RMS Structures and Utilities on VAX/VMS

Student Guide

Prepared by Educational Services
of
Digital Equipment Corporation

Book production was done by Educational Services Development and Publishing in Bedford, MA.

Printed in U.S.A.

CONTENTS

MODULE 5. INDEXED FILE ORGANIZATION -- INTERNAL STRUCTURE AND OVERHEAD

MODULE 6. RMS UTILITIES

COURSE DESCRIPTION

This course is designed for application programmers who are responsible for the processing of data files using the Record Management Services (RMS). File optimization strategies are approached from two perspectives, with emphasis placed on indexed file structures.

1. Features that can be implemented at the DCL level

2. Features that can be implemented only within program control.

This course teaches students how to use the RMS utilities and how to call RMS services directly from their programming language (specifically in BASIC, COBOL, FORTRAN, PASCAL or MACRO).

COURSE ORGANIZATION

Length: 5 days

Format: Lecture/Lab (2/3 Lecture, 1/3 Lab)

PREREQUISITES

1. Completion of the VAX/VMS Utilities and Commands course or its equivalent.

2. At least three months of programming experience in one of the following languages: BASIC, COBOL, FORTRAN, PASCAL, or MACRO. This experience should include the use of regular file I/O for the programming language of the user's choice to read and write records to a file, and to update or delete records.

COURSE GOALS

This course is designed to prepare students to perform the following tasks.

- Use the RMS utilities (FDL, CONVERT, ANALYZE) and selected DCL commands (DUMP, SET FILE, SET RMS_DEFAULT).
- Interpret statistical output from ANALYZE/RMS/STATISTICS.
- Tune files on an on-going basis.
- Identify and implement run-time file options that might optimize file performance for a particular application.
- Perform benchmarks on file performance.
- Calculate and set the number of buffers needed for a particular file.
- Identify when global buffers should be enabled for a shared file.
- Access RMS control blocks (FAB, RAB) directly from the programming language of the user's choice (BASIC, COBOL, FORTRAN, PASCAL, or MACRO).
- Call RMS services directly from the programming language of the user's choice (BASIC, COBOL, FORTRAN, PASCAL, or MACRO).
- Enable RMS alternative locking options available within program control that control record locking and unlocking.
- Recover data from corrupted files.

NON-GOALS

This course is not designed for users who must:

- Write programs in VAX languages in which they have no prior experience (covered in the VAX generic language courses).

- Write programs that call system services or Run-Time Library routines (covered in the Utilizing VMS Features from VAX courses).

- Monitor and tune overall system file performance (covered in the Managing Performance on VAX/VMS course).

- Write programs that perform DECnet file operations (covered in the DECnet courses).

RESOURCES

For complete mastery of this course, the following resources from the VAX/VMS documentation set should be available to you.

Guide to VAX/VMS File Applications

VAX Record Management Services Reference Manual

VAX/VMS Analyze/RMS-File Utility Reference Manual

VAX/VMS Convert and Convert/Reclaim Utility Reference Manual

VAX/VMS File Definition Language Facility Reference Manual

MODULE 1
OVERVIEW OF RMS DATA STRUCTURES AND SERVICES

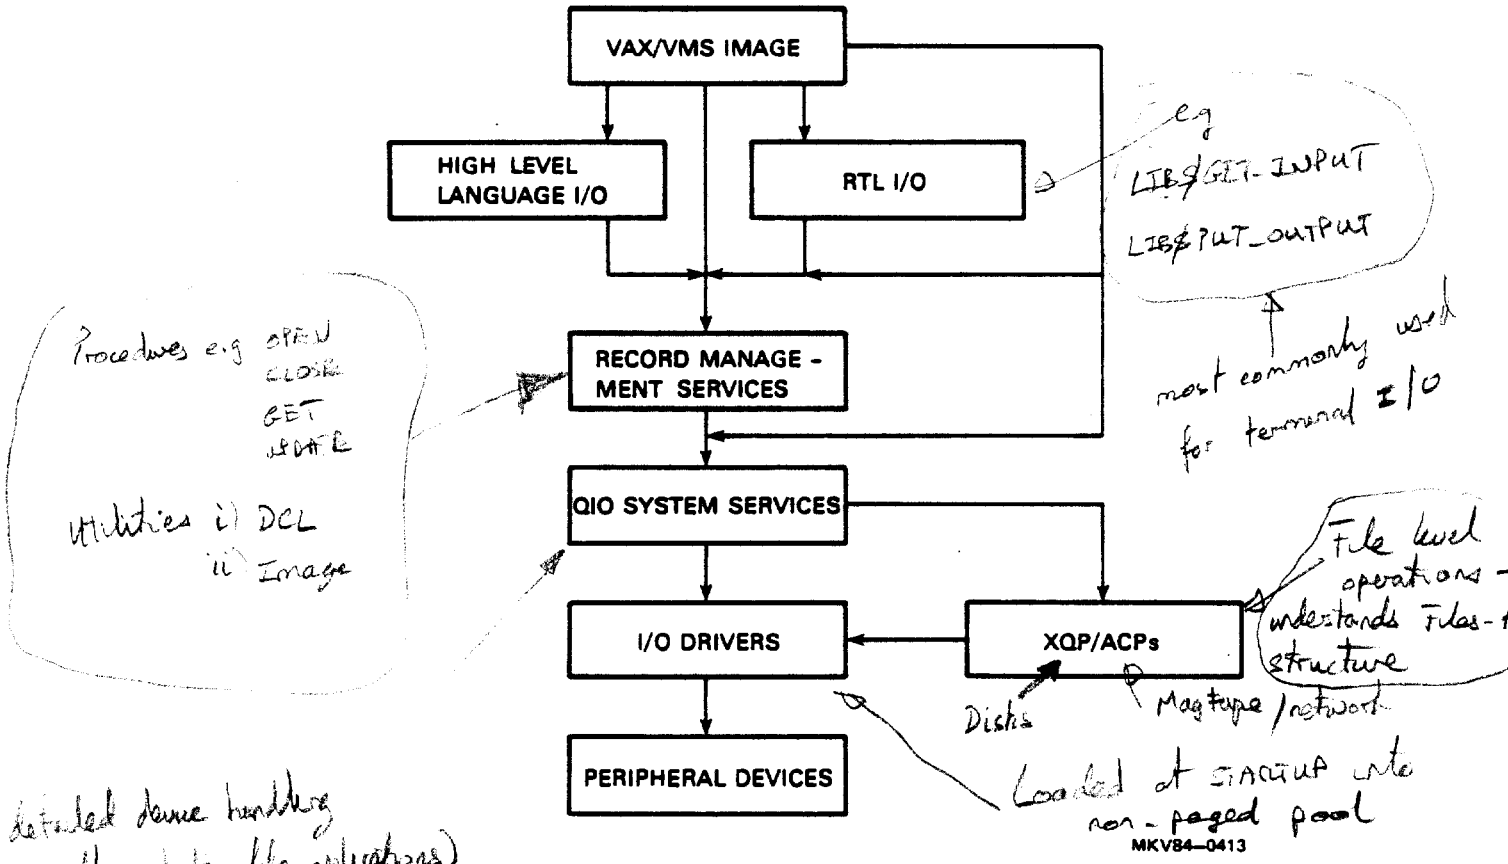
Major Topics

- Components of VAX/VMS I/O system
- VAX RMS user control blocks (FAB, RAB, XAB, NAM)
- RMS naming conventions
- RMS services/procedures

Source

RMS Reference Manual — Sections 1 and 2

COMPONENTS OF THE VAX/VMS I/O SYSTEM



- Extended QIO Procedures (XQPs) used to perform disk functions.
- Ancillary Control Processes (ACPs) used for:

  magnetic tape handling functions
  network functions

- I/O drivers that perform device-lev l operations.

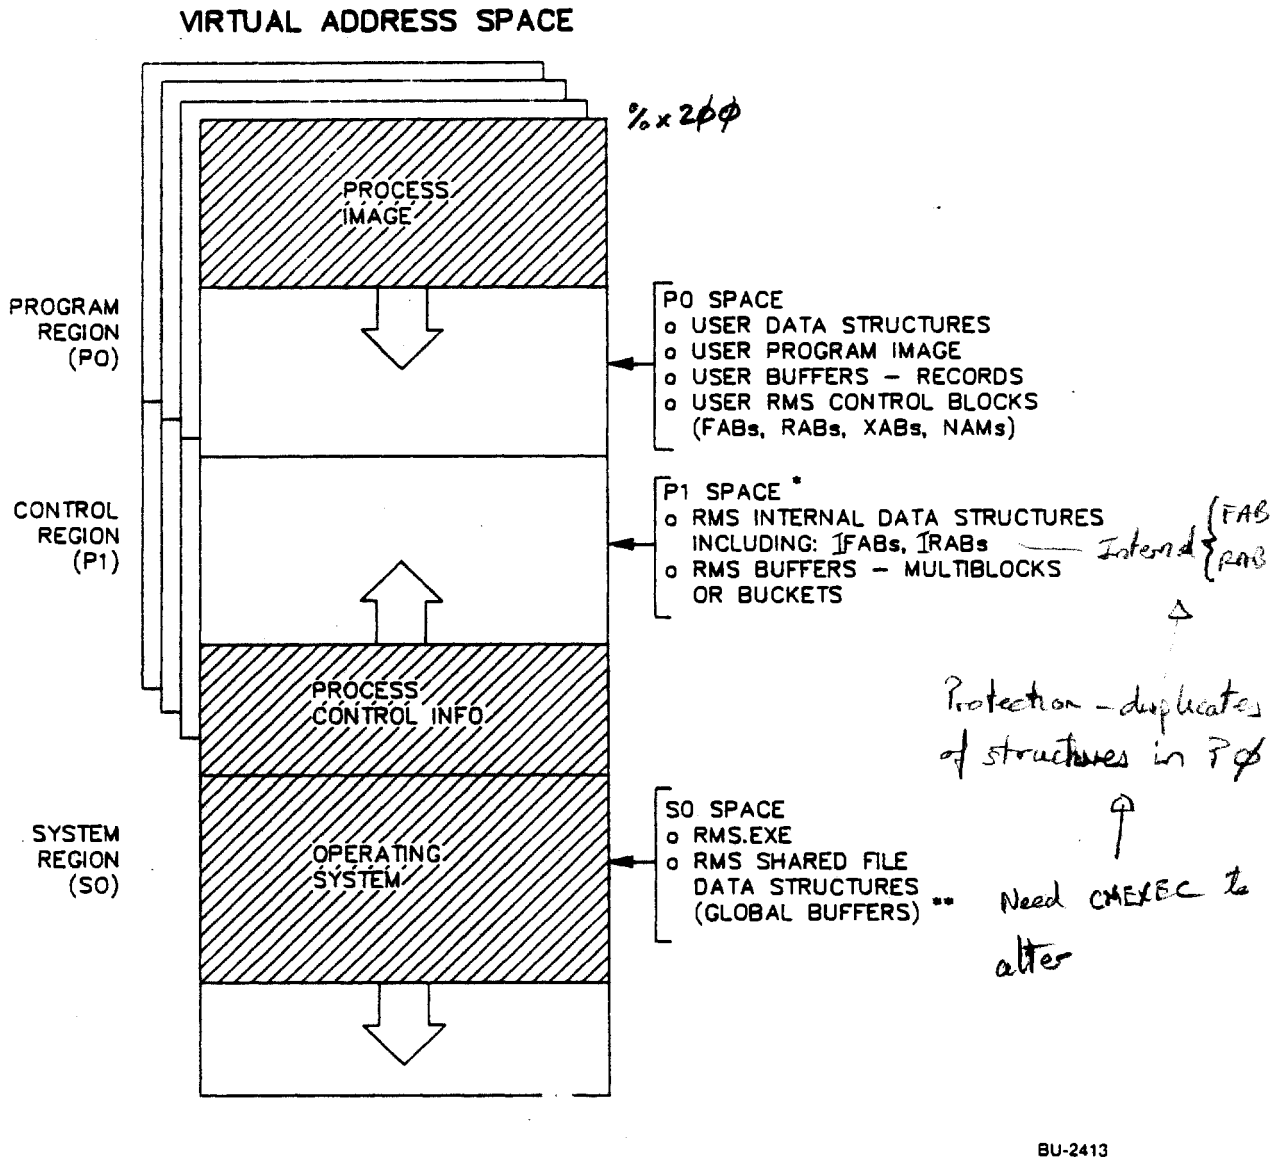
VAX RMS USER CONTROL BLOCKS

- VAX RMS communicates with control blocks.
- The File Definition Language (FDL) and RMS utilities provide access to RMS control blocks to all programmers.

RMS Control Blocks

Structure	Function	Mechanism
File Access Block	Describes a file and contains file-related information	$FAB
Record Access Block	Describes a record and contains record-related information	$RAB
Extended Attribute Blocks	Contains file attribute information beyond that in the File Access Block or record-related information beyond that in the Record Access Block	$XABxxx
Name Block	Contains file specification information beyond that in the File Access Block	$NAM

User Program and RMS Data Structures and Buffers



* Process permanent files have their RMS internal structures in P1. Normal (image) files begin in P1 but can overflow into P0, unless the image was linked using the option IOSEGMENT=NOP0BUFS. This latter option is rarely used.

** Global buffers are page file global sections. They appear to a process that is mapped to them to be in P0 or P1, although they are maintained in S0.

File Access Block (FAB)

The FAB is used for exchanging information with RMS before and after any RMS file operation. The user program sets fields to tell RMS what is needed, and RMS sets fields to show the results of the operation.

As long as the program is not executing RMS file operations, RMS does not access the user's FAB. RMS has its own internal FAB which it maintains for its own purposes. This allows you to use one-user FAB for more than one file, if that is appropriate.

Note that RMS uses certain FAB fields to exchange information with the program when performing file operations. The FAB must be available for use when any file operation is to be performed. Programs using asynchronous operations should allocate a FAB (and all the other control blocks) permanently for each file.

File Access Block -- $FAB

ALQ = allocation-qty	GBC = global buffer count
BKS = bucket-size	MRN = max-rec-number
BLS = tape block-size	MRS = max-rec-size
CTX = user-value	NAM = name address block
DEQ = extention-qty	ORG = file-organization
DEV = device characteristics	RAT = record-attributes
DNA = default filespec-address	RFM = record-format: <value>
DNS = filespec-size	RTV = window-size
FAC = file-access: <value>	SDC = secondary device characteristics
FNA = filespec-address	SHR = file-sharing: <value>
FNS = filespec-size	STS = completion status code
FOP = file-option: <value>	STV = status value
FSZ = header-size	XAB = xab-address

Record Access Block (RAB)

The Record Access Block (RAB) is used and maintained in the same way as the FAB, except that the RAB is involved in RMS record operations rather than file operations.

The RAB is associated with a record stream, so there could be more than one RAB concurrently associated with the same file. For this reason, the RAB contains a field pointing to the FAB, rather than the other way around (this pointer is for your use, not RMS).

RMS maintains an internal RAB and does not use the user RAB unless a record operation is executing. You will find it difficult to use one RAB for more than one file. There are usually many record operations in the course of a program run. If there is only one RAB, the program will continually need to restore the contents of the RAB from copies that it will have to maintain.

Record Access Block -- $RAB

BKT = bucket-code	RBF = record-buffer-address
CTX = user-value	RFA = record-file-address
FAB = fab-address	RHB = header-buffer-address
KBF = key-buffer-address	ROP = record-options: <value>
KRF = key reference number	RSZ = record-size
KSZ = key-size	STS = completion status code
MBC = multiblock count	STV = completion value
MBF = multibuffer count	TMO = seconds
PBF = prompt-buffer-address	UBF = user-buffer-address
PSZ = prompt-buffer-size	USZ = user-buffer-size
RAC = record-access-mode	XAB = next XAB address

Extended Attribute Blocks (XABs)

The Extended Attribute Blocks (XABs) are a family of related blocks that are linked to the FAB to communicate to VAX RMS any file attributes beyond those described in the FAB.

An XAB can both supersede and supplement the file characteristics specified in the FAB. Each type of XAB has a 6-letter mnemonic name consisting of the prefix XAB followed by three letters that are associated with the function the XAB provides. For instance, the XAB that provides the RMS Create service with file allocation information that supplements and supersedes the file allocation information in the FAB is called an allocation control XAB, or XABALL. Multiple XABs can be used for the same file.

The XABs are described in Chapters 8 through 15 of the VAX Record Management Services Reference Manual. The XABs are generally smaller and simpler than the FAB, RAB, and NAM blocks because each describes information about a single aspect of the file. They are all optional; you use only the ones that you need for any given call to an RMS service routine.

There are seven types of XABs provided by RMS for file operations.

1. Allocation control XAB (XABALL) allows greater control over disk file allocation and positioning during file allocation.

2. Date and time XAB (XABDAT) specifies backup, creation, expiration, and revision date-time values, and also the revision number.

3. File header characteristics XAB (XABFHC) receives the information contained in the header block of a file, which consists of certain file characteristics. This information is restricted to user output.

4. Key definition XAB (XABKEY) defines the key characteristics to be associated with an indexed file.

5. File protection XAB (XABPRO) defines file protection characteristics that specify what class of users or list of users can have certain specified access rights. In the case of an ANSI magnetic tape file with HDR1 labels, XABPRO defines the accessibility field character.

6. Revision date and time XAB (XABRDT) specifies the revision date-time value and revision number to be associated with a file.

7. Summary XAB (XABSUM) receives file characteristics associated with an indexed file, which are not returned by XABFHC. This information is restricted to user output.

The XABs used for any given RMS service call are connected to the FAB in a linked list. The head of the list is the FAB$L_XAB field in the FAB. This field contains the address of the first XAB to be used. Each successive XAB in the list links to the next using the XAB$L_NXT field. This field cqntains the address of the next XAB in the list.

One XAB type, XABTRM, is associated with the RAB rather than with the FAB. Its purpose is to allow extended control over terminal read operations via RMS, rather than by using the QIO system service.

Name Block (NAM)

The name block (NAM block) supplements the file specification information available in a FAB. A NAM block is useful for opening and locating files, especially if the file specification was entered by a terminal user, or if wildcards or a search list logical name may be present in a file specification, representing multiple files.

There is only one type of NAM block, and usually only one NAM block is associated with each file. To provide an extra level of defaults for a file specification, RMS will apply defaults using additional NAM blocks that contain the file specifications of related files.

RMS NAMING CONVENTIONS

Field Names

RMS uses mnemonic names to identify each field in a control block. For example, the mnemonic name for the field in the FAB that contains the allocation quantity is ALQ.

The mnemonic name (usually three characters in length) serves as a suffix to a symbolic name that identifies the location of each control block field. Use of the supplied symbolic names ensures that you will place values in the correct control block fields. RMS defines each symbolic name as a constant value equal to the offset, in bytes, from the beginning of that control block to the beginning of the field location. These symbolic names are called symbolic offsets. The general format of the symbolic offset is:

```
CCC$X_fff
```

The components of this format are summarized below.

Component	Length	Description
ccc	3 letters	Identifies the type of control block: FAB, NAM, XAB (for all XABs), and RAB
$	1 character	Separator character; always a dollar sign ($)
x	1 letter	Identifies the length of the field: • B for byte • W for word • L for longword • Q for quadword • T for text buffer address
_	1 character	Separator character; always an underscore (_)
fff	3 or more letters	Identifies the mnemonic name of the field, which is used in the VAX MACRO control block macro or higher-level language USEROPEN functions. Some mnemonics contain more than three letters; for example, symbolic offset XAB$B_PROLOG (from XABKEY).

Example

The FAB field whose mnemonic is ALQ has a length of one longword and is identified by the symbolic offset FAB$L_ALQ.

Field Values

Field values involve four different naming conventions.

1. xxx$C_fff

   The first kind of symbolic field values are simple symbolic field values. These are identified by the presence of a C_ immediately following the block prefix in their name. For example, the RAB$B_RAC field has three symbolic values, one each for sequential, keyed, and RFA access modes. The symbolic names for these values are RABC_SEQ, RABC_KEY, and RAB$C_RFA. These symbolic field values are used in simple assignment statements.

   The C symbol is used for any field that can have only one value (a constant).

2. xxx$M_fff

   The second kind of symbolic field value uses mask values to define bit offsets rather than explicit values. These are identified by the presence of M_ immediately following the block prefix in their name. For example, the FAB$L_FOP field is a longword field with the individual bits treated as flags. Each flag has a mask value for specifying a particular file processing option.

FAB$M_CBT	Contiguous 'best try'
FAB$M_CTG	Contiguous
FAB$M_TEF	Truncate at end of file

   The M symbol is used for any fields in which several options may be specified simultaneously. These options are identified by bits within the field.

   The masking value is an integer value that sets the appropriate bit(s).

3. xxx$V_fff -- bit offset

4. xxx$S_fff -- size

   The third and fourth kinds of symbolic field values are also used to define flag fields within a larger named field. These are identified by the S_ and V_ values immediately following the block prefix in their names. The S_ form of the name defines the size of that flag field (usually the value 1 for single bit flag fields), and the V_ form defines the bit offset from the beginning of the larger field. These forms can be used with the symbolic bit manipulation functions to set or clear the fields without destroying the other flags.

The V symbol is an alternative to the M symbol to be used for any fields containing options identified by bits.

The RMS Reference Manual identifies field options by the V symbol. However, every V symbol has a corresponding M version.

For most of the FAB, RAB, NAM, and XAB fields that are not supplied using symbolic values, you will need to supply sizes or pointers. For the sizes, you can use ordinary numeric constants or other numeric scalar quantities.

RMS SERVICES/PROCEDURES

RMS services can be called from any VAX language using the VAX Procedure and Condition Handling standard. RMS services are system services and are identified by the entry point prefix SYS$ followed by three or more characters. In the corresponding VAX MACRO macro name, the SYS$ prefix is not used. For example, the Create service has an entry point of SYS$CREATE and a VAX MACRO macro name of $CREATE.

RMS Services

Service Name	Macro Name	Description
File Processing and File Naming		
SYS$CLOSE	$CLOSE	Terminates file processing and disconnects all record streams
SYS$CREATE	$CREATE	Creates and opens a new file of any organization
SYS$DISPLAY	$DISPLAY	Returns the attributes of an open file to the user program
SYS$ENTER*	$ENTER	Enters a file name into a directory
SYS$ERASE	$ERASE	Deletes a file and removes its directory entry
SYS$EXTEND	$EXTEND	Extends the allocated space of a file
SYS$OPEN	$OPEN	Opens an existing file and initiates file processing
SYS$PARSE	$PARSE	Parses a file specification
SYS$REMOVE*	$REMOVE	Removes a file name from a directory
SYS$RENAME	$RENAME	Assigns a new name to (renames) a file
SYS$SEARCH	$SEARCH	Searches a directory, or possibly multiple directories, for a file name

RMS Services (Cont.)

Service Name	Macro Name	Description
Record Processing		
SYS$CONNECT	$CONNECT	Establishes a record stream by associating a RAB with an open file
SYS$DELETE	$DELETE	Deletes a record from a relative or indexed file
SYS$DISCONNECT	$DISCONNECT	Terminates a record stream by disconnecting a RAB from an open file
SYS$FIND	$FIND	Locates and positions to a record and returns its RFA
SYS$FLUSH	$FLUSH	Writes (flushes) modified I/O buffers and file attributes
SYS$FREE	$FREE	Unlocks all records previously locked by the record stream
SYS$GET	$GET	Retrieves a record from a file
SYS$NXTVOL*	$NXTVOL	Causes processing of a magnetic tape file to continue to the next volume of a volume set
SYS$PUT	$PUT	Writes a new record to a file
SYS$RELEASE	$RELEASE	Unlocks a record pointed to by the contents of the RAB$W_RFA field
SYS$REWIND	$REWIND	Positions to the first record of a file
SYS$TRUNCATE	$TRUNCATE	Truncates a sequential file
SYS$UPDATE	$UPDATE	Rewrites (updates) an existing record in a file
SYS$WAIT	$WAIT	Awaits the completion of an asynchronous record operation

* This service is not supported for DECnet operations involving remote file access between two VAX/VMS systems.

RMS Services (Cont.)

Service Name	Macro Name	Description
Block I/O Processing		
SYS$READ	$READ	Retrieves a specified number of bytes from a file, beginning on block boundaries
SYS$SPACE	$SPACE	Positions forward or backward in a file to a block boundary
SYS$WRITE	$WRITE	Writes a specified number of bytes to a file, beginning on block boundaries

RMS Library Routines

Procedure	Operation
FDL$CREATE	Creates a file from an FDL specification and then closes the file.
FDL$GENERATE	Produces an FDL specification by interpreting a set of RMS control blocks. It then writes the FDL specification either to an FDL file or to a character string.
FDL$PARSE	Parses an FDL specification, allocates RMS control blocks, and then fills in the relevant fields.
FDL$RELEASE	Deallocates the virtual memory used by the RMS control blocks created by FDL$PARSE. Use FDL$PARSE to fill in (populate) the control blocks if you plan to release the memory with FDL$RELEASE later.

MODULE 2
RMS UTILITIES

Major Topics

Part 1. Introduction
- RMS Utilities
- Creating FDL Files
- Creating Data Files
  - CREATE/FDL
  - CONVERT/FDL

Part 2. Evaluating/utilizing
- FDL — INVOKE script
- FDL graphics output
- FDL — TOUCHUP script

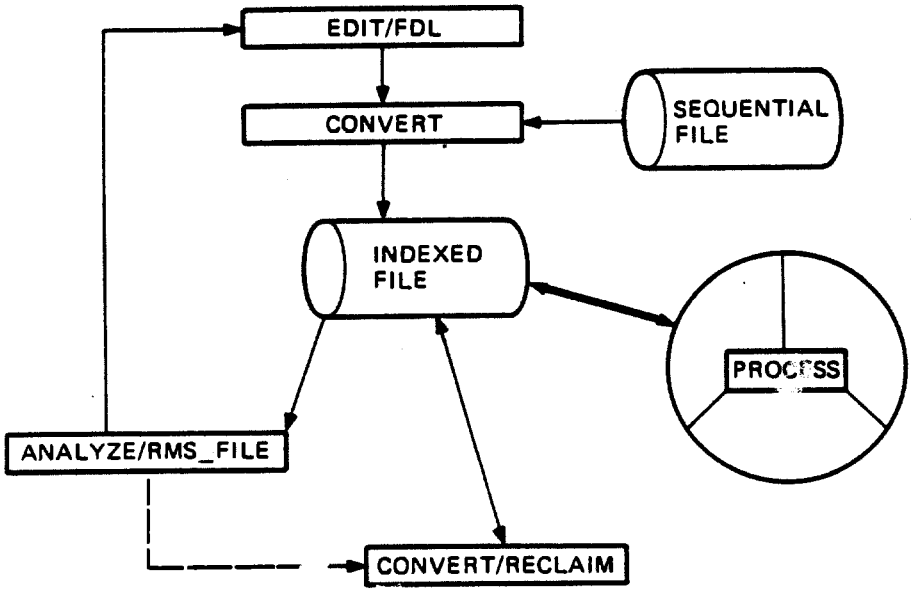
PART 1. INTRODUCTION

RMS UTILITIES

- VAX RMS provides the following set of tools to assist in designing and creating data files.
  - EDIT/FDL
  - CREATE/FDL
  - CONVERT/FDL
  - ANALYZE/RMS_FILE/FDL

Tuning Cycle



MKV84-1827

CREATING FDL FILES

- The File Definition Language (FDL) editor allows you to:
  - create and modify data file specifications
  - specify all create-time options
  - model data files
  - optimize FDL files
- The specifications are written in the FDL
- To generate an FDL file from an existing data file, type:

  ```
  $ ANALYZE/RMS_FILE/FDL file-spec
  ```

```
                Parsing Definition File
                Definition Parse Complete

CREATING DATA FILES

To create an empty data file from the specifications in an FDL file, type:

```
$ CREATE/FDL=fdl-filespec data-file-spec
```

or

```
FDL$CREATE (fdl-str, [file-spec-str], [default-name],
            [result-name], [FID-bld], [flags],
            [stmnt_num], [retlen], [sts], [stv])
```

Example 2. Creating Data Files

```
$ CREATE/FDL=INDXBACK
$ DIR/FULL INDXBACK.DAT

Directory DISK$INSTRUCTOR:[WOODS.RMS.COURSE]

INDXBACK.DAT:1                File ID:  (32055,21.0)
Size:          184/184        Owner:    [VMS.WOODS]
Created:  15-JAN-1986 10:16   Revised:  15-JAN-1986 10:16 (1)
Expires:   <None specified>   Backup:    <No backup done>
File organization:  Indexed, Prolog: 3, Using 1 key
                            In 2 areas
File attributes:    Allocation: 184, Extend: 45. Maximum bucket size: 3
                    Global buffer count: 0. No version limit
                    Contiguous best try
Record format:      Fixed length 50 byte records
Record attributes:  Carriage return carriage control
File protection:    System:R. Owner:RWED. Group:R. World:
Access Cntrl List:  None

Total of 1 file. 184/184 blocks.

 $ T INDXBACK.DAT

 $     <---- Null file
```

Use the CONVERT/FDL command to transfer data from any organization and format to any other organization and record format.

```
$ CONVERT/FDL=fdl-file input-file output-file

        or

CONV$PASS_FILES  (input-file-spec, output-file-spec,
                  [fdl-file-spec,] [exception-file-spec],
                  [flags])

CONV$PASS_OPTIONS ([parameter-list-address], [flags])

CONV$CONVERT ([status-block-address], [flags])
```

Example 3. Transferring Data Using CONVERT

```
$ CONVERT/FDL=INDXBACK/STATISTICS BACKWARDS.DAT INDXBACK.DAT

       or                  |_____ default SYS$OUTPUT

$ ASSIGN/USER INDXBACK.STAT SYS$OUTPUT
$ REC CONV
$ CONVERT/FDL=INDXBACK/STATISTICS BACKWARDS.DAT INDXBACK.DAT
$ TYPE INDXBACK.STAT

DISK$INSTRUCTOR:[WOODS.RMS.COURSE]INDEX1.FDL;1   65 lines
```

FDL Graphics Output

FDL has two graphics modes:

1. Line

   bucket size versus index depth

2. Surface

   bucket size versus load fill percent versus index depth

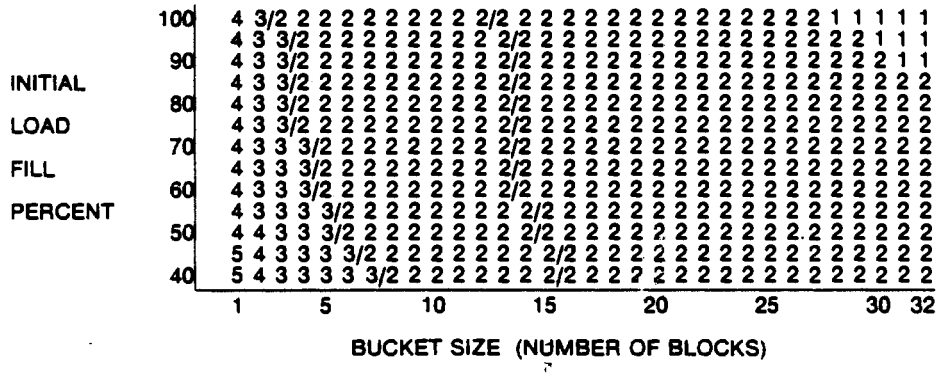
   bucket size versus key length versus index depth

   bucket size versus record size versus index depth

   bucket size versus initial load record count versus index depth

   bucket size versus additional record count versus index depth

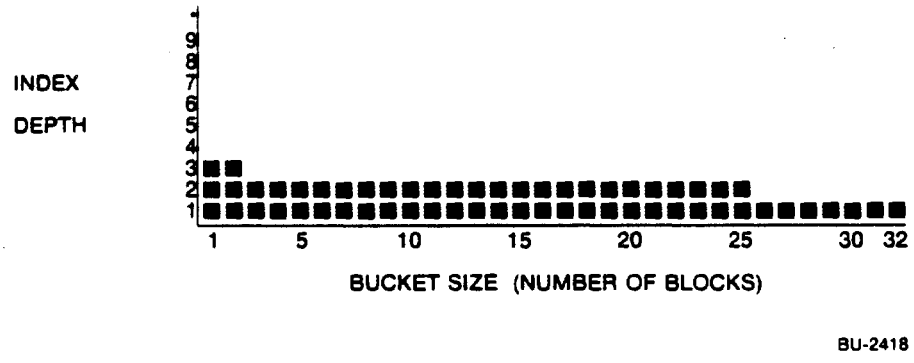
A Surface_Plot Graph



The variable on the graph's X axis is bucket size. The numbers in the field portion of the graph indicate the number of levels at each bucket size for each of the other values.

The area on the graph within the slash marks represents combinations that RMS will find acceptable. A fill factor of 70% and a bucket size of 10 blocks is a good combination. However, a fill factor of 70% and a bucket size of 15 blocks is poor because it falls outside of the slash boundaries.

A Line_Plot Graph



Evaluating Line Plot

Breakpoints	# Blocks/Bucket
3 to 2	3
2 to 1	~~25~~ 26

General rule: Select the smallest bucket size that corresponds to 2 to 3 levels of index. Round out to a multiple of the disk cluster size.

Example 5. Utilizing EDIT/FDL Touchup to Obtain Surface Graphics Output

```
$ EDIT/FDL INDX1.FDL

MODULE 3
OVERVIEW OF FILES-11
ON-LINE DISK FILE STRUCTURE

Major Topics

- Disk file structure on VAX/VMS
- File characteristics
- Disk physical characteristics
- Disk organization

Source

Guide to VAX/VMS File Applications — Chapter 1 (Sections 1.1 and 1.2)

DISK FILE STRUCTURE ON VAX/VMS

- The VMS default disk file structure is Files-11 Structure Level 2, also called On-Disk Structure 2 (ODS-2).
- Used by XQPs to maintain and control data on disk volumes.

