.00 sec)
```

Trailing space handling in comparisons. Nonbinary strings have `PADSPACE` behavior for all collations, including `_bin` collations. Trailing spaces are insignificant in comparisons:

```
mysql> SET NAMES utf8 COLLATE utf8_bin;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
+------------+
|          1 |
+------------+
1 row in set (0.00 sec)
```

For binary strings, all characters are significant in comparisons, including trailing spaces:

```
mysql> SET NAMES binary;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
+------------+
|          0 |
+------------+
1 row in set (0.00 sec)
```

Trailing space handling for inserts and retrievals. `CHAR(N)` columns store nonbinary strings. Values shorter than *N* characters are extended with spaces on insertion. For retrieval, trailing spaces are removed.

`BINARY(N)` columns store binary strings. Values shorter than *N* bytes are extended with `0x00` bytes on insertion. For retrieval, nothing is removed; a value of the declared length is always returned.

```
mysql> CREATE TABLE t1 (
    ->   a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin,
    ->   b BINARY(10)
    -> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t1 VALUES ('a','a');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(a), HEX(b) FROM t1;
+--------+----------------------+
| HEX(a) | HEX(b)               |
+--------+----------------------+
| 61     | 61000000000000000000 |
+--------+----------------------+
1 row in set (0.04 sec)
```

9.1.7.7 The BINARY Operator

The `BINARY` [859] operator casts the string following it to a binary string. This is an easy way to force a comparison to be done byte by byte rather than character by character. `BINARY` [859] also causes trailing spaces to be significant.

```
mysql> SELECT 'a' = 'A';
        -> 1
mysql> SELECT BINARY 'a' = 'A';
        -> 0
mysql> SELECT 'a' = 'a ';
        -> 1
mysql> SELECT BINARY 'a' = 'a ';
        -> 0
```

`BINARY str` is shorthand for `CAST(str AS BINARY)` [859].

The `BINARY` attribute in character column definitions has a different effect. A character column defined with the `BINARY` attribute is assigned the binary collation of the column character set. Every character set has a binary collation. For example, the binary collation for the `latin1` character set is `latin1_bin`, so if the table default character set is `latin1`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET latin1 COLLATE latin1_bin
```

The effect of `BINARY` as a column attribute differs from its effect prior to MySQL 4.1. Formerly, `BINARY` resulted in a column that was treated as a binary string. A binary string is a string of bytes that has no character set or collation, which differs from a nonbinary character string that has a binary collation. For both types of strings, comparisons are based on the numeric values of the string unit, but for nonbinary

strings the unit is the character and some character sets support multi-byte characters. Section 10.4.2, “The BINARY and VARBINARY Types”.

The use of CHARACTER SET binary in the definition of a CHAR, VARCHAR, or TEXT column causes the column to be treated as a binary data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

9.1.7.8 Examples of the Effect of Collation

Example 1: Sorting German Umlauts

Suppose that column X in table T has these latin1 column values:

```
Muffler
Müller
MX Systems
MySQL
```

Suppose also that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use ORDER BY with different collations.

latin1_swedish_ci	latin1_german1_ci	latin1_german2_ci
Muffler	Muffler	Müller
MX Systems	Müller	Muffler
Müller	MX Systems	MX Systems
MySQL	MySQL	MySQL

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the SELECT using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the SELECT using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the SELECT using the German DIN-2 rule, which says that U-umlaut sorts with UE.

Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (
    ->   c CHAR(10)
    -> ) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (
    ->   c CHAR(10)
    -> ) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (
    ->   c CHAR(10)
    -> ) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an `A = Ä` equality, and one has no such equality (`latin1_german2_ci`). For that reason, you'll get these results in comparisons:

```
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bar  |
| Bär  |
+------+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bär  |
+------+
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bar  |
| Bär  |
+------+
```

This is not a bug but rather a consequence of the sorting properties of `latin1_german1_ci` and `utf8_unicode_ci` (the sorting shown is done according to the German DIN 5007 standard).

9.1.8 Operations Affected by Character Set Support

This section describes operations that take character set information into account as of MySQL 4.1.

9.1.8.1 Result Strings

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` [804] returns a string whose character string and collation are the same as that of *X*. The same applies for `INSTR()` [797], `LCASE()` [797], `LOWER()` [798], `LTRIM()` [799], `MID()` [799], `REPEAT()` [800], `REPLACE()` [800], `REVERSE()` [800], `RIGHT()` [800], `RPAD()` [800], `RTRIM()` [801], `SOUNDEX()` [801], `SUBSTRING()` [802], `TRIM()` [803], `UCASE()` [803], and `UPPER()` [804].

Note: The REPLACE() [800] function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has no character set or collation. This can be checked by using the CHARSET() [870] and COLLATION() [871] functions, both of which return binary to indicate that their argument is a binary string:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+--------------------+----------------------+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+--------------------+----------------------+
| binary              | binary               |
+--------------------+----------------------+
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit COLLATE *X* occurs, use *X*.
- If explicit COLLATE *X* and COLLATE *Y* occur, raise an error.
- Otherwise, if all collations are *X*, use *X*.
- Otherwise, the result has no collation.

For example, with CASE ... WHEN a THEN b WHEN b THEN c COLLATE *X* END, the resulting collation is *X*. The same applies for UNION, || [787], CONCAT() [795], ELT() [795], GREATEST() [784], IF() [790], and LEAST() [786].

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the character_set_connection [408] and collation_connection [409] system variables. This applies only to CAST() [859], CHAR() [794], CONV() [818], FORMAT() [796], HEX() [796], and SPACE() [801].

If you are uncertain about the character set or collation of the result returned by a string function, you can use the CHARSET() [870] or COLLATION() [871] function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+---------------+-----------------+-------------------+
| USER()        | CHARSET(USER()) | COLLATION(USER()) |
+---------------+-----------------+-------------------+
| test@localhost | utf8            | utf8_general_ci   |
+---------------+-----------------+-------------------+
```

9.1.8.2 CONVERT() and CAST()

CONVERT() [859] provides a way to convert data between different character sets. The syntax is:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8table (utf8column)
```

```
    SELECT CONVERT(latin1field USING utf8) FROM latin1table;
```

`CONVERT(... USING ...)` [859] is implemented according to the standard SQL specification.

You may also use `CAST()` [859] to convert a string to a different character set. The syntax is:

```
CAST(character_string AS character_data_type CHARACTER SET charset_name)
```

Example:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8);
```

If you use `CAST()` [859] without specifying `CHARACTER SET`, the resulting character set and collation are defined by the `character_set_connection` [408] and `collation_connection` [409] system variables. If you use `CAST()` [859] with `CHARACTER SET X`, the resulting character set and collation are `X` and the default collation of `X`.

You may not use a `COLLATE` clause inside a `CONVERT()` [859] or `CAST()` [859] call, but you may use it outside. For example, `CAST(... COLLATE ...)` [859] is illegal, but `CAST(...) COLLATE ...` [859] is legal:

```
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

9.1.8.3 `SHOW` Statements and `INFORMATION_SCHEMA`

Several `SHOW` statements are added or modified in MySQL 4.1 to provide additional character set information. `SHOW CHARACTER SET`, `SHOW COLLATION`, and `SHOW CREATE DATABASE` are new. `SHOW CREATE TABLE` and `SHOW COLUMNS` are modified. These statements are described here briefly. For more information, see Section 12.4.5, “`SHOW` Syntax”.

The `SHOW CHARACTER SET` statement shows all available character sets. It takes an optional `LIKE` [804] clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

The output from `SHOW COLLATION` includes all available character sets. It takes an optional `LIKE` [804] clause that indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-------------------+---------+----+---------+----------+---------+
| Collation         | Charset | Id | Default | Compiled | Sortlen |
+-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5 |         |          |       0 |
| latin1_swedish_ci | latin1  |  8 | Yes     | Yes      |       0 |
| latin1_danish_ci  | latin1  | 15 |         |          |       0 |
| latin1_german2_ci | latin1  | 31 |         | Yes      |       2 |
| latin1_bin        | latin1  | 47 |         | Yes      |       0 |
| latin1_general_ci | latin1  | 48 |         |          |       0 |
```

```
| latin1_general_cs | latin1  | 49 |         |          |       0 |
| latin1_spanish_ci | latin1  | 94 |         |          |       0 |
+-------------------+---------+----+---------+----------+---------+
```

`SHOW CREATE DATABASE` displays the `CREATE DATABASE` statement that creates a given database:

```
mysql> SHOW CREATE DATABASE test;
+----------+-----------------------------------------------------------------+
| Database | Create Database                                                 |
+----------+-----------------------------------------------------------------+
| test     | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+----------+-----------------------------------------------------------------+
```

If no `COLLATE` clause is shown, the default collation for the character set applies.

`SHOW CREATE TABLE` is similar, but displays the `CREATE TABLE` statement to create a given table. The column definitions indicate any character set specifications, and the table options include character set information.

The `SHOW COLUMNS` statement displays the collations of a table's columns when invoked as `SHOW FULL COLUMNS`. Columns with `CHAR`, `VARCHAR`, or `TEXT` data types have collations. Numeric and other noncharacter types have no collation (indicated by `NULL` as the `Collation` value). For example:

```
mysql> SHOW FULL COLUMNS FROM person\G
*************************** 1. row ***************************
     Field: id
      Type: smallint(5) unsigned
 Collation: NULL
      Null: NO
       Key: PRI
   Default: NULL
     Extra: auto_increment
Privileges: select,insert,update,references
   Comment:
*************************** 2. row ***************************
     Field: name
      Type: char(60)
 Collation: latin1_swedish_ci
      Null: NO
       Key:
   Default:
     Extra:
Privileges: select,insert,update,references
   Comment:
```

The character set is not part of the display but is implied by the collation name.

9.1.9 Unicode Support

As of MySQL version 4.1, there are two new character sets for storing Unicode data:

- `ucs2`, the UCS-2 encoding of the Unicode character set using 16 bits per character
- `utf8`, a UTF-8 encoding of the Unicode character set using one to three bytes per character

These two character sets support the characters from the Basic Multilingual Plane (BMP) of Unicode Version 3.0. BMP characters have these characteristics:

- Their code values are between 0 and 65535 (or `U+0000` .. `U+FFFF`)

- They can be encoded with a fixed 16-bit word, as in `ucs2`
- They can be encoded with 8, 16, or 24 bits, as in `utf8`
- They are sufficient for almost all characters in major languages

The `ucs2` and `utf8` character sets do not support supplementary characters that lie outside the BMP.

A similar set of collations is available for each Unicode character set. For example, each has a Danish collation, the names of which are `ucs2_danish_ci` and `utf8_danish_ci`. All Unicode collations are listed at Section 9.1.12.1, “Unicode Character Sets”.

The MySQL implementation of UCS-2 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values will need to be performed when transferring data between those systems and MySQL.

MySQL uses no BOM for UTF-8 values.

Client applications that need to communicate with the server using Unicode should set the client character set accordingly; for example, by issuing a `SET NAMES 'utf8'` statement. `ucs2` cannot be used as a client character set, which means that it does not work for `SET NAMES` or `SET CHARACTER SET`. (See Section 9.1.4, “Connection Character Sets and Collations”.)

The following sections provide additional detail on the Unicode character sets in MySQL.

9.1.9.1 The `ucs2` Character Set (UCS-2 Unicode Encoding)

In UCS-2, every character is represented by a two-byte Unicode code with the most significant byte first. For example: `LATIN CAPITAL LETTER A` has the code `0x0041` and it is stored as a two-byte sequence: `0x00 0x41`. `CYRILLIC SMALL LETTER YERU` (Unicode `0x044B`) is stored as a two-byte sequence: `0x04 0x4B`. For Unicode characters and their codes, please refer to the Unicode Home Page.

In MySQL, the `ucs2` character set is a fixed-length 16-bit encoding for Unicode BMP characters.

9.1.9.2 The `utf8` Character Set (Three-Byte UTF-8 Unicode Encoding)

UTF-8 (Unicode Transformation Format with 8-bit units) is an alternative way to store Unicode data. It is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. Currently, MySQL support for UTF-8 does not include four-byte sequences. (An older standard for UTF-8 encoding, RFC 2279, describes UTF-8 sequences that take from one to six bytes. RFC 3629 renders RFC 2279 obsolete; for this reason, sequences with five and six bytes are no longer used.)

The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a two-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use three-byte sequences.

Tip: To save space with UTF-8, use `VARCHAR` instead of `CHAR`. Otherwise, MySQL must reserve three bytes for each character in a `CHAR CHARACTER SET utf8` column because that is the maximum

possible length. For example, MySQL must reserve 30 bytes for a `CHAR(10) CHARACTER SET utf8` column.

9.1.10 UTF-8 for Metadata

Metadata is "the data about the data." Anything that *describes* the database—as opposed to being the *contents* of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from `SHOW` are metadata.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, `SHOW` wouldn't work properly because different rows in the same column would be in different character sets.
- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the `USER()` [876], `CURRENT_USER()` [872], `SESSION_USER()` [876], `SYSTEM_USER()` [876], `DATABASE()` [872], and `VERSION()` [876] functions have the UTF-8 character set by default.

The server sets the `character_set_system` [409] system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+----------------------+-------+
| Variable_name        | Value |
+----------------------+-------+
| character_set_system | utf8  |
+----------------------+-------+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` [409] character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` [408] system variable, which has a default value of `latin1`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` [408] and other related system variables. (See Section 9.1.4, "Connection Character Sets and Collations".) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client perform the conversion, but this option is not available for many clients until late in the MySQL 4.x product cycle.

If `character_set_results` [408] is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system` [409]).

Beginning with MySQL 4.1.1, error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` [876] function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` [876] are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see Section 9.1.7.5, “Collation of Expressions”.

9.1.11 Upgrading Character Sets from MySQL 4.0

What about upgrading from older versions of MySQL? MySQL 4.1 is almost upward compatible with MySQL 4.0 and earlier for the simple reason that almost all the features are new, so there is nothing in earlier versions to conflict with. However, there are some differences and a few things to be aware of.

It is important to note that the “MySQL 4.0 character set” contains both character set and collation information in one single entity. Beginning in MySQL 4.1, character sets and collations are separate entities. Though each collation corresponds to a particular character set, the two are not bundled together.

There is a special treatment of national character sets in MySQL 4.1. `NCHAR` is not the same as `CHAR`, and `N'...'` literals are not the same as `'...'` literals.

Finally, there is a different file format for storing information about character sets and collations. Make sure that you have reinstalled the `/share/mysql/charsets/` directory containing the new configuration files.

If you want to start `mysqld` from a 4.1.x distribution with data created by MySQL 4.0, you should start the server with the same character set and collation. In this case, you won't need to reindex your data.

There are two ways to do so:

```
shell> ./configure --with-charset=... --with-collation=...
shell> ./mysqld --default-character-set=... --default-collation=...
```

If you used `mysqld` with, for example, the MySQL 4.0 `danish` character set, you should use the `latin1` character set and the `latin1_danish_ci` collation:

```
shell> ./configure --with-charset=latin1 \
           --with-collation=latin1_danish_ci
shell> ./mysqld --default-character-set=latin1 \
           --default-collation=latin1_danish_ci
```

Use the table shown in Section 9.1.11.1, “4.0 Character Sets and Corresponding 4.1 Character Set/Collation Pairs”, to find old 4.0 character set names and their 4.1 character set/collation pair equivalents.

If you have non-`latin1` data stored in a 4.0 `latin1` table and want to convert the table column definitions to reflect the actual character set of the data, use the instructions in Section 9.1.11.2, “Converting 4.0 Character Columns to 4.1 Format”.

9.1.11.1 4.0 Character Sets and Corresponding 4.1 Character Set/Collation Pairs

ID	4.0 Character Set	4.1 Character Set	4.1 Collation
1	big5	big5	big5_chinese_ci
2	czech	latin2	latin2_czech_ci
3	dec8	dec8	dec8_swedish_ci
4	dos	cp850	cp850_general_ci
5	german1	latin1	latin1_german1_ci
6	hp8	hp8	hp8_english_ci
7	koi8_ru	koi8r	koi8r_general_ci
8	latin1	latin1	latin1_swedish_ci
9	latin2	latin2	latin2_general_ci
10	swe7	swe7	swe7_swedish_ci
11	usa7	ascii	ascii_general_ci
12	ujis	ujis	ujis_japanese_ci
13	sjis	sjis	sjis_japanese_ci
14	cp1251	cp1251	cp1251_bulgarian_ci
15	danish	latin1	latin1_danish_ci
16	hebrew	hebrew	hebrew_general_ci
17	win1251	(removed)	(removed)
18	tis620	tis620	tis620_thai_ci
19	euc_kr	euckr	euckr_korean_ci
20	estonia	latin7	latin7_estonian_ci
21	hungarian	latin2	latin2_hungarian_ci
22	koi8_ukr	koi8u	koi8u_ukrainian_ci
23	win1251ukr	cp1251	cp1251_ukrainian_ci
24	gb2312	gb2312	gb2312_chinese_ci
25	greek	greek	greek_general_ci
26	win1250	cp1250	cp1250_general_ci
27	croat	latin2	latin2_croatian_ci
28	gbk	gbk	gbk_chinese_ci
29	cp1257	cp1257	cp1257_lithuanian_ci
30	latin5	latin5	latin5_turkish_ci
31	latin1_de	latin1	latin1_german2_ci

9.1.11.2 Converting 4.0 Character Columns to 4.1 Format

Normally, the server runs using the `latin1` character set by default. If you have been storing column data that actually is in some other character set that the 4.1 server supports directly, you can convert the column. However, you should avoid trying to convert directly from `latin1` to the "real" character set. This may result in data loss. Instead, convert the column to a binary data type, and then from the binary type to a nonbinary type with the desired character set. Conversion to and from binary involves no attempt at

character value conversion and preserves your data intact. Suppose that you have a 4.0 table with three columns that are used to store values represented in `latin1`, `latin2`, and `utf8`:

```
CREATE TABLE t
(
    latin1_col CHAR(50),
    latin2_col CHAR(100),
    utf8_col CHAR(150)
);
```

For MySQL 4.1, you want to convert this table to leave `latin1_col` alone but change the `latin2_col` and `utf8_col` columns to have character sets of `latin2` and `utf8`. Before upgrading to 4.1, back up your table, then convert the columns as follows:

```
ALTER TABLE t MODIFY latin2_col BLOB;
ALTER TABLE t MODIFY utf8_col BLOB;
```

Then, after upgrading to 4.1, complete the conversion by issuing these statements:

```
ALTER TABLE t MODIFY latin2_col CHAR(100) CHARACTER SET latin2;
ALTER TABLE t MODIFY utf8_col CHAR(150) CHARACTER SET utf8;
```

The first two statements “remove” the character set information from the `latin2_col` and `utf8_col` columns. The second two statements assign the proper character sets to the two columns.

If you like, you can combine the to-binary conversions and from-binary conversions into single statements. In MySQL 4.0, do this:

```
ALTER TABLE t
    MODIFY latin2_col BLOB,
    MODIFY utf8_col BLOB;
```

After upgrading to 4.1, do this:

```
ALTER TABLE t
    MODIFY latin2_col CHAR(100) CHARACTER SET latin2,
    MODIFY utf8_col CHAR(150) CHARACTER SET utf8;
```

If you can ensure that the tables will not otherwise be modified before you perform the character set conversion, you can issue all of the `ALTER TABLE` statements after upgrading to MySQL 4.1.

If you specified attributes when creating a column initially, you should also specify them when altering the table with `ALTER TABLE`. For example, if you specified `NOT NULL` and an explicit `DEFAULT` value, you should also provide them in the `ALTER TABLE` statement. Otherwise, the resulting column definition will not include those attributes.

9.1.12 Character Sets and Collations That MySQL Supports

MySQL supports 70+ collations for 30+ character sets. This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

You can always list the available character sets and their default collations with the `SHOW CHARACTER SET` statement:

```
mysql> SHOW CHARACTER SET;
```

```
+----------+-----------------------------+---------------------+
| Charset  | Description                 | Default collation   |
+----------+-----------------------------+---------------------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     |
| dec8     | DEC West European           | dec8_swedish_ci     |
| cp850    | DOS West European           | cp850_general_ci    |
| hp8      | HP West European            | hp8_english_ci      |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |
| latin1   | cp1252 West European        | latin1_swedish_ci   |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   |
| swe7     | 7bit Swedish                | swe7_swedish_ci     |
| ascii    | US ASCII                    | ascii_general_ci    |
| ujis     | EUC-JP Japanese             | ujis_japanese_ci    |
| sjis     | Shift-JIS Japanese          | sjis_japanese_ci    |
| hebrew   | ISO 8859-8 Hebrew           | hebrew_general_ci   |
| tis620   | TIS620 Thai                 | tis620_thai_ci      |
| euckr    | EUC-KR Korean               | euckr_korean_ci     |
| koi8u    | KOI8-U Ukrainian            | koi8u_general_ci    |
| gb2312   | GB2312 Simplified Chinese   | gb2312_chinese_ci   |
| greek    | ISO 8859-7 Greek            | greek_general_ci    |
| cp1250   | Windows Central European    | cp1250_general_ci   |
| gbk      | GBK Simplified Chinese      | gbk_chinese_ci      |
| latin5   | ISO 8859-9 Turkish          | latin5_turkish_ci   |
| armscii8 | ARMSCII-8 Armenian          | armscii8_general_ci |
| utf8     | UTF-8 Unicode               | utf8_general_ci     |
| ucs2     | UCS-2 Unicode               | ucs2_general_ci     |
| cp866    | DOS Russian                 | cp866_general_ci    |
| keybcs2  | DOS Kamenicky Czech-Slovak  | keybcs2_general_ci  |
| macce    | Mac Central European        | macce_general_ci    |
| macroman | Mac West European           | macroman_general_ci |
| cp852    | DOS Central European        | cp852_general_ci    |
| latin7   | ISO 8859-13 Baltic          | latin7_general_ci   |
| cp1251   | Windows Cyrillic            | cp1251_general_ci   |
| cp1256   | Windows Arabic              | cp1256_general_ci   |
| cp1257   | Windows Baltic              | cp1257_general_ci   |
| binary   | Binary pseudo charset       | binary              |
| geostd8  | GEOSTD8 Georgian            | geostd8_general_ci  |
| cp932    | SJIS for Windows Japanese   | cp932_japanese_ci   |
| eucjpms  | UJIS for Windows Japanese   | eucjpms_japanese_ci |
+----------+-----------------------------+---------------------+
```

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

Collation-Charts.Org is a useful site for information that shows how one collation compares to another.

9.1.12.1 Unicode Character Sets

MySQL 4.1 has two Unicode character sets:

- `ucs2`, the UCS-2 encoding of the Unicode character set using 16 bits per character
- `utf8`, a UTF-8 encoding of the Unicode character set using one to three bytes per character

You can store text in about 650 languages using these character sets. This section lists the collations available for each Unicode character set and describes their differentiating properties. For general information about the character sets, see Section 9.1.9, “Unicode Support”.

A similar set of collations is available for each Unicode character set. These are shown in the following list, where *`xxx`* represents the character set name. For example, *`xxx`*`_danish_ci` represents the Danish collations, the specific names of which are `ucs2_danish_ci` and `utf8_danish_ci`.

- *xxx*_bin
- *xxx*_czech_ci
- *xxx*_danish_ci
- *xxx*_estonian_ci
- *xxx*_general_ci (default)
- *xxx*_icelandic_ci
- *xxx*_latvian_ci
- *xxx*_lithuanian_ci
- *xxx*_persian_ci
- *xxx*_polish_ci
- *xxx*_roman_ci
- *xxx*_romanian_ci
- *xxx*_slovak_ci
- *xxx*_slovenian_ci
- *xxx*_spanish_ci
- *xxx*_spanish2_ci
- *xxx*_swedish_ci
- *xxx*_turkish_ci
- *xxx*_unicode_ci

There is a limitation in MySQL 4.1 that results in two characters not being correctly handled when a user tries to change their case using LOWER() [798] or UPPER() [804]:

- LATIN SMALL LETTER DOTLESS i
- LATIN CAPITAL LETTER I WITH DOT ABOVE

Here are two workarounds for MySQL 4.1:

1. Use ucs2 if you have Turkish data.
2. Use these function calls:

```
CONVERT(LOWER(CONVERT(col USING ucs2)) USING utf8)
```

MySQL implements the *xxx*_unicode_ci collations according to the Unicode Collation Algorithm (UCA) described at http://www.unicode.org/reports/tr10/. The collation uses the version-4.0.0 UCA weight keys: http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt. Currently, the *xxx*_unicode_ci collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported yet. Also,

combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo.

MySQL implements language-specific Unicode collations only if the ordering with *`xxx`*`_unicode_ci` does not work well for a language. Language-specific collations are UCA-based. They are derived from *`xxx`*`_unicode_ci` with additional language tailoring rules.

For any Unicode character set, operations performed using the *`xxx`*`_general_ci` collation are faster than those for the *`xxx`*`_unicode_ci` collation. For example, comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. The reason for this is that `utf8_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, in German and some other languages "ß" is equal to "`ss`". `utf8_unicode_ci` also supports contractions and ignorable characters. `utf8_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci` (for the effect this has in comparisons or when doing searches, see Section 9.1.7.8, "Examples of the Effect of Collation"):

```
Ä = A
Ö = O
Ü = U
```

A difference between the collations is that this is true for `utf8_general_ci`:

```
ß = s
```

Whereas this is true for `utf8_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):

```
ß = ss
```

MySQL implements language-specific collations for the `utf8` character set only if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German dictionary order and French, so there is no need to create special `utf8` collations.

`utf8_general_ci` also is satisfactory for both German and French, except that "ß" is equal to "`s`", and not to "`ss`". If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. Otherwise, use `utf8_unicode_ci` because it is more accurate.

`xxx``_swedish_ci` includes Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

```
Ü = Y < Ö
```

The *`xxx`*`_spanish_ci` and *`xxx`*`_spanish2_ci` collations correspond to modern Spanish and traditional Spanish, respectively. In both collations, "ñ" (n-tilde) is a separate letter between "`n`" and "`o`". In addition, for traditional Spanish, "`ch`" is a separate letter between "`c`" and "`d`", and "`ll`" is a separate letter between "`l`" and "`m`"

In the *`xxx`*`_roman_ci` collations, `I` and `J` compare as equal, and `U` and `V` compare as equal.

For additional information about Unicode collations in MySQL, see Collation-Charts.Org (utf8).

9.1.12.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
  - `ascii_bin`
  - `ascii_general_ci` (default)
- `cp850` (DOS West European) collations:
  - `cp850_bin`
  - `cp850_general_ci` (default)
- `dec8` (DEC Western European) collations:
  - `dec8_bin`
  - `dec8_swedish_ci` (default)
- `hp8` (HP Western European) collations:
  - `hp8_bin`
  - `hp8_english_ci` (default)
- `latin1` (cp1252 West European) collations:
  - `latin1_bin`
  - `latin1_danish_ci`
  - `latin1_general_ci`
  - `latin1_general_cs`
  - `latin1_german1_ci`
  - `latin1_german2_ci`
  - `latin1_spanish_ci`
  - `latin1_swedish_ci` (default)

  `latin1` is the default character set. MySQL's `latin1` is the same as the Windows `cp1252` character set. This means it is the same as the official `ISO 8859-1` or IANA (Internet Assigned Numbers Authority) `latin1`, except that IANA `latin1` treats the code points between `0x80` and `0x9f` as "undefined," whereas `cp1252`, and therefore MySQL's `latin1`, assign characters for those positions. For example, `0x80` is the Euro sign. For the "undefined" entries in `cp1252`, MySQL translates `0x81` to Unicode `0x0081`, `0x8d` to `0x008d`, `0x8f` to `0x008f`, `0x90` to `0x0090`, and `0x9d` to `0x009d`.

  The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for *Deutsches Institut für Normung* (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see Section 9.1.7.8, “Examples of the Effect of Collation”.

- `latin1_german1_ci` (dictionary) rules:

```
Ä = A
Ö = O
Ü = U
ß = s
```

- `latin1_german2_ci` (phone-book) rules:

```
Ä = AE
Ö = OE
Ü = UE
ß = ss
```

In the `latin1_spanish_ci` collation, “ñ” (n-tilde) is a separate letter between “n” and “o”.

- `macroman` (Mac West European) collations:
  - `macroman_bin`
  - `macroman_general_ci` (default)
- `swe7` (7bit Swedish) collations:
  - `swe7_bin`
  - `swe7_swedish_ci` (default)

For additional information about Western European collations in MySQL, see Collation-Charts.Org (ascii, cp850, dec8, hp8, latin1, macroman, swe7).

9.1.12.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- `cp1250` (Windows Central European) collations:
  - `cp1250_bin`
  - `cp1250_croatian_ci`
  - `cp1250_czech_cs`
  - `cp1250_general_ci` (default)
- `cp852` (DOS Central European) collations:
  - `cp852_bin`
  - `cp852_general_ci` (default)

- `keybcs2` (DOS Kamenicky Czech-Slovak) collations:
  - `keybcs2_bin`
  - `keybcs2_general_ci` (default)
- `latin2` (ISO 8859-2 Central European) collations:
  - `latin2_bin`
  - `latin2_croatian_ci`
  - `latin2_czech_cs`
  - `latin2_general_ci` (default)
  - `latin2_hungarian_ci`
- `macce` (Mac Central European) collations:
  - `macce_bin`
  - `macce_general_ci` (default)

For additional information about Central European collations in MySQL, see Collation-Charts.Org (cp1250, cp852, keybcs2, latin2, macce).

9.1.12.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMSCII-8 Armenian) collations:
  - `armscii8_bin`
  - `armscii8_general_ci` (default)
- `cp1256` (Windows Arabic) collations:
  - `cp1256_bin`
  - `cp1256_general_ci` (default)
- `geostd8` (GEOSTD8 Georgian) collations:
  - `geostd8_bin`
  - `geostd8_general_ci` (default)
- `greek` (ISO 8859-7 Greek) collations:
  - `greek_bin`
  - `greek_general_ci` (default)
- `hebrew` (ISO 8859-8 Hebrew) collations:
  - `hebrew_bin`

  - `hebrew_general_ci` (default)
- `latin5` (ISO 8859-9 Turkish) collations:
  - `latin5_bin`
  - `latin5_turkish_ci` (default)

For additional information about South European and Middle Eastern collations in MySQL, see Collation-Charts.Org (armscii8, cp1256, geostd8, greek, hebrew, latin5).

9.1.12.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:
  - `cp1257_bin`
  - `cp1257_general_ci` (default)
  - `cp1257_lithuanian_ci`
- `latin7` (ISO 8859-13 Baltic) collations:
  - `latin7_bin`
  - `latin7_estonian_cs`
  - `latin7_general_ci` (default)
  - `latin7_general_cs`

For additional information about Baltic collations in MySQL, see Collation-Charts.Org (cp1257, latin7).

9.1.12.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- `cp1251` (Windows Cyrillic) collations:
  - `cp1251_bin`
  - `cp1251_bulgarian_ci`
  - `cp1251_general_ci` (default)
  - `cp1251_general_cs`
  - `cp1251_ukrainian_ci`
- `cp866` (DOS Russian) collations:
  - `cp866_bin`
  - `cp866_general_ci` (default)

- `koi8r` (KOI8-R Relcom Russian) collations:
  - `koi8r_bin`
  - `koi8r_general_ci` (default)
- `koi8u` (KOI8-U Ukrainian) collations:
  - `koi8u_bin`
  - `koi8u_general_ci` (default)

For additional information about Cyrillic collations in MySQL, see Collation-Charts.Org (cp1251, cp866, koi8r, koi8u).).

9.1.12.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See The `cp932` Character Set, for additional information about the `cp932` and `sjis` character sets.

- `big5` (Big5 Traditional Chinese) collations:
  - `big5_bin`
  - `big5_chinese_ci` (default)
- `cp932` (SJIS for Windows Japanese) collations:
  - `cp932_bin`
  - `cp932_japanese_ci` (default)
- `eucjpms` (UJIS for Windows Japanese) collations:
  - `eucjpms_bin`
  - `eucjpms_japanese_ci` (default)
- `euckr` (EUC-KR Korean) collations:
  - `euckr_bin`
  - `euckr_korean_ci` (default)
- `gb2312` (GB2312 Simplified Chinese) collations:
  - `gb2312_bin`
  - `gb2312_chinese_ci` (default)
- `gbk` (GBK Simplified Chinese) collations:
  - `gbk_bin`
  - `gbk_chinese_ci` (default)
- `sjis` (Shift-JIS Japanese) collations:

  - `sjis_bin`
  - `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
  - `tis620_bin`
  - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
  - `ujis_bin`
  - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

For additional information about Asian collations in MySQL, see Collation-Charts.Org (big5, cp932, eucjpms, euckr, gb2312, gbk, sjis, tis620, ujis).

The `cp932` Character Set

Why is `cp932` needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See http://www.iana.org/assignments/character-sets.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM extended characters.

Since MySQL 4.1, many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems. It is available as of MySQL 4.1.12.

Before MySQL 4.1, it was safe to use any version of “SHIFT JIS” in conjunction with the `sjis` character set. However, because MySQL supports character set conversion beginning with 4.1, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

How does cp932 differ from sjis?

The cp932 character set differs from sjis in the following ways:

- cp932 supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
- Some cp932 characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to cp932, one of the code points must be selected. For this "round trip conversion," the rule recommended by Microsoft is used. (See http://support.microsoft.com/kb/170559/EN-US/.)

  The conversion rule works like this:

  - If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
  - If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
  - If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

  The table shown at http://www.microsoft.com/globaldev/reference/dbcs/932.htm provides information about the Unicode values of cp932 characters. For cp932 table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (ucs2) encoding. For table entries with an underlined two-digit value appears, there is a range of cp932 character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the cp932 characters that begin with those digits.

  The following links are of special interest. They correspond to the encodings for the following sets of characters:

  - NEC special characters:

    ```
    http://www.microsoft.com/globaldev/reference/dbcs/932/932_87.htm
    ```

  - NEC selected—IBM extended characters:

    ```
    http://www.microsoft.com/globaldev/reference/dbcs/932/932_ED.htm
    http://www.microsoft.com/globaldev/reference/dbcs/932/932_EE.htm
    ```

  - IBM selected characters:

    ```
    http://www.microsoft.com/globaldev/reference/dbcs/932/932_FA.htm
    http://www.microsoft.com/globaldev/reference/dbcs/932/932_FB.htm
    http://www.microsoft.com/globaldev/reference/dbcs/932/932_FC.htm
    ```

For some characters, conversion to and from ucs2 is different for sjis and cp932. The following tables illustrate these differences.

Conversion to ucs2:

sjis/cp932 Value	sjis -> ucs2 Conversion	cp932 -> ucs2 Conversion
5C	005C	005C

sjis/cp932 Value	sjis -> ucs2 Conversion	cp932 -> ucs2 Conversion
7E	007E	007E
815C	2015	2015
815F	005C	FF3C
8160	301C	FF5E
8161	2016	2225
817C	2212	FF0D
8191	00A2	FFE0
8192	00A3	FFE1
81CA	00AC	FFE2

Conversion from ucs2:

ucs2 value	ucs2 -> sjis Conversion	ucs2 -> cp932 Conversion
005C	815F	5C
007E	7E	7E
00A2	8191	3F
00A3	8192	3F
00AC	81CA	3F
2015	815C	815C
2016	8161	3F
2212	817C	3F
2225	3F	8161
301C	8160	3F
FF0D	3F	817C
FF3C	3F	815F
FF5E	3F	8160
FFE0	3F	8191
FFE1	3F	8192
FFE2	3F	81CA

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` [385] (or `--skip-character-set-client-handshake` [385]) has an important effect. See Section 5.1.2, “Server Command Options”.

9.2 Using the German Character Set

In MySQL 4.0, to get German sorting order, you should start `mysqld` with a `--default-character-set=latin1_de` [385] option. This affects server behavior in several ways:

- When sorting and comparing strings, the following mapping is performed on the strings before doing the comparison:

```
ä  ->  ae
ö  ->  oe
ü  ->  ue
ß  ->  ss
```

- All accented characters are converted to their unaccented uppercase counterpart. All letters are converted to uppercase.
- When comparing strings with `LIKE` [804], the one-character to two-character mapping is not done. All letters are converted to uppercase. Accents are removed from all letters except Ü, ü, Ö, ö, Ä, and ä.

In MySQL 4.1 and up, character set and collation are specified separately. You should select the `latin1` character set and either the `latin1_german1_ci` or `latin1_german2_ci` collation. For example, to start the server with the `latin1_german1_ci` collation, use the `--character-set-server=latin1` [385] and `--collation-server=latin1_german1_ci` [385] options.

For information on the differences between these two collations, see Section 9.1.12.2, “West European Character Sets”.

9.3 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can also be displayed in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish.

You can select which language the server uses for error messages using the instructions in this section.

To start `mysqld` with a particular language for error messages, use the `--language` [388] or `-L` option. The option value can be a language name or the full path to the error message file. For example:

```
shell> mysqld --language=swedish
```

Or:

```
shell> mysqld --language=/usr/local/share/swedish
```

The language name should be specified in lowercase.

By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

For information about changing the character set for error messages (rather than the language), see Section 9.1.6, “Character Set for Error Messages”.

You can change the content of the error messages produced by the server using the instructions in the MySQL Internals manual, available at MySQL Internals: Error Messages. If you do change the content of error messages, remember to repeat your changes after each upgrade to a newer version of MySQL.

9.4 Adding a New Character Set

This section discusses the procedure for adding a new character set to MySQL. You must have a MySQL source distribution to use these instructions. There is one procedure for MySQL 4.1 and a different one for MySQL 4.0 or older. For either procedure, the instructions depend on whether the character set is simple or complex:

- If the character set does not need to use special string collating routines for sorting and does not need multi-byte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

In the following instructions, *`MYSET`* represents the name of the character set that you want to add.

If you have MySQL 4.1, use this procedure to add a new character set:

1. Add a `<charset>` element for *`MYSET`* to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents.

   The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default collation. The default collation is usually named using a suffix of `general_ci` (general, case insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

   You must assign a unique ID number to each collation, chosen from the range 1 to 254. To see the currently used collation IDs, use this query:

   ```
   SHOW COLLATION;
   ```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multi-byte functions, or both.

   For a simple character set, create a configuration file, *`MYSET`*`.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. (You can use a copy of `latin1.xml` as the basis for this file.) The syntax for the file is very simple:

   - Comments are written as ordinary XML comments (`<!-- text -->`).
   - Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
   - Each word within `<map>` array elements must be a number in hexadecimal format.
   - The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See Section 9.4.1, “The Character Definition Arrays”.
   - For each collation listed in the `<charset>` element for the character set in `Index.xml`, *`MYSET`*`.xml` must contain a `<collation>` element that defines the character ordering.

   For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

   a. Create the file `ctype-`*`MYSET`*`.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_`*`MYSET`*, `to_lower_`*`MYSET`*, and so on. These correspond to the arrays for a simple character set. See Section 9.4.1, “The Character Definition Arrays”.

   b. For each collation listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-`*`MYSET`*`.c` file must provide an implementation of the collation.

c. If you need string collating functions, see Section 9.4.2, “String Collating Support”.

d. If you need multi-byte character support, see Section 9.4.3, “Multi-Byte Character Support”.

3. Follow these steps to modify the configuration information. Use the existing configuration information as a guide to adding information for *MYSYS*. The example here assumes that the character set has default and binary collations, but more lines will be needed if *MYSET* has additional collations.

   a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

      Add these lines to the “declaration” section:

```
#ifdef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

      Add these lines to the “registration” section:

```
#ifdef HAVE_CHARSET_MYSET
  add_compiled_collation(&my_charset_MYSET_general_ci);
  add_compiled_collation(&my_charset_MYSET_bin);
#endif
```

   b. If the character set uses `ctype-MYSET.c`, edit `strings/Makefile.am` and add `ctype-MYSET.c` to each definition of the `CSRCS` variable, and to the `EXTRA_DIST` variable.

   c. If the character set uses `ctype-MYSET.c`, edit `libmysql/Makefile.shared` and add `ctype-MYSET.lo` to the `mystringsobjects` definition.

   d. Edit `configure.in`:

      i. Add *MYSET* to one of the `define(CHARSETS_AVAILABLE...)` lines in alphabetic order.

      ii. Add *MYSET* to `CHARSETS_COMPLEX`. This is needed even for simple character sets, or `configure` will not recognize `--with-charset=MYSET` [97].

      iii. Add *MYSET* to the first `case` control structure. Omit the `USE_MB` and `USE_MB_IDENT` lines for 8-bit character sets.

```
MYSET)
  AC_DEFINE(HAVE_CHARSET_MYSET, 1, [Define to enable charset MYSET])
  AC_DEFINE([USE_MB], 1, [Use multi-byte character routines])
  AC_DEFINE(USE_MB_IDENT, 1)
  ;;
```

      iv. Add *MYSET* to the second `case` control structure:

```
MYSET)
  default_charset_default_collation="MYSET_general_ci"
  default_charset_collations="MYSET_general_ci MYSET_bin"
  ;;
```

4. Reconfigure, recompile, and test.

If you have MySQL 4.0 or older, use this procedure to add a new character set:

1. Add *MYSET* to the end of the sql/share/charsets/Index file. Assign a unique number to it.

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multi-byte functions, or both.