The ODS-2 Reserved Files

- Define the Files-11 disk file structure
- Are created when a volume is initialized
- Are cataloged in the Master File Directory [0,0] of the volume

Volume Information Contained in ODS-2 Reserved Files

Reserved File	Information
Index File (INDEXF.SYS)	Bootstrap block, home block, back-up homr block, back-up index file header, index file bit map, file headers
Storage Bit Map File (BITMAP.SYS)	Location of available clusters on a volume
Bad Block File (BADBLK.SYS)	Areas of volume not suitable for use
Pending Bad Block Log File (BADLOG.SYS)	Areas of volume suspected of being unsuitable for use
Master File Directory (000000.DIR)	Pointers to all User File Directories
Core Image File (CORIMG.SYS)	Not used by VMS. Provided to preserve structure of previous versions
Volume Set List File (VOLSET.SYS)	Labels of other volumes in the volume set (if more than one)
Continuation File (CONTIN.SYS)	The extension file identifier, if a file crosses from one volume to another in a loosely coupled volume set
Backup Log File (BACKUP.SYS)	History of backups on the volume

Comparing the ODS-1 and ODS-2 Structures

ODS-1 and ODS-2 Comparison

Characteristics	ODS-1	ODS-2
Transportable to RSX/IAS	Yes	No
Subdirectories	No	Yes
Alphanumeric directory names	No	Yes
Alphabetized directory files	No	Yes
Clustered allocation	No	Yes
Tightly coupled volume sets	No	Yes
Backup home block	No	Yes
Extended map pointers	No	Yes
Meaning of protection code E	Extend	Execute

ODS-2 Directories

- Directories associate symbolic file name with file ID.
- User File Directories (UFDs) are entered in the Master File Directory (MFD).
- Subfile directories (SFDs) are entered in their parent directory file.
- Directory names may be in the following formats.
  - UIC forma with the group and member fields in the range 0 to 377 oct 1
  - Alphanumeric format of not more than eight characters
- Subdirectory names must be alphanumeric.

62 fid entries per directory file disk block

Once a directory file is > 128 blocks it is no longer cached in memory

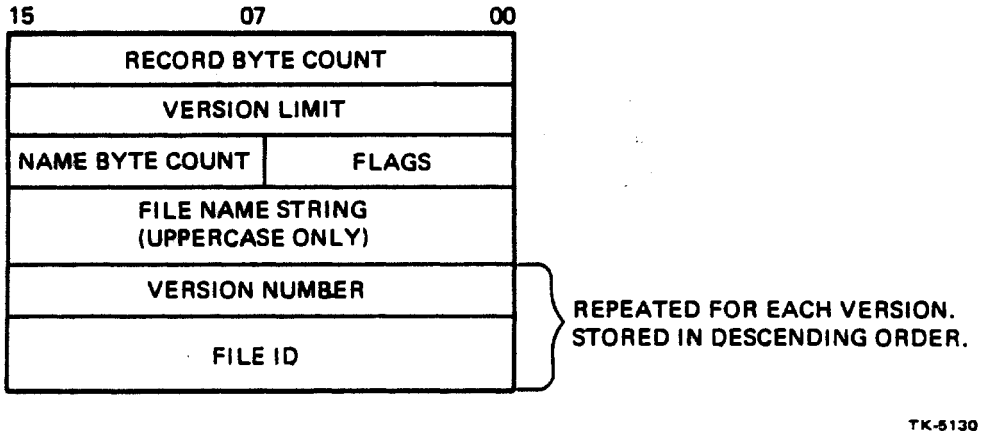
- Directory files
  - alphanumeric_name.DIR;1
  - UIC formatted directory names converted to their numeric equivalent

    [123,012] = 123012.DIR;1
- VAX/VMS supports up to seven levels of subdirectories beneath the UFD level.

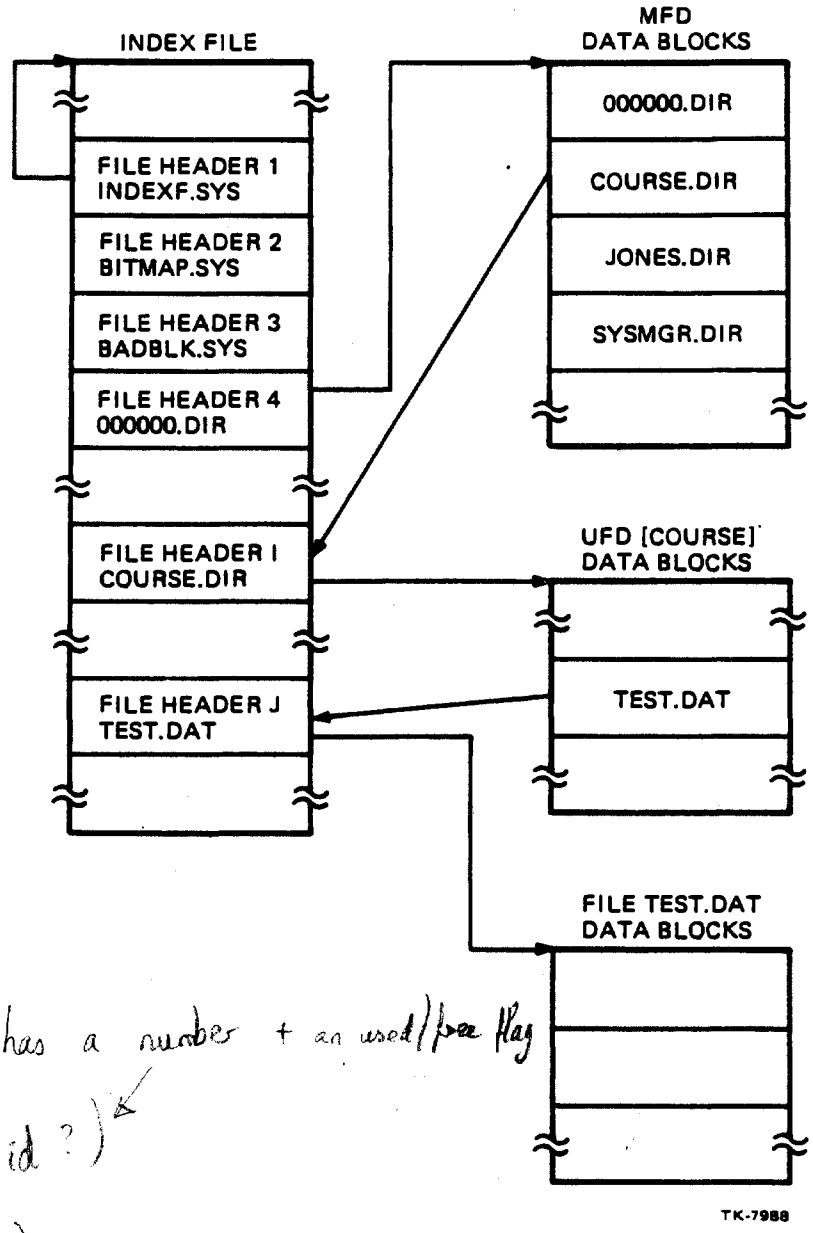
Directory File Structure

Directory File Characteristics

- Contiguous
- Sequential
- Variable-length records
- No span blocks enabled
- The directory bit is set in the file header
- A file protection code of S:RWE,O:RWE,G:RWE,W:RE
- File entries are stored in alphabetical order



Using ODS-2 File Headers to Access a File



Each file header has a number + an used/free flag

$dir/full ($ dir/id ?)

⇒ (n, m, p)

file_header_no

no of times this file_header_no used

Vol. no. in multi-volume set

FILE CHARACTERISTICS

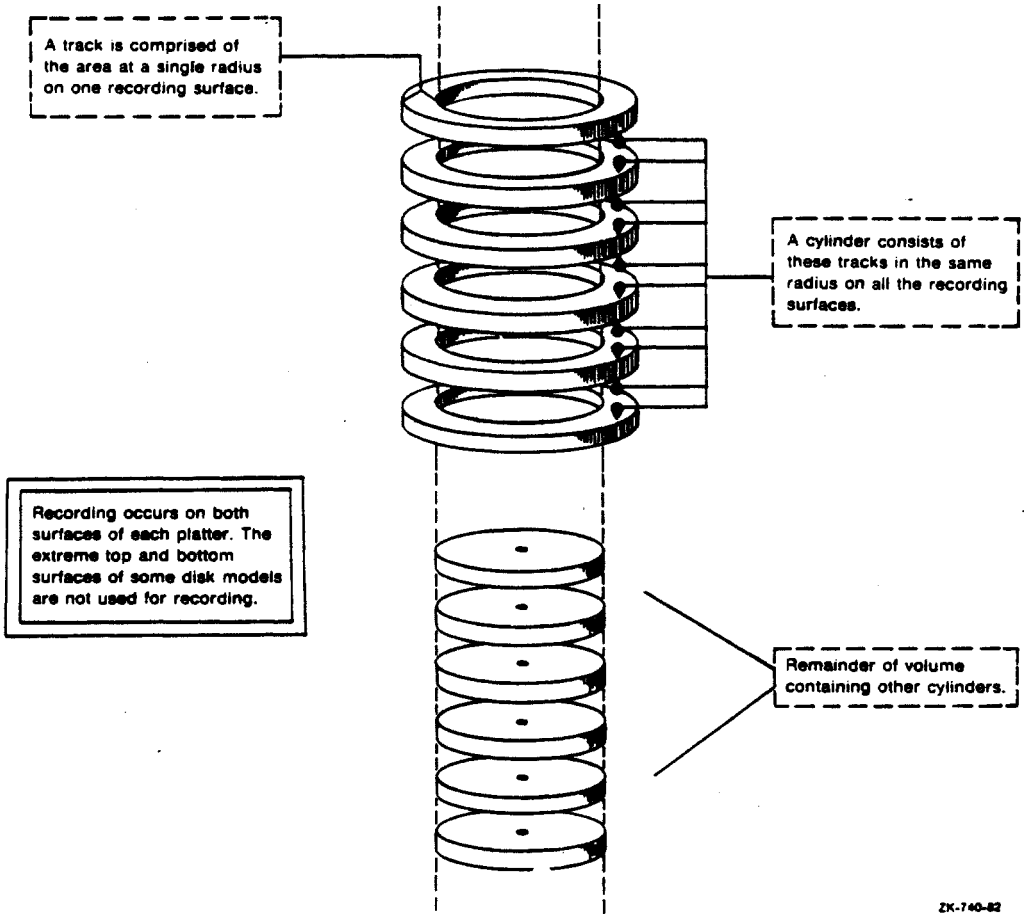
Files on a Files-11 Disk Volume have the following characteristics.

- Two major data structures
  1. A file header with identification and protection information
  2. One or more data blocks
- Composed of logical disk blocks
- Each logical block corresponds to a virtual block in the file
- Blocks are grouped into clusters
- Contiguous clusters are called extents

ODS-2 File Headers

- Part of the volume index file
- Not part of the file it describes
- Divided into six areas
  1. Header Area -- contains basic information for checking access validity
  2. Ident Area -- contains identification and accounting information
  3. Map Area -- contains pointers to the blocks allocated to the file
  4. Access Area -- contains access control list entries if any defined
  5. Reserved Area -- reserved for use by customers and DIGITAL
  6. Checksum Area -- validity check on the header's contents (the last word of the header) — STANDARD CHECKSUM VALUE
- Used to locate file data blocks on the disk.

DISK PHYSICAL CHARACTERISTICS



Seek time	Time needed to position the read/write heads over the correct radius.
Rotational latency time	Time it takes the desired block to move under the read/write heads, once the read/write heads are at the correct radius.

NOTE

The average seek time usually exceeds the average rotational latency by a factor of 2 to 4. Placing related blocks that are likely to be accessed as a unit at or close to the same radius on the disk will provide the best performance for the transfer of data between the disk surface and RMS-maintained buffers.

DISK ORGANIZATION

- Hardware

  Blocks
  Tracks
  Cylinders

- Software

  Clusters

  - Each disk must have at least 100 clusters

  - Defaults

    1 if # blocks < 50,000
    3 if # blocks > 50,000

  - Small clusters

    Efficient use of disk space
    More clusters ==> more overhead

  - Large clusters

    More wasted space
    Less system overhead

  - Each cluster ==> 1 bit in bit-map

  - Consider clusters that are a multiple/fraction of track size:

Disk	Track-Size	Cluster-Size
RA80	31	1, 31
RA81	51	1, 3, 17, 51

MODULE 4
OVERVIEW OF RMS FILE ORGANIZATIONS, RECORD FORMATS, AND ACCESS METHODS

Major Topics

- RMS File Organization
- Record Format
- Record Access Options

Source

Guide to VAX/VMS File Applications — Chapter 2 (Sections 2.1-2.2)
Chapter 8

RMS FILE ORGANIZATION

File organizations are as follows:

1. Sequential
2. Relative
3. Indexed Sequential

Sequential Files

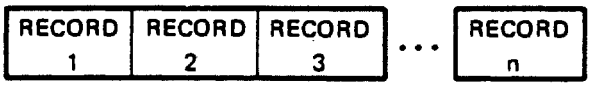
In sequential file organization, records in the file are arranged one after the other. This organization is the only one that supports all record formats: fixed-length, variable-length, variable with fixed-control, and stream (including undefined records).

Sequential files with fixed-length records have no overhead.

Records in sequential files are aligned on an even byte. If record size is an odd number, one more byte is inserted on the disk before the next record. This is transparent to programmers, except when a dump is examined.

Unlike relative and indexed sequential files, sequential files do not have a prolog. Instead, all information about a sequential file is stored in the file header, which can be viewed with the DCL commands DIRECTORY/FULL and DUMP/HEADER, as well as with the Analyze/RMS_File Utility.

Sequential File Organization

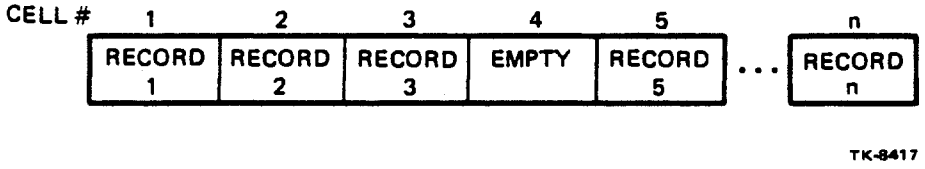


TK-8416

Relative Files

In the relative file organization, records are stored in a series of fixed-length positions called cells. This organization allows random retrieval of records by means of the relative record number, which identifies the position of the record cell relative to the beginning of the file. Relative files also contain a prolog.

Relative File Organization



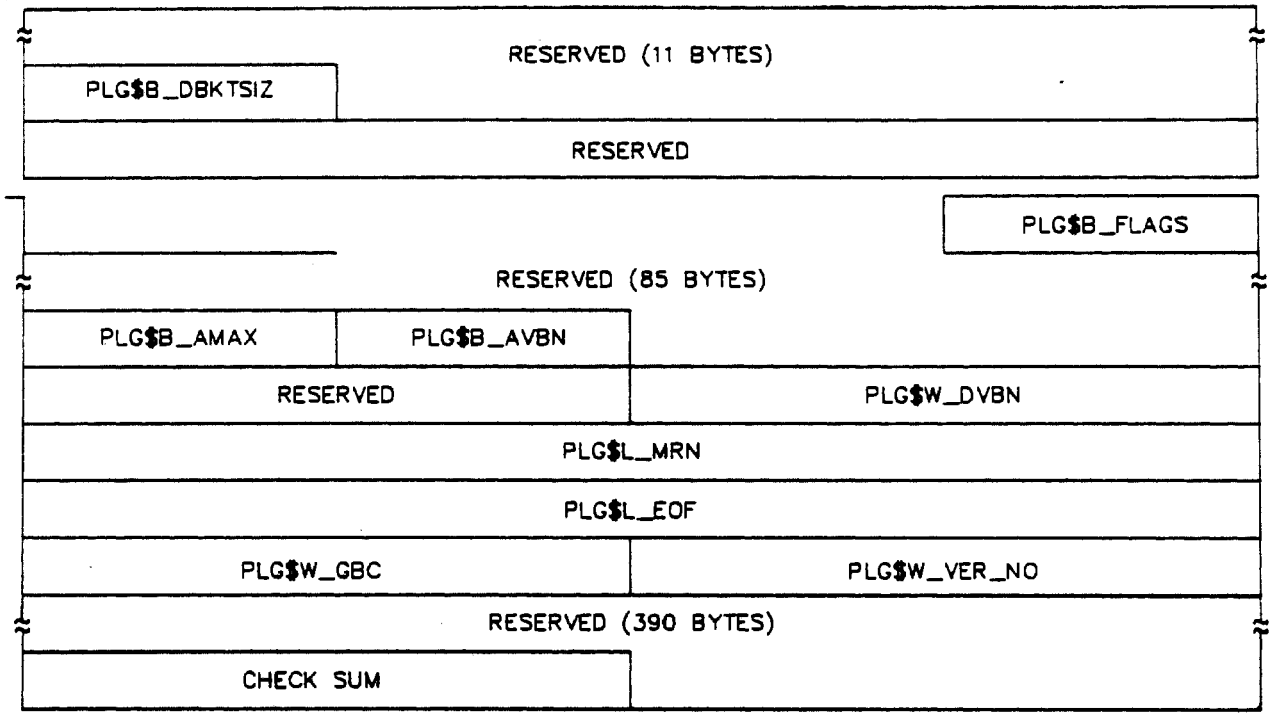
Prolog Description

A relative file starts with a 1-block prolog that contains specific information about the file as a whole. The prolog is located at virtual block 1, and the data buckets begin at virtual block 2. The most important fields for a relative file are the maximum record number field (PLG$L_MRN) and the field containing the end-of-file block number (PLG$L_EOF). The last word of the prolog contains the standard Files-11 additive checksum field.

Format of a Prolog for a Relative File

NOTE

The fields of the figure run from right-to-left



BU-2424

Contents of a Record Prolog for a Relative File

Field Name	Description
PLG$B_DBKTSIZ	Data bucket size. This field is not used for relative files. The FAT$B_BKTSIZE field defines the bucket size for a relative file.
PLG$B_FLAGS	Flag bits. This field contains a bit vector specifying characteristics of the file that this prolog defines. The following field is defined within PLG$B_FLAGS. PLG$V_NOEXTEND — If set, the file cannot be extended. This field is 1 bit long, and starts at bit 0.
PLG$B_AVBN	This field is not used for relative files.
PLG$B_AMAX	This field is not used for relative files.
PLG$W_DVBN	VBN of the first data bucket. This field contains the 16-bit virtual block number of the first data bucket in a relative file. This field always contains a value of 2.
PLG$L_MRN	Maximum record number. This field contains the maximum number of records that the user specified. If the user specified 0, which is the default, then this field contains the maximum number possible (2,147,483,647)*. This field can be set with the RMS field FAB$L_MRN and the FDL attribute FILE MAX_RECORD_NUMBER.
PLG$L_EOF	VBN of the end-of-file. This field represents the logical end of the file. It contains the virtual block number of the last bucket initialized. Buckets are filled with all zeroes when they are initialized.
PLG$W_VER_NO	This field is not used for relative files.
PLG$W_GBC	This field is not used for relative files.
Checksum	Additive checksum.

* The maximum value may be limited by the number of blocks on the device to be used.

Relative Data Cell and Bucket Format

Records are stored in fixed-length cells in unformatted buckets. The fixed-length cells are numbered consecutively from 1 to n. This number is the relative record number, which indicates the record's position relative to the beginning of the file.

Records are stored starting at byte 0 of each bucket. They are packed contiguously so that they are byte-aligned. Cells (and thus records) cannot span bucket boundaries. If the bucket size is not a multiple of the cell size, then the remaining space in the bucket is unused. The next record in the file is stored in the first cell of the next bucket.

Each bucket contains a fixed number of fixed-length cells, and there are no overhead bytes in the bucket. The virtual blocks in the buckets are initialized (zeroed) when they are first allocated to support the way deleted records are handled.

Each cell contains at least one byte of record overhead. If the cell contains variable-length records, then the overhead is three bytes, which accounts for the 2-byte record-length field.

CELL SIZE = MAXIMUM RECORD SIZE + 1

BU-2425

Control Byte

bit 3 — 0 = Cell never contained a record.
1 = A record is present in the cell (though it may have been deleted).

bit 2 — 1 = Record has been deleted.

RECORD FORMAT

Record formats are:

1. Fixed
2. Variable
3. Variable with fixed control (disk only)
4. Stream (disk only)
5. Undefined (PAGEFILE.SYS, SWAPFILE.SYS) ← not accessed via RMS

Combinations of File Organization and Record Format Accepted by VAX RMS

File Organization	Record Format			
	Fixed	Variable	VFC	Stream
Sequential	Yes	Yes	Yes	Yes
Relative	Yes	Yes	Yes	No
Indexed	Yes	Yes	No	No

RECORD ACCESS OPTIONS

Record access methods are as follows:

1. Sequential
2. Random by key value/relative record number
3. Random by the record's file address (RFA)

Record Access Methods for File Organizations Supported by VAX RMS

Record Access Mode Permitted	File Organization		
	Sequential	Relative	Indexed
Sequential	Yes	Yes	Yes
Random by relative record number	Yes*	Yes	No
Random by key value	No	No	Yes
Random by record's file address	Yes**	Yes	Yes

* Random access by relative record number for sequential files is permitted for fixed-length record format on disk devices.

** Random access by record's file address is permitted only on disk devices.

Random Access to Indexed Files

Each of the program's Get requests in random access mode to an indexed file must specify both a key value and the index that RMS must search (for example, primary index, first alternate key index, second alternate key index, and so on). When RMS finds, by means of the index, the record that matches the key value, it reads the record and passes it to the program. Random access can be accomplished on any key by any of the following methods:

1. Exact match of key values.

2. Approximate match of key values. For example, if accessing an index in ascending sort order, RMS returns the record either equal to the user-supplied key value or with the next greater key value; conversely, if accessing the index in descending sort order (as of VMS 4.4), RMS returns the record either equal to the user-supplied key value or with the next lesser key value.

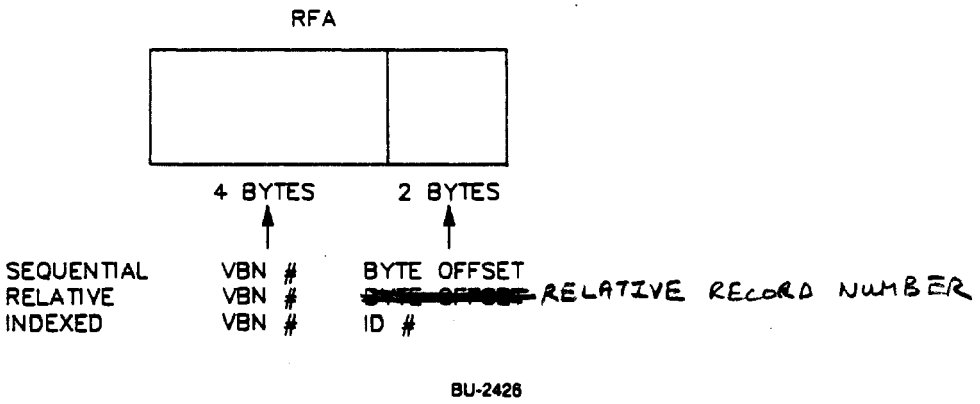
3. Generic match of key values. Generic match is applicable to string data-type keys only. A generic match is a match of some number of leading characters in the key. The number is determined by specifying a search key smaller than the entire field.

4. Combination of approximate and generic match.

Access by Record's File Address

Random-by-RFA access is supported for all file organizations provided that the files reside on disk devices. Whenever a record is accessed successfully from a file of any organization (using any of the record access modes already discussed) an internal representation of the record's location within the file is returned in the RAB field RAB$W_RFA. RMS can later examine the value in the RAB$W_RFA field and use it to retrieve that record, if specifically requested to do so (with a random-by-RFA access request).

The RFA is six bytes in length, which vary in content by file organization, as follows:



In the case of relative and indexed files, the VBN # is the number associated with the beginning block of a bucket.

Example

One example of the use of RFA access is to establish a record position for subsequent sequential access, which also could be done using other random record access modes (except for certain sequential files). Consider a sequential file with variable-length records that can only be accessed randomly using RFA access. Assume the file consists of a list of transactions, sorted previously by account value. Each account may have multiple transactions, so each account value may have multiple records for it in the file. Instead of reading the entire file until it finds the first record for the desired account number, it uses a previously saved RFA value and random-by-RFA access to set the current record position using a Find service at the first record of the desired account number. It can then switch to sequential record access and read all successive records for that account, until the account number changes or the end of the file is reached.

Record Processing Operations for
Sequential, Relative, and Indexed Files

Record Operation Permitted	File Organization		
	Sequential	Relative	Indexed
Read (Get)	Yes	Yes	Yes
Write (Put)	Yes*	Yes	Yes
Find	Yes	Yes	Yes
Delete	No	Yes	Yes
Update***	Yes**	Yes	Yes

* In a sequential file, VAX RMS allows records to be added at the end of the file only. (Records can be written to other points in the file using a Put with the update-if option to overwrite existing records.)

** When performing an update operation to a sequential file, the programmer cannot change the length of the record.

*** VAX RMS allows update operations on disk devices only.

Summary of Advantages and Disadvantages of RMS File Organization

Organization	Advantages	Disadvantages
Sequential	Uses disk and memory efficiently	Limited random access
	Provides optimal usage if the application accesses all records sequentially on each run	Cannot delete records
	Provides flexible record format	Can insert records only at the end of file.
	Allows data to be stored on different types of media	
	Allows records to be read- and write-shared*	
Relative	Allows sequential and random access for all languages	Allows data to be stored on disk only for accessing by relative cell number
	Allows random record deletion and insertion	Requires that files contain a record cell for each relative number allocated (files may not be densely populated)
	Allows records to be read- and write-shared	Requires that record cells be the same size
		Allows record insertion only to empty cells (or at the end of the file)
		Duplicate relative cell numbers are not allowed
Indexed	Allows sequential and random access by key value for all languages and by RFA for some languages	Allows data to be stored on disk only
	Allows random record deletion and insertion	Requires more disk space
	Allows records to be read- and write-shared	Uses more CPU time to process records
	Allows variable-length records to change length on update	Generally requires multiple disk accesses to process a record
	Duplicate key values possible	
	Automatic sort of records by primary and alternate keys; available during sequential access	

* Prior to VAX/VMS Version 4.4, write-sharing for sequential files was restricted to fixed-length 512-byte records.

MODULE 5
INDEXED FILE ORGANIZATION — INTERNAL STRUCTURE AND OVERHEAD

Major Topics

Part 1. Internals

- Overall tree structure and prolog
- Key descriptors
- Area descriptors
- Data bucket structure
- RRVs and bucket splits
- Key and data compression (Prolog 3)
- Index bucket
- Index compression
- Binary versus nonbinary index search
- Secondary index buckets and data records (SIDRs)

Part 2. Simulated Data Example

NOTE

The figures and tables presented in this module are based on preliminary materials prepared for *File and Record Management Internals* presently being written within DIGITAL (anticipated publication date, 1987). Although these materials are still undergoing technical review, they provide the most up-to-date, detailed documentation of the internal layouts used for VAX/VMS indexed files by RMS.

PART 1. INTERNALS

OVERALL TREE STRUCTURE AND PROLOG

- Indexed files contain:
  - a prolog
  - key descriptors
  - area descriptors
  - primary index structure
  - secondary index structure(s)

- There are three types of indexed files:
  - Prolog 1
  - Prolog 2
  - Prolog 3 (default)

Characteristics	VMS 3.7+ Prologue 1*	VMS 3.7+ Prologue 2*	VMS 3.7 Prologue 3	VMS 4.0+ Prologue 3
Key data types	String data only	String and numeric data (2 and 4 bytes)	String data only	String data, packed decimal, and binary and integer numbers (2, 4, and 8 bytes)
Number of alternate keys	1-255	1-255	0 (restricted primary key)	1-255
Overlapping segmented keys				
Primary	Yes	Yes	No	No
Alternate	Yes	Yes	--	Yes
Values for alternates can change	Yes	Yes	--	Yes
Values for alternates can be null	Yes	Yes	--	Yes
Data, key, and index compression	No	No	Yes	Yes
CONVERT/RECLAIM	No	No	Yes**	Yes**

* Prologues 1 and 2 operate identically except for differences in key data types supported by each.

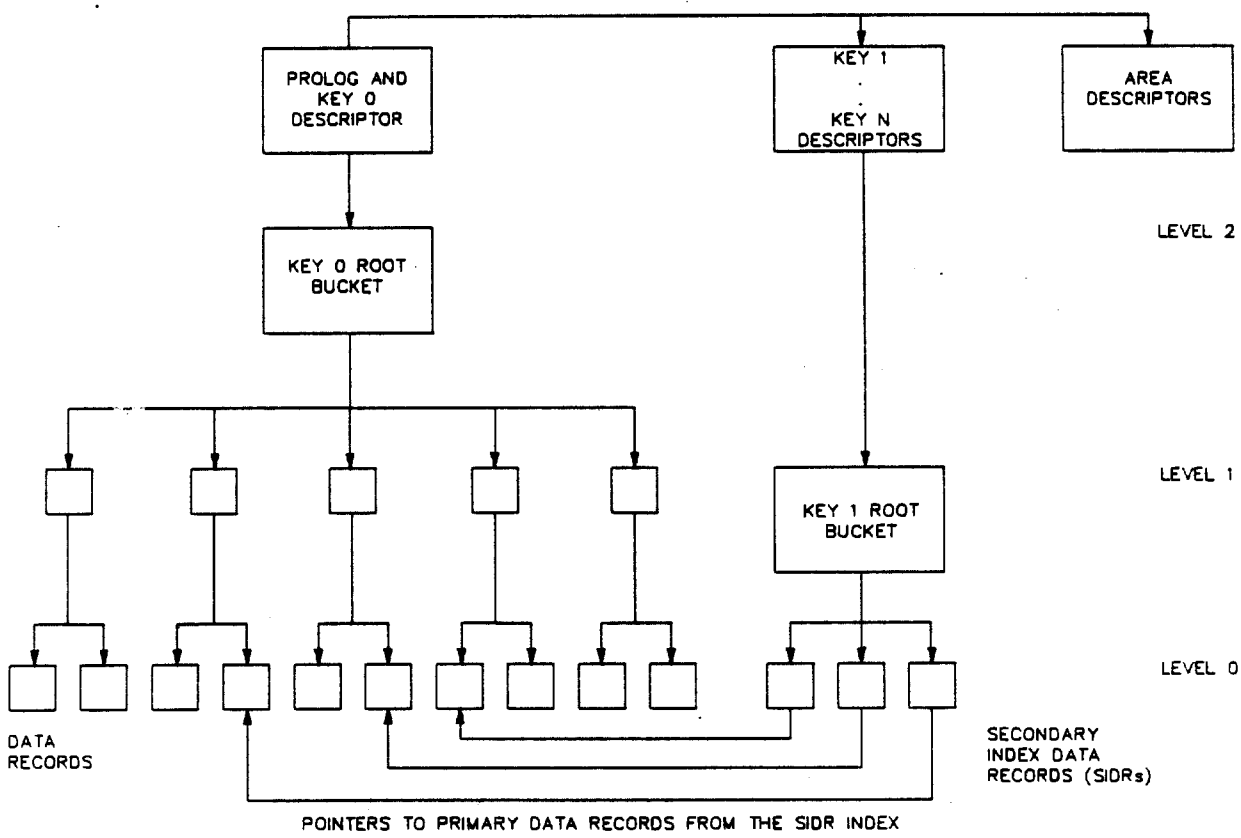
** Empty buckets (all records have been deleted) can be reclaimed for Prologue 3 files without rewriting the file.

Indexed Sequential Files

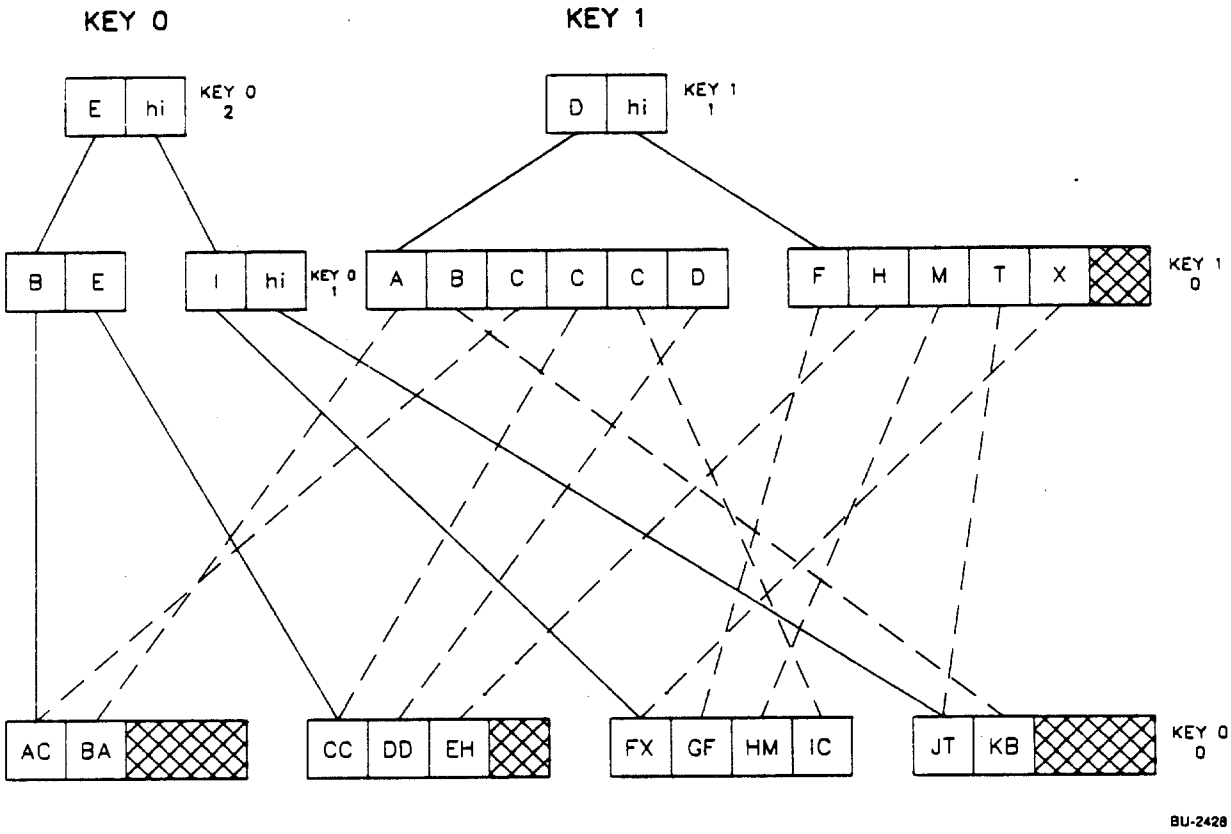
In the indexed sequential (ISAM) file organization, records are stored in a specified order defined by a key value. The records can be retrieved either sequentially or randomly.

A basic ISAM file has a primary key, a prolog, an index associated with the primary key descriptor, and user data associated with the primary index. An ISAM file with alternate keys has, in addition to these structures, alternate key descriptors for each alternate key, an index associated with each alternate key, and RMS information associated with each index. This information contains pointers into the user data for the records meeting the various key values.

Index Structure of an Indexed Sequential File



Tree Structure Associated with Each Key



NOTES

- Level 0 of each tree always contains data buckets.
- Level 1 and higher of each tree contain index buckets, with root index bucket always at the highest level of each tree.
- Within each tree, level 0 data buckets may have a different size than index buckets if at least two different areas are defined. A maximum of three areas can be defined for each tree, with a maximum of 255 areas for the total file. There is no restriction on the data or index buckets having to be the same size across trees.

- Four areas were defined for the above figure:

  -- Area 0 for key 0 level 0 data buckets

  -- Area 1 for key 0 level 1 and higher index buckets

  -- Area 2 for key 1 level 0 data buckets

  -- Area 3 for key 1 level 1 and higher index buckets

  A maximum of six areas could have been defined for these two trees. A minimum of three areas would have been necessary in order to obtain the three different bucket sizes depicted.

- FDL by default uses one bucket size for both the data and index buckets within each tree. The area definition produced by FDL has to be modified by the user in order to obtain a different bucket size for the data and index levels within any tree.

Prolog Description

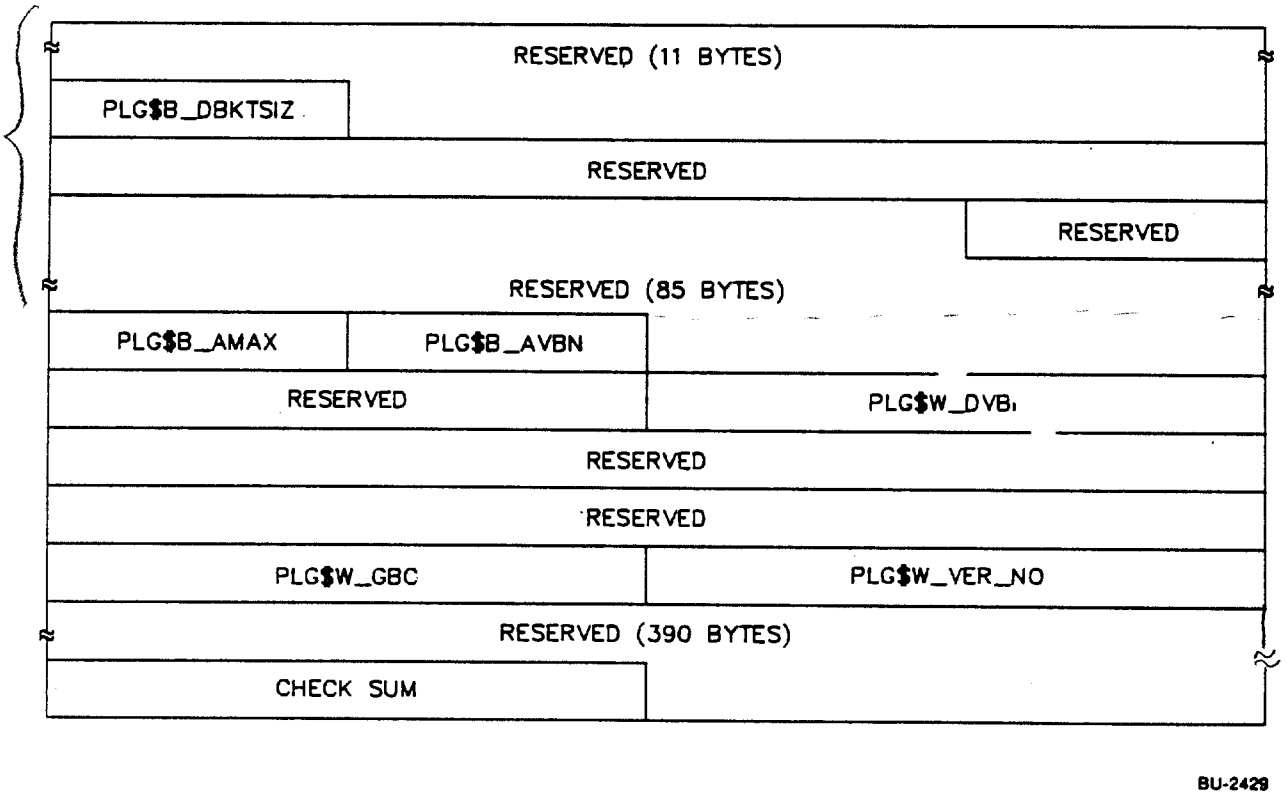
Like a relative file, an ISAM file begins with a prolog, which is a map to the rest of the file. The file-related overhead, which includes structures such as key and area descriptors, may range from 2 to 84 blocks long, starting with virtual block 1. These blocks are allocated from Area 0.

VBN 1 contains the prolog and the primary key descriptor, and the area descriptor follows in VBN 2 if the file has no alternate keys. The prolog descriptor for the primary key has one field in common with the key descriptor--the data bucket size field (PLG$B_DBKTSIZ)-- and the key descriptor for the primary key "overlays" the prolog descriptor. The last word of the prolog contains the standard Files-11 checksum field. The primary key descriptor begins in byte 0 of VBN 1.

Format of a Prolog for an Indexed Sequential File

NOTE

The fields in all the figures in this module run right-to-left.

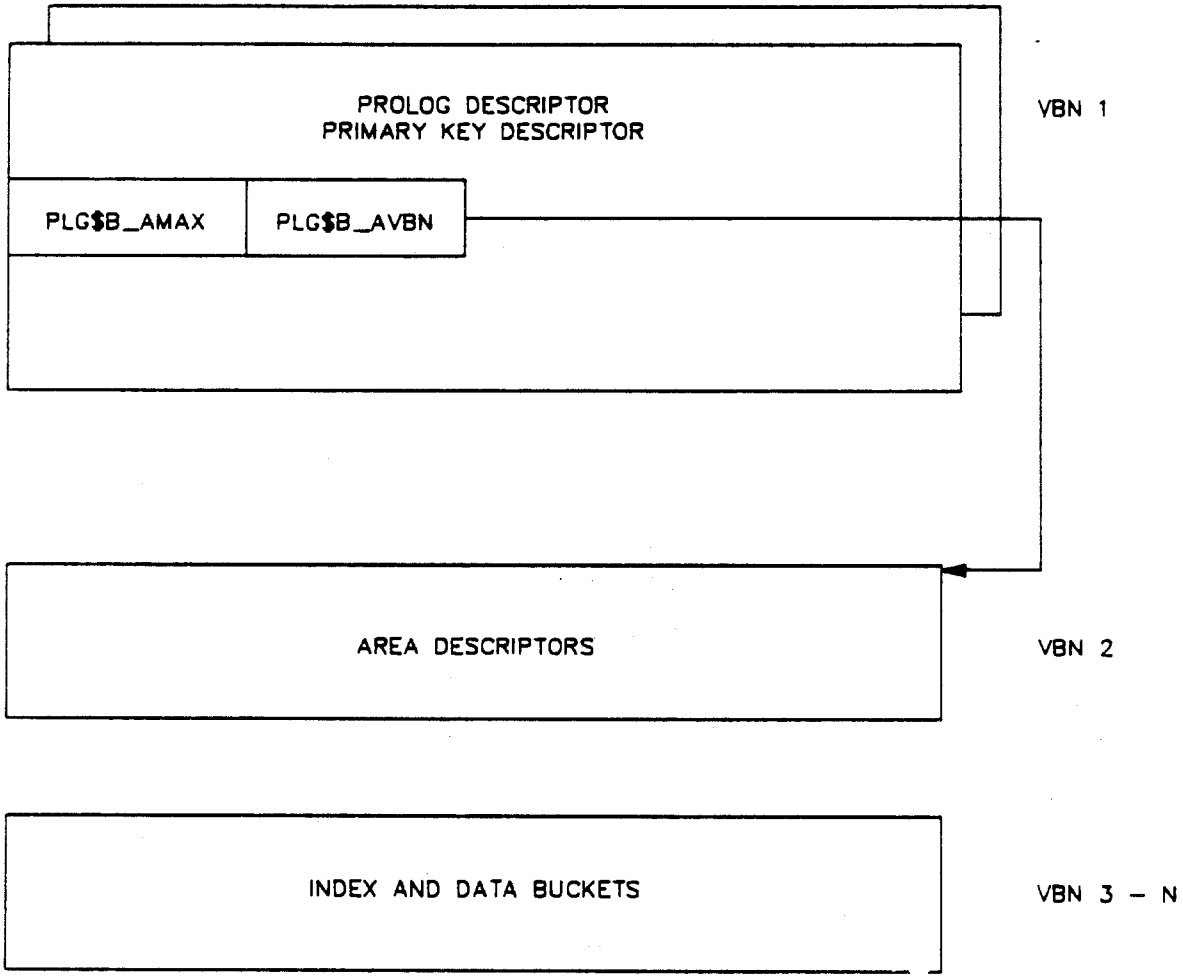


Contents of a Record Prolog for an Indexed Sequential File

Field Name	Description
PLG$B_DBKTSIZ	Data bucket size. This byte contains the bucket size for all data level (level 0) buckets.
PLG$B_AVBN	VBN of the first area descriptor. This field contains the virtual block number (which can range from 2 to 255) of the first area descriptor. Area descriptors are virtually contiguous and can be directly accessed by area number.
PLG$B_AMAX	Maximum number of areas. This field contains the maximum number of defined area descriptors (which can range from 1 to 255) for this file. Eight area descriptors can fit in one virtual block because each is 64 bytes long.
PLG$W_DVBN	VBN of the first data bucket. This field contains the 16-bit virtual block number of the first data bucket in ~~an indexed~~ a relative file.
PLG$W_VER_NO	Prolog version number. The following constants are defined for this field.
PLG$C_VER_NO	Prolog 1. This version supports string keys only.
PLG$C_VER_IDX	Prolog 2. This version supports key types other than string.
PLG$C_VER_3	Prolog 3. This version supports compression and space reclamation for indexed files.
PLG$W_GBC	Default global buffer count. This field contains the number of global buffers the user requested for the file. The number may range from 0 to 32,767; a value of 0 disables global buffering. This field can be set by the RMS field FAB$W_GBC and the FDL attribute FILE GLOBAL_BUFFER_COUNT.

A maximum of three area descriptors are allowed for any given key. However, up to 255 area descriptors are allowed for a file with multiple keys.

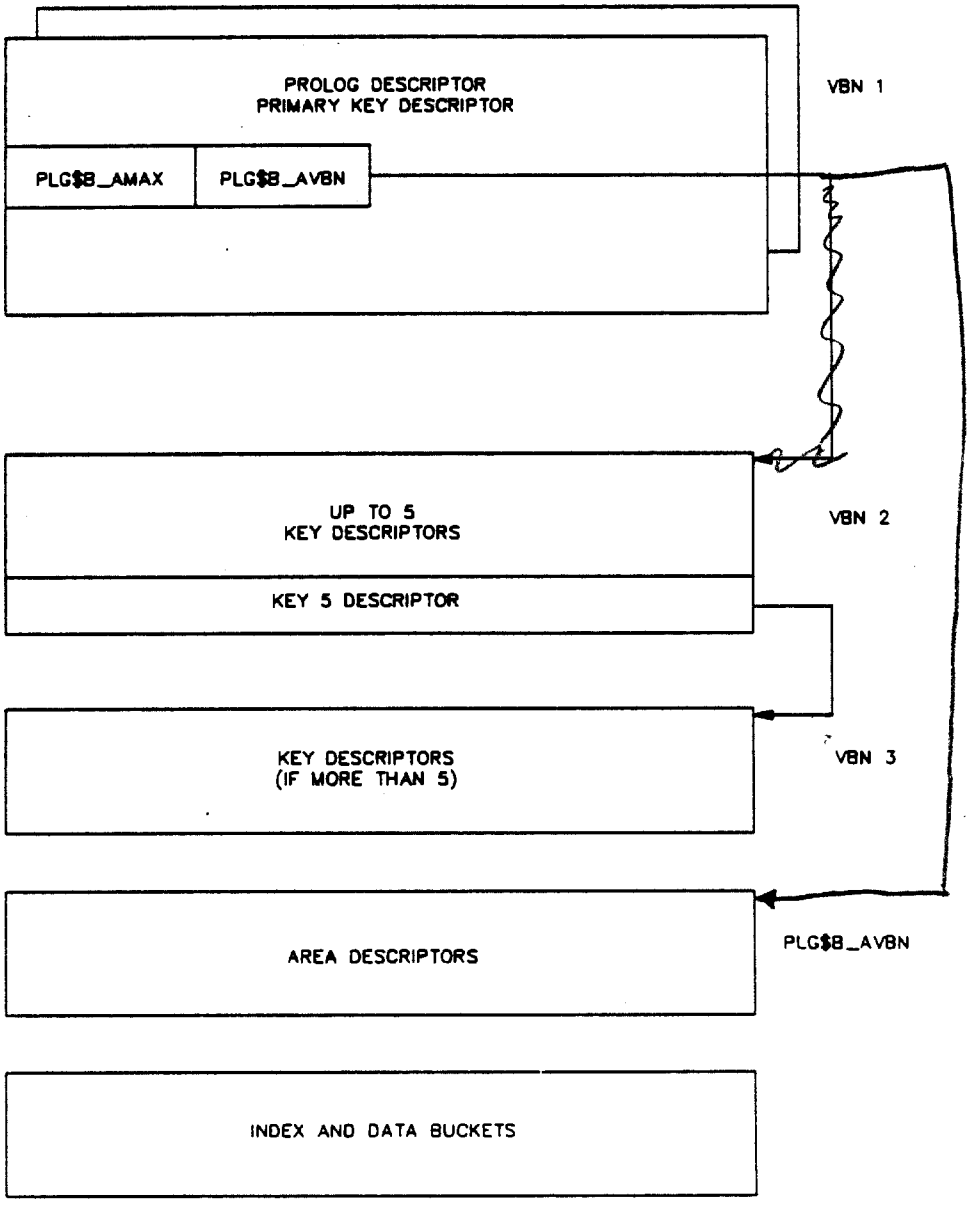
Format of a Prolog for a File with a Single Key



For a file with multiple keys, the virtual blocks containing the index and data buckets start at the value given by the following equation.

```
PLG$B_AMAX
----------  + PLG$B_AVBN
8 (truncated)
```

Format of a Prolog for a File with Multiple Keys



BU-2431

KEY DESCRIPTORS

A key descriptor gives information about the characteristics of a key in an ISAM file. It supplies all the information RMS needs to retrieve, insert, update, and delete records. Every key has a corresponding key descriptor. Every file has a primary key, therefore it has at least one key descriptor. The primary key descriptor is located at virtual block 1 of the file (byte 0).

Key descriptors for secondary keys are called alternate key descriptors. They start at virtual block 2 of the prolog. An alternate key descriptor is identical to a primary key descriptor. Up to five alternate key descriptors can fit in a single block.

Key descriptors are linked into a chain by two fields: the virtual block number of the next key descriptor (KEY$L_IDXFL) and the byte offset within the block for the next key descriptor (KEY$W_NOFF).

The three possible areas for each defined key are described by the KEYB_IANUM, KEYB_LANUM, and KEY$B_DANUM fields.

Format of a Key Descriptor

KEY$L_IDXFL			
KEY$B_LANUM	KEY$B_IANUM	KEY$W_NOFF	
KEY$B_DATBKTSZ	KEY$B_IDXBKTSZ	KEY$B_ROOTLEV	KEY$B_DANUM
KEY$L_ROOTVBN			
KEY$B_NULLCHAR	KEY$B_SEGMENTS	KEY$B_DATATYPE	KEY$B_FLAGS
KEY$W_MINRECSZ		KEY$B_KEYREF	KEY$B_KEYSZ
KEY$W_DATFILL		KEY$W_IDXFILL	
KEY$W_POSITION1		KEY$W_POSITION	
KEY$W_POSITION3		KEY$W_POSITION2	
KEY$W_POSITION5		KEY$W_POSITION4	
KEY$W_POSITION7		KEY$W_POSITION6	
KEY$B_SIZE3	KEY$B_SIZE2	KEY$B_SIZE1	KEY$B_SIZE
KEY$B_SIZE7	KEY$B_SIZE6	KEY$B_SIZE5	KEY$B_SIZE4
KEY$T_KEYNAM (32 BYTES)			
KEY$L_LDVBN			
KEY$B_TYPE3	KEY$B_TYPE2	KEY$B_TYPE1	KEY$B_TYPE
KEY$B_TYPE7	KEY$B_TYPE6	KEY$B_TYPE5	KEY$B_TYPE4

BU-2432

* 96 bytes
* max of 5 to a block
* Prolog holds 1° Key Descriptor

Contents of a Key Descriptor

Field Name	Description
KEY$L_IDXFL	VBN for next key descriptor. This field is checked only when the KEY$W_NOFF field contains a value of 0. When the KEY$L_IDXFL and the KEY$W_NOFF fields both contain a value of 0, the last key descriptor has been found.
KEY$W_NOFF	Offset to next key descriptor. This field contains the offset to the next key descriptor in the chain of key descriptors. This offset is relative to the beginning of the virtual block number contained in the KEY$L_IDXFL field.
KEY$B_IANUM	Index area number. This field contains the index bucket area number to be used for the index buckets for the key, from level 2 to the root bucket. It represents the area identification number contained in the AREA$B_AREAID field. It can range from 0 to 254. The default is 0, which indicates area 0. This field is set with the RMS field XAB$B_IAN and the FDL attribute KEY INDEX_AREA.
KEY$B_LANUM	Level 1 area number. This field contains the area number of the lowest level (level 1) of the index. It represents the area identification number contained in the AREA$B_AREAID field, ranging from 0 to 254. If this field contains a value of 0, only the KEY$B_IANUM field is used. This field is set with the RMS field XAB$B_LAN.
KEY$B_DANUM	Data area number. This field contains the area number of the data level (level 0) of the index buckets for the key. It represents the area identification number contained in the AREA$B_AREAID field. It can range from 0 to 254. The default is 0, which indicates area 0. This field is set with the RMS field XAB$B_DAN and the FDL attribute KEY DATA_AREA.

Contents of a Key Descriptor (Cont.)

Field Name	Description
KEY$B_ROOTLEV	Root level. This field contains the level number of the root bucket for the key. In other words, this field contains the height of the index tree. Levels are numbered from 0 to n, where 0 indicates the data level and n indicates the root level. This field sets the RMS field XAB$B_LVL after an Open or Display service.
KEY$B_IDXBKTSZ	Index bucket size. This field contains the size (number of virtual blocks) of the index-level buckets (level 1 to n) for the key. This field sets the RMS field XAB$B_IBS after an Open or Display service.
KEY$B_DATBKTSZ	Data bucket size. This field contains the size (number of virtual blocks) of the data-level buckets (level 0) for the key. This field sets the RMS field XAB$B_DBS after an Open or Display service.
KEY$L_ROOTVBN	VBN of the root bucket. Contains the virtual block number of the index root bucket for the key. After an Open or Display service, this field sets the RMS field XAB$L_RVB.
KEY$B_FLAGS	Flag bits. This field may be set with the RMS field XAB$B_FLG. The following 1-bit fields are defined within KEY$B_FLAGS.
KEY$V_DUPKEYS	Set if duplicate key values are allowed. This field starts at bit 0. It may be set with the RMS field XAB$V_DUP.
KEY$V_CHGKEYS	Set if the key value may change on an update operation. This field starts at bit 1. It may be set with the RMS field XAB$V_CHG.
KEY$V_NULKEYS	Set if a null key character is enabled. This field starts at bit 2. It may be set with the RMS field XAB$V_NUL.

Contents of a Key Descriptor (Cont.)

Field Name	Description	
KEY$B_FLAGS (Cont.)	KEY$V_IDX_COMPR	Set if the index is compressed. This field starts at bit 3. This field may be cleared with the RMS field XAB$V_IDX_NCMPR.
	KEY$V_INITIDX	Set if the index must be initialized. This field is used only when RMS creates the index for this key. Because area number information is not normally stored in memory for an open indexed file, the required area numbers to create (and initialize) the index are stored in the root bucket field. When a bucket split occurs and additional space has to be allocated, the area number stored in the bucket which is splitting is used as the area number for the new bucket. This field starts at bit 4.
	KEY$V_KEY_COMPR	Set if the key is compressed in data records. The key must be a Prolog 3 string key. This field starts at bit 6. This field may be overridden with the RMS field XAB$V_KEY_NCMPR.
	KEY$V_REC_COMPR	Set if the data portion of the record is compressed. This bit applies only to Prolog 3 files. This field starts at bit 7. This field may be overridden with the RMS field XAB$V_DAT_NCMPR.

Contents of a Key Descriptor (Cont.)

Field Name	Description	
KEY$B_DATATYPE	Key data type. This field is used at file creation to declare the type of data in the key within each data record. It may be set with the RMS field XAB$B_DTP. The following constants may be specified.	
	KEY$C_STRING	Left-justified string of unsigned, 8-bit bytes. This is the default.
	KEY$C_SGNWORD	Signed binary word.
	KEY$C_UNSGNWORD	Unsigned binary word.
	KEY$C_SGNLONG	Signed binary longword.
	KEY$C_UNSGNLONG	Unsigned binary longword.
	KEY$C_PACKED	Packed decimal string.
	KEY$C_SGNQUAD	Signed binary quadword.
	KEY$C_UNSGNQUAD	Unsigned binary quadword.
	KEY$C_DSTRING	String data type for descending keys (as of VMS 4.4).
	KEY$C_DSGNWORD	Signed binary word data type for descending keys (as of VMS 4.4).
	KEY$C_DUNSGNWORD	Unsigned binary word data type for descending keys (as of VMS 4.4).
	KEY$C_DSGNLONG	Signed binary longword data type for descending keys (as of VMS 4.4).
	KEY$C_DUNSGNLONG	Unsigned binary longword data type for descending keys (as of VMS 4.4).
	KEY$C_DPACKED	Packed decimal string data type for descending keys (as of VMS 4.4).

Contents of a Key Descriptor (Cont.)

Field Name	Description	
KEY$B_DATATYPE (Cont.)	KEY$C_DSGNQUAD	Signed binary quadword for descending keys (as of VMS 4.4).
	KEY$C_DUNSGNQUAD	Unsigned binary quadword for descending keys (as of VMS 4.4).
KEY$B_SEGMENTS	Number of segments. This field contains the number of key segments that make up the key. Only string keys may have multiple segments. A maximum of eight segments is allowed. After an Open or Display service, this field sets the RMS field XAB$B_NSG.	
KEY$B_NULLCHAR	Null character. This field contains any user-selected ASCII character value. This field is set with the RMS field XAB$B_NUL.	
KEY$B_KEYSZ	Total key size. This field contains the sum (in bytes) of the values in the fields KEY$B_SIZE through KEY$B_SIZ7. After an Open or Display service, this field sets the RMS field XAB$B_TKS.	
KEY$B_KEYREF	Key of reference. This field tells whether a primary key or an alternate key has been defined. It contains a value ranging from 0 to 254, indicating which key has been defined. A value of 0 indicates the primary key, 1 indicates the first alternate key, and so on. This field is set with the RMS field XAB$B_REF.	
KEY$W_MINRECSZ	Minimum record length. This field contains the minimum length (in bytes) needed to hold the key. After an Open or Display service, this field sets the RMS field XAB$W_MRL.	

Contents of a Key Descriptor (Cont.)

Field Name	Description
KEY$W_IDXFILL	Index fill quantity. This field indicates the maximum number of bytes in an index bucket. The largest possible fill is the bucket size, in blocks, multiplied by 512. This field is set with the RMS field XAB$W_IFL.
KEY$W_DATFILL	Data fill quantity. This field indicates the maximum number of data bytes in a data bucket. The largest possible fill size is the bucket size, in blocks, multiplied by 512. This field is set with the RMS field XAB$W_DFL.
KEY$W_POSITION	Segment position. This field marks the beginning position of the first of up to eight key segments. It is set with the RMS field XAB$W_POS0.
KEY$W_POSITION1	Position 1. This field marks the beginning position of the second key segment. It is set with the RMS field XAB$W_POS1.
KEY$W_POSITION2	Position 2. This field marks the beginning position of the third key segment. It is set with the RMS field XAB$W_POS2.
KEY$W_POSITION3	Position 3. This field marks the beginning position of the fourth key segment. It is set with the RMS field XAB$W_POS3.
KEY$W_POSITION4	Position 4. This field marks the beginning position of the fifth key segment. It is set with the RMS field XAB$W_POS4.
KEY$W_POSITION5	Position 5. This field marks the beginning position of the sixth key segment. It is set with the RMS field XAB$W_POS5.
KEY$W_POSITION6	Position 6. This field marks the beginning position of the seventh key segment. It is set with the RMS field XAB$W_POS6.
KEY$W_POSITION7	Position 7. This field marks the beginning position of the eighth (and last) key segment. It is set with the RMS field XAB$W_POS7.

Contents of a Key Descriptor (Cont.)

Field Name	Description
KEY$B_SIZE	Segment size. This field contains the size of the first key segment. It is set with the RMS field XAB$B_SIZ0.
KEY$B_SIZE1	Size 1. This field contains the size of the second key segment. It is set with the RMS field XAB$B_SIZ1.
KEY$B_SIZE2	Size 2. This field contains the size of the third key segment. It is set with the RMS field XAB$B_SIZ2.
KEY$B_SIZE3	Size 3. This field contains the size of the fourth key segment. It is set with the RMS field XAB$B_SIZ3.
KEY$B_SIZE4	Size 4. This field contains the size of the fifth key segment. It is set with the RMS field XAB$B_SIZ4.
KEY$B_SIZE5	Size 5. This field contains the size of the sixth key segment. It is set with the RMS field XAB$B_SIZ5.
KEY$B_SIZE6	Size 6. This field contains the size of the seventh key segment. It is set with the RMS field XAB$B_SIZ6.
KEY$B_SIZE7	Size 7. This field contains the size of the eighth key segment. It is set with the RMS field XAB$B_SIZ7.
KEY$T_KEYNAM	Optional key name. This 32-byte field contains the name of the key as an ASCII string. It is set with the RMS field XAB$L_KNM.
KEY$L_LDVBN	VBN of the first data bucket. This field contains the starting virtual block number for the first data-level bucket for the key. After an Open or Display service, this field sets the RMS field XAB$L_DVB.

Contents of a Key Descriptor (Cont.)

Field Name	Description
KEY$B_TYPE	This field is not supported by VAX/VMS Version 4.4.
KEY$B_TYPE1	This field is not supported by VAX/VMS Version 4.4.