   For a simple character set, create a configuration file that describes the character set properties. Create the file *MYSET*.conf file in the sql/share/charsets directory. (You can use a copy of latin1.conf as the basis for this file.) The syntax for the file is very simple:

   - Comments start with a "#" character and continue to the end of the line.
   - Words are separated by arbitrary amounts of whitespace.
   - When defining the character set, every word must be a number in hexadecimal format.
   - The ctype array takes up the first 257 words. The to_lower[], to_upper[], and sort_order[] arrays take up 256 words each after that. See Section 9.4.1, "The Character Definition Arrays".

   For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

   a. Create the file ctype-*MYSET*.c in the strings directory. Look at one of the existing ctype-*.c files (such as ctype-big5.c) to see what needs to be defined. The arrays in your file must have names like ctype_*MYSET*, to_lower_*MYSET*, and so on. These correspond to the arrays for a simple character set. See Section 9.4.1, "The Character Definition Arrays".

   b. Near the top of the file, place a special comment like this:

```
/*
 * This comment is parsed by configure to create ctype.c,
 * so don't change it unless you know what you are doing.
 *
 * .configure. strxfrm_multiply_MYSET=N
 * .configure. mbmaxlen_MYSET=N
 */
```

      The configure program uses this comment to include the character set into the MySQL library automatically.

      If you need string collating functions, you must specify the strxfrm_multiply_*MYSET*=*N* value in the special comment at the top of the source file. *N* must be a positive integer that indicates the maximum ratio to which strings may grow during execution of the my_strxfrm_*MYSET*() function.

      If you need multi-byte character set functions, you must specify the mbmaxlen_*MYSET*=*N* value in the special comment at the top of the ctype-*MYSET*.c source file for your character set. *N* should be set to the size in bytes of the largest character in the set.

   c. If you need string collating functions, see Section 9.4.2, "String Collating Support".

   d. If you need multi-byte character support, see Section 9.4.3, "Multi-Byte Character Support".

3. Follow these steps to modify the configuration information. Use the existing configuration information as a guide to adding information for *MYSYS*.

   a. Add the character set name to the CHARSETS_AVAILABLE list in configure.in.

   b. If the character set uses `ctype-MYSET.c`, edit `strings/Makefile.am` and add `ctype-MYSET.c` to the `EXTRA_DIST` variable.

4. Reconfigure, recompile, and test.

The `sql/share/charsets/README` file includes additional instructions.

9.4.1 The Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. The file is named `MYSET.xml` for MySQL 4.1 and `MYSET.conf` for MySQL 4.0 or older.

For MySQL 4.1, `MYSET.xml` files use `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character
- `<lower>` and `<upper>` list the lowercase and uppercase characters
- `<unicode>` maps 8-bit character values to Unicode values
- `<collation>` elements indicate character ordering for comparisons and sorts, one element per collation (binary collations need no `<map>` element because the character codes themselves provide the ordering)

For MySQL 4.0 or older, `MYSET.conf` files list character set properties using these arrays:

- `ctype[]` defines attributes for each character
- `to_lower[]` and `to_upper[]` list the lowercase and uppercase characters
- `sort_order[]` indicates character ordering for comparisons and sorts

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See the existing `ctype-*.c` files for examples. For MySQL 4.1, see the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

The `ctype` array is indexed by character value + 1 and has 257 elements. This is an old legacy convention for handling `EOF`. The other arrays are indexed by character value and have 256 elements.

`ctype` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```
#define _MY_U   01      /* Upper case */
#define _MY_L   02      /* Lower case */
#define _MY_NMR 04      /* Numeral (digit) */
#define _MY_SPC 010     /* Spacing character */
#define _MY_PNT 020     /* Punctuation */
#define _MY_CTR 040     /* Control character */
#define _MY_B   0100    /* Blank */
#define _MY_X   0200    /* heXadecimal digit */
```

The `ctype` value for a given character should be the union of the applicable bitmask values that describe the character. For example, `'A'` is an uppercase character (`_MY_U`) as well as a hexadecimal digit (`_MY_X`), so its `ctype` value should be defined like this:

```
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `ctype` array in *`MYSET`*`.xml` (or *`MYSET`*`.conf`) should be written as hexadecimal values.

The `lower` and `upper` (or `to_lower` and `to_upper`) arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `collation` (or `sort_order`) array is a map indicating how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `upper` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in Section 9.4.2, “String Collating Support”.

9.4.2 String Collating Support

For simple character sets in MySQL 4.1, sorting rules are specified in the *`MYSET`*`.xml` configuration file using `<map>` array elements within `<collation>` elements. (For MySQL 4.0 or older, the rules are given by the `sort_order` array in *`MYSET`*`.conf`.) If the sorting rules for your language are too complex to be handled with simple arrays, you need to define string collating functions in the `ctype-`*`MYSET`*`.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. For MySQL 4.1, take a look at the `MY_COLLATION_HANDLER` structures to see how they are used, and see the `CHARSET_INFO.txt` file in the `strings` directory for additional information. For MySQL 4.0 or older, look at the `CHARSET_INFO` structures.

9.4.3 Multi-Byte Character Support

If you want to add support for a new character set that includes multi-byte characters, you need to use multi-byte character functions in the `ctype-`*`MYSET`*`.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. For MySQL 4.1, take a look at the `MY_CHARSET_HANDLER` structures to see how they are used, and see the `CHARSET_INFO.txt` file in the `strings` directory for additional information. For MySQL 4.0 or older, look at the `CHARSET_INFO` structures.

9.5 How to Add a New Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

MySQL supports several collation implementations, as discussed in Section 9.5.1, “Collation Implementation Types”. Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets

- UCA-based collations for Unicode character sets
- Binary (*xxx*_bin) collations

The following discussion describes how to add simple collations for 8-bit character sets. In MySQL 4.1, this is the only type of collation that can be added without recompiling. To add a UCA-based Unicode collation, MySQL 5.0 or higher is required.

All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new collation:

1. Choose a collation ID
2. Add configuration information that names the collation and describes the character-ordering rules
3. Restart the server
4. Verify that the collation is present

The instructions here cover only collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in Section 9.4, “Adding a New Character Set”. However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add new data structures, functions, and configuration information for the new collation. For an example, see the MySQL Blog article in the following list of additional resources.

Additional Resources

- The Unicode Collation Algorithm (UCA) specification: http://www.unicode.org/reports/tr10/
- The Locale Data Markup Language (LDML) specification: http://www.unicode.org/reports/tr35/
- MySQL Blog article “Instructions for adding a new Unicode collation”: http://blogs.mysql.com/peterg/2008/05/19/instructions-for-adding-a-new-unicode-collation/

9.5.1 Collation Implementation Types

MySQL implements several types of collations:

Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. latin1_swedish_ci is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a' = 'A';
+-----------+
| 'a' = 'A' |
+-----------+
|         1 |
+-----------+
1 row in set (0.00 sec)
```

Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in Section 9.4, “Adding a New Character Set”.

Collations for non-Unicode multi-byte character sets

For this type of collation, 8-bit (single-byte) and multi-byte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters `'a'` and `'A'` both have a weight of `0x41`.) For multi-byte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. `sjis_japanese_ci` is an example of this kind of collation. The multi-byte character `'ぢ'` has a character code of `0x82C0`, and the weight is also `0x82C0`.
- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. `gbk_chinese_ci` is an example of this kind of collation. The multi-byte character `'膰'` has a character code of `0x81B0` but a weight of `0xC286`.

Collations for Unicode multi-byte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case insensitive and accent insensitive. `utf8_general_ci` is an example: `'a'`, `'A'`, `'À'`, and `'á'` each have different character codes but all have a weight of `0x0041` and compare as equal.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a' = 'A', 'a' = 'À', 'a' = 'á';
+-----------+-----------+-----------+
| 'a' = 'A' | 'a' = 'À' | 'a' = 'á' |
+-----------+-----------+-----------+
|         1 |         1 |         1 |
+-----------+-----------+-----------+
1 row in set (0.06 sec)
```

UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits)
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: `'a'` has a weight of `0x0E33`.
- A character may have many weights. This is an expansion. Example: The German letter `'ß'` (SZ ligature, or SHARP S) has a weight of `0x0FEA0FEA`.
- Many characters may have one weight. This is a contraction. Example: `'ch'` is a single letter in Czech and has a weight of `0x0EE2`.

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

9.5.2 Choosing a Collation ID

Each collation must have a unique ID. To add a new collation, you must choose an ID value that is not currently used. The value must be in the range from 1 to 254. The collation ID that you choose will show up in these contexts:

- The `Id` column of `SHOW COLLATION` output
- The `charsetnr` member of the `MYSQL_FIELD` C API data structure

To display a list of the currently used collation IDs, use this statement:

```
mysql> SHOW COLLATION;
+----------------------+----------+-----+---------+----------+---------+
| Collation            | Charset  | Id  | Default | Compiled | Sortlen |
+----------------------+----------+-----+---------+----------+---------+
| big5_chinese_ci      | big5     |   1 | Yes     | Yes      |       1 |
| big5_bin             | big5     |  84 |         | Yes      |       1 |
...
| latin1_german1_ci    | latin1   |   5 |         | Yes      |       1 |
| latin1_swedish_ci    | latin1   |   8 | Yes     | Yes      |       1 |
| latin1_danish_ci     | latin1   |  15 |         | Yes      |       1 |
| latin1_german2_ci    | latin1   |  31 |         | Yes      |       2 |
| latin1_bin           | latin1   |  47 |         | Yes      |       1 |
| latin1_general_ci    | latin1   |  48 |         | Yes      |       1 |
| latin1_general_cs    | latin1   |  49 |         | Yes      |       1 |
| latin1_spanish_ci    | latin1   |  94 |         | Yes      |       1 |
| latin2_czech_cs      | latin2   |   2 |         | Yes      |       4 |
| latin2_general_ci    | latin2   |   9 | Yes     | Yes      |       1 |
| latin2_hungarian_ci  | latin2   |  21 |         | Yes      |       1 |
| latin2_croatian_ci   | latin2   |  27 |         | Yes      |       1 |
| latin2_bin           | latin2   |  77 |         | Yes      |       1 |
...
+----------------------+----------+-----+---------+----------+---------+
```

Look through the values in the `Id` column and pick a value that is not used.

Warning

If you upgrade MySQL, you may find that the collation ID you choose has been assigned to a collation included in the new MySQL distribution. In this case, you will need to choose a new value for your own collation.

In addition, before upgrading, you should save the configuration files that you change. If you upgrade in place, the process will replace the your modified files.

9.5.3 Adding a Simple Collation to an 8-Bit Character Set

To add a simple collation for an 8-bit character set without recompiling MySQL, use the following procedure. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in Section 9.5.2, “Choosing a Collation ID”. The following steps use an ID of 56.
2. You will need to modify the `Index.xml` and `latin1.xml` configuration files. These files will be located in the directory named by the `character_sets_dir` [409] system variable. You can check the variable value as follows, although the path name might be different on your system:

   ```
   mysql> SHOW VARIABLES LIKE 'character_sets_dir';
   ```

```
+--------------------+----------------------------------------+
| Variable_name      | Value                                  |
+--------------------+----------------------------------------+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+--------------------+----------------------------------------+
```

3. Choose a name for the collation and list it in the `Index.xml` file. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID. For example:

```
<charset name="latin1">
  ...
  <!-- associate collation name with its ID -->
  <collation name="latin1_test_ci" id="56"/>
  ...
</charset>
```

4. In the `latin1.xml` configuration file, add a `<collation>` element that names the collation and that contains a `<map>` element that defines a character code-to-weight mapping table. Each word within the `<map>` element must be a number in hexadecimal format.

```
<collation name="latin1_test_ci">
<map>
 00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
 10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
 20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
 30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
 40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
 50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
 60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
 50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
 80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
 90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
 A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
 B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
 41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
 44 4E 4F 4F 4F 4F 5C D7 5C 55 55 55 59 59 DE DF
 41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
 44 4E 4F 4F 4F 4F 5C F7 5C 55 55 55 59 59 DE FF
</map>
</collation>
```

5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION LIKE 'latin1_test_ci';
+----------------+---------+----+---------+----------+---------+
| Collation      | Charset | Id | Default | Compiled | Sortlen |
+----------------+---------+----+---------+----------+---------+
| latin1_test_ci | latin1  | 56 |         |          |       1 |
+----------------+---------+----+---------+----------+---------+
```

9.6 Character Set Configuration

You can change the default server character set and collation with the `--character-set-server` [385] and `--collation-server` [385] options when you start the server. The collation must be a legal collation for the default character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.) See Section 5.1.2, “Server Command Options”.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- Your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory). This can be fixed by using the `--character-sets-dir` option when you run the program in question. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets

[client]
character-sets-dir="C:/Program Files/MySQL/MySQL Server 4.1/share/charsets"
```

- The character set is a complex character set that cannot be loaded dynamically. In this case, you must recompile the program with support for the character set.
- The character set is a dynamic character set, but you do not have a configuration file for it. In this case, you should install the configuration file for the character set from a new MySQL distribution.
- If your character set index file does not contain the name for the character set, your program displays an error message. In MySQL 4.1, the file is named `Index.xml` and the message is:

```
Character set 'charset_name' is not a compiled character set and is not
specified in the '/usr/share/mysql/charsets/Index.xml' file
```

  Before MySQL 4.1, the file is named `Index` and the message is:

```
ERROR 1105: File '/usr/local/share/mysql/charsets/charset_name.conf'
not found (Errcode: 2)
```

  To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` [409] differs from `character_set_server` [408] or `character_set_client` [408], and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=system_character_set` [260]—that is, setting the client character set to match the system character set—should fix the problem.

For `MyISAM` tables, you can check the character set name and number for a table with `myisamchk -dvv tbl_name`.

9.7 MySQL Server Time Zone Support

You can set the system time zone for MySQL Server at startup with the `--timezone=timezone_name` [245] option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`. The permissible values for `--timezone` [245] or `TZ` are system-dependent. Consult your operating system documentation to see what values are acceptable.

Before MySQL 4.1.3, the server operates only in the system time zone set at startup. Beginning with MySQL 4.1.3, the server maintains several time zone settings, some of which can be modified at runtime:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` [430] system variable. The value does not change thereafter.
- The server's current time zone. The global `time_zone` [431] system variable indicates the time zone the server currently is operating in. The initial value for `time_zone` [431] is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone.

  The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone=timezone` [386] option on the command line, or you can use the following line in an option file:

  ```
  default-time-zone='timezone'
  ```

  If you have the `SUPER` [493] privilege, you can set the global server time zone value at runtime with this statement:

  ```
  mysql> SET GLOBAL time_zone = timezone;
  ```

- Per-connection time zones. Each client that connects has its own time zone setting, given by the session `time_zone` [431] variable. Initially, the session variable takes its value from the global `time_zone` [431] variable, but the client can change its own time zone with this statement:

  ```
  mysql> SET time_zone = timezone;
  ```

The current session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` [837] or `CURTIME()` [829], and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the current time zone to UTC for storage, and from UTC to the current time zone for retrieval.

The current time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` [843] or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values. If you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current values of the global and client-specific time zones can be retrieved like this:

```
mysql> SELECT @@global.time_zone, @@session.time_zone;
```

`timezone` values can be given in several formats, none of which are case sensitive:

- The value `'SYSTEM'` indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as `'+10:00'` or `'-6:00'`.
- The value can be given as a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, or `'MET'`. Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated.

The MySQL installation procedure creates the time zone tables in the `mysql` database, but does not load them. You must do so manually using the following instructions. (If you are upgrading to MySQL 4.1.3 or later from an earlier version, you can create the tables by upgrading your `mysql` database. Use the

instructions in Section 4.4.5, “mysql_fix_privilege_tables — Upgrade MySQL System Tables”. After creating the tables, you can load them.)

Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. For example, the rules for Daylight Saving Time in the United States, Mexico, and parts of Canada changed in 2007. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See the notes at the end of this section.

If your system has its own *zoneinfo database* (the set of files describing time zones), you should use the `mysql_tzinfo_to_sql` program for filling the time zone tables. Examples of such systems are Linux, FreeBSD, Sun Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a zoneinfo database, you can use the downloadable package described later in this section.

The `mysql_tzinfo_to_sql` program is used to load the time zone tables. On the command line, pass the zoneinfo directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or to generate leap second information:

- To load a single time zone file *`tz_file`* that corresponds to a time zone name *`tz_name`*, invoke `mysql_tzinfo_to_sql` like this:

  ```
  shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
  ```

  With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone needs to account for leap seconds, initialize the leap second information like this, where *`tz_file`* is the name of your time zone file:

  ```
  shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
  ```

- After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

If your system is one that has no zoneinfo database (for example, Windows or HP-UX), you can use the package of pre-built time zone tables that is available for download at the MySQL Developer Zone:

```
http://dev.mysql.com/downloads/timezones.html
```

This time zone package contains `.frm`, `.MYD`, and `.MYI` files for the `MyISAM` time zone tables. These tables should be part of the `mysql` database, so you should place the files in the `mysql` subdirectory of your MySQL server's data directory. The server should be stopped while you do this and restarted afterward.

Warning

Do not use the downloadable package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

For information about time zone settings in replication setup, please see Section 14.7, “Replication Features and Issues”.

9.7.1 Staying Current with Time Zone Changes

As mentioned earlier, when the time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are two factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the Web site for your operating system vendor for an update that addresses the time changes.
- If you replace the system's `/etc/localtime` timezone file with a version that uses rules differing from those in effect at `mysqld` startup, you should restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.
- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date. If your system has its own zoneinfo database, you should reload the MySQL time zone tables whenever the zoneinfo database is updated, using the instructions given earlier in this section. For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace your current time zone tables. `mysqld` caches time zone information that it looks up, so after replacing the time zone tables, you should restart `mysqld` to make sure that it does not continue to serve outdated time zone data.
- For versions of MySQL older than 4.1.3 that do not have time zone support, the server always tracks the operating system time (much like a time zone setting of `SYSTEM` in 4.1.3 and up). Assuming that the server host itself has its operating system updated to handle any changes to Daylight Saving Time rules, the MySQL server should know the correct time.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
+----------+
| COUNT(*) |
+----------+
|        0 |
+----------+
```

A count of zero indicates that the table is empty. In this case, no one can be using named time zones, and you don't need to update the tables. A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, you should be sure to reload your time zone tables so that anyone who uses named time zones will get correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses these two queries:

```
SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you would see an incorrect result like this:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----------------------------------------------------------+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----------------------------------------------------------+
| 2007-03-11 01:00:00                                       |
+-----------------------------------------------------------+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----------------------------------------------------------+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----------------------------------------------------------+
| 2007-03-11 02:00:00                                       |
+-----------------------------------------------------------+
```

After updating the tables, you should see the correct result:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central');
+-----------------------------------------------------------+
| CONVERT_TZ('2007-03-11 2:00:00','US/Eastern','US/Central') |
+-----------------------------------------------------------+
| 2007-03-11 01:00:00                                       |
+-----------------------------------------------------------+

mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central');
+-----------------------------------------------------------+
| CONVERT_TZ('2007-03-11 3:00:00','US/Eastern','US/Central') |
+-----------------------------------------------------------+
| 2007-03-11 01:00:00                                       |
+-----------------------------------------------------------+
```

9.8 MySQL Server Locale Support

Beginning with MySQL 4.1.21, the locale indicated by the `lc_time_names` [417] system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()` [832], `DAYNAME()` [833], and `MONTHNAME()` [837] functions.