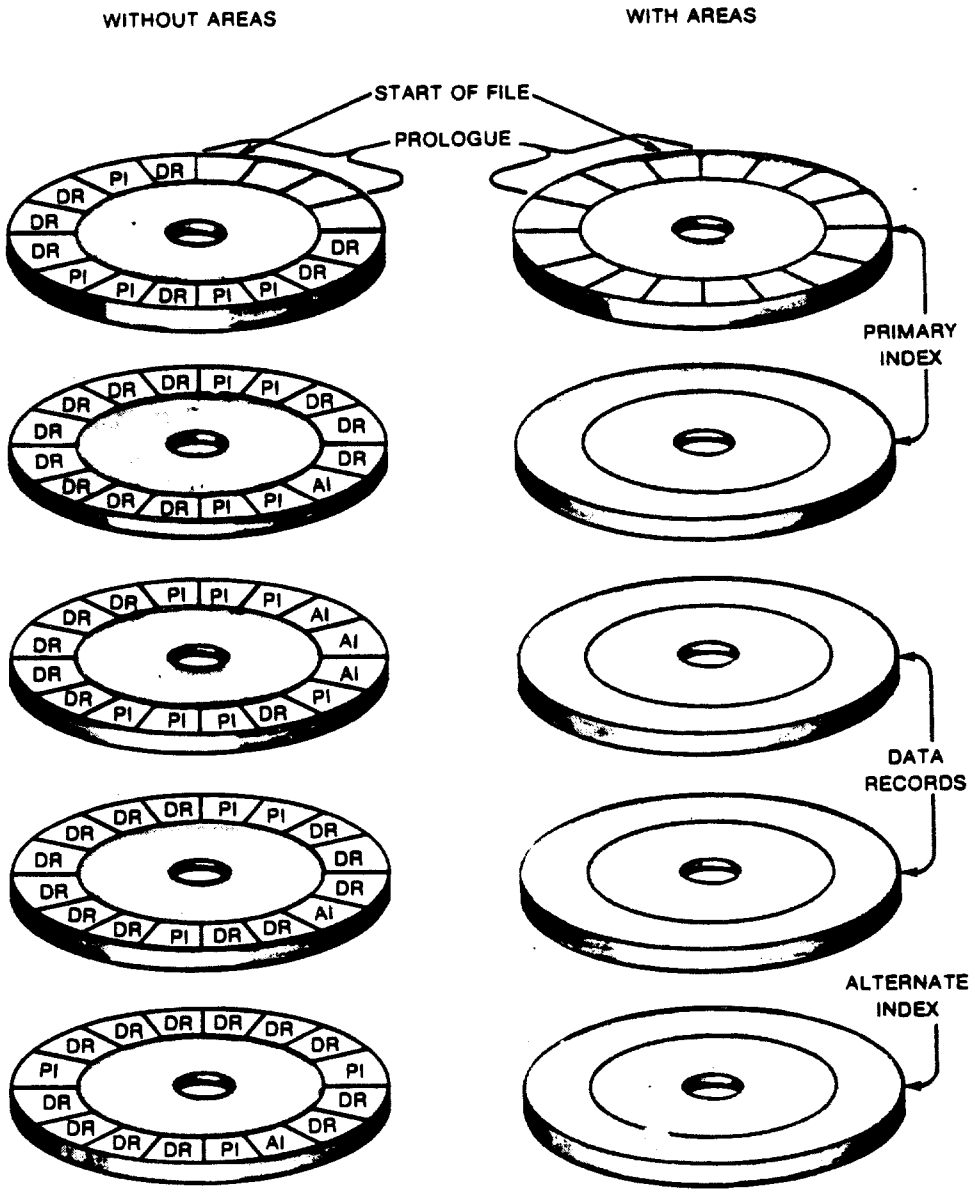
KEY$B_TYPE4	This field is not supported by VAX/VMS Version 4.4.
KEY$B_TYPE5	This field is not supported by VAX/VMS Version 4.4.
KEY$B_TYPE6	This field is not supported by VAX/VMS Version 4.4.
KEY$B_TYPE7	This field is not supported by VAX/VMS Version 4.4.

Indexed File With and Without Areas



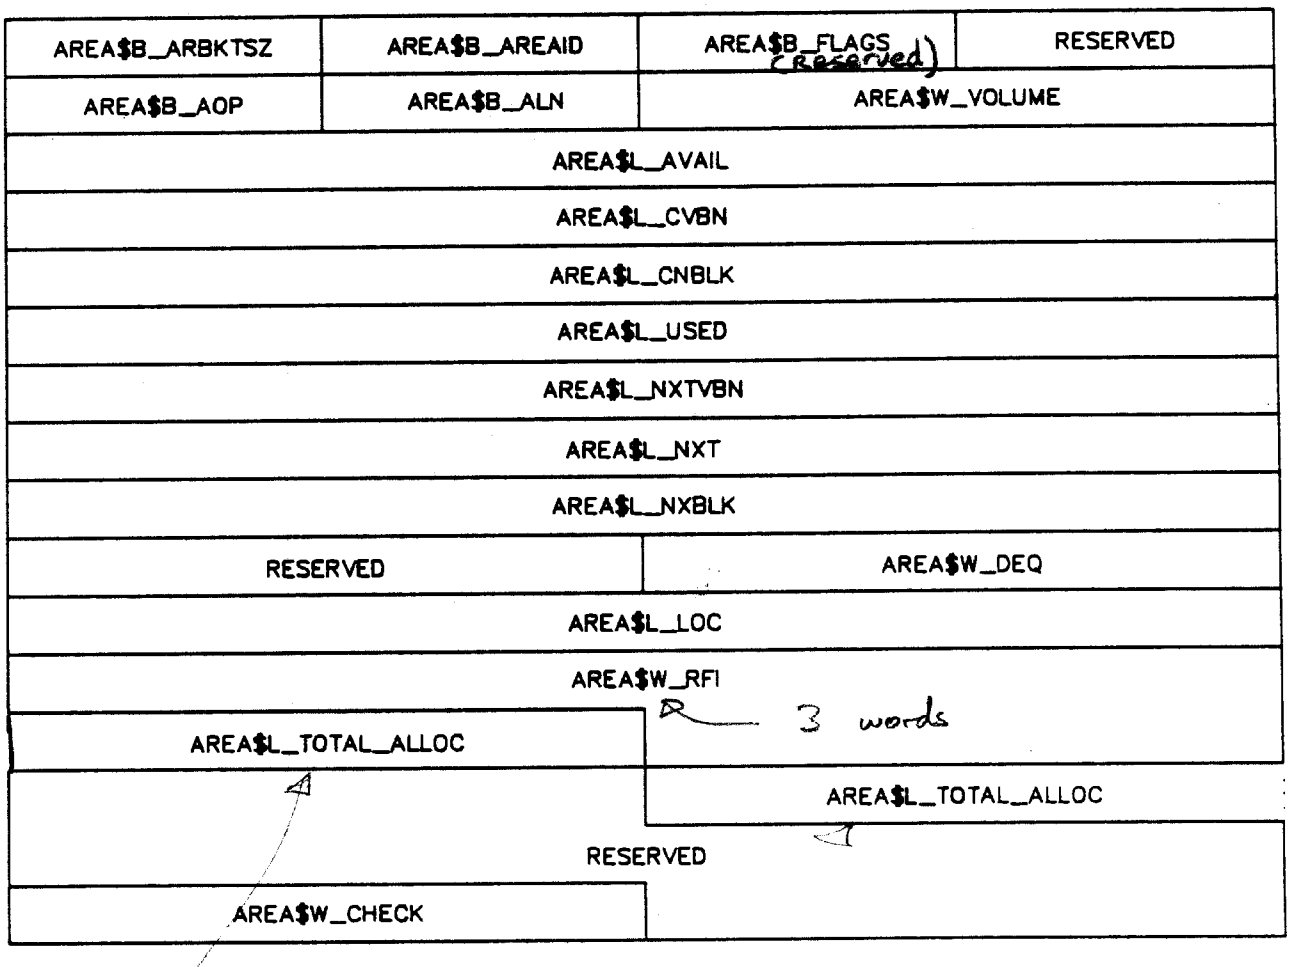
AREA DESCRIPTORS

In an ISAM file, the user may independently allocate and manage sections of contiguous virtual blocks, called areas, according to how each will be used. The area descriptor contains this function-specific information. There is an area descriptor for every area in the file.

Defining multiple areas allows the user to declare different bucket sizes for index buckets and data buckets. Areas also allow the user to control where the various elements or sections of the file are placed on the disk.

Area descriptors follow the last key descriptor of the file and occupy contiguous virtual blocks. Up to eight area descriptors can fit in one virtual block.

Format of an Area Descriptor



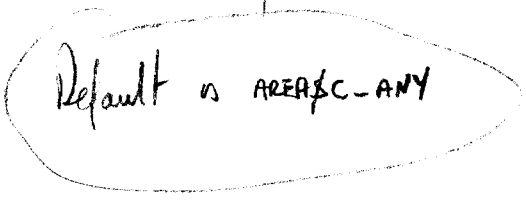
BU-2433

Contents of an Area Descriptor

Field Name	Description
AREA$B_AREAID	Area ID. This field contains the area identification number, which can range from 0 to 254. It indicates the target area for RMS operations. It is also used as a redundancy check because all area descriptors are located at a fixed position relative to the start of the area descriptor blocks. This field is set by the RMS field XAB$B_AID or the FDL attribute AREA n, where n indicates the area number.
AREA$B_ARBKTSZ	Area bucket size. This field contains the bucket size for the area, which can range from 1 to 63 blocks. It represents the granularity of the allocation. This field is set by the RMS field XAB$B_BKZ and the FDL attribute AREA BUCKET_SIZE.
AREA$W_VOLUME	Relative volume number. This field contains the relative volume number on which the file was allocated. The relative volume number ranges from 0 through 255. The default is 0, which indicates the current member of the volume set. This field may be set with the RMS field XAB$W_VOL or the FDL attribute AREA VOLUME.
AREA$B_ALN	Extent allocation alignment. This field indicates the type of alignment for the area to be allocated. It allows placement control to be specified for the file. The following options are valid for this field. If no value is set for this field, RMS assumes that placement control was not requested. AREA$C_CYL — This option indicates that the alignment starts at the specified cylinder number. It is set with the RMS field XAB$L_LOC or the FDL attribute AREA POSITION CYLINDER.

Contents of an Area Descriptor (Cont.)

Field Name	Description	
AREA$B_ALN (Cont.)	AREA$C_LBN	This option indicates that the alignment starts at the specified logical block. It may be set with the RMS field XAB$L_LOC or the FDL attribute AREA POSITION LOGICAL.
	AREA$C_RFI	This option indicates that the alignment starts as close as possible to the file specified by the related file identification field (XAB$W_RFI), at the virtual block number of the file specified in the location field (XAB$L_LOC). It is also set with the FDL attribute AREA POSITION FILE_ID or the FDL attribute AREA POSITION FILE_NAME.
	AREA$C_VBN	Virtual block alignment. This option indicates that the alignment starts at the specified virtual block. It is set with the RMS field XAB$L_LOC or the FDL attribute AREA POSITION VIRTUAL.
	This field is set with the RMS field XAB$B_ALN or the FDL attribute AREA POSITION.	
AREA$B_AOP	Alignment options. This field is a binary bit field where each allocation option is defined by a certain bit. Each option is identified by a symbolic bit offset and has a corresponding mask value. The following fields (or masks) are defined for this field.	
	AREA$V_HARD	This option specifies absolute alignment. If the requested alignment cannot be performed, an error is returned. This option starts at bit 24. It is set with the RMS field XAB$B_AOP (the XAB$V_HRD option) or the FDL attribute AREA EXACT_POSITIONING.



Contents of an Area Descriptor (Cont.)

Field Name	Description	
AREA$B_AOP (Cont.)	AREA$V_ONC	This option requests that RMS locate the allocation on any available cylinder boundary. This option starts at bit 25. It is set with the RMS field XAB$B_AOP (the XAB$V_ONC option) or the FDL attribute AREA POSITION ANY_POSITION.
	AREA$V_CBT	This option indicates that the allocation or a later extension should occupy contiguous blocks, if possible. This option starts at bit 29. It is set with the RMS field XAB$B_AOP (the XAB$V_CBT option) or the FDL attribute AREA BEST_TRY_CONTIGUOUS.
	AREA$V_CTG	This option indicates that the initial allocation or later extensions must use only contiguous blocks. This option starts at bit 31. It is set with the RMS field XAB$B_AOP (the XAB$V_CTG option) or the FDL attribute AREA CONTIGUOUS.
	AREA$L_AVAIL	Available buckets. This field contains the 32-bit virtual block number of the first available bucket in a chain of reclaimed buckets (from the CONVERT/RECLAIM utility). The rest of the buckets on the chain are linked via the BKT$L_NXTBKT field in each bucket header.
AREA$L_CVBN	Starting VBN for the current extent. This field contains the first virtual block number of the current extent, which is the extent from which buckets are allocated.	

Contents of an Area Descriptor (Cont.)

Field Name	Description
AREA$L_CNBLK	Number of blocks in current extent. This field contains the number of blocks that were allocated to this extent. The AREA$L_CVBN and AREA$L_CNBLK fields describe the result of an Extend operation for the current extent.
AREA$L_USED	Number of blocks used. This field contains the number of blocks that have been allocated from the current extent.
AREA$L_NXTVBN	Next VBN to use. This field contains the virtual block number of the starting block number of the next bucket allocated from the current extent.
AREA$L_NXT	Starting VBN for next extent. This field contains the starting virtual block number for the next extent in the chain. When there are no more empty blocks in the current extent, the next extent is made the current extent, and the next extent is initialized (zeroed). The area can only be extended when the next extent description has been zeroed. Thus, a value of 0 indicates that the current extent is the last (or only) extent in the chain.
AREA$L_NXBLK	Number of blocks in next extent. This field contains the number of blocks that were allocated to the next extent. The AREA$L_NXT and AREA$L_NXBLK fields describe the result of an Extend operation for the next extent.
AREA$W_DEQ	Default extend quantity. This field contains the default ~~file~~ extend quantity, which is the number of blocks to be added when RMS needs to extend the area. The user specifies this value, which can range from 0 through 65,535. If a value of 0 is specified, the file will be extended using a default extension value determined by RMS. A size less than 1 bucket will never be used. This field is set with the RMS field XAB$W_DEQ or the FDL attribute AREA EXTENSION.
AREA$L_LOC	Starting LBN on volume. This field contains the starting logical block number of the last extent of the area.

area

Contents of an Area Descriptor (Cont.)

Field Name	Description
AREA$W_RFI	Related file ID. This field contains the file ID of a related file.
AREA$L_TOTAL_ALLOC	Total block allocation. This field contains the total number of blocks initially allocated for an area during a Create operation or the number of blocks to be added to the area during an Extend operation. This field sets the XAB$L_ALQ field during Open, Create, Display, and Extend services.
AREA$W_CHECK	Checksum. This field allows the standard Files-11 checksum value to be stored in the last word of the area descriptor block.

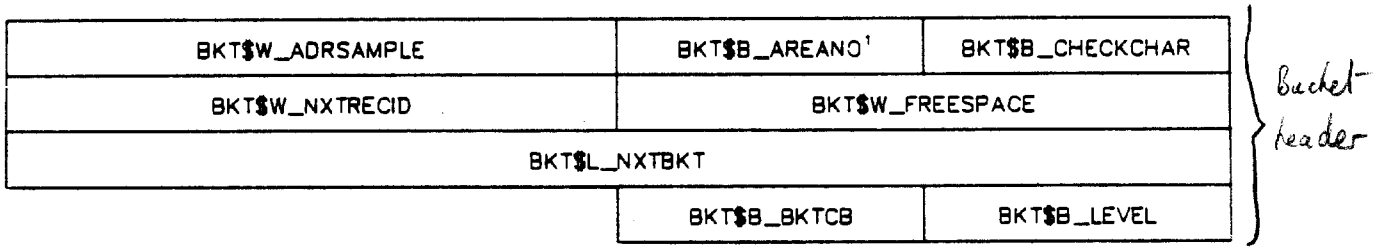
DATA BUCKET STRUCTURE

Following the prolog, key, and area descriptors in an ISAM file are storage structures called buckets, which can either be data buckets or index buckets. The size of a bucket is always a multiple of 512 bytes (1 to 63 blocks).

The bucket size is defined by the user. The size of the index buckets may be different within the same index, but the bucket size on each level for each key of reference is the same.

Buckets have two logical regions: a header area and an area that may be used to store records. The size of the actual bucket header is 14 bytes although the total size of bucket overhead is 15 bytes; the extra byte is a check byte at the end of each bucket.

Format of a Data Bucket for an Indexed Sequential File



[1] BKT$B_INDEXNO FOR PROLOG 3 FILES

BU-2434

Contents of a Data Bucket

Field Name	Description
BKT$B_CHECKCHAR	Bucket check character. This field contains a 1-byte check character. Whenever a bucket is written, the value in the check byte is incremented and copied into the first and last byte of the bucket. Whenever a bucket is read, the check bytes are compared for equality. By this technique, hardware failures during transfer are detectable.
BKT$B_AREANO	Area number or index number (BKT$B_INDEXNO).
BKT$B_INDEXNO	For Prolog 1 and 2 files, BKT$B_AREANO contains the area number of the area from which the bucket was allocated. For Prolog 3 files, BKT$B_INDEXNO contains the index number to which this bucket belongs. For example, a value of 0 represents the primary index, and values of 1, 2, 3, and so on represent alternate indexes.
BKT$W_ADRSAMPLE	Low-order word of the bucket VBN. This field contains the low 16 bits of the first block number in the bucket. This field is written when the bucket is formatted and is checked when the bucket is read into memory.
BKT$W_FREESPACE	First free byte of unused space in the bucket. This field contains the byte address relative to the start of the bucket of the first free byte in the unused portion of the record storage area of the bucket.
BKT$W_NXTRECID	Next available record ID. This field contains the ID number to use for the next record placed in the bucket. When the current ID is used, the value in this field is incremented by 1. The record ID does not depend on the record's physical position in the bucket because records are ordered by key value. Record IDs are assigned in different ways, depending on the prolog version of the file.

Contents of a Data Bucket (Cont.)

Field Name	Description
BKT$W_NXTRECID (Cont.)	For Prolog 3 files, the way the record ID is assigned depends on whether the bucket is newly created or a reclaimed bucket. If the bucket is new, the first record is assigned an ID of 1, and subsequent record IDs are assigned in order. If the bucket is reclaimed, the record ID is assigned from the value in the BKT$W_NXTRECID field, and subsequent IDs are assigned in order. For Prolog 1 and 2 files, the BKT$W_NXTRECID field consists of two 1-byte fields, BKT$B_NXTRECID and BKT$B_LSTRECID, that indicate a range of record IDs. The low byte (BKT$B_NXTRECID) contains the next record ID that can be assigned. The high byte contains the upper limit of 255 (hex FF), which is the highest record ID that can be assigned. However, if the bucket is new, the first record is always assigned an ID of 1.
BKT$L_NXTBKT	VBN of the next bucket. This field contains the starting virtual block number of the next bucket at this level of data buckets; it is a horizontal link to the next bucket. This pointer always points to a bucket of the same size. The last bucket in a level points to the first bucket in the level.
BKT$B_LEVEL	Bucket level number. This field contains the level number relative to the data level for this bucket. Data-level buckets contain a value of 0. The lowest level in the index structure is represented by a value of 1, the next highest level by a value of 2, and so on. The root level of the index always has the highest value.

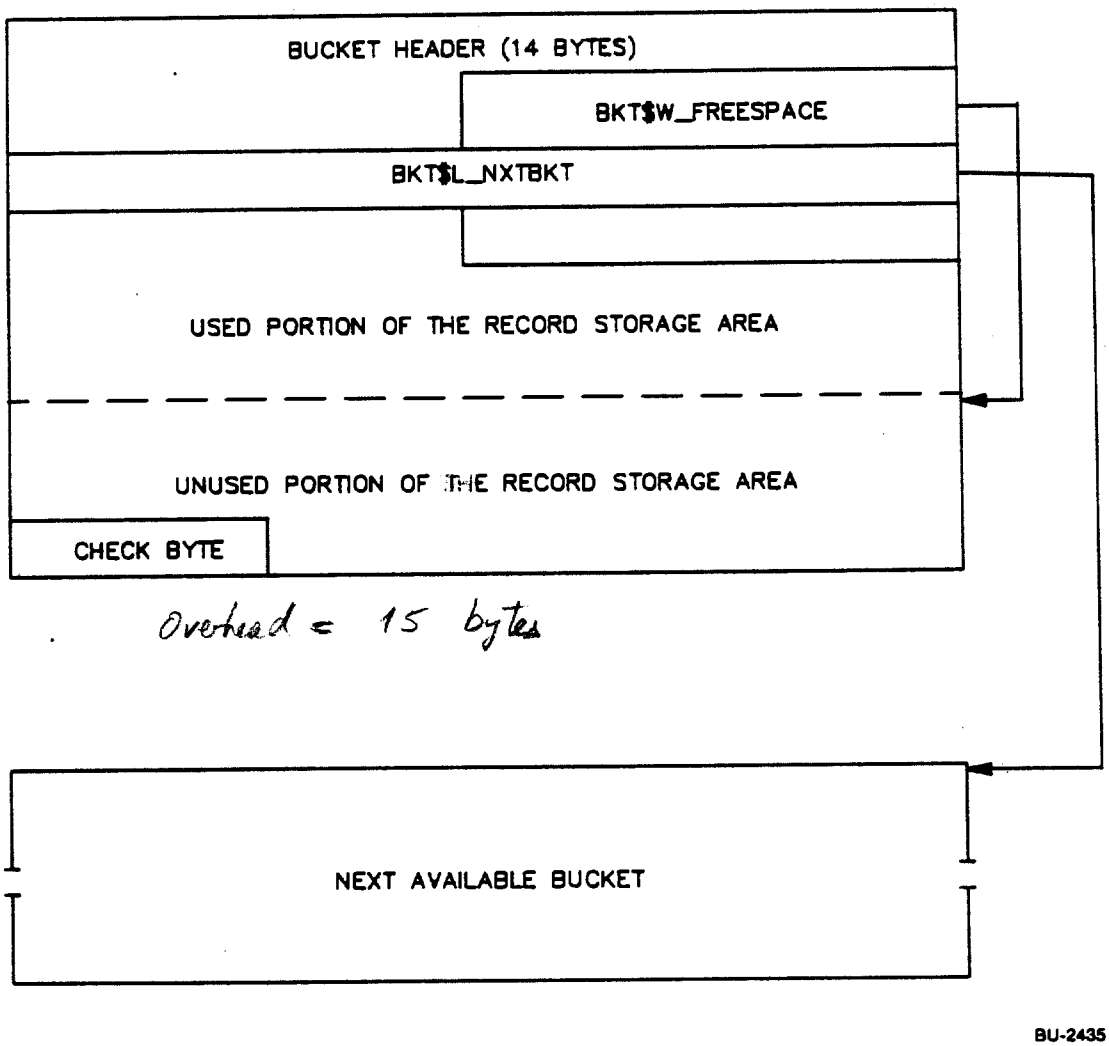
Contents of a Data Bucket (Cont.)

Field Name	Description
BKT$B_BKTCB	Bucket control bits. This field is a bit-encoded byte field and is used when RMS processes a bucket. The following bits are defined within this field.
	BKT$V_LASTBKT — Last bucket in the horizontal chain for that level. This 1-bit field starts at bit 0.
	BKT$V_ROOTBKT — Root bucket. This 1-bit field starts at bit 1.
	BKT$V_PTR_SZ — Size of the VBN pointers in this bucket. This 2-bit field starts at bit 3 and is used only for Prolog 3 index buckets.

The record storage region has two parts: a used portion occupied by records, and an unused portion. The used portion of the record storage region starts at the first byte after the bucket header area, and it ends at the byte address that is a byte less than the address stored in the BKT$W_FREESPACE field. The record structures in the bucket depend on how the bucket is used.

The unused portion of the record storage area starts at the byte address stored in the BKT$W_FREESPACE field and ends at the byte before the check byte field, which is the last byte in the bucket. Available buckets are chained together in a linked list.

The Format of a Bucket



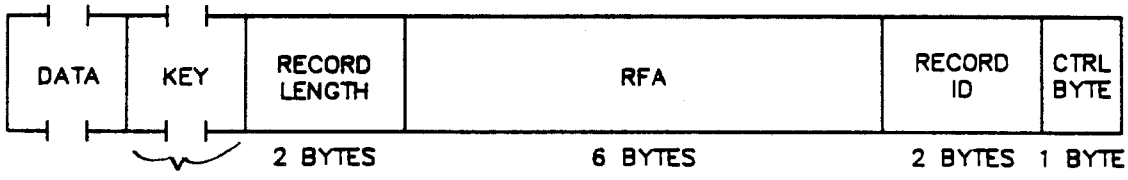
Data Record Format

The format of a data record depends on whether the file is a Prolog 3 file or a Prolog 1 or 2 file. Prolog 3 data records are the only records that allow data or key compression.

As the record of a Prolog 3 file is inserted in the bucket, the key is always placed at the front of the data record, even if there is no key compression. If the key field is in the middle of the record, it is still extracted and placed at the front of the record to improve performance. However, it is inserted at the proper place before the record is retrieved and returned to the user.

Data record overhead for Prolog 3 files with no compression and variable-length records is eleven bytes. With fixed-length records and no compression, the overhead is nine bytes.

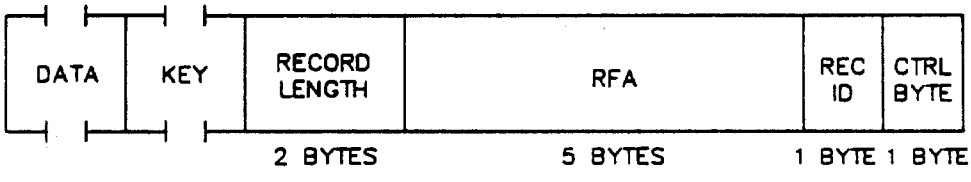
Format of a Prolog 3 Variable-Length Data Record with No Compression



This is extracted from the data & NOT duplicated.

For Prolog 1 and 2 files with variable-length records, the overhead is nine bytes. With fixed-length records, the overhead is seven bytes. The size of the record ID and the RFA fields are smaller by one byte than the corresponding Prolog 3 fields.

Format of a Prolog 1 or 2 Variable-Length Data Record



* Note that 'Guide to File Applications' does not explain this in full.

The fields of a data record are described in the following table.

Field Name	Description
Control byte	Record control byte. The bits are defined as follows: 0-1 VBN pointer size 2 Deleted record flag 3 Record reference vector record flag The Analyze/RMS_File Utility (ANALYZE/RMS_FILE) can display the position and state of high-order six bits that indicate whether the record is deleted or whether it is an record reference vector (RRV). The low-order 2 bits are relatively meaningless. For example, a typical record that has not been deleted and is not an RRV has a control byte of hex 02, which has no particular significance because all data records have RFA VBN pointer sizes of four bytes.
Record ID	Record identifier. This field occupies two bytes.*
RFA	Record file address. This field serves as a record reference pointer if the record is an RRV. The RRV pointer is six bytes long and is composed of the record identifier field and the virtual block number. The VBN portion of the RFA has a fixed size of four bytes, and the record ID occupies two bytes.**
Record length	Size of the record. This 2-byte field is present only for variable-length records and fixed-length records for which either data or key compression is enabled.

* For Prolog 3 files. For Prolog 1 and 2 files, the record ID occupies one byte.

** For Prolog 3 files. For Prolog 1 and 2 files, an RRV occupies five bytes because the record ID is only one byte.

RECORD REFERENCE VECTORS (RRVs) AND BUCKET SPLITS

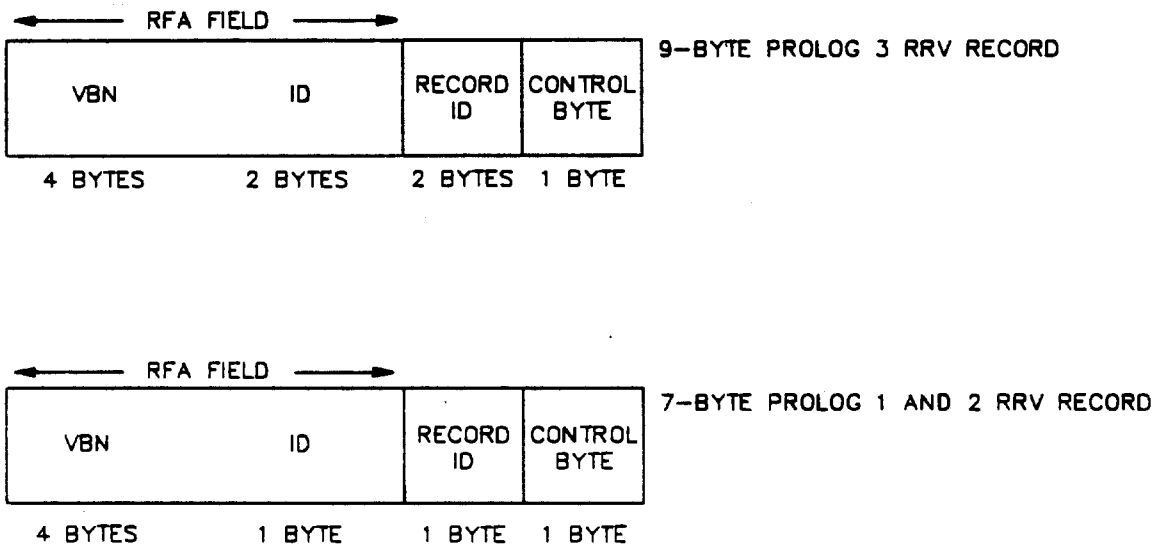
When RMS tries to insert a record into an already full bucket, some of the old records must be moved to a new bucket to make room for the new record. This process is called a bucket split.

When the records are moved out of their original bucket, RMS creates special records in the original bucket that act as pointers to the new bucket to which the records have been moved. These special records are called record reference vectors, or RRVs, and they remain in the bucket in which the records were originally inserted to act as "forwarding addresses."

An RRV is created only when a record is moved for the first time. If the record has been moved before, an RRV is not created; RMS finds the RRV in the record's original bucket and updates it with the record's new address. Even in a worst-case situation where a record has been moved many times, RMS can find the record with its RRV with only one level of indirection.

RRV records are nine bytes long in Prolog 3 files and seven bytes long in Prolog 1 or 2 files. Every data record contains an RFA portion consisting of a 1- or 2-byte record ID and a 4-byte VBN. Initially, the record ID refers to itself (that is, it contains a copy of the preceding field, the record's own ID) and the VBN is the virtual block number of the bucket in which the record is currently located.

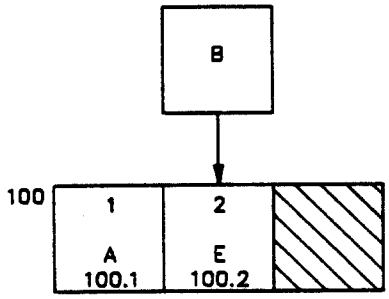
Formats of RRV Records



Simple Bucket Splits

Example 1. Simple Bucket Split

Record B is Added to the File

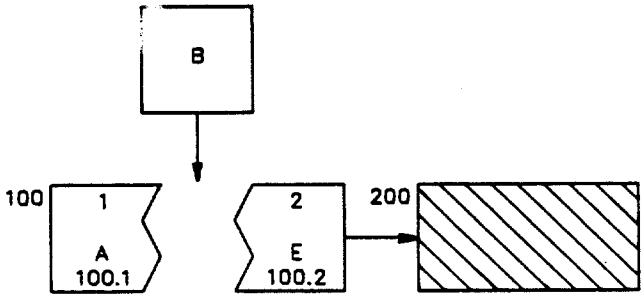


VBN = 100
Rec ID = 1, 2

BU-2439

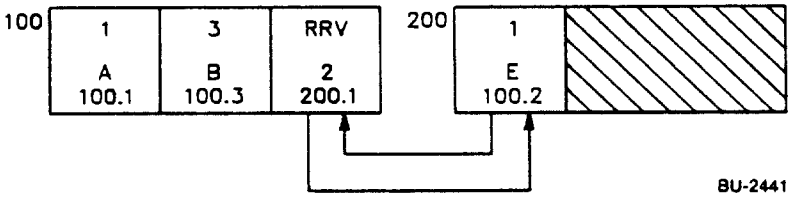
In general, RMS tries to keep about half of the records in the original bucket and move the others to a new bucket, with the bucket with the most space available containing the most data after the split.

Record B Causes a Bucket Split



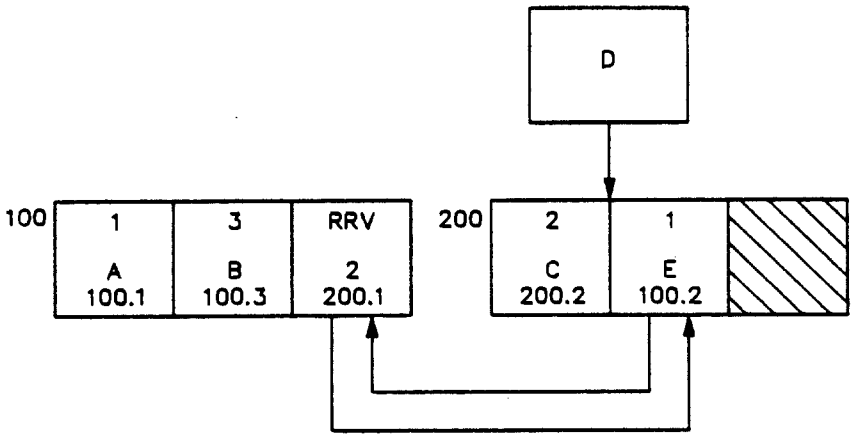
BU-2440

Record E is Moved



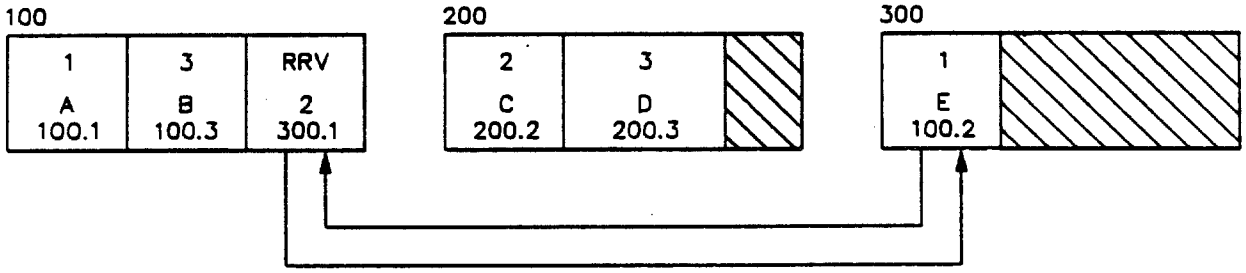
BU-2441

Records C and D are Added to the File



BU-2442

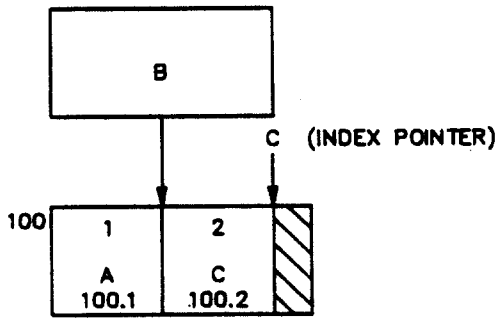
Record E is Moved to a New Bucket



BU-2443

Example 2. Multibucket Split

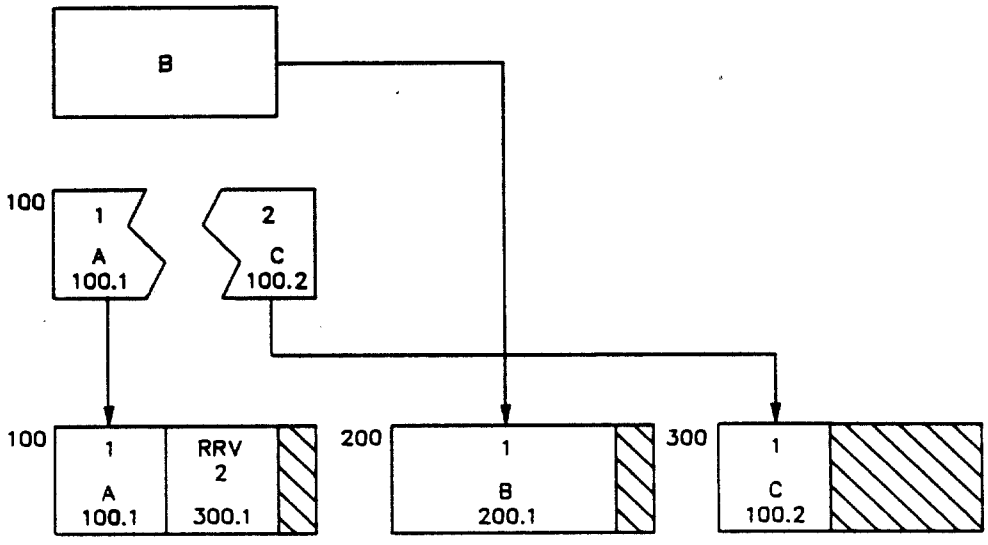
Record B is Added to the File



BU-2444

To resolve this situation, a multibucket split must take place. The existing bucket containing records A and C is split. Two new buckets are created; record B is moved into the middle bucket, and record C is moved from the old bucket into the last bucket.

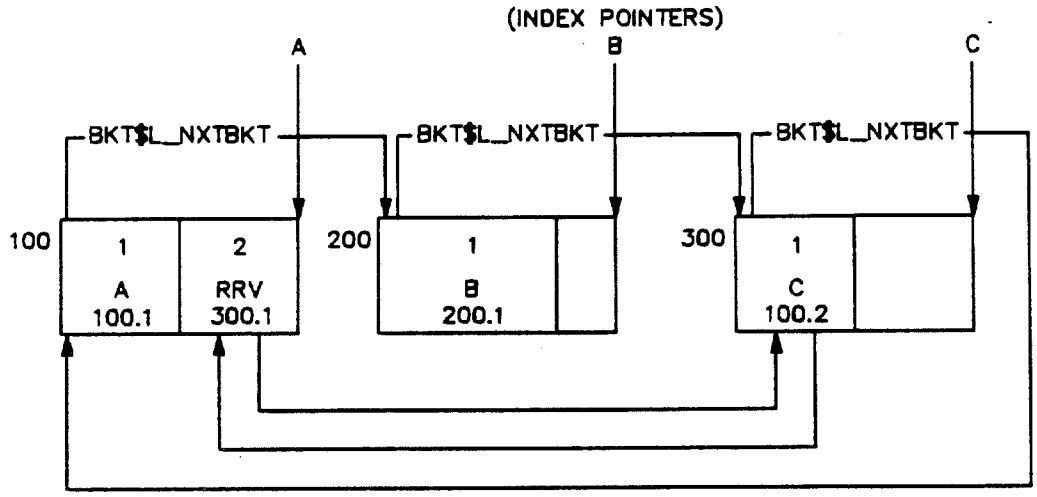
A Multibucket Split Occurs



BU-2445

An RRV record is created in the old bucket to point to the new location of record C, and record C points back to its original location. The next-bucket pointers are also updated. The last bucket in the chain points back to the first bucket.

The Bucket Structure and Index are Updated



The index structure is also updated. The index pointer to the left bucket still points to VBN 100, but its key value now becomes A. Two new index records have to be created as a result of the split. First, an index pointer with key value B must be created to point to VBN 200. A pointer with key value C must be created to point to VBN 300.

Bucket Splits with Duplicate Records

If duplicate records are involved, bucket splits can become even more complicated. When duplicate records occupy more than one bucket, the overflow buckets are called continuation buckets. RMS tries to keep duplicates together when buckets are split.

Continuation buckets do not have a pointer to the index. There is an index pointer to the first bucket only, and RMS must follow the horizontal data bucket links contained in the BKT$L_NXTBKT field to find any continuation buckets.

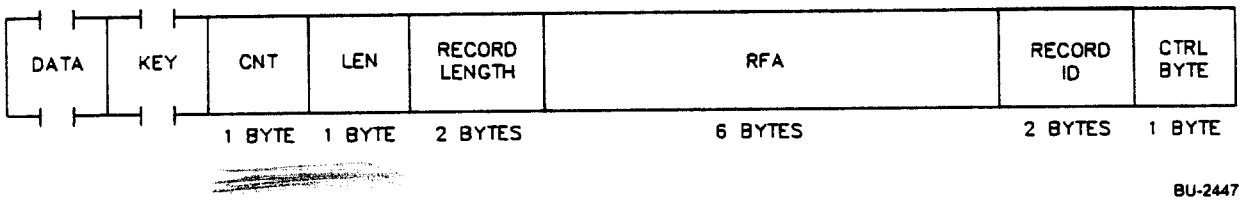
KEY AND DATA COMPRESSION (PROLOG 3)

Compression of data and the primary key is allowed for Prolog 3 data records.

Primary Key Compression

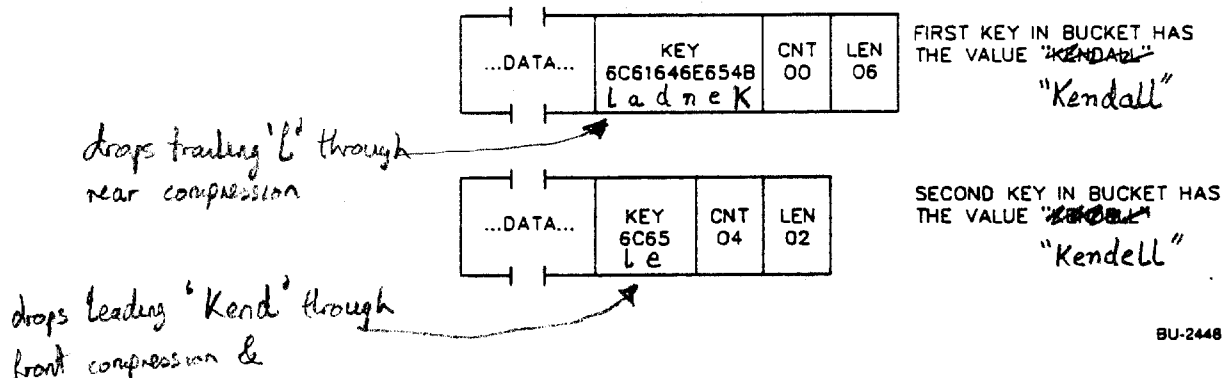
The primary key can be compressed if it is the string data type and at least six bytes long. The overhead is two bytes: a 1-byte key length field and a 1-byte front compression count. RMS allows both front and rear compression. Front compression suppresses leading characters that the key has in common with the previous key. Rear compression suppresses repeating trailing characters.

Format of a Compressed Data Record



Field Name	Description
Record length	Size of the record after compression. This field is two bytes long.
Len	Length of the key with compression. This 1-byte field gives the length of the key as it is stored on the disk. This value allows for the truncation of repeating end characters (rear compression) because the true length of the key may be obtained from the key descriptor. Any difference in size not accounted for by the front compression is due to the rear compression. The last character in the key is the character compressed. This length does not include the count field.
Cnt	Count of the front bytes with compression. This field contains the number of front characters the key has in common with the previous key; the first key in a bucket is always fully expanded although repeating characters at the end of the key are truncated.

Example 3. Two Data Records with Key Compression



The following table shows a longer example of key compression. The first column shows the original(uncompressed) keys of the file. The second and third columns show the length and count fields after compression. The fourth column shows the resulting compressed key.

	After Compression		
Original Key	Length	Count	Compressed Key
Barren*	7	0	Barren*
Barret*	2	5	t*
Barrett	1	6	t
Barron*	3	4	on*
Benson*	6	1	enson*

Total Length = LEN + CNT + X

- LEN: # bytes physically stored
- CNT: # bytes front compressed
- X: # bytes rear compressed

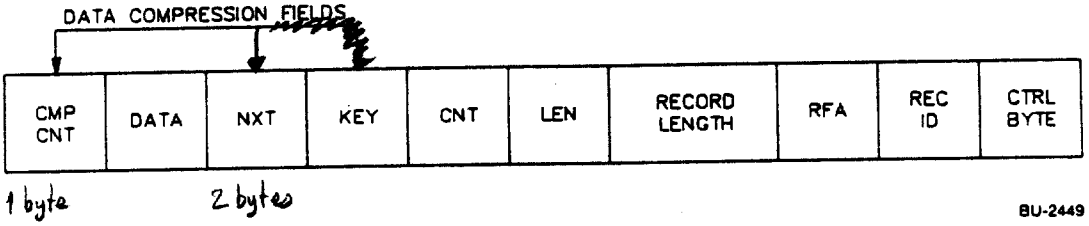
X = Total Length - (LEN + CNT)

X: # bytes rear end compressed

Data Compression — typically string but others allowed

The data portion of a data record can also be compressed if the sequence of repeating characters is five or more characters. The overhead required for this type of compression is three bytes. The compression control information is stored within the data instead of in the record header.

Format of a Data Record with Compressed Data

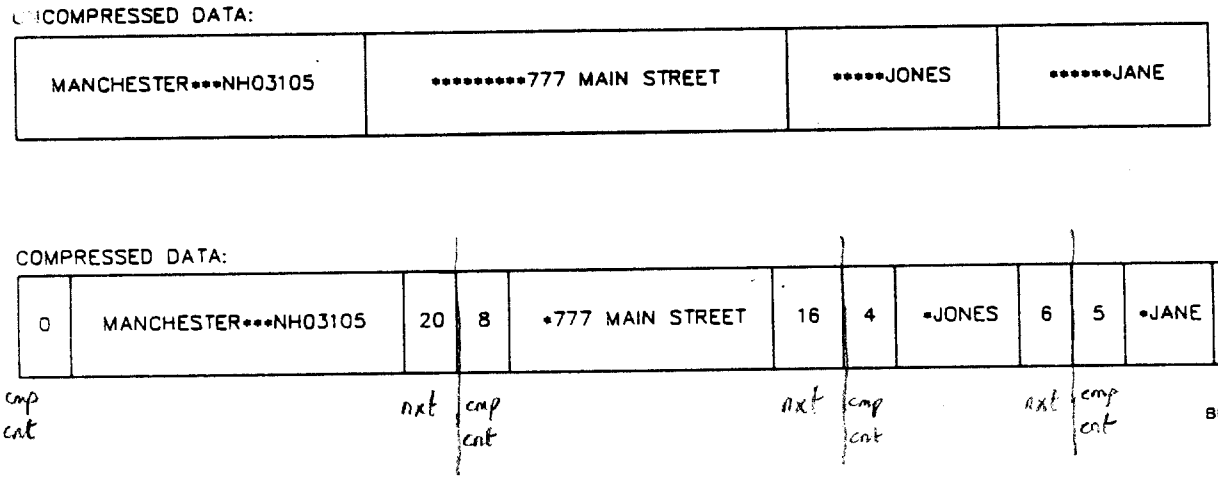


The nxt field is a count of characters in the data field that follows it. It occupies one word. If no repeating characters were found in the data section and no characters were compressed, this field contains the size of the whole data field.

The cmp cnt field is a count of the characters that were compressed. It is 1 byte long. If no characters were compressed, the cmp cnt field contains a value of 0.

Example 4 shows how a 66-byte record with repeating sequences within the data portion compressed to a 59-byte record. Note that the fields (but not the characters) of the record run right-to-left.

Example 4. Compressed Data Record



INDEX BUCKET

The index of an ISAM file is structured as a balanced tree. The buckets of the index structure are the nodes of the tree. Each bucket contains a logical range of key values.

Index buckets generally resemble one another, regardless of their position in the index. The value in the BKT$B_INDEXNO field reflects which key of reference the index bucket belongs to, where a value of 0 indicates the primary key, a 1 indicates the first alternate key, a 2 indicates the second, and so on.

Prolog 1 and 2 buckets generally resemble Prolog 3 buckets. Two differences are that the BKT$B_AREANO field becomes the BKT$B_INDEXNO field for Prolog 3 files and the BKT$W_NXTRECID field is a byte, not a word.

The value in the BKT$B_LEVEL field reflects the bucket's position in the index, where 1 indicates the lowest level of the index (the level above the data). The data level of the index is always level 0, and the root level is always the highest level.

Each level of the index is horizontally linked by the next bucket pointers. The linked list is circular because the last bucket (its address is contained in the BKT$L_NXTBKT field) points back to the first bucket. The BKT$V_LASTBKT flag is set in the last bucket to indicate that it is the last bucket in the chain and that the next bucket in the chain will be the first.

For all three prolog versions, RMS saves index bucket space by using the smallest possible field size to represent the VBN pointer of a bucket. For Prolog 3 files, however, all VBN pointers in a particular index bucket are the same size, which is the length of the largest pointer in the bucket.

Bits 3 and 4 of the bucket control byte (BKT$B_BKTCB) indicate the pointer size for a Prolog 3 index bucket. The following table shows the bit patterns and their meanings.

Bits	Meaning
00	2-byte pointers. Three bytes for Prolog 1 and 2.
01	3-byte pointers. Four bytes for Prolog 1 and 2.
10	4-byte pointers. Five bytes for Prolog 1 and 2.

Index Record Format

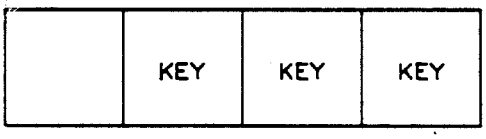
Index records for the primary key and for the upper-level alternate indexes have the same format. However, the format depends on the prolog version of the file; index records for Prolog 1 and 2 files differ from Prolog 3 files.

Prolog 3 index records have two parts: the key and the VBN pointer. They have no overhead. Keys are stored in either ascending or descending order starting at the beginning of the record storage area of the bucket. The associated VBN pointers are stored after the keys at the end of the used portion of the record storage area. In other words, the keys and the VBNs are at opposite ends of the bucket; RMS does not consider the VBN pointer to be part of the index record.

The key part of the index record includes the key and control information needed to describe the key. The key represents the highest possible key value in the bucket pointed to by the bucket pointer in the record. When RMS performs an index search, it follows the first path for which the search key is less than or equal to the key value stored in the index record. Index records may be either fixed- or variable-length.

Fixed-length index records are used for keys that have not been compressed. These records have no control information, and each key is the same length.

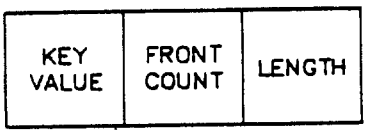
Format of the Key Part of a Fixed-Length Index Record



BU-2451

Variable-length index records are used for keys that have been compressed. All variable index records have count fields to represent the front and rear compression.

Format of the Key Part of a Variable-Length Index Record With Compression



BU-2452

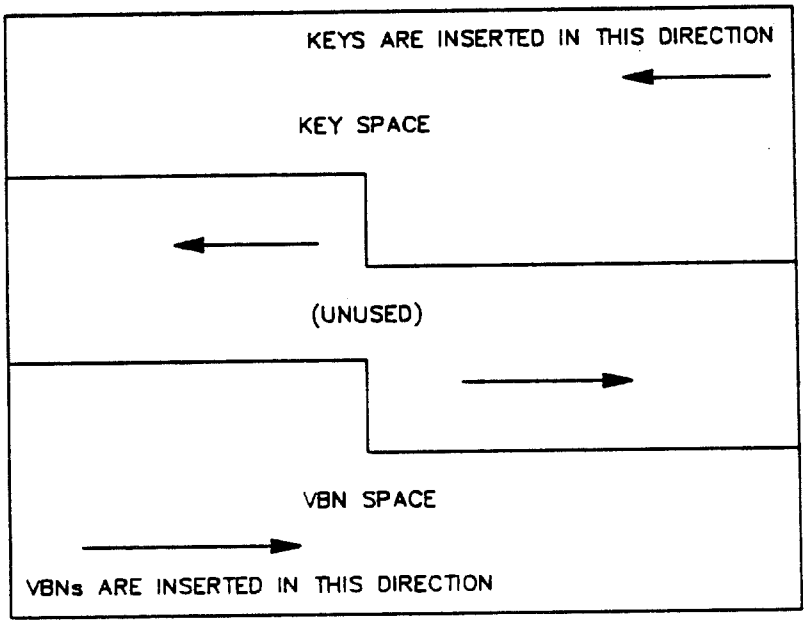
The length field contains the number of characters in the key value, including the compressed characters if index key compression is enabled. The front count field contains the number of leading characters that were compressed.

The VBN pointer associated with each index record is stored at the end of the index bucket. The size of all the VBN pointers within a bucket is the same, but it may vary from bucket to bucket. There is no overhead associated with the VBN pointer list.

In a Prolog 3 index bucket with uncompressed keys, the VBN pointer for the first key of the bucket is at the end of the bucket VBN space. As more keys and more VBNs are added to the bucket, they approach one another.

Format of the VBN Pointer List

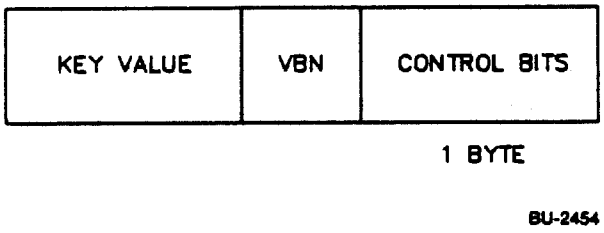
May be fixed length or variable length keys (latter only applies if index compression is used)



BU-2453

Prolog 1 and 2 records cannot be compressed. Therefore, the format of index records for the primary key and the upper-level alternate indexes for these files are identical.

Format of a Prolog 1 or 2 Index Record



The first field contains index record control bits and a pointer size. It is a 1-byte bit-encoded field. Bits 0 and 1 represent the VBN pointer size. The following table shows the bit patterns and their meanings.

Bits	Meaning
00	2-byte pointer size
01	3-byte pointer size
10	4-byte pointer size

The second field is a variable-byte bucket pointer containing the virtual block number of associated data bucket.

The third field is a variable-byte key value representing the highest key value in the corresponding data bucket.

INDEX COMPRESSION

Index records, like data records, can be compressed to save space in the file. Index compression is done exactly like data key compression. RMS compresses both repeating leading and trailing characters by default, as well as character strings with a length greater than six characters.

With front compression, all the leading characters in the key of an index record that are the same as those in the key of the preceding record are suppressed. This type of compression is particularly useful at the lowest levels of the index where many keys may start with the same characters. RMS performs no front compression on the first record in a bucket; it is fully expanded except for the suppression of repeating trailing characters. On all other keys, a field in the key overhead contains the front compression count.

With rear compression, RMS suppresses repeating trailing characters in the key. A key length field is used to determine the number of characters truncated. When the key is expanded, RMS gets the fixed-length of the key from the appropriate key descriptor.

The following table shows the index key compression of a lower-level index, where many of the keys begin and end with identical characters. The length of the string keys is fixed at eleven bytes.

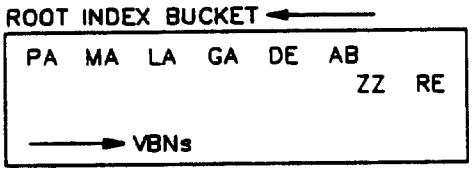
Original Key (Total length = 11)	After Compression Len	Cnt	Rear End	Compressed Key	Description
Barren*****	7	0	4	Barren*	This key is the first, so it is fully expanded except for the truncation of 4 repeating trailing characters. The total length of the key after the truncation is 7 charecters and no leading characters were compressed.
Barret*****	2	5	4	t*	The 5 leading characters of this key were compressed, which reduced the length of the key to 2 characters.
Barrette***	3	6	2	te*	The 6 leading characters of this key were compressed, which reduced the length of the key to 3 characters.
Barron*****	3	4	4	on*	The 4 leading characters of this key were compressed, which reduced the length of the key to 3 characters.
Benson*****	6	1	4	enson*	Only the initial leading character of this key was compressed, which reduced the length of the key to 6 characters.
Johns******	6	0	5	Johns*	This key has no characters in common with the preceeding key, so it is fully expanded except for the truncation of 5 repeating trailing characters. The total length of the key after the truncation is 5 characters.
Johnson****	3	5	3	on*	The 5 leading characters of this key were compressed, which reduced the length of the key to 3 characters.
Johnston***	4	5	2	ton*	The 5 leading characters of this key were compressed, which reduced the length of the key to 4 characters.
Johnstone**	2	8	1	e*	The 8 leading characters of this key were compressed, which reduced the length of the key to 2 characters.

Can give 30% improvement in CPU but greater overhead in disk I/O

BINARY VERSUS NONBINARY INDEX SEARCH

If index compression has not been enabled, RMS will do a binary search through index buckets for the requested key value, including binary and integer keys. This is why all the VBN pointers in a given index bucket for a Prolog 3 file are the same size.

Example 5. Retrieval of Record With Key Value = RA



BU-2455

1. If index compression is not enabled, a binary search of the index bucket is performed.

   Step

   1) LA | MA

   2) PA | RE

2. If index compression is enabled, a nonbinary search of the index bucket is performed.

	# Comparisons
Binary Search	2
Nonbinary	7

Conclusion

When might you want to enable index compression? Enable index compression if there are large string key values that, if compressed, could cache the whole index tree in memory in, for example, half the space. In this case, consider making the index bucket smaller in order to have more levels in the tree than normal to reduce the CPU time required to do the nonbinary search.

SECONDARY INDEX BUCKETS AND DATA RECORDS (SIDRs)

Secondary Index Bucket Format

The alternate index of a file is very similar in structure to the primary index. The main difference is that instead of containing data records at level 0, alternate indexes contain secondary index data records (SIDRs), which are individual pointers to primary index records with a particular alternate key value.

Alternate index buckets are similar in structure to primary index buckets. The only difference is that alternate index buckets do not have a check byte as the last byte of the bucket.

The bucket overhead of a Prolog 3 SIDR bucket differs from that of a Prolog 1 and 2 SIDR bucket. In the bucket header, the index number (BKT$B_INDEXNO) replaces the area number (BKT$B_AREANO), and the next record ID (BKT$W_NXTRECID) is a word instead of a byte.

Secondary Index Data Record Format

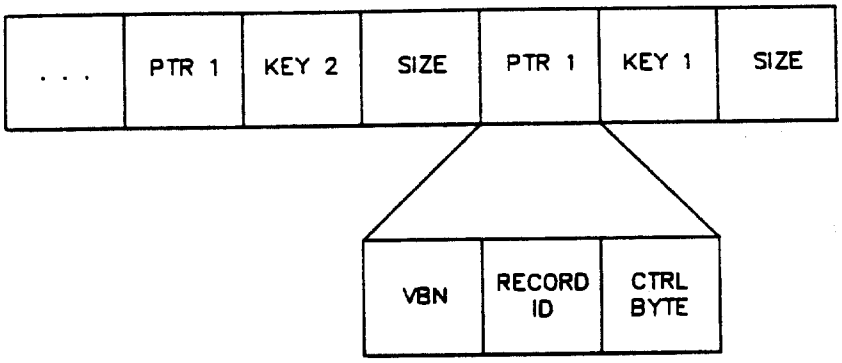
Like the primary index, the alternate index has at least two levels: an upper level containing the actual index entries for that particular key, and a data level.

Upper-level secondary index records for Prolog 1, 2, and 3 files look just like their corresponding upper-level primary index records.

However, instead of data, the lowest level of an alternate index contains a pointer array. This array is a list of pointers called SIDRs, which point back to the data level (level 0) of the primary index. SIDRs consist of a key and an RRV pointer. It is the RRV pointer that actually points back to the primary data record with that secondary key value.

Secondary data index records have a different format in Prolog 3 files than in Prolog 1 and 2 files. Keys may either be compressed or uncompressed, which is specified by the KEYNCMPR option in the key XAB.

Format of Prolog 3 Secondary Index Data Records



BU-2456

The 2-byte field reflects the size in bytes of the whole pointer array.

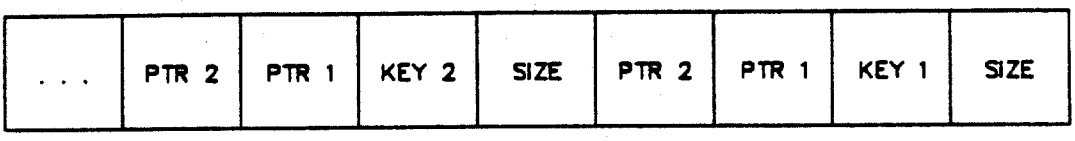
Three bits are defined within the control byte field.

Bit Name	Position	Meaning
DELETED	Bit 2	If set, the record has been deleted.
NOPTRSZE	Bit 4	If set, the record has no RRV, and the SIDR has been deleted.
FIRST_KEY	Bit 7	If set, the record is the first entry for that SIDR.

Like ordinary data records, SIDRs can also have duplicate records. Duplicates for SIDRs mean that more than one pointer exists for the same key value.

SIDR duplicates are not separate records. For each duplicate, another pointer field is appended to the SIDR. The overhead of Prolog 3 SIDRs is fixed whether or not duplicates are allowed. In this example, both key 1 and key 2 have duplicate records.

Format of Prolog 3 Secondary Index Data Records with Duplicates



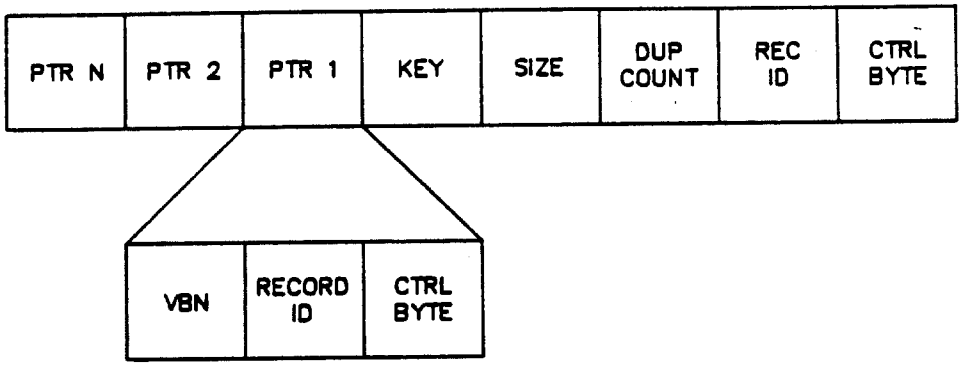
BU-2457

The fields of the record are described in the following table.

Field Name	Description
Size	Size field. This 2-byte field contains the size in bytes of the SIDR array. It reflects the number of bytes between the current SIDR and the next (the number of bytes per SIDR); it does not include itself in the size.
Key	Key field. This field contains the alternate key value. It's length is specified by the user.
Key ptr	Pointer field. This field is the RRV pointer from the alternate key back to the primary key with which it is associated. It is 4 to 7 bytes long and has three parts:
Ctrl byte	The control byte indicates the size of the VBN and has flags that indicate whether the record has been deleted (or is a pointer to a deleted record).
Record ID	This word contains the record ID of the primary data record that contains the given secondary key.
VBN	This field contains the VBN of the bucket where the given primary data record is located. It can range from 2 to 4 bytes long. The combination of the record ID and the VBN forms the RFA of the primary data record that contains the secondary key.

SIDR format for a Prolog 1 or 2 file differs from SIDR format for a Prolog 3 file. Prolog 1 and 2 SIDRs have three fields that Prolog 3 SIDRs do not have: the control byte, the record ID, and the duplicate count. They do not have the Prolog 3 flags field. Also, Prolog 1 and 2 overhead depends on whether duplicates are allowed, which determines whether or not the duplicate count field is present in the record.