Locale names have language and region subtags listed by IANA (http://www.iana.org/assignments/language-subtag-registry) such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting, but any client can examine or set its `lc_time_names` [417] value as shown in the following example:

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
+-----------------+
| en_US           |
+-----------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+----------------------+------------------------+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+----------------------+------------------------+
| Friday                | January                |
+----------------------+------------------------+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----------------------------------------+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----------------------------------------+
| Friday Fri January Jan                  |
+-----------------------------------------+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----------------+
| @@lc_time_names |
+-----------------+
| es_MX           |
+-----------------+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+----------------------+------------------------+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+----------------------+------------------------+
| viernes               | enero                  |
+----------------------+------------------------+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----------------------------------------+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----------------------------------------+
| viernes vie enero ene                   |
+-----------------------------------------+
1 row in set (0.00 sec)
```

The day or month name for each of the affected functions is converted from `utf8` to the character set indicated by the `character_set_connection` [408] system variable.

`lc_time_names` [417] may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

`ar_AE`: Arabic - United Arab Emirates	`ar_BH`: Arabic - Bahrain
`ar_DZ`: Arabic - Algeria	`ar_EG`: Arabic - Egypt

lc_time_names [417] currently does not affect the STR_TO_DATE() [838] or GET_FORMAT() [835] function.

Chapter 10 Data Types

Table of Contents

MySQL supports a number of data types in several categories: numeric types, date and time types, and string (character and byte) types. This chapter provides an overview of these data types, a more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overview is intentionally brief. The more detailed descriptions later in the chapter should be consulted for additional information about particular data types, such as the permissible formats in which you can specify values.

MySQL 4.1 and up also supports extensions for handing spatial data. For information about these data types, see Chapter 16, *Spatial Extensions*.

Data type descriptions use these conventions:

- *M* indicates the maximum display width for integer types. For floating-point and fixed-point types, *M* is the total number of digits that can be stored (the precision). For string types, *M* is the maximum length. The maximum permissible value of *M* depends on the data type.
- *D* applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than *M*–2.
- Square brackets (“`[`” and “`]`”) indicate optional parts of type definitions.

10.1 Data Type Overview

10.1.1 Numeric Type Overview

A summary of the numeric data types follows. For additional information about properties and storage requirements of the numeric types, see Section 10.2, “Numeric Types”, and Section 10.5, “Data Type Storage Requirements”.

M indicates the maximum display width for integer types. The maximum legal display width is 255. Display width is unrelated to the range of values a type can contain, as described in Section 10.2, “Numeric Types”. For floating-point and fixed-point types, *M* is the total number of digits that can be stored.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Numeric data types that permit the `UNSIGNED` attribute also permit `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

As of MySQL 4.1, `SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

Warning

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION` [459] SQL mode is enabled. See Section 11.10, “Cast Functions and Operators”.

- `BIT`

  In versions of MySQL up to and lincluding 4.1, `BIT` is a synonym for `TINYINT(1)`.

- `TINYINT[(M)] [UNSIGNED] [ZEROFILL]`

  A very small integer. The signed range is `-128` to `127`. The unsigned range is `0` to `255`.

- `BOOL`, `BOOLEAN`

  These types are synonyms for `TINYINT(1)`. The synonym `BOOLEAN` was added in MySQL 4.1.0. A value of zero is considered false. Nonzero values are considered true:

```
mysql> SELECT IF(0, 'true', 'false');
+-----------------------+
| IF(0, 'true', 'false') |
+-----------------------+
| false                 |
+-----------------------+

mysql> SELECT IF(1, 'true', 'false');
+-----------------------+
| IF(1, 'true', 'false') |
+-----------------------+
| true                  |
+-----------------------+

mysql> SELECT IF(2, 'true', 'false');
+-----------------------+
| IF(2, 'true', 'false') |
+-----------------------+
| true                  |
+-----------------------+
```

However, the values TRUE and FALSE are merely aliases for 1 and 0, respectively, as shown here:

```
mysql> SELECT IF(0 = FALSE, 'true', 'false');
+--------------------------------+
| IF(0 = FALSE, 'true', 'false') |
+--------------------------------+
| true                           |
+--------------------------------+

mysql> SELECT IF(1 = TRUE, 'true', 'false');
+-------------------------------+
| IF(1 = TRUE, 'true', 'false') |
+-------------------------------+
| true                          |
+-------------------------------+

mysql> SELECT IF(2 = TRUE, 'true', 'false');
+-------------------------------+
| IF(2 = TRUE, 'true', 'false') |
+-------------------------------+
| false                         |
+-------------------------------+

mysql> SELECT IF(2 = FALSE, 'true', 'false');
+--------------------------------+
| IF(2 = FALSE, 'true', 'false') |
+--------------------------------+
| false                          |
+--------------------------------+
```

The last two statements display the results shown because 2 is equal to neither 1 nor 0.

- SMALLINT[(*M*)] [UNSIGNED] [ZEROFILL]

  A small integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535.

- MEDIUMINT[(*M*)] [UNSIGNED] [ZEROFILL]

  A medium-sized integer. The signed range is -8388608 to 8388607. The unsigned range is 0 to 16777215.

- INT[(*M*)] [UNSIGNED] [ZEROFILL]

  A normal-size integer. The signed range is -2147483648 to 2147483647. The unsigned range is 0 to 4294967295.

- INTEGER[(*M*)] [UNSIGNED] [ZEROFILL]

  This type is a synonym for INT.

- BIGINT[(*M*)] [UNSIGNED] [ZEROFILL]

  A large integer. The signed range is -9223372036854775808 to 9223372036854775807. The unsigned range is 0 to 18446744073709551615.

  As of MySQL 4.1, SERIAL is an alias for BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE.

  Some things you should be aware of with respect to BIGINT columns:

  - All arithmetic is done using signed BIGINT or DOUBLE values, so you should not use unsigned big integers larger than 9223372036854775807 (63 bits) except with bit functions! If you do that, some

of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

MySQL 4.0 can handle `BIGINT` in the following cases:

- When using integers to store large unsigned values in a `BIGINT` column.
- In `MIN(col_name)` [884] or `MAX(col_name)` [884], where `col_name` refers to a `BIGINT` column.
- When using operators (`+` [815], `-` [815], `*` [816], and so on) where both operands are integers.

- You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The `-` [815], `+` [815], and `*` [816] operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than `9223372036854775807`.

- `DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]`

  An unpacked fixed-point number. Behaves like a `CHAR` column; “unpacked” means the number is stored as a string, using one character for each digit of the value. `M` is the total number of digits and `D` is the number of digits after the decimal point. The decimal point and (for negative numbers) the “`-`” sign are not counted in `M`, although space for them is reserved. If `D` is 0, values have no decimal point or fractional part. The maximum range of `DECIMAL` values is the same as for `DOUBLE`, but the actual range for a given `DECIMAL` column may be constrained by the choice of `M` and `D`. If `D` is omitted, the default is 0. If `M` is omitted, the default is 10.

  `UNSIGNED`, if specified, disallows negative values.

  

  Note

  Before MySQL 3.23, the value of `M` must be large enough to include the space needed for the sign and the decimal point characters.

- `DEC[(M[,D])] [UNSIGNED] [ZEROFILL]`, `NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL]`, `FIXED[(M[,D])] [UNSIGNED] [ZEROFILL]`

  These types are synonyms for `DECIMAL`. The `FIXED` synonym was added in MySQL 4.1.0 for compatibility with other database systems.

- `FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]`

  A small (single-precision) floating-point number. Permissible values are `-3.402823466E+38` to `-1.175494351E-38`, `0`, and `1.175494351E-38` to `3.402823466E+38`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

  `M` is the total number of digits and `D` is the number of digits following the decimal point. If `M` and `D` are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

  `UNSIGNED`, if specified, disallows negative values.

Using FLOAT might give you some unexpected problems because all calculations in MySQL are done with double precision. See Section B.5.5.7, “Solving Problems with No Matching Rows”.

- DOUBLE[(*M*,*D*)] [UNSIGNED] [ZEROFILL]

  A normal-size (double-precision) floating-point number. Permissible values are -1.7976931348623157E+308 to -2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

  M is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

  UNSIGNED, if specified, disallows negative values.

- DOUBLE PRECISION[(*M*,*D*)] [UNSIGNED] [ZEROFILL], REAL[(*M*,*D*)] [UNSIGNED] [ZEROFILL]

  These types are synonyms for DOUBLE. Exception: If the REAL_AS_FLOAT [460] SQL mode is enabled, REAL is a synonym for FLOAT rather than DOUBLE.

- FLOAT(*p*) [UNSIGNED] [ZEROFILL]

  A floating-point number. *p* represents the precision in bits, but MySQL uses this value only to determine whether to use FLOAT or DOUBLE for the resulting data type. If *p* is from 0 to 24, the data type becomes FLOAT with no *M* or *D* values. If *p* is from 25 to 53, the data type becomes DOUBLE with no *M* or *D* values. The range of the resulting column is the same as for the single-precision FLOAT or double-precision DOUBLE data types described earlier in this section.

  As of MySQL 3.23, this data type holds true floating-point values. In earlier MySQL versions, FLOAT(*p*) always has two decimals.

  FLOAT(*p*) syntax is provided for ODBC compatibility.

10.1.2 Date and Time Type Overview

A summary of the temporal data types follows. For additional information about properties and storage requirements of the temporal types, see Section 10.3, “Date and Time Types”, and Section 10.5, “Data Type Storage Requirements”. For descriptions of functions that operate on temporal values, see Section 11.7, “Date and Time Functions”.

For the DATE and DATETIME range descriptions, “supported” means that although earlier values might work, there is no guarantee.

- DATE

  A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays DATE values in 'YYYY-MM-DD' format, but permits assignment of values to DATE columns using either strings or numbers.

- DATETIME

A date and time combination. The supported range is `'1000-01-01 00:00:00'` to `'9999-12-31 23:59:59'`. MySQL displays `DATETIME` values in `'YYYY-MM-DD HH:MM:SS'` format, but permits assignment of values to `DATETIME` columns using either strings or numbers.

- `TIMESTAMP[(M)]`

  A timestamp. The range is `'1970-01-01 00:00:01'` UTC to `'2038-01-19 03:14:07'` UTC. `TIMESTAMP` values are stored as the number of seconds since the epoch (`'1970-01-01 00:00:00'` UTC). A `TIMESTAMP` cannot represent the value `'1970-01-01 00:00:00'` because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing `'0000-00-00 00:00:00'`, the "zero" `TIMESTAMP` value.

  MySQL displays `TIMESTAMP` values in `'YYYY-MM-DD HH:MM:SS'` format. To convert the value to a number, add `+0`.

  A `TIMESTAMP` column is useful for recording the date and time of an `INSERT` or `UPDATE` operation. By default, the first `TIMESTAMP` column in a table is automatically set to the date and time of the most recent operation if you do not assign it a value yourself. You can also set any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value. Variations on automatic initialization and update properties are described in Section 10.3.1.2, "`TIMESTAMP` Properties as of MySQL 4.1".

  In MySQL 4.1, `TIMESTAMP` is returned as a string with the format `'YYYY-MM-DD HH:MM:SS'`. Display widths (used as described in the following paragraphs) are no longer supported; the display width is fixed at 19 characters. To obtain the value as a number, add `+0`.

  In MySQL 4.0 and earlier, `TIMESTAMP` values are displayed in `YYYYMMDDHHMMSS`, `YYMMDDHHMMSS`, `YYYYMMDD`, or `YYMMDD` format, depending on whether *`M`* is 14 (or missing), 12, 8, or 6, but permits you to assign values to `TIMESTAMP` columns using either strings or numbers. The *`M`* argument affects only how a `TIMESTAMP` column is displayed, not storage. Its values always are stored using four bytes each. From MySQL 4.0.12, the `--new` option can be used to make the server behave as in MySQL 4.1.

  Note that `TIMESTAMP(M)` columns where *`M`* is 8 or 14 are reported to be numbers, whereas other `TIMESTAMP(M)` columns are reported to be strings. This is just to ensure that you can reliably dump and restore the table with these types.

  

  Note

  The behavior of `TIMESTAMP` columns changed considerably in MySQL 4.1. For complete information on the differences with regard to this data type in MySQL 4.1 and later versions (as opposed to MySQL 4.0 and earlier versions), be sure to see Section 10.3.1.1, "`TIMESTAMP` Properties Prior to MySQL 4.1", and Section 10.3.1.2, "`TIMESTAMP` Properties as of MySQL 4.1".

- `TIME`

  A time. The range is `'-838:59:59'` to `'838:59:59'`. MySQL displays `TIME` values in `'HH:MM:SS'` format, but permits assignment of values to `TIME` columns using either strings or numbers.

- `YEAR[(2|4)]`

  A year in two-digit or four-digit format. The default is four-digit format. In four-digit format, the permissible values are `1901` to `2155`, and `0000`. In two-digit format, the permissible values are `70` to `69`, representing years from 1970 to 2069. MySQL displays `YEAR` values in `YYYY` format, but permits assignment of values to `YEAR` columns using either strings or numbers. The `YEAR` type is unavailable prior to MySQL 3.22.

The SUM() [884] and AVG() [881] aggregate functions do not work with temporal values. (They convert the values to numbers, which loses the part after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

10.1.3 String Type Overview

A summary of the string data types follows. For additional information about properties and storage requirements of the string types, see Section 10.4, “String Types”, and Section 10.5, “Data Type Storage Requirements”.

In some cases, MySQL may change a string column to a type different from that given in a CREATE TABLE or ALTER TABLE statement. See Section 12.1.5.2, “Silent Column Specification Changes”.

In MySQL 4.1 and up, string data types include some features that you may not have encountered in working with versions of MySQL prior to 4.1:

- As of version 4.1, MySQL interprets length specifications in character column definitions in character units. (Before MySQL 4.1, column lengths were interpreted in bytes.) This applies to CHAR, VARCHAR, and the TEXT types.
- Column definitions for many string data types can include attributes that specify the character set or collation of the column. These attributes apply to the CHAR, VARCHAR, the TEXT types, ENUM, and SET data types:
  - The CHARACTER SET attribute specifies the character set, and the COLLATE attribute specifies a collation for the character set. For example:

    ```
    CREATE TABLE t
    (
        c1 VARCHAR(20) CHARACTER SET utf8,
        c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
    );
    ```

    This table definition creates a column named c1 that has a character set of utf8 with the default collation for that character set, and a column named c2 that has a character set of latin1 and a case-sensitive collation.

    The rules for assigning the character set and collation when either or both of the CHARACTER SET and COLLATE attributes are missing are described in Section 9.1.3.4, “Column Character Set and Collation”.

    CHARSET is a synonym for CHARACTER SET.
  - From MySQL 4.1.2 on, specifying the CHARACTER SET binary attribute for a character data type causes the column to be created as the corresponding binary data type: CHAR becomes BINARY, VARCHAR becomes VARBINARY, and TEXT becomes BLOB. For the ENUM and SET data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

    ```
    CREATE TABLE t
    (
      c1 VARCHAR(10) CHARACTER SET binary,
      c2 TEXT CHARACTER SET binary,
      c3 ENUM('a','b','c') CHARACTER SET binary
    ```

```
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

- From MySQL 4.1.0 on, the `ASCII` attribute is shorthand for `CHARACTER SET latin1`.
- From MySQL 4.1.1 on, the `UNICODE` attribute is shorthand for `CHARACTER SET ucs2`.
- As of MySQL 4.1.2, the `BINARY` attribute is shorthand for specifying the binary collation of the column character set. In this case, sorting and comparison are based on numeric character values. (Before MySQL 4.1.2, `BINARY` caused a column to store binary strings and sorting and comparison were based on numeric byte values. This is the same as using character values for single-byte character sets, but not for multi-byte character sets.)

- Character column sorting and comparison are based on the character set assigned to the column. (Before MySQL 4.1, sorting and comparison were based on the collation of the server character set.) For the `CHAR`, `VARCHAR`, `TEXT`, `ENUM`, and `SET` data types, you can declare a column with a binary collation or the `BINARY` attribute to cause sorting and comparison to use the underlying character code values rather than a lexical ordering.

Section 9.1, “Character Set Support”, provides additional information about use of character sets in MySQL 4.1 and up.

- `[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`

  A fixed-length string that is always right-padded with spaces to the specified length when stored. *`M`* represents the column length in characters. The range of *`M`* is 0 to 255. (1 to 255 prior to MySQL 3.23). If *`M`* is omitted, the length is 1.

  

  Note

  Trailing spaces are removed when `CHAR` values are retrieved.

  In MySQL 4.1, a `CHAR` column with a length specification greater than 255 is converted to the smallest `TEXT` type that can hold values of the given length. For example, `CHAR(500)` is converted to `TEXT`, and `CHAR(200000)` is converted to `MEDIUMTEXT`. This is a compatibility feature. However, this conversion causes the column to become a variable-length column, and also affects trailing-space removal.

  `CHAR` is shorthand for `CHARACTER`. `NATIONAL CHAR` (or its equivalent short form, `NCHAR`) is the standard SQL way to define that a `CHAR` column should use some predefined character set. MySQL 4.1 and up uses `utf8` as this predefined character set. Section 9.1.3.6, “National Character Set”.

  From MySQL 4.1.2 on, the `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

  MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you have to be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column

that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `''` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

  A variable-length string. *`M`* represents the maximum column length in characters. The range of *`M`* is 1 to 255 before MySQL 4.0.2, and 0 to 255 as of MySQL 4.0.2.

  MySQL stores `VARCHAR` values as a one-byte length prefix plus data. The length prefix indicates the number of bytes in the value.

  

  Note

  Trailing spaces are removed when `VARCHAR` values are stored. This differs from the standard SQL specification.

  In MySQL 4.1, a `VARCHAR` column with a length specification greater than 255 is converted to the smallest `TEXT` type that can hold values of the given length. For example, `VARCHAR(500)` is converted to `TEXT`, and `VARCHAR(200000)` is converted to `MEDIUMTEXT`. This is a compatibility feature. However, this conversion affects trailing-space removal.

  `VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MySQL 4.1 and up uses `utf8` as this predefined character set. Section 9.1.3.6, “National Character Set”. As of MySQL 4.1.1, `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

- `BINARY(M)`

  The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than nonbinary character strings. *`M`* represents the column length in bytes.

  This type was added in MySQL 4.1.2.

- `VARBINARY(M)`

  The `VARBINARY` type is similar to the `VARCHAR` type, but stores binary byte strings rather than nonbinary character strings. *`M`* represents the maximum column length in bytes.

  This type was added in MySQL 4.1.2.

- `TINYBLOB`

  A `BLOB` column with a maximum length of 255 (2^8 – 1) bytes. Each `TINYBLOB` value is stored using a one-byte length prefix that indicates the number of bytes in the value.

- `TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

  A `TEXT` column with a maximum length of 255 (2^8 – 1) characters. The effective maximum length is less if the value contains multi-byte characters. Each `TINYTEXT` value is stored using a one-byte length prefix that indicates the number of bytes in the value.

- `BLOB[(M)]`

  A `BLOB` column with a maximum length of 65,535 (2^{16} – 1) bytes. Each `BLOB` value is stored using a two-byte length prefix that indicates the number of bytes in the value.

Beginning with MySQL 4.1, an optional length *M* can be given for this type. MySQL creates the column as the smallest BLOB type large enough to hold values *M* bytes long.

- TEXT[(*M*)] [CHARACTER SET *charset_name*] [COLLATE *collation_name*]

  A TEXT column with a maximum length of 65,535 (2^{16} – 1) characters. The effective maximum length is less if the value contains multi-byte characters. Each TEXT value is stored using a two-byte length prefix that indicates the number of bytes in the value.

  Beginning with MySQL 4.1, an optional length *M* can be given for this type. MySQL creates the column as the smallest TEXT type large enough to hold values *M* characters long.

- MEDIUMBLOB

  A BLOB column with a maximum length of 16,777,215 (2^{24} – 1) bytes. Each MEDIUMBLOB value is stored using a three-byte length prefix that indicates the number of bytes in the value.

- MEDIUMTEXT [CHARACTER SET *charset_name*] [COLLATE *collation_name*]

  A TEXT column with a maximum length of 16,777,215 (2^{24} – 1) characters. The effective maximum length is less if the value contains multi-byte characters. Each MEDIUMTEXT value is stored using a three-byte length prefix that indicates the number of bytes in the value.

- LONGBLOB

  A BLOB column with a maximum length of 4,294,967,295 or 4GB (2^{32} – 1) bytes. Up to MySQL 3.23, the client/server protocol and MyISAM tables had a limit of 16MB per communication packet or table row. As of MySQL 4.0, the effective maximum length of LONGBLOB columns depends on the configured maximum packet size in the client/server protocol and available memory. Each LONGBLOB value is stored using a four-byte length prefix that indicates the number of bytes in the value.