Format of Prolog 1 and 2 Secondary Index Data Records with Duplicate Records



BU-2458

Field Name	Description
Ctrl byte	Pointer size and data record control bits. This 1-byte field contains one of two values: 01 The 4-byte duplicates count field is present. 10 There is no duplicates count field. Prolog 3 SIDRs do not have this field.
Rec ID	Record ID. This field is 1 byte long. Prolog 3 SIDRs do not have this field.
Dup count	Duplicates count. This 4-byte field contains the number of duplicate records, unless the value in the control byte field is 10 binary, which indicates this field is not present. Prolog 3 SIDRs do not have this field. It is not supported by VAX/VMS Version 4.4, so it always contains a value of 0.
Size	Size of the rest of the array. This field is 2 bytes long, and the size does not include itself.
Key	Key field. This field contains the alternate key value. It's length is specified by the user.

Field Name	Description
Ptr	Key pointer. This field is the RRV pointer from the alternate key back to the primary key with which it is associated. It is 5 to 7 bytes long and has three parts:
	Cntl byte — Bits 0 and 1 of the control byte indicate the size of the VBN. The following values are defined: 00 — 2 bytes 01 — 3 bytes 10 — 4 bytes Two other bits of the control byte are defined. If bit 2 is set, the record has been deleted. If bit 5 is set, the pointer has been deleted because an Update operation changed the key value.
	Record ID — This byte contains the ID of the primary data record entry.
	VBN — This field contains the VBN of the bucket where the given primary data record is located.
	The pointer field is repeated for every duplicate record.
	If the array continues into another index bucket, everything is repeated, except that the duplicates count is absent; this absence is reflected in the data record control bits.

Compression

As in the primary index, keys may also be compressed in the secondary index. The two bytes at the front of the key field indicate the key length and number of characters that were compressed at the front of the key.

PART 2. SIMULATED DATA EXAMPLE

Bucket = 1 block (all areas)

Record = Fixed-length 112 (no compression)

Bytes

0 - 109	Name	Primary index
110 - 111	Seq_No	Alternate index

Example 1 is a step-by-step illustration of an indexed file. Eleven records are entered in random order as follows:

Order of Entry

1 RAKOS

2 ASHE

3 TODD

4 JONES

5 VAIL

6 BUSH

7 EVANS

8 SACK

9 MAYO

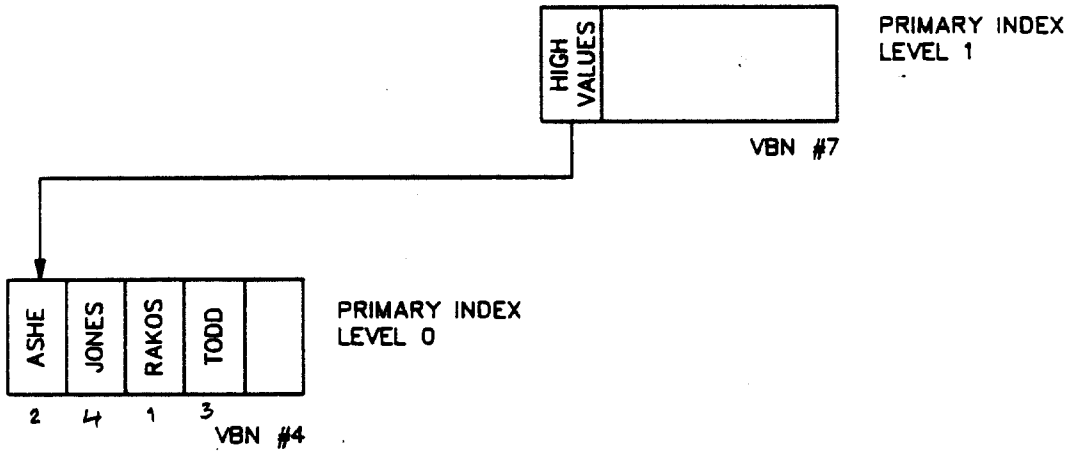
10 WOODS

11 SMITH

Bucket will contain: 14 bytes bucket header
1 byte checksum
4 * { 9 bytes record header
112 bytes data
~~112 bytes key~~
~~5047~~

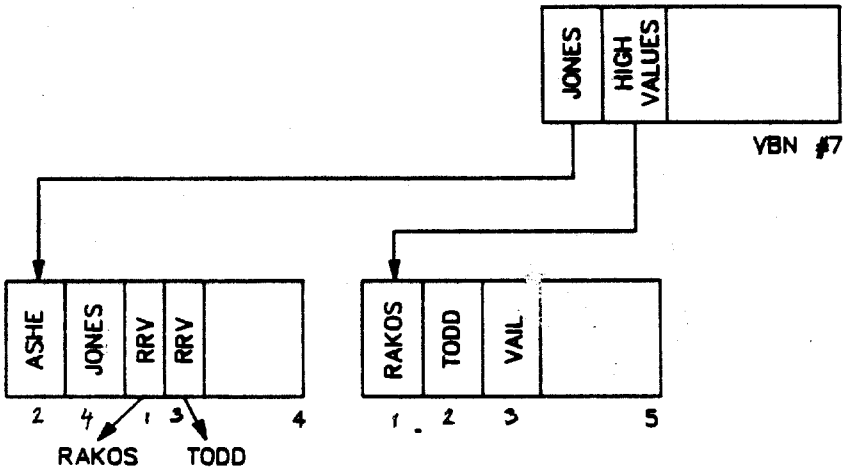
Example 1. Entering Data Records into a New Indexed File in Random Order from Program Control

Indexed File After Four Records Added



BU-2459

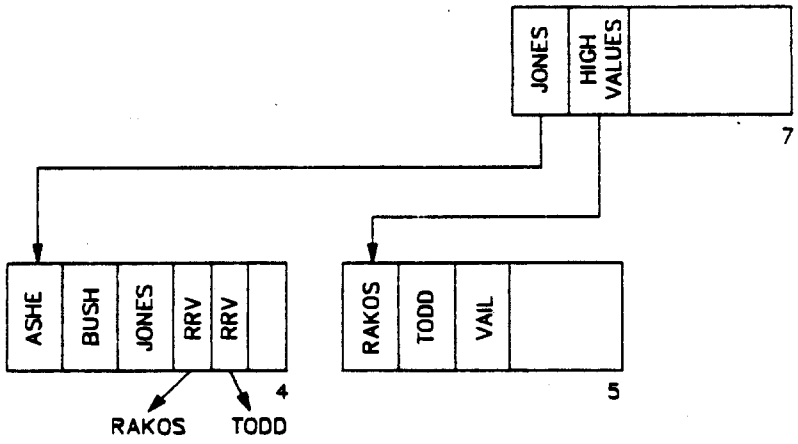
VAIL Inserted



BU-2460

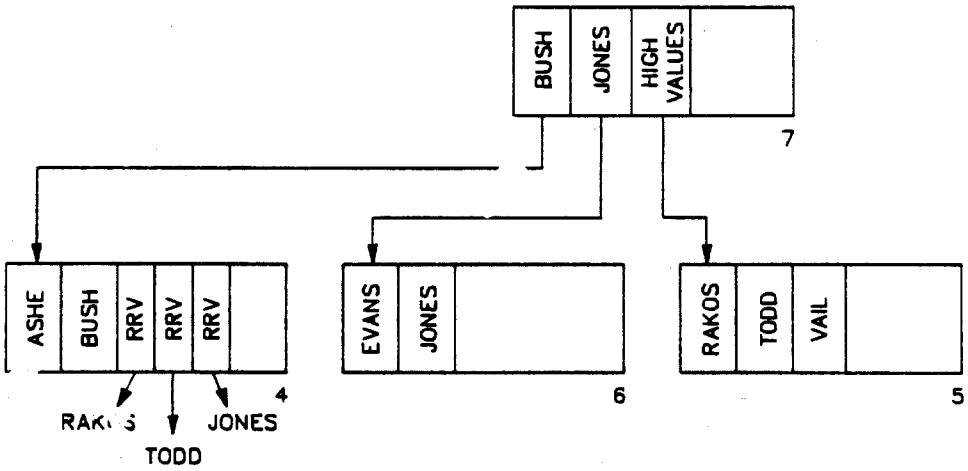
Split occurs because records not added in sorted order (RMS bases this on order of last two records in bucket)

BUSH Inserted



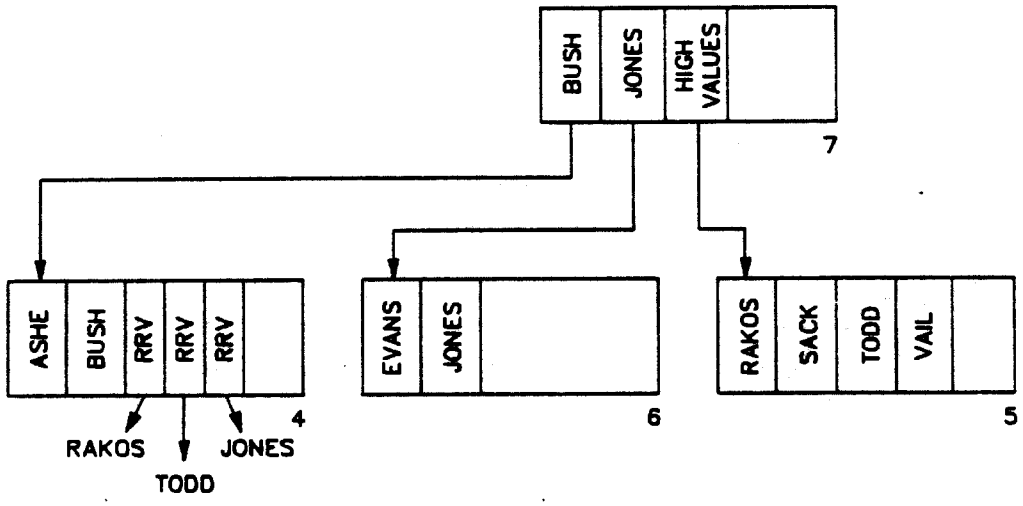
BU-2461

EVANS Inserted



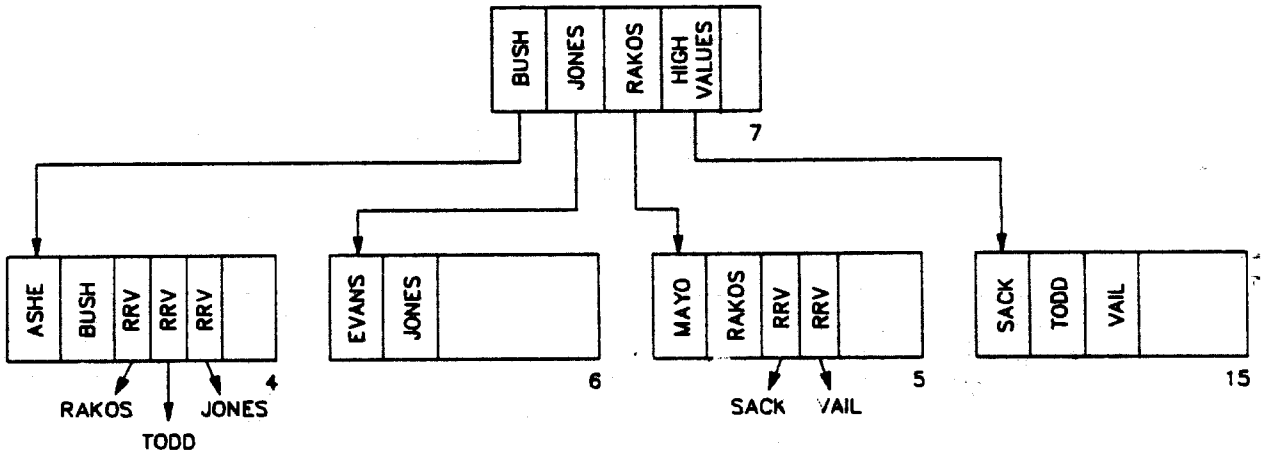
BU-2462

SACK Inserted



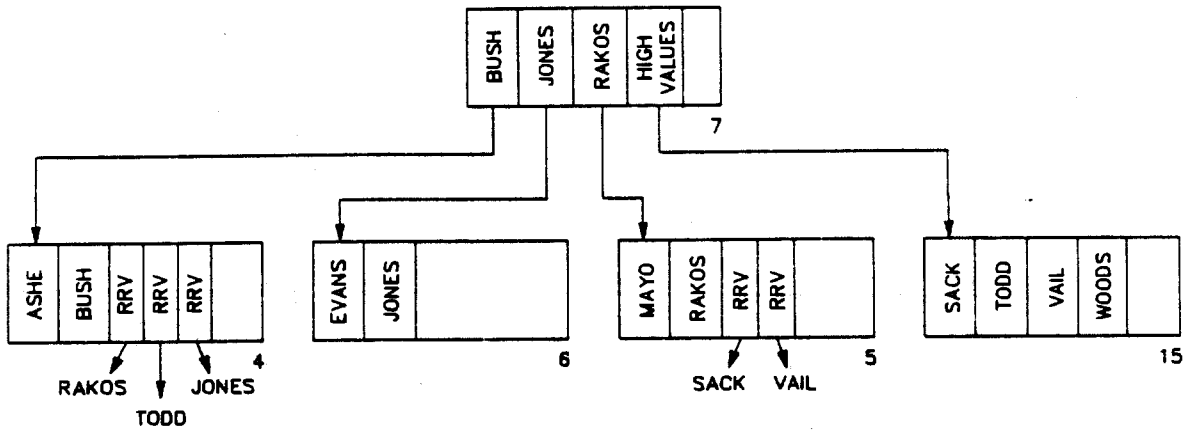
BU-2463

MAYO Inserted



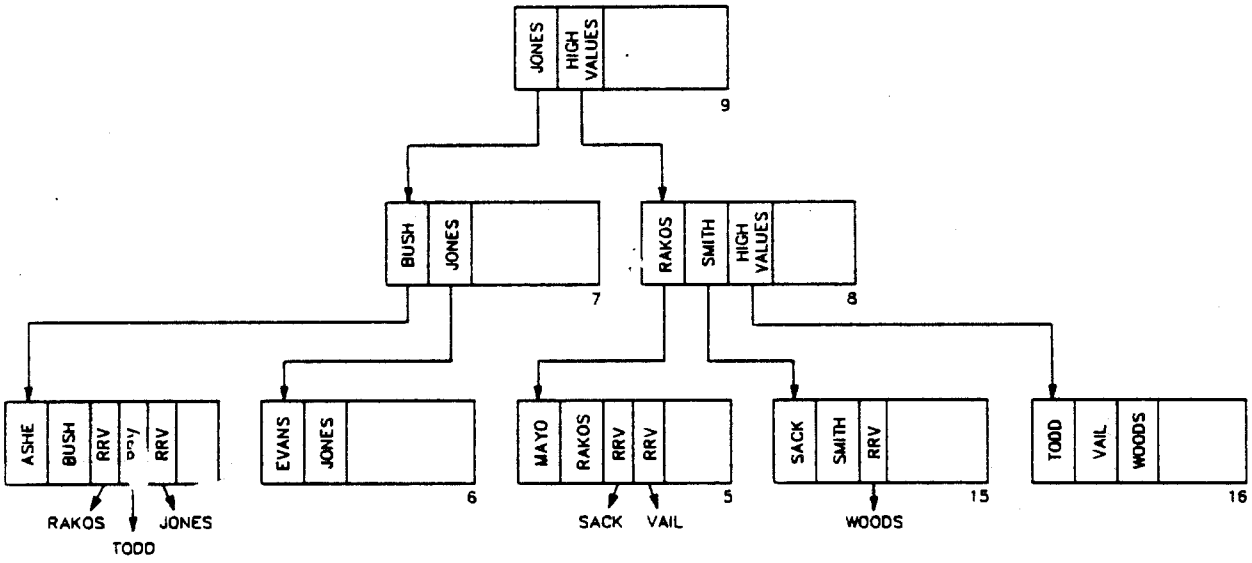
BU-2464

WOODS Inserted



BU-2465

SMITH Inserted



BU-2466

If the eleven records in Example 1 had been entered sorted in the order of the primary key, the indexed file organization at the end of the data load would have been:

	Random Data Entry	Sorted* Data Entry
# Index Levels	2	1
# Index Buckets - Primary	3	1
# Data Buckets - Primary	5	3
# RRVs	5	0

* Sorted in order of primary key of reference

Example 2. Statistics Produced by ANALYZE for the Indexed File Created in Example 1

PART 3. INTRODUCTION

Analyzing File Structure

ANALYZE/RMS_FILE

- Produces a statistical report on the file structure

  $ ANALYZE/RMS_FILE/STATISTICS file-spec

- Produces a summary report containing file structure information

  $ ANALYZE/RMS_FILE/SUMMARY file-spec

- Produces a summary of the file structure and checks its integrity

  $ ANALYZE/RMS_FILE/CHECK file-spec

  This option will be covered in Module 17, Data Recovery.

- Allows you to explore the structure of a file interactively. For example, in an indexed file you can follow the whole path from prolog block 1 down to a data record, using any index, and dumping any buckets you want on the way down.

  $ ANALYZE/RMS_FILE/INTERACTIVE file-spec

  This option will be covered in Module 16, RMS Utilities (Part 6).

- ANALYZE/RMS FILE/FDL can be used to create an FDL file from an existing data file.

NOTE

Use the following qualifier for output to be copied to a file rather than to be sent to the SYS$OUTPUT default.

/OUTPUT=file-spec

Measuring Run-Time Performance

The five available statistics for measuring run-time performance are listed below.

Shown on line	Description
ELAPSED = hhhh:mm:ss.cc	Elapsed real time
CPU = hhhh:mm:ss.cc	Elapsed CPU time
BUFIO = nnnn	Count of buffered I/O operations
DIRIO = nnnn	Count of direct I/O operations
PAGEFAULTS = nnnn	Count of page faults

LIB$SHOW_TIMER returns the times and counts accumulated since the last call to LIB$INIT_TIMER. By default, when neither code nor action-rtn is specified in the call, LIB$SHOW_TIMER writes to SYS$OUTPUT a line giving the information listed above.

LIB$STAT_TIMER returns to its caller one of five available statistics. Unlike LIB$SHOW_TIMER, which formats the values for output, LIB$STAT_TIMER returns the value as an unsigned longword or quadword.

The elapsed time is returned in the system quadword format. Therefore, the receiving area should be eight bytes long. All other returned values are longwords.

The following summary illustrates the differences between LIB$SHOW_TIMER and LIB$STAT_TIMER.

Code	Statistic	Format for LIB$SHOW_TIMER	Format for LIB$STAT_TIMER
1	Elapsed real time	hhhh:mm:ss.cc	Quadword in system time format
2	Elapsed CPU time	hhhh:mm:ss.cc	Longword in 10-millisecond increments
3	Count of buffered I/O operations	nnnn	Longword
4	Count of direct I/O operations	nnnn	Longword
5	Count of page faults	nnnn	Longword

Example 1. Measuring Performance with RTL Routines

This example illustrates the use of Run-Time Library routines to measure the performance of a program. The routines are used to collect and display information on the resource usage of the program.

BASIC

- The call to LIB$INIT_TIMER stores the current values of the program statistics to be measured. Since no storage block was specified, the values are kept in storage space maintained by the RTL routines.
- Initializing the array consumes system resources.
- The call to LIB$SHOW_TIMER obtains the accumulated times and counts since the call to LIB$INIT_TIMER. Because no code or action-routine has been specified, the statistics are output to the terminal in ASCII format.

Example 1 (Sheet 1 of 5)

```
 1      10 !                                                    LIBTIMER.BAS
 2         !
 3         !        This program illustrates the use of the RTL
 4         !        performance measurement routines.
 5         !
 6          EXTERNAL LONG FUNCTION LIB$INIT_TIMER, LIB$SHOW_TIMER
 7          DECLARE LONG result, j, k
 8          DIMENSION  LONG iarray (99%, 99%)
 9         !
10          result = LIB$INIT_TIMER()
11          CALL LIB$STOP (result BY VALUE) IF (result AND 1%)=0%
12         !
13         !        Initialize the array
14          FOR k = 0% TO 99% STEP 1%
15              FOR j = 0% to 99% STEP 1%
16                  iarray (j,k) = 1%
17              NEXT j
18          NEXT k
19         !
20          result = LIB$SHOW_TIMER()
21          PRINT 'Usage values after array initialization'
22          CALL LIB$STOP (result BY VALUE) IF (result AND 1%)=0%
23         !
24          END

$ BASIC LIBTIMER

MODULE 7
FILE SHARING AND RECORD/BUCKET LOCKING: SEQUENTIAL, RELATIVE, AND INDEXED FILES

Major Topics

- File sharing
- Record locking
- Alternative record locking controlling options

Source

Guide to VAX/VMS File Applications — Chapter 7 (Sections 7.1-7.2)

FILE SHARING

File sharing for READs (GETs) is supported for all RMS file organizations without restriction.

As of VAX/VMS Version 4.4, WRITE (PUTs, UPDATEs, DELETEs) sharing is also supported for all RMS file organizations without restriction. Prior to Version 4.4, write sharing for sequential files was restricted to fixed-length 512-byte records.

The combination of values specified for file sharing and file access by the initial accessor of the file determines the type of file access that will be allowed for subsequent users. In addition to the comparison of the file access values that subsequent accessors specify with the file sharing values of the initial accessor, the values specified for file sharing by subsequent accessors must be compatible with the values specified for file access by the initial accessor.

Initial File Access and Subsequent File Sharing

Initial Accessor Access	Subsequent Accessor Sharing
ACCESS GET*	SHARING GET*
ACCESS DELETE	SHARING DELETE
ACCESS PUT	SHARING PUT
ACCESS UPDATE	SHARING UPDATE
ACCESS TRUNCATE**	No access allowed

* May be implied by default
** Specifying ACCESS TRUNCATE disables file sharing

Because the initial accessor can specify multiple access values, a subsequent accessor whose sharing values match all of the initial accessor's access values is allowed access; when the subsequent accessor specifies a sharing value that the initial accessor did not specify as an access value (an exception is ACCESS GET, which is implied), access will be denied.

File Access and Sharing Options

	File Access Open Keywords	File Sharing Open Keywords
BASIC	ACCESS	ALLOW
	READ	READ
	WRITE	WRITE (locks against delete or scratch)
	MODIFY	MODIFY (unlimited access)
	SCRATCH	
	APPEND (sequential)	NONE
	DEFAULT - MODIFY	DEFAULT If access READ - READ and other access - NONE
COBOL		ALLOWING
	INPUT	READERS
	OUTPUT	WRITERS
	EXTEND	UPDATERS
	I-O	ALL
		NO OTHERS
	DEFAULT No default - must specify one of above keywords.	DEFAULT If input - READERS all other modes - NO OTHERS
FORTRAN	READ ONLY	SHARED
	DEFAULT If above keyword not present in OPEN - read-write	DEFAULT If above keyword omitted, no sharing
PASCAL	History	Sharing
	OLD	READONLY
	NEW	READWRITE
	UNKNOWN	
	READONLY	NONE
	DEFAULT - NEW (except if external file opened using RESET or EXTEND - OLD)	DEFAULT If History = READONLY - READONLY If History ≠ READONLY - NONE

```

RECORD LOCKING

RMS provides a record-locking capability for relative files, indexed files, and sequential files. This capability affords control over operations when two or more streams or processes are accessing the file simultaneously. Record locking ensures that when a program is adding, deleting, or modifying a record on a given stream, another stream or process cannot access the same record.

Shared sequential files have one capability not common to shared relative or indexed files. This capability is associated with Append operations. If more than one process is connected to the end-of-file of a shared sequential file and is sequentially putting records to the end of the file, RMS guarantees the records will be appended in temporal order, even in a VAXcluster environment.

To prevent simultaneous updates of the same records, RMS uses the VAX/VMS lock manager to lock a record that has been read and will be modified later by the same program.

Whether or not record locking can occur on a file depends on the file access and file sharing specified by the initial accessor and whether another user has successfully opened the file for shared access.

- RMS automatically locks records when one or more of the processes with SHARED FILE ACCESS has opened the file for access other than read (for example, WRITE/PUT, MODIFY/UPDATE, DELETE).

- RMS handles automatic locking of an entire bucket for the short period of time required to access the record initially. This automatic locking also occurs later when the contents of the bucket are modified. In the interim, the record remains locked, but other records in the bucket can be accessed and modified as required. See Appendix A for a summary of the specific points in RMS-coded instructions for index files when locking is done at record, bucket, or f le level.

- In the case of shared sequential files, buck t locking is done on a 'virtual' bucket, the size of which is determined by the first accessor's multiblock count (MBC). A common buffer size has to be found to be used over all the processes sharing access to a particular file. Since there is nothing in the file header for a sequential file which could be used for this purpose, it is set equal to the first accessor's MBC. The typical system default for MBC is 16 blocks. When VMS 4.4 and 4.3 act as partners in accessing a shared sequential file on a VAXcluster, a multiblock count of one will be assumed by RMS.

NOTE

Shared sequential files may not be used in a VAXcluster environment in which VMS 4.2 or earlier is being run on any of the nodes. They may be accessed concurrently from nodes running VMS 4.3 and any other node running VMS 4.4 on the same cluster, but for this purpose VMS 4.4 will operate in a 4.3 fallback mode.

- The default RMS record locking actions can be modified to varying extents on a per operation basis, as described in the next section.

- Records can be locked automatically or manually. RMS handles automatic record locking transparently. The default is automatic record locking, which is appropriate when you are dealing with a lock on a single record at a time. Manual record locking requires additional effort on the programmer's part. Use it when dealing with locks on multiple records at one time.

Automatic Record Locking (RMS Default)

For a process which opened the file specifying WRITE ACCESS, each GET or FIND operation locks a record. RMS assumes an UPDATE or DELETE operation may follow. Lock is released when:

- the next record is accessed (FIND, GET or PUT),
- the current record is updated or deleted,
- an I/O error occurs,
- the record stream is disconnected,
- the file is closed, or
- a Free or Release service (or its equivalent) is called.

For a process which opened the file specifying READONLY access but sharing WRITE, each read (GET or FIND) operation will still incur some locking activities but to a lesser extent than if the process had specified WRITE access. A query lock will be used for each read operation. The query lock is briefly taken out in order to find out whether the record is locked against the process, and is then immediately released.* The query lock call to the lock manager requests "concurrent read" access rather than "exclusive" access.

* The only case in which a readonly process will hold onto a record lock is if the special locking option RAB$V_REA was set in the RAB$L_ROP field (see the next section).

Manual Record Unlocking

When enabled, any record that would have automatically been unlocked will remain locked until:

- a Free or Release service is called,
- the record stream is disconnected, or
- the file is closed.

Some examples of when manual control over unlocking of records may be useful are as follows:

- Multiple records must be modified in a single transaction. The programmer does not want any of the updates to be done unless all the updates are successfully completed. The programmer is responsible for restoring the original contents of any record already updated if the update for any other record within the transaction is unsuccessful.
- While the updates are being done to several related records, the programmer does not want a other user to be able to access any of the records in the related set.

There are three ways manual record unlocking can be enabled.

1. Set option directly in RAB$L_ROP.

```
   $V
RAB$M_ULK
```

2. Set FDL CONNECT MANUAL_UNLOCKING and call FDL$PARSE within the program before opening the file.

3. Some higher-level languages have a keyword available in the OPEN statement to set this option.

BASIC - UNLOCK EXPLICIT

COBOL - I-O CONTROL
LOCK-HOLDING

FORTRAN - N/A

PASCAL - N/A

MACRO - RAB$L_ROP = RAB$V_ULK

ALTERNATIVE RECORD LOCKING CONTROLLING OPTIONS

There are several record locking options available that can be set in the RAB$L_RDP field (or its FDL equivalent). These provide the user with varying degrees of control over the default RMS record locking actions.

As described above for the readonly/sharing write case, none of these special record locking options will turn off completely record locking activities. There is no way to avoid RMS calls to the lock manager to request a lock and then release it. The locking control these options provide is that they can cut down the length of time a lock will be held, and the access mode requested of the lock manager. As described for the readonly process in the previous section, a query lock will be briefly taken out and then released for any of these special locking options. Even if the NLK (do not lock records) option is enabled, a query lock is requested in order to find out whether the record is locked against the process.

RAB$V_NLK
Do not lock record; specifies that the record accessed through a Get or Find service is not to be locked. The RAB$V_NLK option takes precedence over the RAB$V_ULK option.

This option corresponds to the FDL attribute CONNECT NOLOCK.

RAB$V_NXR
Nonexistent record processing; specifies that if the record randomly accessed through a Get or Find service does not exist (was never inserted into the file or was deleted), the service is to be performed anyway. This option applies to relative files only. For a Get service, the previous contents of a deleted record are returned. The processing of a deleted record returns a completion status code of RMS$_OK_DEL, and the processing of a record that never existed returns RMS$_OK_RNF.

This option corresponds to the FDL attribute CONNECT NONEXISTENT_RECORD.

RAB$V_REA
Lock record for read; specifies that the record is to be locked for a read operation for this process, while allowing other accessors to read (but not to modify) the record. Use this option only when you do not want the file to be modified by any subsequent activities. Use the RAB$V_RLK option to allow possible subsequent modification of the file.

This option corresponds to the FDL attribute CONNECT LOCK_ON_READ.

RAB$V_RLK
Lock record for write; specifies that a user who locks a record for modification is allowing the locked record to be read by other accessors. If both RAB$V_RLK and RAB$V_REA bits are specified, the RAB$V_REA bit is ignored. The RAB$V_NLK bit takes precedence

over all others.

This option corresponds to the FDL attribute CONNECT LOCK_ON_WRITE.

RAB$V_RRL
Read regardless of lock; read the record even if another stream has locked the record. This option allows the reader some control over access. If a record is locked against all access and if a Put or Get service is requested, then the record will be returned anyway (if the RAB$V_RRL option is specified), with the alternate status RMS$_OK_RRL.

This option corresponds to the FDL attribute CONNECT READ_REGARDLESS.

RAB$V_TMO
Timeout; specifies that if the RAB$V_WAT option was specified, the RAB$B_TMO field contains the maximum time value, in seconds, to be allowed for a record input wait caused by a locked record. If the timeout period expires and the record is still locked, RMS will abort the record operation with the RMS$_TMO completion status. Note that the maximum time allowed for a timeout is 255 seconds. Other functions of the RAB$V_TMO option are listed under "Miscellaneous Options."

This option corresponds to the FDL attribute CONNECT TIMEOUT_ENABLE.

This option is not supported for DECnet operations; it is ignored.

RAB$V_ULK
Manual unlocking; specifies that RMS will not automatically unlock records. Instead, once locked (through a Get, Find or Put service), a record must be specifically unlocked by a Free or Release service. The RAB$V_NLK option takes precedence over the RAB$V_ULK option.

This option corresponds to the FDL attribute CONNECT MANUAL_UNLOCKING.

RAB$V_WAT
Wait; if the record is currently locked by another stream, wait until it is available. This option may be used with the RAB$V_TMO option to limit waiting periods to a specified time interval.

This option corresponds to the FDL attribute CONNECT WAIT_FOR_RECORD.