- LONGTEXT [CHARACTER SET *charset_name*] [COLLATE *collation_name*]

  A TEXT column with a maximum length of 4,294,967,295 or 4GB (2^{32} – 1) characters. The effective maximum length is less if the value contains multi-byte characters. Up to MySQL 3.23, the client/server protocol and MyISAM tables had a limit of 16MB per communication packet or table row. As of MySQL 4.0, the effective maximum length of LONGTEXT columns depends on the configured maximum packet size in the client/server protocol and available memory. Each LONGTEXT value is stored using a four-byte length prefix that indicates the number of bytes in the value.

- ENUM('*value1*','*value2*',...) [CHARACTER SET *charset_name*] [COLLATE *collation_name*]

  An enumeration. A string object that can have only one value, chosen from the list of values '*value1*', '*value2*', ..., NULL or the special '' error value. An ENUM column can have a maximum of 65,535 distinct values. ENUM values are represented internally as integers.

- SET('*value1*','*value2*',...) [CHARACTER SET *charset_name*] [COLLATE *collation_name*]

  A set. A string object that can have zero or more values, each of which must be chosen from the list of values '*value1*', '*value2*', ... A SET column can have a maximum of 64 members. SET values are represented internally as integers.

10.1.4 Data Type Default Values

The DEFAULT *value* clause in a data type specification indicates a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as NOW() [837] or CURRENT_DATE [829]. The exception is that you can specify CURRENT_TIMESTAMP [829] as the default for a TIMESTAMP column as of MySQL 4.1.2. See Section 10.3.1.2, "TIMESTAMP Properties as of MySQL 4.1".

If a column definition includes no explicit DEFAULT value, MySQL determines the default value as follows:

If the column can take NULL as a value, the column is defined with an explicit DEFAULT NULL clause.

If the column cannot take NULL as the value, MySQL defines the column with an explicit DEFAULT clause, using the implicit default value for the column data type. Implicit defaults are defined as follows:

- For numeric types, the default is 0, with the exception that for integer or floating-point types declared with the AUTO_INCREMENT attribute, the default is the next value in the sequence.
- For date and time types other than TIMESTAMP, the default is the appropriate "zero" value for the type. For the first TIMESTAMP column in a table, the default value is the current date and time. See Section 10.3, "Date and Time Types".
- For string types other than ENUM, the default value is the empty string. For ENUM, the default is the first enumeration value.

BLOB and TEXT columns cannot be assigned a default value.

For a given table, you can use the SHOW CREATE TABLE statement to see which columns have an explicit DEFAULT clause.

SERIAL DEFAULT VALUE in the definition of an integer column is an alias for NOT NULL AUTO_INCREMENT UNIQUE.

10.2 Numeric Types

MySQL supports all the standard SQL numeric data types. These types include the exact numeric data types (INTEGER, SMALLINT, DECIMAL, and NUMERIC), as well as the approximate numeric data types (FLOAT, REAL, and DOUBLE PRECISION). The keyword INT is a synonym for INTEGER, and the keyword DEC is a synonym for DECIMAL. MySQL treats DOUBLE as a synonym for DOUBLE PRECISION (a nonstandard extension). MySQL also treats REAL as a synonym for DOUBLE PRECISION (a nonstandard variation), unless the REAL_AS_FLOAT [460] SQL mode is enabled.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see Section 10.2.5, "Out-of-Range and Overflow Handling".

For information about numeric type storage requirements, see Section 10.5, "Data Type Storage Requirements".

The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see Section 11.6.1, "Arithmetic Operators".

10.2.1 Integer Types (Exact Value)

MySQL supports the SQL standard integer types INTEGER (or INT) and SMALLINT. As an extension to the standard, MySQL also supports the integer types TINYINT, MEDIUMINT, and BIGINT. The following table shows the required storage and range for each integer type.

Type	Storage	Minimum Value	Maximum Value
	(Bytes)	(Signed/Unsigned)	Signed/Unsigned)
TINYINT	1	-128	127
		0	255
SMALLINT	2	-32768	32767
		0	65535
MEDIUMINT	3	-8388608	8388607
		0	16777215
INT	4	-2147483648	2147483647
		0	4294967295
BIGINT	8	-9223372036854775808	9223372036854775807
		0	18446744073709551615

10.2.2 Fixed-Point Types (Exact Value)

The DECIMAL and NUMERIC types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, NUMERIC is implemented as DECIMAL, so the following remarks about DECIMAL apply equally to NUMERIC.

Through version 4.1, MySQL stores DECIMAL values as strings, rather than in binary format. One character is used for each digit of the value, the decimal point (if the scale is greater than 0), and the "-" sign (for negative numbers).

In a DECIMAL column declaration, the precision and scale can be (and usually is) specified; for example:

```
salary DECIMAL(5,2)
```

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that DECIMAL(5,2) be able to store any value with five digits and two decimals, so values that can be stored in the salary column range from -999.99 to 999.99. In versions up to and including 4.1, MySQL varies from this limit in two ways due to the use of string format for value storage:

- On the positive end of the range, the column actually can store numbers up to 9999.99. For positive numbers, MySQL uses the byte reserved for the sign to extend the upper end of the range.
- DECIMAL columns in MySQL before 3.23 are stored differently and cannot represent all the values required by standard SQL. This is because for a type of DECIMAL(*M*,*D*), the value of *M* includes the bytes for the sign and the decimal point. The range of the salary column before MySQL 3.23 would be -9.99 to 99.99.

In standard SQL, the syntax DECIMAL(*M*) is equivalent to DECIMAL(*M*,0). Similarly, the syntax DECIMAL is equivalent to DECIMAL(*M*,0), where the implementation is permitted to decide the value of *M*. As of MySQL 3.23.6, both of these variant forms of DECIMAL syntax are supported. The default value of *M* is 10. Before 3.23.6, *M* and *D* both must be specified explicitly.

If the scale is 0, DECIMAL values contain no decimal point or fractional part.

The maximum range of DECIMAL values is the same as for DOUBLE, but the actual range for a given DECIMAL column can be constrained by the precision or scale for a given column. When such a column is

assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

10.2.3 Floating-Point Types (Approximate Value)

The `FLOAT` and `DOUBLE` types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For `FLOAT`, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses. MySQL also supports this optional precision specification, but the precision value is used only to determine storage size. A precision from 0 to 23 results in a four-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an eight-byte double-precision `DOUBLE` column.

MySQL permits a nonstandard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here, "`(M,D)`" means than values can be stored with up to `M` digits in total, of which `D` digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` will look like `-999.9999` when displayed. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see Section B.5.5.8, "Problems with Floating-Point Values"

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

10.2.4 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, `INT(4)` specifies an `INT` with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used or not is up to the application.)

The display width does *not* constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as `SMALLINT(3)` has the usual `SMALLINT` range of `-32768` to `32767`, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) attribute `ZEROFILL`, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(4) ZEROFILL`, a value of `5` is retrieved as `0005`.

Note

The `ZEROFILL` attribute is ignored when a column is involved in expressions or `UNION` queries.

If you store values larger than the display width in an integer column that has the `ZEROFILL` attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

All integer types can have an optional (nonstandard) attribute `UNSIGNED`. Unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the

column. For example, if an `INT` column is `UNSIGNED`, the size of the column's range is the same but its endpoints shift from `-2147483648` and `2147483647` up to `0` and `4294967295`.

As of MySQL 4.0.2, floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

Integer or floating-point data types can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is *`value`*`+1`, where *`value`* is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

10.2.5 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, MySQL clips the value to the appropriate endpoint of the range and stores the resulting value instead.

For example, when an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range. If you store 256 into a `TINYINT` or `TINYINT UNSIGNED` column, MySQL stores 127 or 255, respectively. When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Column-assignment conversions that occur due to clipping are reported as warnings for `ALTER TABLE`, `LOAD DATA INFILE`, `UPDATE`, and multiple-row `INSERT` statements.

In MySQL 4.1, overflow handling during numeric expression evaluation depends on the types of the operands:

- Integer overflow results in silent wraparound.
- `DECIMAL` overflow results in a truncated result and a warning.
- Floating-point overflow produces a `NULL` result. Overflow for some operations can result in `+INF`, `-INF`, or `NaN`.

For example, the largest signed `BIGINT` value is 9223372036854775807, so the following expression wraps around to the minimum `BIGINT` value:

```
mysql> SELECT 9223372036854775807 + 1;
+--------------------------+
| 9223372036854775807 + 1 |
+--------------------------+
|    -9223372036854775808 |
+--------------------------+
```

To enable the operation to succeed in this case, convert the value to unsigned;

```
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-----------------------------------------+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
+-----------------------------------------+
|                      9223372036854775808 |
+-----------------------------------------+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because DECIMAL values have a larger range than integers:

```
mysql> SELECT 9223372036854775807.0 + 1;
+--------------------------+
| 9223372036854775807.0 + 1 |
+--------------------------+
|     9223372036854775808.0 |
+--------------------------+
```

Subtraction between integer values, where one is of type UNSIGNED, produces an unsigned result by default. If the result would otherwise have been negative, it becomes the maximum integer value. If the NO_UNSIGNED_SUBTRACTION [459] SQL mode is enabled, the result is negative.

```
mysql> SET sql_mode = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+-------------------------+
|    18446744073709551615 |
+-------------------------+

mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+-------------------------+
|                      -1 |
+-------------------------+
```

If the result of such an operation is used to update an UNSIGNED integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if NO_UNSIGNED_SUBTRACTION [459] is enabled.

10.3 Date and Time Types

The date and time types for representing temporal values are DATE, TIME, DATETIME, TIMESTAMP, and YEAR. Each temporal type has a range of legal values, as well as a “zero” value that is used when you specify an illegal value that MySQL cannot represent. The TIMESTAMP type has special automatic updating behavior, described later on. For temporal type storage requirements, see Section 10.5, “Data Type Storage Requirements”.

MySQL versions through 4.1 accept certain “illegal” values for dates, such as '2009-11-31'. This is useful when you want to store a possibly incorrect value specified by a user (for example, in a web form) in the database for future processing. MySQL verifies only that the month is in the range from 0 to 12 and that the day is in the range from 0 to 31. These ranges are defined to include zero because MySQL permits you to store dates where the day or month and day are zero in a DATE or DATETIME column. This is extremely useful for applications that need to store a birthdate for which you do not know the exact date. In this case, you simply store the date as '2009-00-00' or '2009-01-00'. If you store dates such as these, you should not expect to get correct results for functions such as DATE_SUB() [833] or DATE_ADD() [829] that require complete dates.

MySQL also permits you to store '0000-00-00' as a “dummy date.” This is in some cases more convenient (and uses less data and index space) than storing NULL values.

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date

and time types, see Section 8.1.3, “Date and Time Literals”. It is expected that you supply legal values. Unpredictable results may occur if you use values in other formats.

- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, `'98-09-04'`), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, `'09-04-98'`, `'04-09-98'`).
- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  - Year values in the range `70-99` are converted to `1970-1999`.
  - Year values in the range `00-69` are converted to `2000-2069`.

  See also Section 10.3.6, “Two-Digit Years in Dates”.
- Conversion of values from one temporal type to another occurs according to the rules in Section 10.3.5, “Conversion Between Date and Time Types”.
- MySQL automatically converts a date or time value to a number if the value is used in a numeric context and vice versa.
- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise illegal for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.
- “Zero” date or time values used through MyODBC are converted automatically to `NULL` in MyODBC 2.50.12 and above, because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values `'0'` or `0`, which are easier to write.

Data Type	“Zero” Value
`DATE`	`'0000-00-00'`
`TIME`	`'00:00:00'`
`DATETIME`	`'0000-00-00 00:00:00'`
`TIMESTAMP` (4.1 and up)	`'0000-00-00 00:00:00'`
`TIMESTAMP` (before 4.1)	`00000000000000`
`YEAR`	`0000`

10.3.1 The DATE, DATETIME, and TIMESTAMP Types

The `DATE`, `DATETIME`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ.

The `DATE` type is used for values with a date part but no time part. MySQL retrieves and displays `DATE` values in `'YYYY-MM-DD'` format. The supported range is `'1000-01-01'` to `'9999-12-31'`.

The `DATETIME` type is used for values that contain both date and time parts. MySQL retrieves and displays `DATETIME` values in `'YYYY-MM-DD HH:MM:SS'` format. The supported range is `'1000-01-01 00:00:00'` to `'9999-12-31 23:59:59'`.

For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The TIMESTAMP data type is used for values that contain both date and time parts. TIMESTAMP has a range of '1970-01-01 00:00:01' UTC to '2038-01-19 03:14:07' UTC. Its properties are described in more detail in Section 10.3.1.2, "TIMESTAMP Properties as of MySQL 4.1".

MySQL recognizes DATE, DATETIME, and TIMESTAMP values in several formats, described in Section 8.1.3, "Date and Time Literals". A DATETIME or TIMESTAMP value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into DATETIME or TIMESTAMP columns. For information about fractional seconds support in MySQL, see Section 10.3.4, "Fractional Seconds in Time Values".

Illegal DATE, DATETIME, or TIMESTAMP values are converted to the "zero" value of the appropriate type ('0000-00-00', '0000-00-00 00:00:00', or 00000000000000).

Be aware of certain problems when specifying date values:

- MySQL permits a "relaxed" format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as '10:11:12' might look like a time value because of the ":" delimiter, but is interpreted as the year '2010-11-12' if used in a date context. The value '10:45:15' is converted to '0000-00-00' because '45' is not a legal month.

- The MySQL server performs only basic checking on the validity of a date: The ranges for year, month, and day are 1000 to 9999, 00 to 12, and 00 to 31, respectively. Any date containing parts not within these ranges is subject to conversion to '0000-00-00'. Please note that this still permits you to store invalid dates such as '2002-04-31'. To ensure that a date is valid, perform a check in your application.

- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

  - Year values in the range 00-69 are converted to 2000-2069.

  - Year values in the range 70-99 are converted to 1970-1999.

  See also Section 10.3.6, "Two-Digit Years in Dates".

10.3.1.1 TIMESTAMP Properties Prior to MySQL 4.1

TIMESTAMP values are converted from the current time zone to UTC for storage, and converted back from UTC to the current time zone for retrieval. (This occurs only for the TIMESTAMP data type, not for other types such as DATETIME.)

The TIMESTAMP data type provides a type that you can use to automatically mark INSERT or UPDATE operations with the current date and time. If you have multiple TIMESTAMP columns in a table, only the first one is updated automatically. (From MySQL 4.1.2 on, you can specify which TIMESTAMP column updates; see Section 10.3.1.2, "TIMESTAMP Properties as of MySQL 4.1".)

Automatic updating of the first TIMESTAMP column in a table occurs under any of the following conditions:

- You explicitly set the column to NULL.

- The column is not specified explicitly in an INSERT or LOAD DATA INFILE statement.

- The column is not specified explicitly in an UPDATE statement and some other column changes value. An UPDATE that sets a column to the value it does not cause the TIMESTAMP column to be updated; if you set a column to its current value, MySQL ignores the update for efficiency.

A TIMESTAMP column other than the first also can be assigned the current date and time by setting it to NULL or to any function that produces the current date and time (NOW() [837], CURRENT_TIMESTAMP [829]).

Note that the information in the following discussion applies to TIMESTAMP columns only for tables not created with MAXDB [460] mode enabled, because such columns are created as DATETIME columns.

You can set any TIMESTAMP column to a value different from the current date and time by setting it explicitly to the desired value. This is true even for the first TIMESTAMP column. You can use this property if, for example, you want a TIMESTAMP to be set to the current date and time when you create a row, but not to be changed whenever the row is updated later:

- Let MySQL set the column when the row is created. This initializes it to the current date and time.
- When you perform subsequent updates to other columns in the row, set the TIMESTAMP column explicitly to its current value:

```
UPDATE tbl_name
    SET timestamp_col = timestamp_col,
        other_col1 = new_value1,
        other_col2 = new_value2, ...
```

Another way to maintain a column that records row-creation time is to use a DATETIME column that you initialize to NOW() [837] when the row is created and do not modify for subsequent updates.

TIMESTAMP values may range from the beginning of 1970 to partway through the year 2038, with a resolution of one second. Values are displayed as numbers. When you store a value in a TIMESTAMP column, it is assumed to be represented in the current time zone, and is converted to UTC for storage. When you retrieve the value, it is converted from UTC back to the local time zone for display. Before MySQL 4.1.3, the server has a single time zone. As of 4.1.3, clients can set their own time zones on a per-connection basis, as described in Section 9.7, “MySQL Server Time Zone Support”.

Prior to version 4.1, the format in which MySQL retrieves and displays TIMESTAMP values depends on the display size, as illustrated in the following table. The “full” TIMESTAMP format is 14 digits, but TIMESTAMP columns may be created with shorter display sizes.

Data Type	Display Format
TIMESTAMP(14)	YYYYMMDDHHMMSS
TIMESTAMP(12)	YYMMDDHHMMSS
TIMESTAMP(10)	YYMMDDHHMM
TIMESTAMP(8)	YYYYMMDD
TIMESTAMP(6)	YYMMDD
TIMESTAMP(4)	YYMM
TIMESTAMP(2)	YY

All TIMESTAMP columns have the same storage size, regardless of display size. The most common display sizes are 6, 8, 12, and 14. You can specify an arbitrary display size at table creation time, but values of 0 or greater than 14 are coerced to 14. Odd-valued sizes in the range from 1 to 13 are coerced to the next higher even number.

TIMESTAMP columns store legal values using the full precision with which the value was specified, regardless of the display size. This has several implications:

- Always specify year, month, and day, even if your column types are TIMESTAMP(4) or TIMESTAMP(2). Otherwise, the value is not a legal date and 0 is stored.

- If you use ALTER TABLE to widen a narrow TIMESTAMP column, information is displayed that previously was “hidden.”
- Similarly, narrowing a TIMESTAMP column does not cause information to be lost, except in the sense that less information is shown when the values are displayed.
- If you are planning to use mysqldump for the database, do not use TIMESTAMP(4) or TIMESTAMP(2). The display format for these data types are not legal dates and 0 will be stored instead. This inconsistency is fixed starting with MySQL 4.1, where display width is ignored. To prepare for transition to versions after 4.0, you should change to use display widths of 6 or more, which will produce a legal display format. You can change the display width of TIMESTAMP data types, without losing any information, by using ALTER TABLE as indicated above.

  If you need to print the timestamps for external applications, you can use MID() [799] to extract the relevant part of the timestamp: for example, to imitate the TIMESTAMP(4) display format.
- Although TIMESTAMP values are stored to full precision, the only function that operates directly on the underlying stored value is UNIX_TIMESTAMP() [841]. Other functions operate on the formatted retrieved value. This means you cannot use a function such as HOUR() [836] or SECOND() [838] unless the relevant part of the TIMESTAMP value is included in the formatted value. For example, the HH part of a TIMESTAMP column is not displayed unless the display size is at least 10, so trying to use HOUR() [836] on shorter TIMESTAMP values produces a meaningless result.

In MySQL 4.1, TIMESTAMP display format changes to be the same as DATETIME, that is, as a string in 'YYYY-MM-DD HH:MM:SS' format rather than as a number in YYYYMMDDHHMMSS format. To test applications written for MySQL 4.0 for compatibility with this change, you can set the new [390] system variable to 1. This variable is available beginning with MySQL 4.0.12. It can be set at server startup by specifying the --new option to mysqld. At runtime, a user who has the SUPER [493] privilege can set the global value with a SET statement:

```
mysql> SET GLOBAL new = 1;
```

Any client can set its session value of new [390] as follows:

```
mysql> SET new = 1;
```

The general effect of setting new [390] to 1 is that values for existing TIMESTAMP columns display as strings rather than as numbers. Also, DESCRIBE displays the column definition as TIMESTAMP(19), rather than as TIMESTAMP(14).

The effect differs somewhat for TIMESTAMP columns that are created while new [390] is set to 1. In this case, column values display as strings and DESCRIBE shows the definition as TIMESTAMP(19), regardless of the current value of new [390].

In other words, with new=1, all TIMESTAMP values display as strings and DESCRIBE shows a display width of 19. For columns created while new=1, they continue to display as strings and to have a display width of 19 even if new [390] is set to 0.

For a TIMESTAMP column that displays as a string, you can display it as a number by retrieving it as *col_name*+0.

10.3.1.2 TIMESTAMP Properties as of MySQL 4.1

In MySQL 4.1 and up, the properties of the TIMESTAMP data type changed in several ways. The following discussion describes the revised syntax and behavior.

Beginning with MySQL 4.1.3, the default current time zone for each connection is the server's time. The time zone can be set on a per-connection basis, as described in Section 9.7, “MySQL Server Time Zone Support”. TIMESTAMP values still are stored in UTC, but are converted from the current time zone for storage, and converted back to the current time zone for retrieval. As long as the time zone setting remains constant, you get back the same value you store. If you store a TIMESTAMP value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the time_zone [431] system variable.

From MySQL 4.1.0 on, TIMESTAMP display format differs from that of earlier MySQL releases:

- TIMESTAMP columns are displayed in the same format as DATETIME columns. In other words, the display width is fixed at 19 characters, and the format is 'YYYY-MM-DD HH:MM:SS'.
- Display widths (used as described in the preceding section) are no longer supported. In other words, for declarations such as TIMESTAMP(2), TIMESTAMP(4), and so on, the display width is ignored.

The following items summarize TIMESTAMP initialization and updating properties prior to MySQL 4.1.2:

- The first TIMESTAMP column in table row automatically is set to the current timestamp when the record is created if the column is set to NULL or is not specified at all.
- The first TIMESTAMP column in table row automatically is updated to the current timestamp when the value of any other column in the row is changed, unless the TIMESTAMP column explicitly is assigned a value other than NULL.
- If a DEFAULT value is specified for the first TIMESTAMP column when the table is created, it is silently ignored.
- Other TIMESTAMP columns in the table can be set to the current TIMESTAMP by assigning NULL to them, but they do not update automatically.

Beginning with MySQL 4.1.2, you have more flexible control over when automatic TIMESTAMP initialization and updating occur and which column should have those behaviors:

- For one TIMESTAMP column in a table, you can assign the current timestamp as the default value and the auto-update value. It is possible to have the current timestamp be the default value for initializing the column, for the auto-update value, or both. It is not possible to have the current timestamp be the default value for one column and the auto-update value for another column.
- Any single TIMESTAMP column in a table can be used as the one that is initialized to the current date and time, or updated automatically. This need not be the first TIMESTAMP column.
- In a CREATE TABLE statement, the first TIMESTAMP column can be declared in any of the following ways:
  - With both DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP clauses, the column has the current timestamp for its default value, and is automatically updated.
  - With neither DEFAULT nor ON UPDATE clauses, it is the same as DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP.
  - With a DEFAULT CURRENT_TIMESTAMP clause and no ON UPDATE clause, the column has the current timestamp for its default value but is not automatically updated.
  - With no DEFAULT clause and with an ON UPDATE CURRENT_TIMESTAMP clause, the column has a default of 0 and is automatically updated.

- With a constant DEFAULT value, the column has the given default and is not automatically initialized to the current timestamp. If the column also has an ON UPDATE CURRENT_TIMESTAMP clause, it is automatically updated; otherwise, it has a constant default and is not automatically updated.

In other words, you can use the current timestamp for both the initial value and the auto-update value, or either one, or neither. (For example, you can specify ON UPDATE to enable auto-update without also having the column auto-initialized.) The following column definitions demonstrate each possibility:

- Auto-initialization and auto-update:

```
ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
```

- Auto-initialization only:

```
ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP
```

- Auto-update only:

```
ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
```

- Neither:

```
ts TIMESTAMP DEFAULT 0
```

- To specify automatic default or updating for a TIMESTAMP column other than the first one, you must suppress the automatic initialization and update behaviors for the first TIMESTAMP column by explicitly assigning it a constant DEFAULT value (for example, DEFAULT 0 or DEFAULT '2003-01-01 00:00:00'). Then, for the other TIMESTAMP column, the rules are the same as for the first TIMESTAMP column, except that if you omit both of the DEFAULT and ON UPDATE clauses, no automatic initialization or updating occurs.

  Example:

```
CREATE TABLE t (
    ts1 TIMESTAMP DEFAULT 0,
    ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
                  ON UPDATE CURRENT_TIMESTAMP);
```

- CURRENT_TIMESTAMP [829] or any of its synonyms (CURRENT_TIMESTAMP() [829], NOW() [837], LOCALTIME [836], LOCALTIME() [836], LOCALTIMESTAMP [836], or LOCALTIMESTAMP() [836]) can be used in the DEFAULT and ON UPDATE clauses. They all mean “the current timestamp.” UTC_TIMESTAMP [843] is not permitted. Its range of values does not align with those of the TIMESTAMP column except when the current time zone is UTC.

- The order of the DEFAULT and ON UPDATE clauses does not matter. If both DEFAULT and ON UPDATE are specified for a TIMESTAMP column, either can precede the other. For example, these statements are equivalent:

```
CREATE TABLE t (ts TIMESTAMP);
CREATE TABLE t (ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP
                             ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t (ts TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
                             DEFAULT CURRENT_TIMESTAMP);
```

The following rules describe the changes in MySQL 4.1 regarding TIMESTAMP and handling of NULL values:

- Before MySQL 4.1.2, TIMESTAMP columns are NOT NULL. They cannot contain NULL values, and assigning NULL assigns the current timestamp. Any DEFAULT clause is ignored.
- From MySQL 4.1.2 to 4.1.5, TIMESTAMP columns are NOT NULL. They cannot contain NULL values, and assigning NULL assigns the current timestamp. A DEFAULT NULL clause can be specified, but it is treated as DEFAULT CURRENT_TIMESTAMP for the first TIMESTAMP column and as DEFAULT 0 for other TIMESTAMP columns.
- As of MySQL 4.1.6, TIMESTAMP columns are NOT NULL by default, cannot contain NULL values, and assigning NULL assigns the current timestamp. However, a TIMESTAMP column can be permitted to contain NULL by declaring it with the NULL attribute. In this case, the default value also becomes NULL unless overridden with a DEFAULT clause that specifies a different default value. DEFAULT NULL can be used to explicitly specify NULL as the default value. (For a TIMESTAMP column not declared with the NULL attribute, DEFAULT NULL is illegal.) If a TIMESTAMP column permits NULL values, assigning NULL sets it to NULL, not to the current timestamp.

The following table contains several TIMESTAMP columns that permit NULL values:

```
CREATE TABLE t
(
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
```

Note that a TIMESTAMP column that permits NULL values will *not* take on the current timestamp except under one of the following conditions:

- Its default value is defined as CURRENT_TIMESTAMP [829]
- NOW() [837] or CURRENT_TIMESTAMP [829] is inserted into the column

In other words, a TIMESTAMP column defined as NULL will auto-initialize only if it is created using a definition such as the following:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

Otherwise—that is, if the TIMESTAMP column is defined to permit NULL values but not using DEFAULT CURRENT_TIMESTAMP, as shown here…

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT NULL);
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
```

…then you must explicitly insert a value corresponding to the current date and time. For example:

```
INSERT INTO t1 VALUES (NOW());
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
```

Note

Beginning with MySQL 4.1.1, the MySQL server can be run with the MAXDB [460] SQL mode enabled. When the server runs with this mode enabled, TIMESTAMP is identical with DATETIME. That is, if this mode is enabled at the time that a table is

> created, TIMESTAMP columns are created as DATETIME columns. As a result, such columns use DATETIME display format, have the same range of values, and there is no automatic initialization or updating to the current date and time.

To enable MAXDB [460] mode, set the server SQL mode to MAXDB [460] at startup using the --sql-mode=MAXDB [394] server option or by setting the global sql_mode [429] variable at runtime:

```
mysql> SET GLOBAL sql_mode=MAXDB;
```

A client can cause the server to run in MAXDB [460] mode for its own connection as follows:

```
mysql> SET SESSION sql_mode=MAXDB;
```

10.3.2 The TIME Type

MySQL retrieves and displays TIME values in 'HH:MM:SS' format (or 'HHH:MM:SS' format for large hours values). TIME values may range from '-838:59:59' to '838:59:59'. The hours part may be so large because the TIME type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes TIME values in several formats, described in Section 8.1.3, “Date and Time Literals”. Some of these formats can include a trailing fractional seconds part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into TIME columns. For information about fractional seconds support in MySQL, see Section 10.3.4, “Fractional Seconds in Time Values”.

Be careful about assigning abbreviated values to a TIME column. MySQL interprets abbreviated TIME values with colons as time of the day. That is, '11:12' means '11:12:00', not '00:11:12'. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of '1112' and 1112 as meaning '11:12:00' (12 minutes after 11 o'clock), but MySQL interprets them as '00:11:12' (11 minutes, 12 seconds). Similarly, '12' and 12 are interpreted as '00:00:12'.

By default, values that lie outside the TIME range but are otherwise legal are clipped to the closest endpoint of the range. For example, '-850:00:00' and '850:00:00' are converted to '-838:59:59' and '838:59:59'. Illegal TIME values are converted to '00:00:00'. Note that because '00:00:00' is itself a legal TIME value, there is no way to tell, from a value of '00:00:00' stored in a table, whether the original value was specified as '00:00:00' or whether it was illegal.

For more restrictive treatment of invalid TIME values, enable strict SQL mode to cause errors to occur. See Section 5.1.6, “Server SQL Modes”.

10.3.3 The YEAR Type

The YEAR type is a one-byte type used for representing years. It can be declared as YEAR(2) or YEAR(4) to specify a display width of two or four characters. The default is four characters if no width is given.

For four-digit format, MySQL displays YEAR values in YYYY format, with a range of 1901 to 2155, or 0000. For two-digit format, MySQL displays only the last two (least significant) digits; for example, 70 (1970 or 2070) or 69 (2069).

You can specify input YEAR values in a variety of formats:

- As a four-digit string in the range '1901' to '2155'.

- As a four-digit number in the range `1901` to `2155`.
- As a two-digit string in the range `'00'` to `'99'`. Values in the ranges `'00'` to `'69'` and `'70'` to `'99'` are converted to `YEAR` values in the ranges `2000` to `2069` and `1970` to `1999`.
- As a two-digit number in the range `1` to `99`. Values in the ranges `1` to `69` and `70` to `99` are converted to `YEAR` values in the ranges `2001` to `2069` and `1970` to `1999`. Note that the range for two-digit numbers is slightly different from the range for two-digit strings, because you cannot specify zero directly as a number and have it be interpreted as `2000`. You must specify it as a string `'0'` or `'00'` or it is interpreted as `0000`.
- As the result of a function that returns a value that is acceptable in a `YEAR` context, such as `NOW()` [837].

Illegal `YEAR` values are converted to `0000`.

See also Section 10.3.6, “Two-Digit Years in Dates”.

10.3.4 Fractional Seconds in Time Values

A trailing fractional seconds part is permissible for temporal values in contexts such as literal values, and in the arguments to or return values from some temporal functions. Example:

```
mysql> SELECT MICROSECOND('2010-12-10 14:12:09.019473');
+-----------------------------------------+
| MICROSECOND('2010-12-10 14:12:09.019473') |
+-----------------------------------------+
|                                   19473 |
+-----------------------------------------+
```

However, when MySQL stores a value into a column of any temporal data type, it discards any fractional part and does not store it.

10.3.5 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of legal values for the resulting type. For example, although `DATE`, `DATETIME`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. `TIMESTAMP` values cannot be earlier than `1970` UTC or later than `'2038-01-19 03:14:07'` UTC. This means that a date such as `'1968-01-01'`, while legal as a `DATE` or `DATETIME` value, is not valid as a `TIMESTAMP` value and is converted to `0`.

Conversion of `DATE` values:

- Conversion to a `DATETIME` or `TIMESTAMP` value adds a time part of `'00:00:00'` because the `DATE` value contains no time information.
- Conversion to a `TIME` value is not useful; the result is `'00:00:00'`.

Conversion of `DATETIME` and `TIMESTAMP` values:

- Conversion to a `DATE` value discards the time part because the `DATE` type contains no time information.
- Conversion to a `TIME` value discards the date part because the `TIME` type contains no date information.

Conversion of `TIME` values:

MySQL converts a time value to a date or date-and-time value by parsing the string value of the time as a date or date-and-time. This is unlikely to be useful. For example, `'23:12:31'` interpreted as a date becomes `'2032-12-31'`. Time values not valid as dates become `'0000-00-00'` or `NULL`.

As of MySQL 4.1.13, conversion of `TIME` or `DATETIME` values to numeric form (for example, by adding `+0`) results in a double-precision value with a microseconds part of `.000000`:

```
mysql> SELECT CURTIME(), CURTIME()+0;
+-----------+---------------+
| CURTIME() | CURTIME()+0   |
+-----------+---------------+
| 10:41:36  | 104136.000000 |
+-----------+---------------+
mysql> SELECT NOW(), NOW()+0;
+---------------------+-----------------------+
| NOW()               | NOW()+0               |
+---------------------+-----------------------+
| 2007-11-30 10:41:47 | 20071130104147.000000 |
+---------------------+-----------------------+
```

Before MySQL 4.1.13, the conversion results in an integer value with no microseconds part.

10.3.6 Two-Digit Years in Dates

Date values with two-digit years are ambiguous because the century is unknown. Such values must be interpreted into four-digit form because MySQL stores years internally using four digits.

For `DATETIME`, `DATE`, `TIMESTAMP`, and `YEAR` types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range `00-69` are converted to `2000-2069`.
- Year values in the range `70-99` are converted to `1970-1999`.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing four-digit year values.

In MySQL, the `YEAR` data type can store the years `0` and `1901` to `2155` in one byte and display them using two or four digits. All two-digit years are considered to be in the range `1970` to `2069`, which means that if you store `01` in a `YEAR` column, MySQL Server treats it as `2001`.

`ORDER BY` properly sorts `YEAR` values that have two-digit years.

Some functions like `MIN()` [884] and `MAX()` [884] convert a `YEAR` to a number. This means that a value with a two-digit year does not work properly with these functions. The fix in this case is to convert the `YEAR` to four-digit year format.

10.4 String Types

The string types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`. This section describes how these types work and how to use them in your queries. For string type storage requirements, see Section 10.5, “Data Type Storage Requirements”.

10.4.1 The `CHAR` and `VARCHAR` Types

The `CHAR` and `VARCHAR` types are similar, but differ in the way they are stored and retrieved.

The CHAR and VARCHAR types are declared with a length that indicates the maximum number of characters you want to store. For example, CHAR(30) can hold up to 30 characters. (Before MySQL 4.1, the length is interpreted as number of bytes.)

The length of a CHAR column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. (Before MySQL 3.23, the length of CHAR may be from 1 to 255.) When CHAR values are stored, they are right-padded with spaces to the specified length. When CHAR values are retrieved, trailing spaces are removed.

Values in VARCHAR columns are variable-length strings. The length can be specified as a value from 1 to 255 before MySQL 4.0.2 and 0 to 255 as of MySQL 4.0.2.

In contrast to CHAR, VARCHAR values are stored as a one-byte length prefix plus data. The length prefix indicates the number of bytes in the value.

If you assign a value to a CHAR or VARCHAR column that exceeds the column's maximum length, the value is truncated to fit. If the truncated characters are not spaces, a warning is generated.

VARCHAR values are not padded when they are stored. Trailing spaces in MySQL version up to and including 4.1 are removed from values when stored in a VARCHAR column; this also means that the spaces are absent from retrieved values.

If you need a data type for which trailing spaces are not removed, consider using a BLOB or TEXT type. If you want to store binary values such as results from an encryption or compression function that might contain arbitrary byte values, use a BLOB column rather than a CHAR or VARCHAR column, to avoid potential problems with trailing space removal that would change data values.

The following table illustrates the differences between CHAR and VARCHAR by showing the result of storing various string values into CHAR(4) and VARCHAR(4) columns (assuming that the column uses a single-byte character set such as latin1).

Value	CHAR(4)	Storage Required	VARCHAR(4)	Storage Required
''	' '	4 bytes	''	1 byte
'ab'	'ab '	4 bytes	'ab'	3 bytes
'abcd'	'abcd'	4 bytes	'abcd'	5 bytes
'abcdefgh'	'abcd'	4 bytes	'abcd'	5 bytes

If a given value is stored into the CHAR(4) and VARCHAR(4) columns, the values retrieved from the columns are not always the same because trailing spaces are removed from CHAR columns upon retrieval.

As of MySQL 4.1, values in CHAR and VARCHAR columns are sorted and compared according to the character set collation assigned to the column. Before MySQL 4.1, sorting and comparison are based on the collation of the server character set; you can declare the column with the BINARY attribute to cause sorting and comparison to be based on the numeric values of the bytes in column values. BINARY does not affect how column values are stored or retrieved.

All MySQL collations are of type PADSPACE. This means that all CHAR and VARCHAR values in MySQL are compared without regard to any trailing spaces. For example:

```
mysql> CREATE TABLE names (myname CHAR(10), yourname VARCHAR(10));
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO names VALUES ('Monty ', 'Monty ');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT myname = 'Monty  ', yourname = 'Monty  ' FROM names;
+--------------------+----------------------+
| myname = 'Monty  ' | yourname = 'Monty  ' |
+--------------------+----------------------+
|                  1 |                    1 |
+--------------------+----------------------+
1 row in set (0.00 sec)
```

This is true for all MySQL versions, and it makes no difference whether your version trims trailing spaces from VARCHAR values before storing them. Nor does the server SQL mode make any difference in this regard.

Note

For more information about MySQL character sets and collations, see Section 9.1, "Character Set Support".

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters will result in a duplicate-key error. For example, if a table contains `'a'`, an attempt to store `'a '` causes a duplicate-key error.

The BINARY attribute is sticky. This means that if a column marked BINARY is used in an expression, the whole expression is treated as a BINARY value.

MySQL may silently change the type of a CHAR or VARCHAR column at table creation time. See Section 12.1.5.2, "Silent Column Specification Changes".

10.4.2 The BINARY and VARBINARY Types

The BINARY and VARBINARY types are similar to CHAR and VARCHAR, except that they contain binary strings rather than nonbinary strings. That is, they contain byte strings rather than character strings. This means that they have no character set, and sorting and comparison are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for BINARY and VARBINARY as it is for CHAR and VARCHAR, except that the length for BINARY and VARBINARY is a length in bytes rather than in characters.

Before MySQL 4.1.2, `BINARY(M)` and `VARBINARY(M)` are treated as `CHAR(M) BINARY` and `VARCHAR(M) BINARY`. As of MySQL 4.1.2, the BINARY and VARBINARY data types are distinct from the `CHAR BINARY` and `VARCHAR BINARY` data types. For the latter types, the BINARY attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary collation for the column character set to be used, and the column itself contains nonbinary character strings rather than binary byte strings. For example, in 4.1.2 and up, `CHAR(5) BINARY` is treated as `CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin`, assuming that the default character set is `latin1`. This differs from `BINARY(5)`, which stores 5-bytes binary strings that have no character set or collation. For information about differences between nonbinary string binary collations and binary strings, see Section 9.1.7.6, "The _bin and binary Collations".

If you assign a value to a BINARY or VARBINARY column that exceeds the column's maximum length, the value is truncated to fit. If the truncated characters are not spaces, a warning is generated.

The handling of trailing spaces is the same for BINARY and VARBINARY as it is for CHAR and VARCHAR. When BINARY values are stored, they are right-padded with spaces to the specified length. When BINARY values are retrieved, trailing spaces are removed. For VARBINARY, trailing spaces are removed when values are stored.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad bytes will result in a duplicate-key error. For example, if a table contains `'a'`, an attempt to store `'a '` causes a duplicate-key error. Trailing spaces are significant in comparisons.

You should consider the preceding padding and stripping characteristics carefully if you plan to use one of these data types for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how space-padding of `BINARY` values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET c = 'a  ';
Query OK, 1 row affected (0.00 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a  ' from t;
+--------+---------+-----------+
| HEX(c) | c = 'a' | c = 'a  ' |
+--------+---------+-----------+
| 61     | 1       | 0         |
+--------+---------+-----------+
1 row in set (0.00 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use one of the `BLOB` data types instead.

10.4.3 The BLOB and TEXT Types

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types are `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`. These differ only in the maximum length of the values they can hold. The four `TEXT` types are `TINYTEXT`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. These correspond to the four `BLOB` types and have the same maximum lengths and storage requirements. See Section 10.5, “Data Type Storage Requirements”.

`BLOB` values are treated as binary strings (byte strings). They have no character set, and sorting and comparison are based on the numeric values of the bytes in column values. `TEXT` values are treated as nonbinary strings (character strings). They have a character set, and values are sorted and compared based on the collation of the character set assigned to the column as of MySQL 4.1. Before 4.1, `TEXT` sorting and comparison are based on the collation of the server character set.

If you assign a value to a `BLOB` or `TEXT` column that exceeds the data type's maximum length, the value is truncated to fit and a warning is generated.

If a `TEXT` or `BLOB` column is indexed, index entry comparisons are not space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will not occur for values that differ only in the number of trailing spaces. For example, if a table contains `'a'`, an attempt to store `'a '` does not cause a duplicate-key error. (This behavior changes in MySQL 5.0 for `TEXT` columns, such that comparisons are space-padded.)

In most respects, you can regard a `BLOB` column as a `VARBINARY` column that can be as big as you like. Similarly, you can regard a `TEXT` column as a `VARCHAR` column. `BLOB` and `TEXT` differ from `VARBINARY` and `VARCHAR` in the following ways:

- There is no trailing-space removal for `BLOB` and `TEXT` columns when values are stored or retrieved. This differs from `VARBINARY` and `VARCHAR`, for which trailing spaces are removed when values are stored.

  On comparisons, `TEXT` is space extended to fit the compared object, exactly like `CHAR` and `VARCHAR`.

- You can have indexes on BLOB and TEXT columns only as of MySQL 3.23.2 for MyISAM tables or MySQL 4.0.14 for InnoDB tables. Previous versions of MySQL did not support indexing these data types.
- For indexes on BLOB and TEXT columns, you must specify an index prefix length. For CHAR and VARCHAR, a prefix length is optional. See Section 7.4.1, “Column Indexes”.
- BLOB and TEXT columns cannot have DEFAULT values.

From MySQL 4.1.0 on, LONG and LONG VARCHAR map to the MEDIUMTEXT data type. This is a compatibility feature. If you use the BINARY attribute with a TEXT data type, the column is assigned the binary collation of the column character set.

MySQL Connector/ODBC defines BLOB values as LONGVARBINARY and TEXT values as LONGVARCHAR.

Because BLOB and TEXT values can be extremely long, you might encounter some constraints in using them:

- Only the first max_sort_length [420] bytes of the column are used when sorting. The default value of max_sort_length [420] is 1024. This value can be changed using the --max_sort_length=*N* [420] option when starting the mysqld server. See Section 5.1.3, “Server System Variables”.

  As of MySQL 4.0.3, you can make more bytes significant in sorting or grouping by increasing the value of max_sort_length [420] at runtime. Any client can change the value of its session max_sort_length [420] variable:

  ```
  mysql> SET max_sort_length = 2000;
  mysql> SELECT id, comment FROM t
      -> ORDER BY comment;
  ```

  Another way to use GROUP BY or ORDER BY on a BLOB or TEXT column containing long values when you want more than max_sort_length [420] bytes to be significant is to convert the column value into a fixed-length object. The standard way to do this is with the SUBSTRING() [802] function. For example, the following statement causes 2000 bytes of the comment column to be taken into account for sorting:

  ```
  mysql> SELECT id, SUBSTRING(comment,1,2000) FROM t
      -> ORDER BY SUBSTRING(comment,1,2000);
  ```

  Before MySQL 3.23.2, you can group on an expression involving BLOB or TEXT values by using a column alias or by specifying the column position:

  ```
  mysql> SELECT id, SUBSTRING(comment,1,2000) AS b
      -> FROM tbl_name GROUP BY b;
  mysql> SELECT id, SUBSTRING(comment,1,2000)
      -> FROM tbl_name GROUP BY 2;
  ```

- Instances of BLOB or TEXT columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the MEMORY storage engine does not support those data types (see Section 7.7.4, “How MySQL Uses Internal Temporary Tables”). Use of disk incurs a performance penalty, so include BLOB or TEXT columns in the query result only if they are really needed. For example, avoid using SELECT *, which selects all columns.
- The maximum size of a BLOB or TEXT object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing

the value of the max_allowed_packet [418] variable, but you must do so for both the server and your client program. For example, both mysql and mysqldump enable you to change the client-side max_allowed_packet [418] value. See Section 7.8.2, “Tuning Server Parameters”, Section 4.5.1, “mysql — The MySQL Command-Line Tool”, and Section 4.5.4, “mysqldump — A Database Backup Program”. You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see Section 10.5, “Data Type Storage Requirements”

Each BLOB or TEXT value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in BLOB or TEXT columns. You may find MySQL's string handling functions useful for working with such data. See Section 11.5, “String Functions”. For security and other reasons, it is usually preferable to do so using application code rather than giving application users the FILE [491] privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (http://forums.mysql.com/).

10.4.4 The ENUM Type

An ENUM is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time.

An enumeration value must be a quoted string literal; it may not be an expression, even one that evaluates to a string value. For example, you can create a table with an ENUM column like this:

```
CREATE TABLE sizes (
    name ENUM('small', 'medium', 'large')
);
```

However, this version of the previous CREATE TABLE statement does *not* work:

```
CREATE TABLE sizes (
    c1 ENUM('small', CONCAT('med','ium'), 'large')
);
```

You also may not employ a user variable as an enumeration value. This pair of statements do *not* work:

```
SET @mysize = 'medium';

CREATE TABLE sizes (
    name ENUM('small', @mysize, 'large')
);
```

If you wish to use a number as an enumeration value, you must enclose it in quotation marks.

The value may also be the empty string (`''`) or NULL under certain circumstances:

- If you insert an invalid value into an ENUM (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a “normal” empty string by the fact that this string has the numeric value 0. More about this later.

  If strict SQL mode is enabled, attempts to insert invalid ENUM values result in an error.

- If an ENUM column is declared to permit NULL, the NULL value is a legal value for the column, and the default value is NULL. If an ENUM column is declared NOT NULL, its default value is the first element of the list of permitted values.

Each enumeration value has an index:

- Values from the list of permissible elements in the column specification are numbered beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following SELECT statement to find rows into which invalid ENUM values were assigned:

```
mysql> SELECT * FROM tbl_name WHERE enum_col=0;
```

- The index of the NULL value is NULL.
- The term “index” here refers only to position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as ENUM('one', 'two', 'three') can have any of the values shown here. The index of each value is also shown.

Value	Index
NULL	NULL
''	0
'one'	1
'two'	2
'three'	3

An enumeration can have a maximum of 65,535 elements.

Starting from MySQL 3.23.51, trailing spaces are automatically deleted from ENUM member values in the table definition when a table is created.

When retrieved, values stored into an ENUM column are displayed using the lettercase that was used in the column definition. Before MySQL 4.1.1, lettercase is irrelevant when you assign values to an ENUM column. As of 4.1.1, ENUM columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase does matter when you assign values to the column.

If you retrieve an ENUM value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an ENUM column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

If you store a number into an ENUM column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does *not* work with LOAD DATA, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an ENUM column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes '1' (the value with index 2). If you store '2', it matches an enumeration value, so it is stored as '2'. If you store '3', it does not match any enumeration value, so it is treated as an index and becomes '2' (the value with index 3).

```
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
```

```
mysql> SELECT * FROM t;
+---------+
| numbers |
+---------+
| 1       |
| 2       |
| 2       |
+---------+
```

ENUM values are sorted according to the order in which the enumeration members were listed in the column specification. (In other words, ENUM values are sorted according to their index numbers.) For example, 'a' sorts before 'b' for ENUM('a', 'b'), but 'b' sorts before 'a' for ENUM('b', 'a'). The empty string sorts before nonempty strings, and NULL values sort before all other enumeration values. If you expect sorting to be done alphabetically, you should specify the ENUM list in alphabetic order. You can also use GROUP BY CAST(col AS CHAR) or GROUP BY CONCAT(col) to make sure that the column is sorted lexically rather than by index number.

Functions such as SUM() [884] or AVG() [881] that expect a numeric argument cast the argument to a number if necessary. For ENUM values, the cast operation causes the index number to be used.

If you want to determine all possible values for an ENUM column, use SHOW COLUMNS FROM *tbl_name* LIKE *enum_col* and parse the ENUM definition in the Type column of the output.

10.4.5 The SET Type

A SET is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. SET column values that consist of multiple set members are specified with members separated by commas (“,”). A consequence of this is that SET member values should not themselves contain commas.

For example, a column specified as SET('one', 'two') NOT NULL can have any of these values:

```
''
'one'
'two'
'one,two'
```

A SET can have a maximum of 64 different members.

Starting from MySQL 3.23.51, trailing spaces are automatically deleted from SET member values in the table definition when a table is created.

When retrieved, values stored into a SET column are displayed using the lettercase that was used in the column definition. Before MySQL 4.1.1, lettercase is irrelevant when you assign values to an SET column. As of 4.1.1, SET columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase does matter when you assign values to the column.

MySQL stores SET values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a SET value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a SET column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a SET column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as SET('a','b','c','d'), the members have the following decimal and binary values.

SET Member	Decimal Value	Binary Value
'a'	1	0001
'b'	2	0010
'c'	4	0100
'd'	8	1000

If you assign a value of 9 to this column, that is 1001 in binary, the first and fourth SET members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one SET element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. For example, suppose that a column is specified as SET('a','b','c','d'):

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5  Duplicates: 0  Warnings: 0
```

Then all these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
+------+
5 rows in set (0.04 sec)
```

If you set a SET column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+---------+------+-------------------------------------------+
| Level   | Code | Message                                   |
+---------+------+-------------------------------------------+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+---------+------+-------------------------------------------+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
```

```
| a,d  |
| a,d  |
| a,d  |
+------+
6 rows in set (0.01 sec)
```

If strict SQL mode is enabled, attempts to insert invalid `SET` values result in an error.

`SET` values are sorted numerically. `NULL` values sort before non-`NULL` `SET` values.

Functions such as `SUM()` [884] or `AVG()` [881] that expect a numeric argument cast the argument to a number if necessary. For `SET` values, the cast operation causes the numeric value to be used.

Normally, you search for `SET` values using the `FIND_IN_SET()` [796] function or the `LIKE` [804] operator:

```
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```

The first statement finds rows where *`set_col`* contains the *`value`* set member. The second is similar, but not the same: It finds rows where *`set_col`* contains *`value`* anywhere, even as a substring of another set member.

The following statements also are legal:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to *`'val1,val2'`* returns different results than comparing values to *`'val2,val1'`*. You should specify the values in the same order in which they are listed in the column definition.

If you want to determine all possible values for a `SET` column, use `SHOW COLUMNS FROM` *`tbl_name`* `LIKE` *`set_col`* and parse the `SET` definition in the `Type` column of the output.

10.5 Data Type Storage Requirements

The storage requirements for each data type supported by MySQL are listed here by category.

The maximum size of a row in a `MyISAM` table is 65,535 bytes. (However, each `BLOB` or `TEXT` column contributes only 9 to 12 bytes toward this size.) This limitation may be shared by other storage engines as well. See Chapter 13, *Storage Engines*, for more information.

Important

For tables using the `NDBCLUSTER` storage engine, there is the factor of *4-byte alignment* to be taken into account when calculating storage requirements. This means that all `NDB` data storage is done in multiples of 4 bytes. Thus, a column value that would take 15 bytes in a table using a storage engine other than `NDB` requires 16 bytes in an `NDB` table. This requirement applies in addition to any other considerations that are discussed in this section. For example, in `NDBCLUSTER` tables, the `TINYINT`, `SMALLINT`, `MEDIUMINT`, and `INTEGER` (`INT`) column types each require 4 bytes storage per record due to the alignment factor.

An exception to this rule is the `BIT` type, which is *not* 4-byte aligned. In MySQL Cluster tables, a `BIT(`*`M`*`)` column takes *`M`* bits of storage space. However, if a

table definition contains 1 or more `BIT` columns (up to 32 `BIT` columns), then `NDBCLUSTER` reserves 4 bytes (32 bits) per row for these. If a table definition contains more than 32 `BIT` columns (up to 64 such columns), then `NDBCLUSTER` reserves 8 bytes (that is, 64 bits) per row.

In addition, while a `NULL` itself does not require any storage space, `NDBCLUSTER` reserves 4 bytes per row if the table definition contains any columns defined as `NULL`, up to 32 `NULL` columns. (If a MySQL Cluster table is defined with more than 32 `NULL` columns up to 64 `NULL` columns, then 8 bytes per row is reserved.)

When calculating storage requirements for MySQL Cluster tables, you must also remember that every table using the `NDBCLUSTER` storage engine requires a primary key; if no primary key is defined by the user, then a “hidden” primary key will be created by `NDB`. This hidden primary key consumes 31-35 bytes per table record.

You may find the `ndb_size.pl` utility to be useful for estimating `NDB` storage requirements. This Perl script connects to a current MySQL (non-Cluster) database and creates a report on how much space that database would require if it used the `NDBCLUSTER` storage engine. See Section 15.4.18, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”, for more information.

Storage Requirements for Numeric Types

Data Type	Storage Required
`TINYINT`	1 byte
`SMALLINT`	2 bytes
`MEDIUMINT`	3 bytes
`INT`, `INTEGER`	4 bytes
`BIGINT`	8 bytes
`FLOAT(`*p*`)`	4 bytes if 0 <= *p* <= 24, 8 bytes if 25 <= *p* <= 53
`FLOAT`	4 bytes
`DOUBLE [PRECISION]`, `REAL`	8 bytes
`DECIMAL(`*M*`,`*D*`)`, `NUMERIC(`*M*`,`*D*`)`	Varies; see following discussion

In MySQL versions up to and including 4.1, `DECIMAL` columns are represented as strings and their storage requirements are:

- *M*+2 bytes, if *D* > 0
- *M*+1 bytes, if *D* = 0
- *D*+2, if *M* < *D*

Storage Requirements for Date and Time Types

Data Type	Storage Required
`DATE`	3 bytes
`TIME`	3 bytes
`DATETIME`	8 bytes
`TIMESTAMP`	4 bytes

Data Type	Storage Required
YEAR	1 byte

For details about internal representation of temporal values, see MySQL Internals: Important Algorithms and Structures.

Storage Requirements for String Types

In the following table, *M* represents the declared column length in characters for nonbinary string types and bytes for binary string types. *L* represents the actual length in bytes of a given string value.

Data Type	Storage Required
CHAR(*M*)	*M* × *w* bytes, 0 <= *M* <= 255, where *w* is the number of bytes required for the maximum-length character in the character set
BINARY(*M*)	*M* bytes, 0 <= *M* <= 255
VARCHAR(*M*), VARBINARY(*M*)	*L* + 1 bytes, 0 <= *L* <= 255
TINYBLOB, TINYTEXT	*L* + 1 bytes, where $L < 2^8$
BLOB, TEXT	*L* + 2 bytes, where $L < 2^{16}$
MEDIUMBLOB, MEDIUMTEXT	*L* + 3 bytes, where $L < 2^{24}$
LONGBLOB, LONGTEXT	*L* + 4 bytes, where $L < 2^{32}$
ENUM('*value1*','*value2*',...)	1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)
SET('*value1*','*value2*',...)	1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is *L* (the byte length of the string). For example, storage for a MEDIUMTEXT value requires *L* bytes to store the value plus three bytes to store the length of the value.

As of MySQL 4.1, to calculate the number of bytes used to store a particular CHAR, VARCHAR, or TEXT column value, you must take into account the character set used for that column and whether the value contains multi-byte characters. In particular, when using the utf8 Unicode character set, you must keep in mind that not all characters use the same number of bytes and can require up to three bytes per character. For a breakdown of the storage used for different categories of utf8 characters, see Section 9.1.9, "Unicode Support".

VARCHAR and the BLOB and TEXT types are variable-length types. For each, the storage requirements depend on the actual length of column values (represented by *L* in the preceding table), rather than on the type's maximum possible size. For example, a VARCHAR(10) column can hold a string with a maximum length of 10 characters. The actual storage required is the length of the string (*L*), plus one byte to record the length of the string. For the string 'abcd', *L* is 4 and the storage requirement is five bytes.

Note

The NDBCLUSTER engine supports only fixed-width columns. This means that a VARCHAR column from a table in a MySQL Cluster will behave almost as if it were of type CHAR (except that each record still has one extra byte overhead). For example, in an NDB table, *each* record in a column declared as VARCHAR(100) will take up 101 bytes for storage, regardless of the length of the string actually stored in any given record.

`TEXT` and `BLOB` columns are implemented differently in the `NDBCLUSTER` storage engine, wherein each record in a `TEXT` column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden table. The records in this second table are always 2,000 bytes long. This means that the size of a `TEXT` column is 256 if *`size`* <= 256 (where *`size`* represents the size of the record); otherwise, the size is `256 + size + (2000 - (size - 256) % 2000)`.

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See Section 10.4.4, “The ENUM Type”.

The size of a `SET` object is determined by the number of different set members. If the set size is *`N`*, the object occupies `(N + 7)/8` bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See Section 10.4.5, “The SET Type”.

10.6 Choosing the Right Type for a Column

For the most efficient use of storage, try to use the most precise type in all cases. For example, if an integer column is used for values in the range from `1` to `99999`, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, it uses the least amount of storage.

For earlier MySQL versions, accurate representation of monetary values was a common problem. In these MySQL versions, you should also use the `DECIMAL` type. In this case the value is stored as a string, so no loss of accuracy should occur on storage. However, calculations on these `DECIMAL` values are done using double-precision operations. If accuracy is not too important or if speed is important, the `DOUBLE` type may also be good enough.

For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values only when necessary.

`PROCEDURE ANALYSE` can be used to obtain suggestions for optimal column data types. For more information, see Section 18.3.1, “PROCEDURE ANALYSE”.

10.7 Using Data Types from Other Database Engines

To make it easier to use code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

Other Vendor Type	MySQL Type
`BINARY(M)`	`CHAR(M) BINARY` (before MySQL 4.1.2)
`BOOL`	`TINYINT`
`BOOLEAN`	`TINYINT`
`CHARACTER VARYING(M)`	`VARCHAR(M)`
`FIXED`	`DECIMAL` (MySQL 4.1.0 on)
`FLOAT4`	`FLOAT`
`FLOAT8`	`DOUBLE`
`INT1`	`TINYINT`
`INT2`	`SMALLINT`

Other Vendor Type	MySQL Type
INT3	MEDIUMINT
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT (MySQL 4.1.0 on)
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL
VARBINARY(*M*)	VARCHAR(*M*) BINARY (before MySQL 4.1.2)

As of MySQL 4.1.2, BINARY and VARBINARY are distinct data types and are not converted to CHAR BINARY and VARCHAR BINARY.

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a DESCRIBE *tbl_name* statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-------+---------------+------+-----+---------+-------+
| Field | Type          | Null | Key | Default | Extra |
+-------+---------------+------+-----+---------+-------+
| a     | tinyint(1)    | YES  |     | NULL    |       |
| b     | double        | YES  |     | NULL    |       |
| c     | mediumtext    | YES  |     | NULL    |       |
| d     | decimal(10,0) | YES  |     | NULL    |       |
+-------+---------------+------+-----+---------+-------+
4 rows in set (0.01 sec)
```

Chapter 11 Functions and Operators

Table of Contents

Expressions can be used at several points in SQL statements, such as in the `ORDER BY` or `HAVING` clauses of `SELECT` statements, in the `WHERE` clause of a `SELECT`, `DELETE`, or `UPDATE` statement, or in `SET` statements. Expressions can be written using literal values, column values, `NULL`, built-in functions, user-defined functions, and operators. This chapter describes the functions and operators that are permitted for writing expressions in MySQL. Instructions for writing user-defined functions are given in Section 18.2, “Adding New Functions to MySQL”. See Section 8.2.3, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for a particular function or operator.

Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function

calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the `--sql-mode=IGNORE_SPACE` [394] option. (See Section 5.1.6, “Server SQL Modes”.) Individual client programs can request this behavior by using the `CLIENT_IGNORE_SPACE` option for `mysql_real_connect()`. In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the `mysql` program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----------+
| mod(29,9) |
+-----------+
|         2 |
+-----------+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
        -> 2
```

11.1 Function and Operator Reference

Note

This table is part of an ongoing process to expand and simplify the information provided on these elements. Further improvements to the table, and corresponding descriptions will be applied over the coming months.