MODULE 8
BUFFER MANAGEMENT: SEQUENTIAL, RELATIVE, AND INDEXED FILES

Major Topics

- Interaction of several RMS options with buffers:
  - Read-ahead and write-behind
  - Deferred write
  - Synchronous or asynchronous
- Local buffers — indexed file example
- Size and number of buffers
- Global buffers and index caching
  - Single node
  - VAXcluster
- Calculating number of buffers needed to cache index

Guide to VAX/VMS File Applications — Chapter 7 (Section 7.3)
Chapter 3 (Section 3.6)

TYPES – (a) Local (in P1 region) – size – ~~native~~ / ~~replicated~~ – Backup
(b) Global sequential – show RMS (Multiblock count = 16)

Calculation (a) how many
(b) size

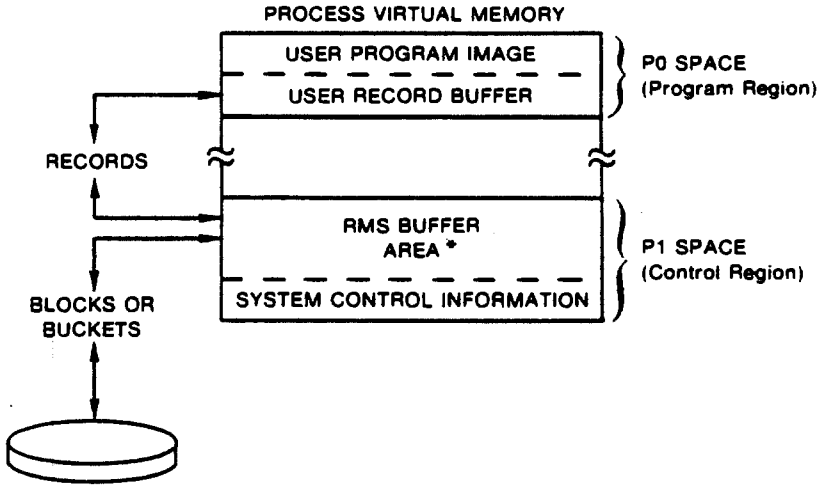
INTERACTION OF RMS OPTIONS WITH BUFFERS

The following RMS options affect buffer flushing.

- Read-ahead/write-behind
- Deferred write
- Asynchronous/synchronous

These options will be explained using an example that assumes eight records can fit into one buffer and a multibuffer count of two buffers.

RMS Buffers and the User Program



* RMS buffers for image-specific files begin in P1 but may overflow into P0 space, unless the user image was linked using the option IOSEGMENT= NOPOBUFS. This latter option is rarely used.

Read-Ahead/Write-Behind

- Applies only to nonshared sequential files
- Set with RAB$M_RAH and RAB$M_WBH bits in RAB$L_ROP
- If either or both of these bits are set, RMS will use two buffers by default
- By default provides asynchronous I/O

NOTE

Even if the write-behind option were not enabled, deferred write is always enabled for sequential files. A buffer is not written back to disk until it is filled (or the file is closed, or the user issues a $FLUSH).

Write-Behind

When a process switches from one buffer to another (for example, a ninth $PUT in a series of sixteen $PUTs), RMS issues an asynchronous QIO to write the contents of the first buffer out to disk. The process does not stall while the QIO is completing. The process is able to continue processing in another buffer while the operation on the first buffer is completing.

The whole purpose of write-behind is to allow the user to make use of another RMS buffer at the same time as I/O is in progress on another buffer. In this example, if write-behind is not enabled on the ninth $PUT, which is to go into the second buffer, RMS does not return control to the user until the first buffer has been written to disk (therefore, the process stalls).

Read-Ahead

The read-ahead option operates slightly different from write-behind. When the user does the first $GET, RMS issues the reads for both buffers at the same time. The process stalls until the first read is completed. The QIO associated with the second read completes asynchronously. In this example, on the seventeenth $GET, when the process turns back to the first buffer, RMS will again issue the reads for both buffers.

Asynchronous Option with Read-Ahead/Write-Behind Interaction

It is best not to use the asynchronous option at the same time as the read-ahead/write-behind (RAH/WBH) options. Except for one special case, when write-behind and read-ahead are enabled, setting the ASY bit has no effect, since asynchronous I/O takes

place anyway. The special case is where the write of an I/O buffer is not completed before the buffer needs to be reused.

In this case, if both ASY and WBH were enabled, after eight $PUTS the first buffer is full. The ninth $PUT goes into the second buffer and an asynchronous request is issued to write the first buffer out to disk. On the sixteenth $PUT, the second buffer is full; on the seventeenth $PUT, RMS issues an asynchronous QIO to write the second buffer out to disk.

Because of the speed of the I/O device or the system load, suppose the first asynchronous buffer write is not yet completed. The seventeenth record needs to go into the first buffer. The setting of the ASY bit affects what action RMS takes in this situation. If the ASY bit is set, RMS returns control to the user immediately. The burden is on the user to refrain from modifying the first buffer storage until the asynchronous I/O completes. If the ASY bit is not set, the user does not get control back from the seventeenth $PUT until it can be successfully moved into the first buffer.

Deferred Write

- Applies to relative and indexed files and, as of VMS 4.4, to shared sequential files
- Set by FAB$M_DFW bit in FAB$L_FOP
- If this bit is set, RMS will use two buffers by default
- The meaning of deferred write is slightly different for nonshared sequential files.

Without deferred write enabled, every $PUT, $UPDATE, or $DELETE to a relative, indexed, or shared sequential file results in at least one direct I/O operation. For example, $PUTs one through eight to a relative file buffer would have resulted in eight writes to the disk and one more direct I/O to bring the bucket into the buffer initially. With DFW enabled, the write to the disk is deferred until a modified buffer is needed. With deferred write turned on, it is possible to perform multiple $PUTs to one buffer and incur only one direct I/O.

One important difference between deferred write and write-behind is that control is not returned to the user while the write is being done to the disk. When the user issues the seventeenth $PUT, RMS will write-back the contents of the first buffer to the disk. Control will only be returned to the user after the write has completed.

While this may suggest that the asynchronous option should be enabled together with DFW, the same danger described above for write-behind is inherent. If both ASY and DFW were enabled, then when the user issues the seventeenth $PUT, RMS would return control immediately to the user. It is possible that the first buffer local storage area could be modified before the write-back to disk has completed. Again, as in the asynchronous write-behind sequential file example, the burden is on the user to refrain from modifying local buffer storage until the write-back to disk has been completed.

In the case of multiple $PUTs which are clustered, deferred write can result in substantial performance gains. There are other factors, however, that have to be taken into account:

- In the case of a system crash, data not written back to disk may be lost. Also, if index buckets are cached, the modified index buckets may not have been written back to disk.

- In the case of shared files, there will be some performance degradation due to blocking AST activity. This will be discussed in the section on global buffers.

NOTE

Not all operations on indexed files can be deferred. Any operation that causes a bucket split will force the write-back of the modified buckets to disk. This forced write-back decreases the chances of lost information should a system failure occur.

Asynchronous I/O

- Applies to all file organizations
- Set by RAB$M_ASY bit in the RAB$L_ROP

Setting this bit allows the user to get control back immediately from RMS, rather than RMS waiting for I/O completion before returning control to the user.

Setting the ASY bit gives the user the opportunity to perform some operations totally unrelated to a particular record stream, such as computations or I/O to other files, while I/O on a particular file is in progress.

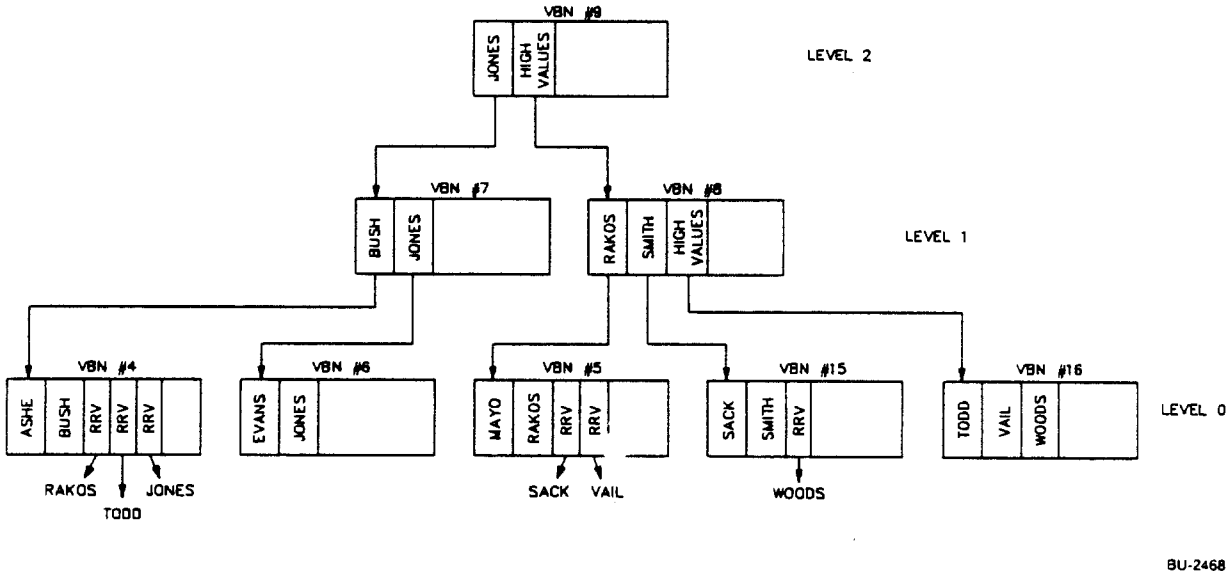
LOCAL BUFFERS

Management of local buffers by RMS will be illustrated using the simulated indexed file data example introduced in Part 2 of Module 5, Indexed File Organization. The illustration will involve an update to an existing indexed file in which new records will be inserted.

Example 1. Local Buffer Illustration

- Keyed $PUTs on primary key
- Multibuffer count = 3
- Exclusive use of file (or sharing read). Sharing write will be discussed in the section on global buffers.
- Synchronous, deferred write (assumes some of the insertions may be clustered)

Primary Index Tree

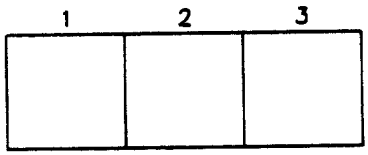


RMS sets up an internal table for local buffers (local list) with the number of cells equal to the number of local buffers.

Among the information maintained in this table are:

- What VBN # the bucket begins with
- Weighting factor (essentially this is the level in the tree structure associated with the bucket)

Local Buffer Internal Table



BU-2470

Update 1. $PUT Record With LAST_NAME = DOG

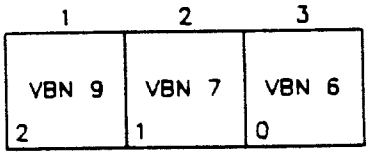
This $PUT involves following buckets to be brought into the local buffer from the disk in order listed:

VBN 9 - ROOT index bucket

VBN 7 - VBN that JONES in VBN 9 is pointing to

VBN 6 - VBN that JONES in VBN 7 is pointing to

Internal Table at End of $PUT DOG



BU-2471

General Steps for Each Bucket Accessed

1. Local list (internal table) is sequentially scanned to determine if the bucket needed is already in the buffer.

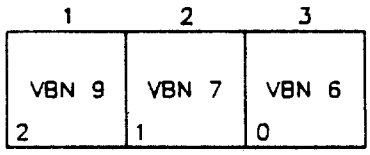
2. If there is no hit in Step 1, the local list is scanned to identify the buffer that will be used to bring in the bucket from the disk. The search routine used will be described later in this module.

3. If the file is write shared, then a request is made to the lock manager for exclusive access to the bucket. Once granted, the access mode is degraded by the lock manager and the bucket is read in from disk. (Write sharing procedures will be described in more detail in the section on global buffers.)

Update 2. $PUT Record With LAST_NAME = FOX

This $PUT involves the same VBNs as the $PUT for DOG. In each case the scan of the local list will lead to a hit.

Internal Table at End of $PUT FOX



BU-2472

Update 3. $PUT Record with LAST_NAME = PIG

This $PUT involves following buck ts to be brought into local buffer from disk in the following order.

VBN 9 - ROOT index bucket ("hit" already in buffer)

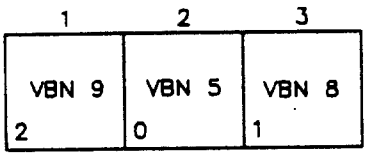
VBN 8 - VBN that high values in VBN 9 is pointing to (no "hit", has to be brought in)

VBN 5 - VBN that RAKOS in VBN 8 is pointing to (no "hit", has to be brought in)

The search routine used to identify which local buffer should be re-used will be illustrated by bringing in VBN 8 and VBN 5 from disk.

- The local list is scanned backwards to identify the first unused buffer with the lowest weight. In scanning through the list, a pointer is maintained to the cell with the lowest weight.
- As an optimization feature, if any unused buffer has an associated weight of zero, the sequential scan stops there, and the bucket will be brought in from disk to this buffer.
- If no unused buffer has an associated weight of zero, the total local list will be sequentially scanned. The bucket will be brought in from disk to the buffer associated with the lowest weight (the first one identified in the backwards scan in case of a tie).
- The scan always begins with the last cell in the local list.
- Unlike global buffers, no weight decrementing is done.

Internal Table at End of $PUT PIG



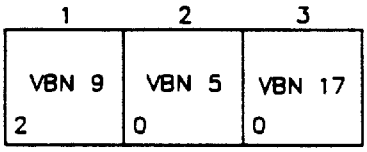
BU-2473

Update 4. $PUT record with LAST_NAME = MOUSE

This $PUT involves the same VBNs as the $PUT for PIG. In each case the scan of the local list will lead to a hit.

This update will involve a bucket split. In the case of a bucket split, the write-back to the disk of any modified buckets is not deferred. Modified buckets are immediately written back out to disk.

Internal Table at End of $PUT MOUSE



BU-2474

SIZE AND NUMBER OF BUFFERS

The size of the buffer is equal to the I/O unit of transfer from disk to memory.

	Unit of Transfer	
Sequential	Multi-blocks	
Relative	Bucket	maximum size = 63 blocks
Indexed	Bucket	

Sequential

Size
The number of blocks to be transferred to or from the disk can be varied each time the file is processed. If not specified by the process, the system default will be used. This is generally 16 blocks (SHOW RMS_DEFAULT).

Buffers
A maximum of two buffers is all that is needed for any sequential file. If either (or both) the read-ahead or write-behind option is enabled, RMS defaults to two buffers.

Relative

Size
Whatever the bucket size is set at when the file is created (or reorganized) will be the fixed size of the buffer. FDL uses the following rules in calculating bucket size for relative files.

Type of Processing	# Records per Bucket
Random	4
"Clustered" access or sequential	16

Buffers
The maximum number ever needed for a relative file is two buffers. If the deferred write option is enabled, RMS will default to two buffers.

Indexed

Size
Whatever the bucket size is set at when the file is created (or reorganized) will be the fixed size of the buffer. The size of each buffer used for a file will be a constant size for all buffers allocated to an indexed file. If areas were used to specify different bucket sizes for index and data buckets, the size of all buffers allocated to that file will be the largest bucket size.

Choosing Data Bucket Size for Indexed Files

- Larger data buckets yield fewer index buckets, which result in fewer DIOs, but longer search times (CPU) at the data level.
- Smaller data buckets yield more index buckets, which result in more DIOs, but shorter search times (CPU) at the data level.

For indexed files, it is the bucket size more than anything else that determines the shape and size of the index. A small bucket size relative to record size will result in an index with many levels, while a large bucket size relative to record size will result in a flatter index. Since each level will result in an additional disk access for each I/O, it is generally desirable to make the index as flat as practical. The flattest index will, of course, result when all the key values can fit in one index bucket (the root bucket). To accomplish this for larger file applications a very large bucket size (maximum of 63 blocks) may be required. However, there are five factors that can cause a large bucket size to adversely affect performance.

1. Data transfer time

   The I/O time required to do one direct I/O is made up of four components:

   I/O TIME = SEEK + LATENCY + DATA TRANSFER + BUCKET SEARCH

   seek time = average time required for the disk head to be positioned over the desired track (28 ms for an RA81).

   latency = average time required for the desired record to pass under the disk head after it has been positioned. This is about the time required for one half a rotation of the platter (8.3 ms for an RA81).

   data transfer = time required to transfer the number of bytes in the bucket, which equals the number of bytes to be transferred (512 times the bucket size) divided by the

transfer rate (2.2 Mbytes/sec for an RA81).

bucket search = average time required for the CPU to search through the bucket for the desired record once it is in memory.

Most of I/O time is consumed by mechanical motion (seek + latency). This is a property of the hardware and cannot be changed by the programmers. The four components of I/O are present for every I/O operation (except, in some cases, bucket search time). A major objective of tuning is to reduce the number of seeks required, since this is the largest single component of I/O.

However, the data transfer time can be controlled to some extent by the programmer since it is directly proportional to the bucket size. The calculations that follow (based on an RA81) demonstrate this relationship across a range of bucket sizes.

Relationship of Bucket Size to Data Transfer Time Based on RA81

Bucket Size	Seek Time	Rotational Latency	Data Transfer	Total	% Data Transfer of Total
1	28 ms	8.3 ms	.2 ms	36.5 ms	0.6%
10	28 ms	8.3 ms	2.3 ms*	38.6 ms**	6.0%***
15	28 ms	8.3 ms	3.5 ms	39.8 ms	8.8%
20	28 ms	8.3 ms	4.7 ms	41.0 ms	11.5%
32	28 ms	8.3 ms	7.4 ms	43.7 ms	16.9%
63	28 ms	8.3 ms	14.7 ms	51.0 ms	28.8%

* Data transfer = (10 x 512)/2200

** Total = 28.0 + 8.3 + 2.3

*** % Data transfer = 2.3/38.6 * 100

Source: VAX Hardware Handbook (Vol. 1, 1986)

The last column of this table reports the percentage of the total time which is represented by data transfer. For small buckets, this is insignificant. However, as the bucket size is increased, the time spent actually transferring the data becomes more and more significant. For sequential access, the

higher data transfer time may be balanced by a smaller number of direct I/Os. In this case, the high data transfer time per I/O is not important because most of the bytes that are transferred will be used by the CPU, whether in one large access or many smaller ones. For random access, only one record in the bucket will be accessed (unless there are multiple buffers set up for caching). Therefore, most of the data transfer work is pure overhead. As a general rule of thumb, it is wise to limit the data transfer time to between ten and fifteen percent of the total.

2. Data bucket search time

Data bucket search time is only significant in random access applications. Sequential access will cause every record in the bucket to be read, while with pseudo-random access, only the first record in a group of records will have to be located in the bucket. From that point on, it will look like sequential access. For large bucket sizes, decreased I/O resulting from a flatter index must be balanced against the time required to search through the buffer for the desired record. The bucket search time is a function of the CPU type and the number of records in the bucket. The larger the number of records, the greater the copy time, on average, to locate the record sequentially within the data bucket.

3. Memory constraints

Buffers are pages of memory in your working set. Each block (512 bytes) is a page of memory. A large bucket size will require more pages of memory. If more pages are required to support the size and number of buffers allocated than the working set supports, excessive paging can result.

4. Bucket locking

In a shared file application, an additional consideration becomes important. As described in the preceding module, buckets are locked intermittently during the period of time a record is locked. While the period of time during which the bucket is locked is small, large bucket size means that a portion of the file could potentially be locked out for some period of time. If there is a great deal of contention in a file sharing environment, these bucket locks could adversely affect performance.

5. Data loss in case of system crash

If the deferred write option is enabled, consideration must be given to how much data could potentially be lost. The number of records that can fit into the bucket is the number of records that potentially can be lost in case of system failure.

Summary -- Indexed Data Bucket Size

The above considerations yield tradeoffs which must be evaluated in the context of the application before a choice for bucket size can be made. If the application is I/O bound, the amount of I/O can be reduced at the expense of a greater load on the CPU. If the application is CPU bound, the load on the CPU can be reduced at the expense of I/O. If the application is both I/O and CPU intensive, the tradeoffs must be carefully studied and a compromise reached.

General Rule -- The data bucket size chosen should allow at least five records (near maximum size, if variable-length records) to fit in a bucket. The size should also be a multiple of the disk volume cluster size. The worst single thing that can be done to performance is to use one tightly fitting record per bucket.

In the final analysis, it may be necessary to experiment to determine the optimal bucket size. Often the best way to find the best buffering strategy for a particular application is to test various combinations of the number of buffers and the buffer size. One approach is to time each combination and measure the number of I/O operations that take place, and then choose the one that improved application performance the most considering the amount of memory used.

Number of Buffers

The number of buffers (CONNECT MULTIBUFFER_COUNT, RAB$B_MBF) is specified at run-time and recommended values can vary greatly for different applications when accessing indexed files. The following suggestions on the use of buffers apply to the type of record access to be performed.

- Completely random processing--When records are processed randomly, the use of as many buffers as your process working set can support is recommended to cache as many index buckets as possible.

- Sequential processing--When records will be accessed sequentially, even after locating the first record randomly, the use of a small multibuffer count, such as the default of two buffers, is sufficient.

Two buffers is the minimum value for indexed files. If your application performs sequential access on your database, two buffers are sufficient. More than two buffers for sequential access could actually degrade performance. During a sequential access, a given bucket will be accessed as many times in a row as there are records in the bucket. After RMS has read the records in that bucket, the bucket will not be referenced again. Therefore, it is unnecessary to cache extra buckets when accessing records sequentially.

When you access indexed files randomly, RMS must read the index portion of the file to locate the record you want to process. RMS tries to keep the higher-level buckets of the index in memory; the buffers for the actual data buckets and the lower-level index buckets tend to be reused first when other buckets need to be cached. Therefore, you should use as many buffers as your process working set can support so you can cache as many buckets as possible.

NOTE

The general idea of using buffers is to use a buffer size and number of buffers that improves application performance without exhausting the virtual memory resources of your process or system. Keep in mind the tradeoffs between file I/O performance and exhausting memory resources. The buffers used by a process are charged against the process's working set. [redacted] Buffers are locked in to the process's working set. You should avoid allocating so many buffers that the CPU spends excessive processing time paging and swapping. For performance-critical applications, consider increasing the size of the process working set and adding additional memory.

GLOBAL BUFFERS AND INDEX CACHING

Two types of buffer caches are available using RMS: local and global.

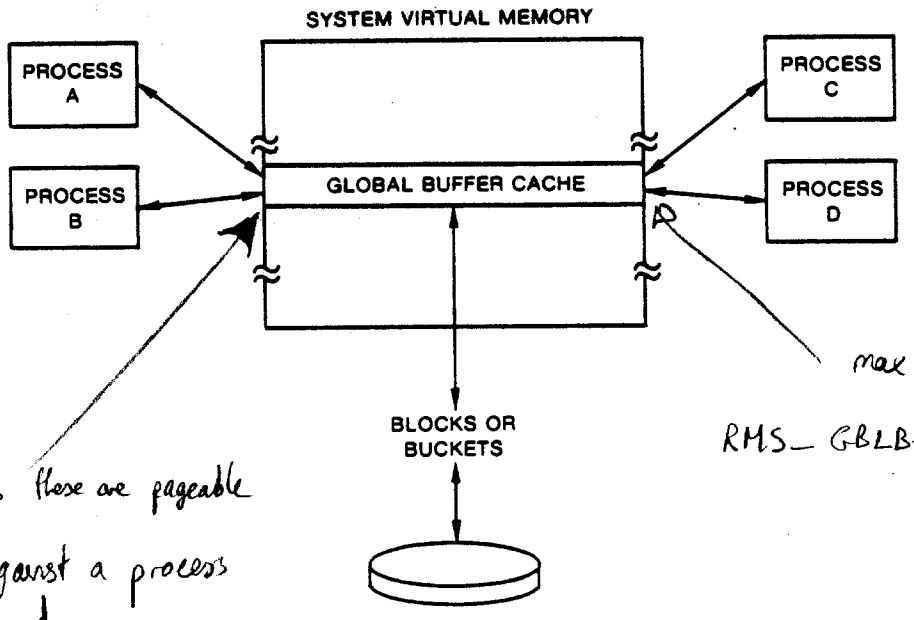
Local buffers reside within process (program) memory space and are not shared among processes, even if multiple processes are accessing the same file and reading the same records. Global buffers, which are designed for applications that access the same file and may even access the same records, do not reside in process memory space (but are charged to each process's working set).

If several processes will share an indexed file, global buffers should be considered. A global buffer is an I/O buffer that two or more processes can access in conjunction with file sharing.

This section is divided into two parts:

1. Global buffers on a single node
2. Global buffers on a VAXcluster

Using Global Buffers for a Shared File



* Unlike local buffers these are pageable
* These are charged against a process when they are mapped
* The first process may either:
  (a) Take the default number of global buffers
  (b) Specify a value

Second & subsequent processes may either:
  (a) Ignore global buffers
  (b) Accept what the 1st process has declared

SINGLE NODE

The greatest benefit of global buffers usually is found with an indexed file that is shared by multiple readers (file is opened by all processes read-only) and has a high locality of reference.

- Use of global buffers should be considered only if:
  - Several processes will be accessing the indexed file concurrently.
  - The processes will be accessing the file randomly, and there is a good probability of a high locality of reference (at a particular point in time, buckets in memory are being asked for by more than one process). The probability associated with index buckets is greater than with data buckets.
- Before implementing the use of global buffers as a general practice for a particular file, benchmarks should be done with and without global buffers.

  Global buffers not only do not always improve performance but may also degrade performance.

  In conducting benchmarks, the number of buffers specified is critical. The number of buffers used has been found to have an important impact on performance through VAX/VMS Version 4.4.

General Guideline

The greatest benefit of global buffers is in caching index buckets, not data buckets.

```
# GLOBAL BUFFERS  =  # buffers needed to cache total index
                     tree(s) + one data bucket
```

Read Only

Optimal performance can be obtained when a file will be open by all processes read only by specifying both of the following file attributes:

```
SHARING  GET                    FAB$B_SHR = FAB$M_SHRGET

                                            +

SHARING MULTISTREAMING                      FAB$M_MSE
```

This will improve performance by eliminating certain internal operations, such as the maintenance of bucket locks in the global buffers.

Not Restricted to Read Only

The search strategy used by RMS for global buffers will be illustrated using the simulated data example introduced in Module 5, Part 2 (see the Primary Index Tree and the Alternate Index Tree). The following illustration assumes that all processes sharing this file are on a single node, which may or may not be true in a VAXcluster.

Example 2. Global Buffer Single Node Illustration

Process A opens the file for shared access write with:

```
ACCESS                  WRITE
SHARING                 WRITE

# local buffers         =  2
# global buffers        =  6

   Calculation of global buffers:

    Primary index          3
    Primary level 0        1
    Alternate key 1 index  1
    Alternate level 0      1
                          ----

          Total global     6

    DEFERRED WRITE  enabled
```

NOTE

The deferred write option was enabled in this example for illustration purposes. In general, it is best not to use deferred write when global buffers are used. (Incurs extra lock management & buffer management)

```
   Key of reference        =  0  (primary key)
```

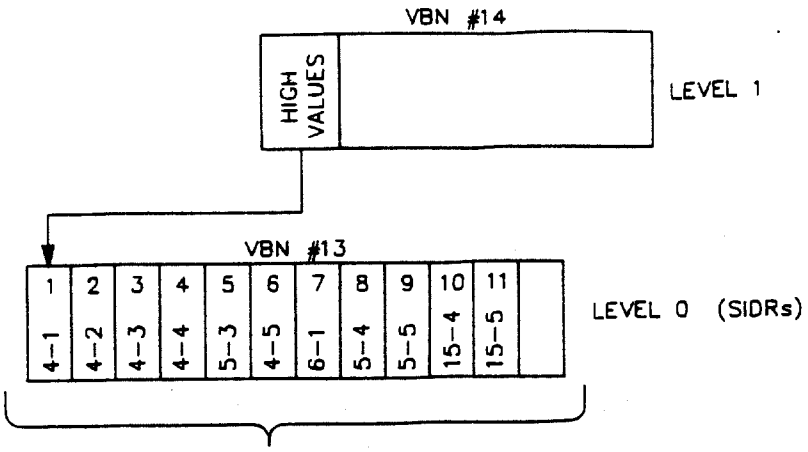
Process B opens file requesting read-only access for the user but allowing shared write access by others. Process B does not specify global buffers (or override global buffers by specifying in program control FAB$W_GBC = 0) so it defaults to global buffers set up by Process A. It also defaults to one local buffer.

```
Access                  Read-Only
Sharing                 Write

# global buffers        =  6   (by default)
# local buffers         =  1   (by default)

key of reference        =  1   (Alternate key 1)
```

Alternate Index Tree



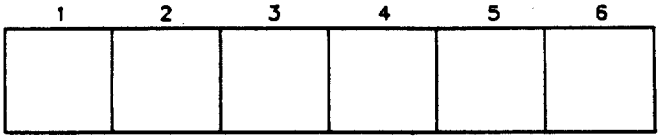
RFA's*	SEQ-NO	NAME
4-1	1	RAKOS
4-2	2	ASHE
4-3	3	TODD
4-4	4	JONES
5-3	5	VAIL
4-5	6	BUSH
6-1	7	EVANS
5-4	8	SACK
5-5	9	MAYO
15-4	10	WOODS
15-5	11	SMITH

*RFA = VBN # - ID #

BU-2469

RMS sets up an internal table for global buffers (global list) with number of cells equal to the number of global buffers.

Global Buffer Internal Table (Global List)



BU-2475

The following information is maintained in this table.

- What VBN # the bucket begins with
- Weighting factor (essentially this is initially the level in the tree structure associated with the bucket)
- Count of users touching (using) this specific buffer
- Sequence number (essentially the number of times a copy of this bucket has been written back to disk)
- What lock ID the system lock for this buffer resource is held with (used by distributed lock manager)

VAXCLUSTER relevance

Retrieval 1

Process A issues FIND ** JONES ** followed by a GET.

General Steps for Retrieval of VBN 9

1. Global list (internal table) is locked (Lock Manager) for scan to determine whether VBN 9 is in global buffer cache.

2. Sequential scan of list. In this case, no hit for VBN 9. If there were a hit, the "touched-by" count associated with this buffer is incremented so that if this process goes into wait state before gaining ownership of this VBN through the lock manager, another process in the interim cannot reuse this buffer to bring in another bucket.

3. Lock on global list is released.

NOTE

If process during list scan ever stalls, the lock on list is released so another process can get in.

4. List for local buffer is checked. In this case, no hit for VBN 9. If there had been a hit in Step 2, this step would be omitted.

5. If no hit in Step 2 or 4, global list is locked for scan to reserve buffer to which VBN 9 will be written. The search routine used will be described when all buffers in the global cache are filled in this illustration. In this case the global buffer associated with cell 1 will have it's "touched-by" count incremented.

6. If no hit in Step 2 or 4, the global list lock is released.

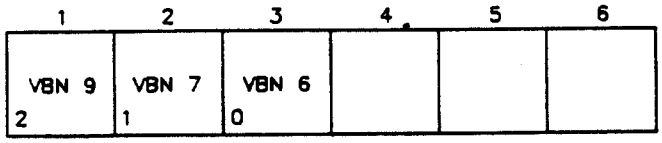
7. Request is made to the lock manager for exclusive access to VBN 9. If request is granted, the lock manager will degrade access mode, and VBN 9 will be written from disk to global buffer.

8. VBN 9 is searched to find the next VBN in the tree leading to the data bucket where JONES record is located.

   The above steps are repeated for VBN 7, and then again for VBN 6.

9. The data bucket (VBN 6) is brought into global buffer. This step will be expanded upon when an actual update is made in this example.

Internal Table at the End of Retrieval 1 (JONES)

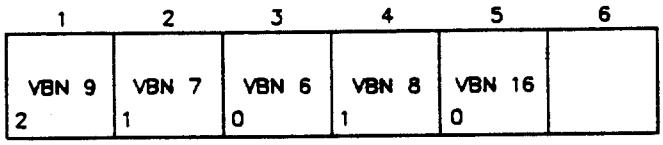


BU-2476

Retrieval 2

Process A issues FIND ** WOODS ** followed by a GET.

Internal Table at the End of Retrieval 2 (WOODS)

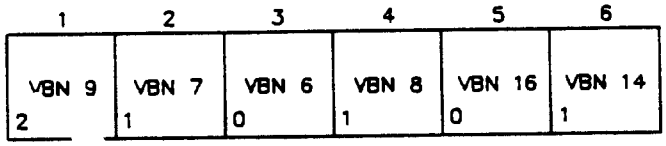


BU-2477

Retrieval 3

Process B issues FIND ** SEQ_NO = 9 (MAYO) ** followed by GET.

Internal Table After the Root Alternate Key Bucket Brought In



BU-2478

After VBN 14 has been brought in, VBN 13 is identified as the SIDR bucket containing the RFA for SEQ_NO = 9. The scan of the global buffers for VBN 13 and the local buffers had no hit.

Step 5 Expanded

Step 5 in Retrieval 1 will now be expanded upon to describe the search routine used to identify which buffer should be re-used.

1. The list is locked for search.

2. A total of eight unused cells in any such search is scanned (this example is atypical because it is limited to only six cells). A pointer is maintained to the last cell scanned in searching to identify which buffer will be recycled by any process. This will be the first cell in the next search performed for any process.

3. In scanning through the eight cells, a pointer is maintained to the cell with the lowest weight.

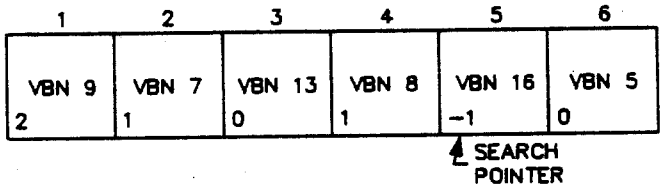
4. The last cell in the scan has its weight decremented by one. If someone uses the bucket in this cell before it is written over, the original weight (its level in the index tree) is restored.

5. The cell identified has its "touched by" count incremented by one in order to reserve it.

6. The lock on the list is released.

7. The bucket is brought in to the global buffer associated with the identified cell.

Internal Table at the End of Retrieval 3 (MAYO)



BU-2479

Retrieval 4

Process A issues FIND ** BUSH ** followed by UPDATE.

Step 9 Expanded

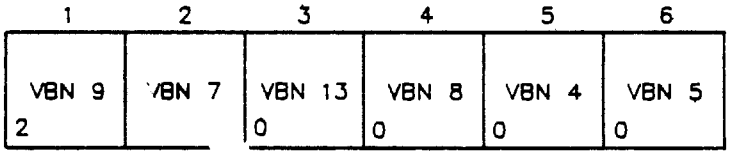
Step 9 in Retrieval 1 will now be expanded upon using the update done to VBN 4 in this example.

In case of no bucket split, the update made by Process A is made to the data record in bucket VBN 4 in the global buffer. When the lock manager is requested to release Process A's ownership of VBN 4, the lock manager will see that the deferred write option was specified. The lock manager must abide by the rule that a bucket that has not been written back to disk cannot be unowned. The lock manager will have ISAM copy the bucket in the global buffer to one of Process A's local buffers and then the lock manager can release ownership of the global buffer. The lock manager still has a lock on VBN 4 but on the local copy. Note the extra overhead involved due to the deferred write option being enabled.

At the end of this step, there is a valid copy of VBN 4 in a local cache and an equally valid copy in the global cache but an invalid copy out on disk. Process A owns the local copy and no one owns the global copy. Retrieval 5 describes what happens when someone wants to access the global copy.

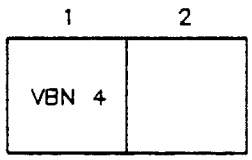
In case of bucket split, an update is made to the bucket in the global cache and the local buffer is used for the new bucket created. The deferred write option becomes inoperative. The buckets involved are immediately written back out to disk.

Internal Table at End of Retrieval 4 (BUSH)



BU-2480

Process A's Local Buffers at the End of Retrieval 4 (No Bucket Split)



BU-2481

Retrieval 5

Process B issues FIND ** SEQ_NO = 2 (ASHE) ** followed by GET.

Step 2 Expanded

In this case, the sequential scan of the internal list will disclose VBN 4 is in the global cache. The scan of the list only discloses that it is in the global cache. At this point, the "touched by" count is incremented in the list so that while Process B is trying to get ownership, if it goes into a wait state, no other process will be able to use this buffer for recycling purposes.

Step 7 Expanded

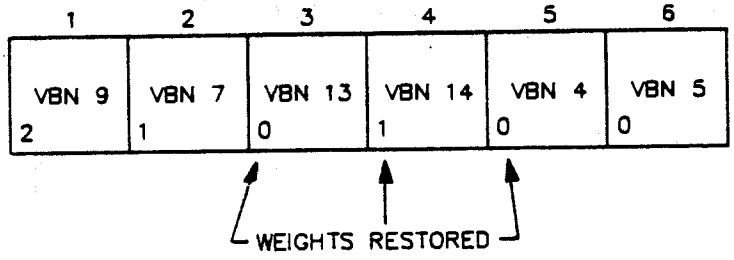
When a request for a lock on VBN 4 for Process B is made to the lock manager, the lock manager will see that a copy of VBN 4 is owned locally. The lock manager will initiate an AST for the local copy to be written out to disk. Once it is copied to disk, the lock manager will release Process A's ownership of it and give ownership of the copy in the global cache to Process B.

NOTE

If the deferred option had not been enabled, a local copy would not have been made and performance would not be degraded by the extra load introduced involving the AST activity. It is for these reasons that performance is usually better if deferred write is turned off when global buffers are used.

Since a valid copy of VBN 4 was already found in the global cache, it will not have to be recopied from disk.

Internal Table at the End of Retrieval 5 (ASHE)



BU-2482

Summary – Global Buffer Performance (as of VAX/VMS Version 4.4) – problems in releases prior to this

1. Each time the global list table is scanned, the entire global list (not buckets) is locked.

2. The scan of the global list is done sequentially. If the number of global buffers gets too large, the search time to scan the list may exceed the time it would take to do direct I/Os.

   Some users have run into very poor performance with global buffers when they try to cache a large number of data buckets and the number of buffers in the global cache becomes very large.

3. General recommendation:

   For a shared file, if you can use global buffers to cache the entire index structure (not data buckets), then everybody wins.

   If you cache the entire index structure locally, then the process may win at the expense of other processes (using more memory). This would be an appropriate strategy only for a nonshared file.

   NOTE

   The argument for caching all or a lot of the index structure falls apart for sequential access, where a small number of buffers (such as two) is plenty.

4. It is usually best that the deferred write option be turned off when global buffers are used. In a high-contention environment where frequent concurrent updating is occurring, deferred write enabled can actually cause performance degradation because of the use of local buffers for the modified buckets and the extra load introduced by the blocking AST activity.

   In general, the performance degradation will usually outweigh any performance gain due to reaccessing buckets that have been modified before the global buffers they are in have been written over.

- Global buffers reside in physical memory so each VAX node in a cluster has its own global buffer cache. There is no performance difference between a single-node system and a VAXcluster if the file sharing takes place on a single node of the cluster.
- There is no performance difference between a single-mode system and a VAXcluster if the file sharing allows read-only.
- Once a file is opened on more than a single node in a VAXcluster with sharing allowing write, the distributed lock manager is invoked.

Example 3. Global Buffers VAXcluster Illustration

- Process A opens PERSONNEL.DAT on NODE ALPHA with a global buffer count (GBC) of 50.
- Process B opens PERSONNEL.DAT on NODE BETA with a GBC of 35.
- There will be two separate global caches in physical memory for PERSONNEL.DAT -- a 50-bucket one on NODE ALPHA and a 35-bucket one on NODE BETA.

One concrete illustration of the overhead added on to the VAXcluster shared file write case:

- Process A updates VBN 4. It doesn't matter whether Process A specified the deferred write option or not.
- The global cache in NODE BETA happens to already have a copy of VBN 4 in its cache from some previous read operation. Process B then asks for VBN 4.
- The scan of the global list on NODE BETA will disclose that VBN 4 is in the global cache.

  If it were to give Process B access to that copy, Process B would be using a stale copy of VBN 4.

  A lot of distributed lock manager overhead is added on to detect when a copy in one of the global caches on the VAXcluster is no longer valid and a new copy must be brought in from the disk.

  This is essentially accomplished through a lock value block maintained by the distributed lock manager for each bucket in a global buffer.

Lock Value Block

- For all bucket locks, the lock value block contains a sequence number, which is the number of times the bucket has been written out to disk. Every time a bucket is written out to disk, the sequence number is bumped and the lock value block written back to the lock manager.

- When the first bucket gets locked, one of the pieces of information gathered about the bucket is its sequence number. Every bucket on the system, in local or global cache, has a sequence number associated with it. The sequence number is also among the pieces of information kept by RMS in the internal tables maintained for global buffers and local buffers.

  When a request is made to the lock manager for a VBN which is already in memory in a global or local buffer, the lock manager checks to see whether the sequence number in the lock value block for that VBN resource matches the sequence number in the internal table. If they don't match, the bucket is read in again from the disk.

  When a bucket in the global buffer is updated and written back to disk, the sequence number maintained for it in the internal global list table is also updated.

- Unfortunately, if no one owns the bucket in the global buffer (no one has a lock on the bucket), the resource managed by the lock manager would go away. Normally no one owns global buffers.

  In order to know whether the bucket in a global buffer is being used by anyone currently, or is still valid, the resource must remain so that the lock value block associated with it is still available.

  In order to accomplish this, there is a system lock maintained on each global buffer. The entire reason for this system lock is to make sure the resource associated with the VBN stays around with its accompanying lock value block. Behind every global buffer there is an invisible system lock.

Performance Recommendations for VAXcluster Global Buffers

The following alternatives to write sharing a large data file on a VAXcluster should be considered.

- File sharing on more than one node of a VAXcluster should be restricted to READ ONLY SHARING if at all possible.

- Processing a file with exclusive access gives better performance than with shared write access on more than one node of a VAXcluster.

- If your application requires write sharing, if possible confine the activity to a single CPU. If sufficient CPU resources and I/O capacity are available, your application will perform faster than if it were spread over many nodes.

30	4:06.69	4:00.21	3	137	49
40	4:05.36	4:00.76	3	137	95

Break-even somewhere round here. Corresponds to previously calculated figure of 17

Reduction in Direct I/O between buffer = 1 and buffer = 20

$$\frac{(2742 - 138)}{2742} = 95.0\% \text{ DIO reduction}$$

Reduction in Elapsed Time between buffer = 1 and buffer = 20

$$\frac{(433.23 - 258.30)}{433.23} = 40.4\% \text{ reduction in Elapsed Time}$$

MODULE 9
RMS UTILITIES

Major Topics

Part 5. Optimizing and reorganizing files
- FDL Optimizing function
- Reorganizing files
  - CONVERT
  - CONVERT/RECLAIM

Source

Guide to VAX/VMS File Applications — Chapter 10

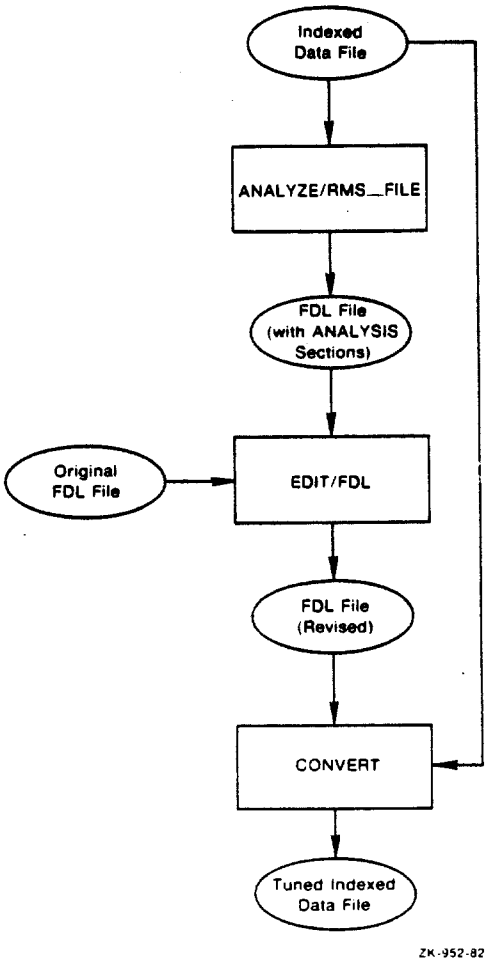
PART 5. OPTIMIZING AND REDESIGNING FILES

To maintain files properly, you must occasionally tune them. Tuning involves adjusting and readjusting the characteristics of the file, generally to make the file run faster or more efficiently, and then reorganizing the file to reflect those changes.

There are basically two ways to tune files. You can redesign your FDL file to change file characteristics or parameters. You can change these characteristics either interactively with EDIT/FDL (the preferred method) or by using a text editor. With the redesigned FDL file you can create a new data file.

You can also optimize your data file by using ANALYZE/RMS_FILE with the /FDL qualifier. This method, rather than actually redesigning your FDL file, produces an FDL file containing certain statistics about the file's use that you can then use to tune your existing data file.

The RMS Tuning Cycle



FDL Optimizing Function

To periodically optimize an indexed file, use the following steps:

1. $ANALYZE/RMS/FDL current_indexed.DAT

   Creates current_indexed.FDL which includes both a regular FDL specification and an analysis section.

2. $EDIT/FDL/ANALYSIS=current_indexed.FDL fdl_indexed.FDL

   Invokes FDL interactively. Choose the OPTIMIZE option* within the INVOKE menu. The default values provided for the interactive session will be taken from fdl_indexed file. Changes in bucket size, allocation size, etc. will be suggested by FDL on the basis of the analysis sections provided in the current_indexed file. A revised FDL file will be output with the name of the fdl_indexed file-spec.

   or

   $EDIT/FDL/ANALYSIS=current_indexed.FDL/NOINTERACTIVE -
   $_fdl_indexed.FDL

3. $CONVERT/NOSORT/FDL=fdl_indexed/STAT current_indexed.DAT -
   $_newindexed.DAT

   Creates a new version of current_indexed.DAT using the optimized fdl_indexed.FDL.

---

* To use the INVOKE/OPTIMIZE function in FDL, two FDL files must be input:

  1. The FDL file-spec provided for the qualifier ANALYSIS which must have analysis sections at the end of it.

  2. The fdl_indexed file-spec. This FDL file may be an old FDL file for this particular file or it may be the same FDL file specified as the file-spec for the ANALYSIS qualifier. It may even include analysis sections at the end of it, though FDL will not use them.

Reorganizing Files

- CONVERT
  - Bucket splits/RRVs disappear
  - Buckets of deleted records are reclaimed
  - RFAs are not preserved

```
$ CONVERT/FDL=fdl-file-spec  input-file-spec output-file-spec
```

- CONVERT/RECLAIM (Prolog 3 files only)

  CONVERT/RECLAIM makes available for reuse those buckets that have been completely emptied by record deletions. The reclaiming is done in place, so no additional space is necessary. if there are severe space and time constraints, this is a useful feature, since the file size is kept to manageable levels. However, this results in negligible performance improvement, since bucket splits are not cleaned up. If performance is a critical issue, then a full CONVERT should be performed as often as possible.

  - Records will retain their original RFAs
  - Reclaims data buckets completely emptied by deletions

```
$ CONVERT/RECLAIM file-spec
```

- Other CONVERT options:
  - /EXCEPTIONS_FILE=file-spec
  - /PAD=value
  - /TRUNCATE
  - /STATISTICS
  - /MERGE=file-spec

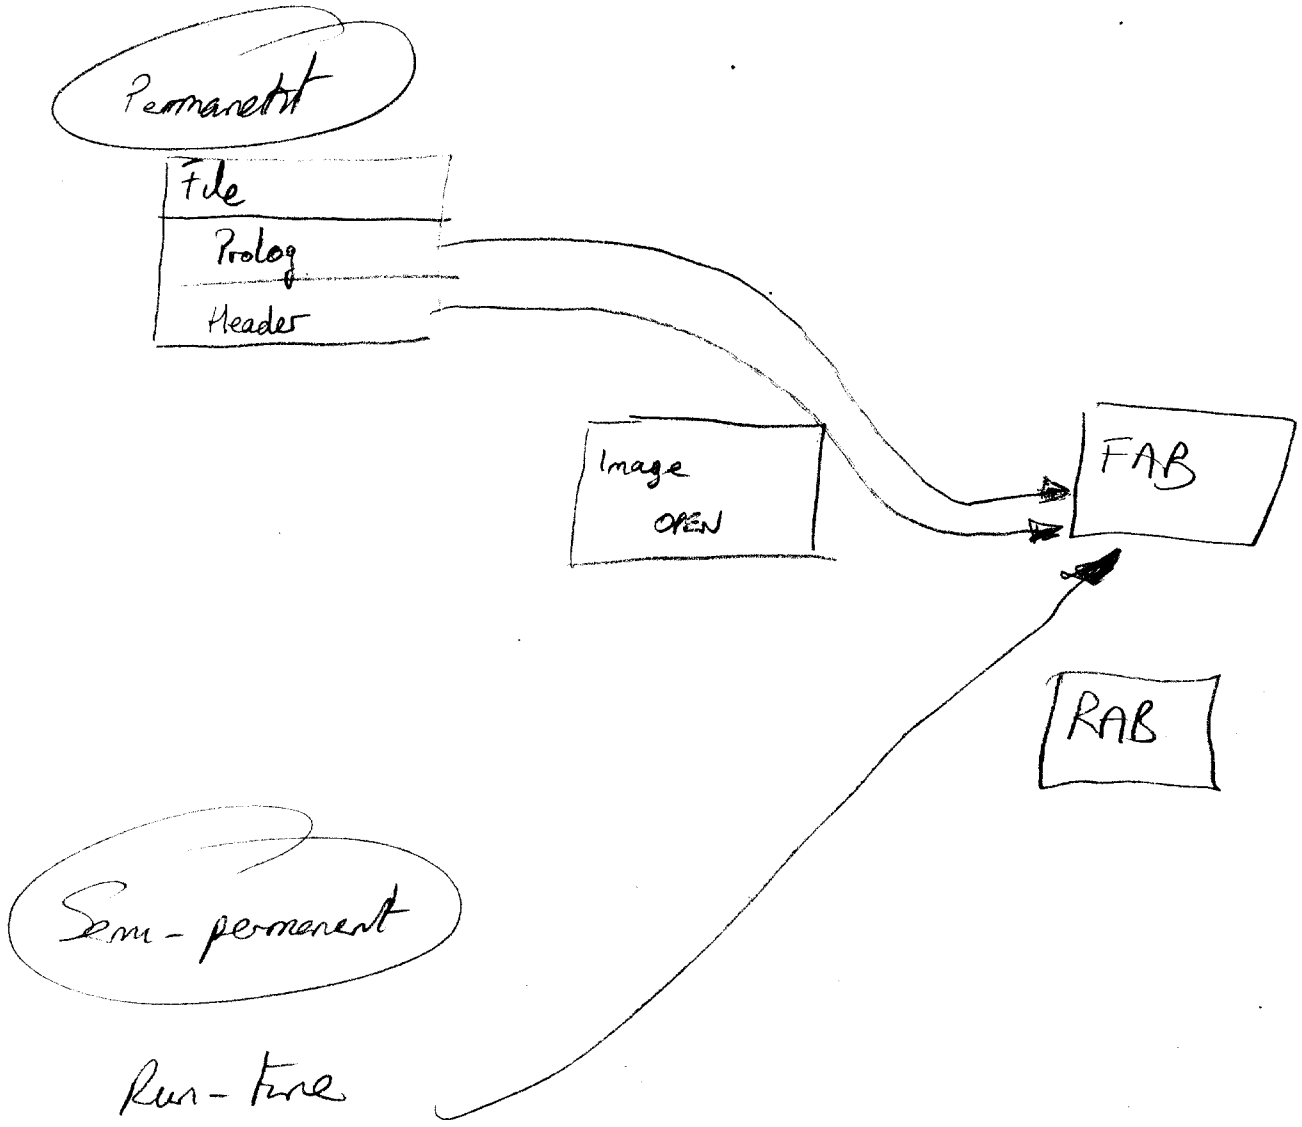
* Causes it to use fill size specified at file creation else uses 100% fill.

** Enabled if ALLOW not equal to WRITE or MODIFY.



MODULE 11
PERMANENT FILE ATTRIBUTES VERSUS RUN-TIME FILE CHARACTERISTICS

Major Topics

- Permanent file attributes
- Run-time file characteristics
- Default settings for RMS control blocks for higher-level language OPENs
- DCL commands for implementing run-time features
  - SET FILE
  - SET RMS_DEFAULT
- Specifying run-time options

Source

Guide to VAX/VMS File Applications — Chapter 9

RMS Reference — Chapter 5 (FAB), Chapter 7 (RAB)

VAX/VMS File Definition Language Utility Reference

PERMANENT FILE ATTRIBUTES

Certain attributes are assigned to a file at file creation time and cannot be changed without creating a new file and transferring the records to it. Use the DCL commands ANALYZE/RMS, EDIT/FDL, CREATE/FDL, and CONVERT to do this.

- File organization
  - Sequential
  - Relative
  - Indexed sequential
- Record type
  - Fixed-length
  - Variable-length
  - Variable with fixed control (VFC)
  - Stream
- Maximum record length
- Area definitions
  - Bucket size
  - Fill size
  - Contiguity options
  - Initial allocation of disk space
- Key attributes
  - Key number
  - Key name
  - Data type for key field
  - Position of key field (can be up to eight segments)
  - Lengths of key segments
  - Duplicates allowed?
  - Changes allowed to (alternate) key fields on updates?
  - Null key character (alternate string keys only)
- Prolog version number
- Compression options for Prolog V3 files:
  - Data record compression (except primary key)
  - Primary key compression in data records
  - Key compressions in index records
- Block-spanning for sequential files
- Carriage-control record attributes

The following attributes are assigned at file creation time and can be changed at any time without making a new copy of the file. The following attributes may be changed with the DCL command SET FILE (or within program control by modifying RMS control blocks).

- Access control list
- Backup action
- Reliability options (read-check and/or write-check)
- Delete action
- Expiration date
- File extend quantity
- Global buffer count
- Owner UIC
- Protection code
- Version limit

RUN-TIME FILE CHARACTERISTICS

Some of the options concerning file use can be dynamically specified at run time. This is usually done when opening the file or by changing the record stream context within the program.

File Open Options

- Global buffer count
- Number of local buffers
- Retrieval window size
- File sharing options
- File processing options which can be set in FAB$L_FOP (for example, deferred write)
- Default extension quantities

Record Connect Options

- Access mode (sequential, keyed, or RFA)
- Record locking and processing options that can be set in RAB$L_ROP (for example, fast delete)

Run-time file open and record connection options that apply to file performance are summarized below.

Option	Description
Asynchronous record processing*	Specifies that record I/O for this record stream will be done asynchronously. FDL: CONNECT ASYNCHRONOUS RMS: RAB$L_ROP RAB$V_ASY
Deferred write*	Allows records to be accumulated in a buffer and written only when the buffer is needed or when the file is closed. FDL: FILE DEFERRED_WRITE RMS: FAB$L_FOP FAB$V_DFW
Default extension quantity	Specifies the number of blocks to be allocated to a file when more space is needed. FDL: FILE EXTENSION RMS: RAB$W_DEQ
Fast delete*	Postpones certain internal operations associated with deleting indexed file records until the record is accessed again. This allows records to be deleted rapidly, but may affect the performance of subsequent accessors reading the file until its next-scheduled convert. FDL: CONNECT FAST_DELETE RMS: RAB$L_ROP RAB$V_FDL
Global buffer count	Specifies whether global buffers will be used and the number to be used if the record stream is the first to connect to the file. FDL: CONNECT GLOBAL_BUFFER_COUNT RMS: FAB$W_GBC
Locate mode*	Allows the use of locate mode, not move mode, when reading records. FDL: CONNECT LOCATE_MODE RMS: RAB$L_ROP RAB$V_LOC

Multiblock count	Allows multiple blocks to be transferred into memory during a single I/O operation; for sequential files only. FDL: CONNECT MULTIBLOCK_COUNT RMS: RAB$B_MBC
Number of buffers	Enables the use of multiple buffers. FDL: CONNECT MULTIBUFFER_COUNT RMS: RAB$B_MBF
Read-ahead*	Alternates buffer use between two buffers; as of VMS 4.4 for nonshared sequential files only. FDL: CONNECT READ_AHEAD RMS: RAB$L_ROP RAB$V_RAH
Retrieval window size	Specifies the number of entries in memory for retrieval windows, which corresponds to the number of extents for a file. FDL: FILE WINDOW_SIZE RMS: RAB$B_RTV
Sequential access only	Indicates that the file will be accessed sequentially only; for sequential files only. FDL: FILE SEQUENTIAL_ONLY RMS: FAB$L_FOP FAB$V_SQO
Write-behind*	Alternates buffer use between two buffers; as of VMS 4.4 for nonshared sequential files only. FDL: CONNECT WRITE_BEHIND RMS: RAB$L_ROP RAB$V_WBH

* Indicates on option that can be specified for each record-processing operation.

FAB$V_MSE	Multistream allowed	1 if INDEXED else 0	Initialized to zero	Initialized to zero
FAB$L_STS	Completion Status Code	Returned by RMS	Returned by RMS	Returned by RMS
FAB$L_XAB	Extended Attribute Block Address	Set to File Header Characteristics (FHC) extended attribute block address to get the longest record length. If keys are specified, FAB$_XAB points to the XABKEYs, and the last key points to XABFHC. DIGITAL may add XABs after the FHC XAB. Your USEROPEN procedure can insert XABs anywhere in the chain as long as the requirements of RMS regarding XAB ordering are satisfied.	The XAB chain has a File Header Characteristics (FHC) extended attribute block to get the longest record length (XAB$W_LRL). If the KEY = keyword is specified, KEY index definition blocks will be present. DIGITAL may add XABs in the future. Your USEROPEN procedure can insert XABs anywhere in the chain as long as the requirements of RMS regarding XAB ordering are satisfied.	The XAB chain has a File Header Characteristics (FHC) and Summary (SUM) XABs linked in for all files. If the file record declaration contains KEY attribute specifiers, one or more XABs will also be present. DIGITAL may add XABs in the future. Your USER_ACTION routine can insert XABs anywhere in the chain as long as the requirements of RMS regarding XAB ordering are satisfied.

Footnotes:

1. BASIC
   MIN (255,BKS)
   where BKS = (511 + (bucketsize * recordsize + X) + Y)/512
   where X represents any byte allowance made for record (variable format, relative control byte, or indexed header)
   Y represents bucket header control byte if indexed file.

2. FORTRAN
   FAB$C_STM if RECORDTYPE = 'STREAM'
   FAB$C_STMCR if RECORDTYPE = 'STREAM_CR'
   FAB$C_STMLF if RECORDTYPE = 'STREAM_LF'

DCL COMMANDS FOR IMPLEMENTING RUN-TIME FEATURES AND SEMI-PERMANENT ATTRIBUTES

SET FILE

The SET FILE command allows various capabilities for changing the semi-permanent attributes of a file. The following commands are of particular interest.

- SET FILE/ACL allows modification of the access control list associated with a file.
- SET FILE/BACKUP determines whether the data in a file will be copied by the BACKUP utility.
- SET FILE/DATA_CHECK specifies the reliability options (read check and/or write check).
- SET FILE/ERASE_ON_DELETE ensures erasure of confidential data when a file is deleted.
- SET FILE/EXPIRATION_DATE changes the expiration date of a file (if any).
- SET FILE/EXTENSION specifies the extend quantity, or allows a change to the existing one. This can save recreating a file if you have made a minor error of judgment. Note that this figure is only used for areas which do not have an explicit extend quantity.
- SET FILE/GLOBAL_BUFFER specifies the number of global buffers to be associated with a file.
- SET FILE/OWNER_UIC changes file ownership.
- SET FILE/PROTECTION changes the protection code of a file.
- SET FILE/TRUNCATE truncates a sequential file at the ~~end-of-file marker~~. This enables you to reclaim disk space if too many blocks have been allocated and the file content has become static.

last cluster

- SET FILE/VERSION_LIMIT changes the number of versions to be retained.
- SET FILE/ENTER=new-file-spec assigns an additional name to a file. The file now has a second name, or alias, but both the original name and the alias reference the same file. For this reason, care should be taken when deleting files which have an alias. In order to keep the file but remove one of its names, use the /REMOVE qualifier with the SET FILE command.

NB $copy is selective or copy of file attributes
$ backup always copies all attributes

RMS uses a number of defaults which can either be set system-wide or for each process. Use the SHOW RMS_DEFAULT command to find out the current defaults, and then use the SET RMS_DEFAULT command to change them.

SHOW RMS_DEFAULT

```
$ SHOW RMS_DEFAULT

            MULTI-  |                    MULTIBUFFER COUNTS                    | NETWORK
            BLOCK   | Indexed  Relative          Sequential                    | BLOCK
            COUNT   |                      Disk  Magtape  Unit Record          | COUNT
Process       0     |   0        0         0       0          0                |   0
System       16     |   0        0         0       0          0                |   8

            Prolog  Extend Quantity
Process       0           0
System        0           0
```

The SHOW RMS_DEFAULT command displays the current process and system default multiblock and multibuffer counts for all types of files. It also displays the current process and system prolog level, extend quantity, and network transfer size.

Note that all of these are defaults. They are overridden by what is specified in the file attributes, or by what is specified at file open time (or later, where possible) in a program. The "default defaults" are taken from the RMS system parameters. They may be overridden for the whole system by using the SET RMS_DEFAULT/SYSTEM command (CMKRNL privilege required).

- SET RMS_DEFAULT/BLOCK_COUNT specifies the number of blocks transferred to or from a sequential file in one I/O operation. The specified count, representing the number of blocks to be allocated for each I/O buffer, can range from 0 through 127. If you specify 0, RMS uses the process default value. If this value is 0, RMS then uses the system default value. If the system default value is also 0, then RMS uses a value of 1.

  The /BLOCK_COUNT qualifier applies only to record I/O operations, not to block I/O operations.

- SET RMS_DEFAULT/BUFFER_COUNT specifies the number of buffers to be used for files of the organization and device type indicated using additional qualifiers. The specified count, representing the number of buffers to be allocated, can range from 0 through 127. ~~A positive value indicates that the specified number of buffers must be locked in the process's working set for the I/O operation.~~ A negative value indicates that the specified number of buffers must be allocated but do not have to be locked. If you specify 0, RMS uses the process default value. If this value is 0, RMS then uses the system default value. If the system default value is also 0, then RMS uses a value of 1.

  /INDEXED qualifier indicates that the specified multibuffer default is to be applied to indexed file operations.

  /RELATIVE qualifier indicates that the specified multibuffer default is to be applied to file operations on relative files.

  /SEQUENTIAL qualifier indicates that the specified multibuffer default is to be applied to all sequential file operations, including operations on disk, magnetic tape, and unit record devices.

  /SEQUENTIAL qualifier is the default if you do not specify either /RELATIVE or /INDEXED.

- SET RMS_DEFAULT/EXTEND_QUANTITY specifies the number of blocks (0 to 65535) by which files should be extended, if not already specified.

- SET RMS_DEFAULT/NETWORK_BLOCK_COUNT specifies a maximum block count for network operations on all file organizations.

- SET RMS_DEFAULT/PROLOGUE specifies the prolog version number for file creation.

Examples

```
$ SET RMS_DEFAULT/BLOCK_COUNT=24
$ SHOW RMS

            MULTI-  |                    MULTIBUFFER COUNTS                    | NETWORK
            BLOCK   | Indexed  Relative          Sequential                    |  BLOCK
            COUNT   |                      Disk  Magtape  Unit Record          |  COUNT
Process      24     |    0        0         0       0          0               |    0
System       16     |    0        0         0       0          0               |    8

            Prolog  Extend Quantity

System        0           0
```

SPECIFYING RUN-TIME OPTIONS

All RMS options are set within the RMS control blocks that are maintained in the user P0 space. There are at least three alternative ways these options can be set from higher-level languages.

1. Some run-time options can be preset using keyword values (or defaults) available in their language OPEN statement.

2. For options not set by default by their language compiler, and not available using the OPEN keywords, languages that have a USEROPEN function in their language OPEN statement are able to directly access the VMS control blocks and set any options as part of the OPEN performed by RMS.

3. Many of the RMS run-time options are available