Table 11.1 Functions/Operators

Name	Description
`ABS()` [817]	Return the absolute value
`ACOS()` [817]	Return the arc cosine
`ADDDATE()` [827]	Add time values (intervals) to a date value
`ADDTIME()` [828]	Add time
`AES_DECRYPT()` [865]	Decrypt using AES
`AES_ENCRYPT()` [865]	Encrypt using AES
`AND`, `&&` [787]	Logical AND
`ASCII()` [793]	Return numeric value of left-most character
`ASIN()` [818]	Return the arc sine
`=` [789]	Assign a value (as part of a `SET` statement, or as part of the `SET` clause in an `UPDATE` statement)
`:=` [788]	Assign a value
`ATAN2()`, `ATAN()` [818]	Return the arc tangent of the two arguments
`ATAN()` [818]	Return the arc tangent
`AVG()` [881]	Return the average value of the argument
`BENCHMARK()` [870]	Repeatedly execute an expression

Name	Description
BETWEEN ... AND ... [783]	Check whether a value is within a range of values
BIN() [794]	Return a string containing binary representation of a number
BINARY [859]	Cast a string to a binary string
BIT_AND() [882]	Return bitwise and
BIT_COUNT() [863]	Return the number of bits that are set
BIT_LENGTH() [794]	Return length of argument in bits
BIT_OR() [882]	Return bitwise or
BIT_XOR() [882]	Return bitwise xor
& [863]	Bitwise AND
~ [863]	Invert bits
| [862]	Bitwise OR
^ [863]	Bitwise XOR
CASE [790]	Case operator
CAST() [859]	Cast a value as a certain type
CEIL() [818]	Return the smallest integer value not less than the argument
CEILING() [818]	Return the smallest integer value not less than the argument
CHAR_LENGTH() [794]	Return number of characters in argument
CHAR() [794]	Return the character for each integer passed
CHARACTER_LENGTH() [794]	Synonym for CHAR_LENGTH()
CHARSET() [870]	Return the character set of the argument
COALESCE() [784]	Return the first non-NULL argument
COERCIBILITY() [871]	Return the collation coercibility value of the string argument
COLLATION() [871]	Return the collation of the string argument
COMPRESS() [866]	Return result as a binary string
CONCAT_WS() [795]	Return concatenate with separator
CONCAT() [795]	Return concatenated string
CONNECTION_ID() [872]	Return the connection ID (thread ID) for the connection
CONV() [818]	Convert numbers between different number bases
CONVERT_TZ() [828]	Convert from one timezone to another
CONVERT() [859]	Cast a value as a certain type
COS() [819]	Return the cosine
COT() [819]	Return the cotangent
COUNT(DISTINCT) [882]	Return the count of a number of different values
COUNT() [882]	Return a count of the number of rows returned
CRC32() [819]	Compute a cyclic redundancy check value
CURDATE() [828]	Return the current date
CURRENT_DATE(), CURRENT_DATE [829]	Synonyms for CURDATE()

Name	Description
CURRENT_TIME(), CURRENT_TIME [829]	Synonyms for CURTIME()
CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP [829]	Synonyms for NOW()
CURRENT_USER(), CURRENT_USER [872]	The authenticated user name and host name
CURTIME() [829]	Return the current time
DATABASE() [872]	Return the default (current) database name
DATE_ADD() [829]	Add time values (intervals) to a date value
DATE_FORMAT() [832]	Format date as specified
DATE_SUB() [833]	Subtract a time value (interval) from a date
DATE() [829]	Extract the date part of a date or datetime expression
DATEDIFF() [829]	Subtract two dates
DAY() [833]	Synonym for DAYOFMONTH()
DAYNAME() [833]	Return the name of the weekday
DAYOFMONTH() [833]	Return the day of the month (0-31)
DAYOFWEEK() [834]	Return the weekday index of the argument
DAYOFYEAR() [834]	Return the day of the year (1-366)
DECODE() [866]	Decodes a string encrypted using ENCODE()
DEFAULT() [877]	Return the default value for a table column
DEGREES() [819]	Convert radians to degrees
DES_DECRYPT() [866]	Decrypt a string
DES_ENCRYPT() [866]	Encrypt a string
DIV [816]	Integer division
/ [816]	Division operator
ELT() [795]	Return string at index number
ENCODE() [867]	Encode a string
ENCRYPT() [867]	Encrypt a string
<=> [782]	NULL-safe equal to operator
= [782]	Equal operator
EXP() [819]	Raise to the power of
EXPORT_SET() [795]	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
EXTRACT() [834]	Extract part of a date
FIELD() [796]	Return the index (position) of the first argument in the subsequent arguments
FIND_IN_SET() [796]	Return the index position of the first argument within the second argument
FLOOR() [820]	Return the largest integer value not greater than the argument

Name	Description
FORMAT() [796]	Return a number formatted to specified number of decimal places
FOUND_ROWS() [872]	For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause
FROM_DAYS() [834]	Convert a day number to a date
FROM_UNIXTIME() [834]	Format UNIX timestamp as a date
GET_FORMAT() [835]	Return a date format string
GET_LOCK() [877]	Get a named lock
>= [782]	Greater than or equal operator
> [783]	Greater than operator
GREATEST() [784]	Return the largest argument
GROUP_CONCAT() [883]	Return a concatenated string
HEX() [796]	Return a hexadecimal representation of a decimal or string value
HOUR() [836]	Extract the hour
IF() [790]	If/else construct
IFNULL() [791]	Null if/else construct
IN() [784]	Check whether a value is within a set of values
INET_ATON() [878]	Return the numeric value of an IP address
INET_NTOA() [878]	Return the IP address from a numeric value
INSERT() [797]	Insert a substring at the specified position up to the specified number of characters
INSTR() [797]	Return the index of the first occurrence of substring
INTERVAL() [785]	Return the index of the argument that is less than the first argument
IS_FREE_LOCK() [879]	Checks whether the named lock is free
IS NOT NULL [783]	NOT NULL value test
IS NULL [783]	NULL value test
IS_USED_LOCK() [879]	Checks whether the named lock is in use. Return connection identifier if true.
ISNULL() [785]	Test whether the argument is NULL
LAST_DAY [836]	Return the last day of the month for the argument
LAST_INSERT_ID() [874]	Value of the AUTOINCREMENT column for the last INSERT
LCASE() [797]	Synonym for LOWER()
LEAST() [786]	Return the smallest argument
<< [863]	Left shift
LEFT() [797]	Return the leftmost number of characters as specified
LENGTH() [797]	Return the length of a string in bytes
<= [782]	Less than or equal operator

Name	Description
< [782]	Less than operator
LIKE [804]	Simple pattern matching
LN() [820]	Return the natural logarithm of the argument
LOAD_FILE() [798]	Load the named file
LOCALTIME(), LOCALTIME [836]	Synonym for NOW()
LOCALTIMESTAMP, LOCALTIMESTAMP() [836]	Synonym for NOW()
LOCATE() [798]	Return the position of the first occurrence of substring
LOG10() [821]	Return the base-10 logarithm of the argument
LOG2() [821]	Return the base-2 logarithm of the argument
LOG() [820]	Return the natural logarithm of the first argument
LOWER() [798]	Return the argument in lowercase
LPAD() [798]	Return the string argument, left-padded with the specified string
LTRIM() [799]	Remove leading spaces
MAKE_SET() [799]	Return a set of comma-separated strings that have the corresponding bit in bits set
MAKEDATE() [836]	Create a date from the year and day of year
MAKETIME() [836]	Create time from hour, minute, second
MASTER_POS_WAIT() [879]	Block until the slave has read and applied all updates up to the specified position
MATCH [845]	Perform full-text search
MAX() [884]	Return the maximum value
MD5() [868]	Calculate MD5 checksum
MICROSECOND() [837]	Return the microseconds from argument
MID() [799]	Return a substring starting from the specified position
MIN() [884]	Return the minimum value
- [815]	Minus operator
MINUTE() [837]	Return the minute from the argument
MOD() [821]	Return the remainder
% or MOD [816]	Modulo operator
MONTH() [837]	Return the month from the date passed
MONTHNAME() [837]	Return the name of the month
NOT BETWEEN ... AND ... [784]	Check whether a value is not within a range of values
!=, <> [782]	Not equal operator
NOT IN() [785]	Check whether a value is not within a set of values
NOT LIKE [806]	Negation of simple pattern matching
NOT REGEXP [808]	Negation of REGEXP
NOT, ! [787]	Negates value

Name	Description
NOW() [837]	Return the current date and time
NULLIF() [791]	Return NULL if expr1 = expr2
OCT() [821]	Return a string containing octal representation of a number
OCTET_LENGTH() [799]	Synonym for LENGTH()
OLD_PASSWORD() [868]	Return the value of the pre-4.1 implementation of PASSWORD
||, OR [787]	Logical OR
ORD() [799]	Return character code for leftmost character of the argument
PASSWORD() [868]	Calculate and return a password string
PERIOD_ADD() [837]	Add a period to a year-month
PERIOD_DIFF() [838]	Return the number of months between periods
PI() [822]	Return the value of pi
+ [815]	Addition operator
POSITION() [799]	Synonym for LOCATE()
POW() [822]	Return the argument raised to the specified power
POWER() [822]	Return the argument raised to the specified power
PROCEDURE ANALYSE()	Analyze the results of a query
QUARTER() [838]	Return the quarter from a date argument
QUOTE() [800]	Escape the argument for use in an SQL statement
RADIANS() [822]	Return argument converted to radians
RAND() [822]	Return a random floating-point value
REGEXP [808]	Pattern matching using regular expressions
RELEASE_LOCK() [879]	Releases the named lock
REPEAT() [800]	Repeat a string the specified number of times
REPLACE() [800]	Replace occurrences of a specified string
REVERSE() [800]	Reverse the characters in a string
>> [863]	Right shift
RIGHT() [800]	Return the specified rightmost number of characters
RLIKE [808]	Synonym for REGEXP
ROUND() [823]	Round the argument
RPAD() [800]	Append string the specified number of times
RTRIM() [801]	Remove trailing spaces
SEC_TO_TIME() [838]	Converts seconds to 'HH:MM:SS' format
SECOND() [838]	Return the second (0-59)
SESSION_USER() [876]	Synonym for USER()
SHA1(), SHA() [869]	Calculate an SHA-1 160-bit checksum
SIGN() [824]	Return the sign of the argument
SIN() [824]	Return the sine of the argument
SOUNDEX() [801]	Return a soundex string

Name	Description
SOUNDS LIKE [801]	Compare sounds
SPACE() [801]	Return a string of the specified number of spaces
SQRT() [824]	Return the square root of the argument
STD() [884]	Return the population standard deviation
STDDEV() [884]	Return the population standard deviation
STR_TO_DATE() [838]	Convert a string to a date
STRCMP() [807]	Compare two strings
SUBDATE() [839]	Synonym for DATE_SUB() when invoked with three arguments
SUBSTR() [802]	Return the substring as specified
SUBSTRING_INDEX() [802]	Return a substring from a string before the specified number of occurrences of the delimiter
SUBSTRING() [802]	Return the substring as specified
SUBTIME() [840]	Subtract times
SUM() [884]	Return the sum
SYSDATE() [840]	Return the time at which the function executes
SYSTEM_USER() [876]	Synonym for USER()
TAN() [824]	Return the tangent of the argument
TIME_FORMAT() [840]	Format as time
TIME_TO_SEC() [841]	Return the argument converted to seconds
TIME() [840]	Extract the time portion of the expression passed
TIMEDIFF() [840]	Subtract time
* [816]	Multiplication operator
TIMESTAMP() [840]	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
TO_DAYS() [841]	Return the date argument converted to days
TRIM() [803]	Remove leading and trailing spaces
TRUNCATE() [825]	Truncate to specified number of decimal places
UCASE() [803]	Synonym for UPPER()
- [815]	Change the sign of the argument
UNCOMPRESS() [869]	Uncompress a string compressed
UNCOMPRESSED_LENGTH() [869]	Return the length of a string before compression
UNHEX() [803]	Return a string containing hex representation of a number
UNIX_TIMESTAMP() [841]	Return a UNIX timestamp
UPPER() [804]	Convert to uppercase
USER() [876]	The user name and host name provided by the client
UTC_DATE() [842]	Return the current UTC date
UTC_TIME() [842]	Return the current UTC time
UTC_TIMESTAMP() [843]	Return the current UTC date and time

Name	Description
UUID() [879]	Return a Universal Unique Identifier (UUID)
VALUES() [880]	Defines the values to be used during an INSERT
VARIANCE() [884]	Return the population standard variance
VERSION() [876]	Returns a string that indicates the MySQL server version
WEEK() [843]	Return the week number
WEEKDAY() [844]	Return the weekday index
WEEKOFYEAR() [844]	Return the calendar week of the date (0-53)
XOR [788]	Logical XOR
YEAR() [844]	Return the year
YEARWEEK() [844]	Return the year and week

11.2 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts numbers to strings as necessary, and vice versa.

```
mysql> SELECT 1+'1';
        -> 2
mysql> SELECT CONCAT(2,' test');
        -> '2 test'
```

It is also possible to convert a number to a string explicitly using the CAST() [859] function. Conversion occurs implicitly with the CONCAT() [795] function because it expects string arguments. (CAST() [859] is preferable, but is unavailable before MySQL 4.0.2.)

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
        -> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
        -> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are NULL, the result of the comparison is NULL, except for the NULL-safe <=> [782] equality comparison operator. For NULL <=> NULL, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a TIMESTAMP or DATETIME column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. Note that this is not done for the arguments to IN() [784]! To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using BETWEEN [783] with date or time values, use CAST() [859] to explicitly convert the values to the desired data type.

- In all other cases, the arguments are compared as floating-point (real) numbers.

For information about conversion of values from one temporal type to another, see Section 10.3.5, “Conversion Between Date and Time Types”.

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
        -> 0
mysql> SELECT 7 > '6x';
        -> 1
mysql> SELECT 0 > 'x6';
        -> 0
mysql> SELECT 0 = 'x6';
        -> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If *`str_col`* is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value `1`, such as `'1'`, `' 1'`, or `'1a'`.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```
mysql> SELECT '18015376320243458' = 18015376320243458;
        -> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
        -> 0
```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```
mysql> SELECT '18015376320243459'+0.0;
        -> 1.8015376320243e+16
```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` [859] so that a value will not be converted implicitly to a float-point number:

```
mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
        -> 1
```

For more information about floating-point comparisons, see Section B.5.5.8, “Problems with Floating-Point Values”.

Implicit conversion of a numeric or temporal value to a string produces a binary string (a `BINARY`, `VARBINARY`, or `BLOB` value). Such implicit conversions to string typically occur for functions that are passed numeric or temporal values when string values are more usual, and thus can have effects beyond

the type of the converted value. Consider the expression `CONCAT(1, 'abc')` [795]. The numeric argument `1` is converted to the binary string `'1'` and the concatenation of that value with the nonbinary string `'abc'` produces the binary string `'1abc'`.

11.3 Operators

Table 11.2 Operators

Name	Description
`AND`, `&&` [787]	Logical AND
`=` [789]	Assign a value (as part of a `SET` statement, or as part of the `SET` clause in an `UPDATE` statement)
`:=` [788]	Assign a value
`BETWEEN ... AND ...` [783]	Check whether a value is within a range of values
`BINARY` [859]	Cast a string to a binary string
`&` [863]	Bitwise AND
`~` [863]	Invert bits
`|` [862]	Bitwise OR
`^` [863]	Bitwise XOR
`CASE` [790]	Case operator
`DIV` [816]	Integer division
`/` [816]	Division operator
`<=>` [782]	NULL-safe equal to operator
`=` [782]	Equal operator
`>=` [782]	Greater than or equal operator
`>` [783]	Greater than operator
`IS NOT NULL` [783]	NOT NULL value test
`IS NULL` [783]	NULL value test
`<<` [863]	Left shift
`<=` [782]	Less than or equal operator
`<` [782]	Less than operator
`LIKE` [804]	Simple pattern matching
`-` [815]	Minus operator
`% or MOD` [816]	Modulo operator
`NOT BETWEEN ... AND ...` [784]	Check whether a value is not within a range of values
`!=`, `<>` [782]	Not equal operator
`NOT LIKE` [806]	Negation of simple pattern matching
`NOT REGEXP` [808]	Negation of REGEXP
`NOT`, `!` [787]	Negates value
`||`, `OR` [787]	Logical OR
`+` [815]	Addition operator
`REGEXP` [808]	Pattern matching using regular expressions

Name	Description
>> [863]	Right shift
RLIKE [808]	Synonym for REGEXP
SOUNDS LIKE [801]	Compare sounds
* [816]	Multiplication operator
- [815]	Change the sign of the argument
XOR [788]	Logical XOR

11.3.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```
INTERVAL
BINARY, COLLATE
!, NOT
- (unary minus), ~ (unary bit inversion)
^
*, /, DIV, %, MOD
-, +
<<, >>
&
|
= (comparison), <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
&&, AND
XOR
||, OR
= (assignment), :=
```

The precedence of = depends on whether it is used as a comparison operator (= [782]) or as an assignment operator (= [789]). When used as a comparison operator, it has the same precedence as <=> [782], >= [782], > [783], <= [782], < [782], <> [782], != [782], IS, LIKE [804], REGEXP [808], and IN [784]. When used as an assignment operator, it has the same precedence as := [788]. Section 12.4.4, “SET Syntax”, and Section 8.4, “User-Defined Variables”, explain how MySQL determines which interpretation of = should apply.

The || [787] operator has a precedence between ^ [863] and the unary operators if the PIPES_AS_CONCAT [460] SQL mode is enabled.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```
mysql> SELECT 1+2*3;
        -> 7
mysql> SELECT (1+2)*3;
        -> 9
```

11.3.2 Comparison Functions and Operators

Table 11.3 Comparison Operators

Name	Description
BETWEEN ... AND ... [783]	Check whether a value is within a range of values

Name	Description
COALESCE() [784]	Return the first non-NULL argument
<=> [782]	NULL-safe equal to operator
= [782]	Equal operator
>= [782]	Greater than or equal operator
> [783]	Greater than operator
GREATEST() [784]	Return the largest argument
IN() [784]	Check whether a value is within a set of values
INTERVAL() [785]	Return the index of the argument that is less than the first argument
IS NOT NULL [783]	NOT NULL value test
IS NULL [783]	NULL value test
ISNULL() [785]	Test whether the argument is NULL
LEAST() [786]	Return the smallest argument
<= [782]	Less than or equal operator
< [782]	Less than operator
LIKE [804]	Simple pattern matching
NOT BETWEEN ... AND ... [784]	Check whether a value is not within a range of values
!=, <> [782]	Not equal operator
NOT IN() [785]	Check whether a value is not within a set of values
NOT LIKE [806]	Negation of simple pattern matching
STRCMP() [807]	Compare two strings

Comparison operations result in a value of 1 (TRUE), 0 (FALSE), or NULL. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```
= > < >= <= <> !=
```

For examples of row comparisons, see Section 12.2.8.5, “Row Subqueries”.

Some of the functions in this section (such as LEAST() [786] and GREATEST() [784]) return values other than 1 (TRUE), 0 (FALSE), or NULL. However, the value they return is based on comparison operations performed according to the rules described in Section 11.2, “Type Conversion in Expression Evaluation”.

To convert a value to a specific type for comparison purposes, you can use the CAST() [859] function. String values can be converted to a different character set using CONVERT() [859]. See Section 11.10, “Cast Functions and Operators”.

By default, string comparisons are not case sensitive and use the current character set. The default is latin1 (cp1252 West European), which also works well for English.

- = [782]

  Equal:

```
mysql> SELECT 1 = 0;
        -> 0
mysql> SELECT '0' = 0;
        -> 1
mysql> SELECT '0.0' = 0;
        -> 1
mysql> SELECT '0.01' = 0;
        -> 0
mysql> SELECT '.01' = 0.01;
        -> 1
```

- <=> [782]

  `NULL`-safe equal. This operator performs an equality comparison like the = [782] operator, but returns `1` rather than `NULL` if both operands are `NULL`, and `0` rather than `NULL` if one operand is `NULL`.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
        -> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
        -> 1, NULL, NULL
```

  <=> was added in MySQL 3.23.0.

- <> [782], != [782]

  Not equal:

```
mysql> SELECT '.01' <> '0.01';
        -> 1
mysql> SELECT .01 <> '0.01';
        -> 0
mysql> SELECT 'zapp' <> 'zappp';
        -> 1
```

- <= [782]

  Less than or equal:

```
mysql> SELECT 0.1 <= 2;
        -> 1
```

- < [782]

  Less than:

```
mysql> SELECT 2 < 2;
        -> 0
```

- >= [782]

  Greater than or equal:

```
mysql> SELECT 2 >= 2;
        -> 1
```

- `>` [783]

  Greater than:

```
mysql> SELECT 2 > 2;
        -> 0
```

- `IS NULL` [783]

  Tests whether a value is `NULL`.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
        -> 0, 0, 1
```

  To work well with ODBC programs, MySQL supports the following extra features when using `IS NULL` [783]:
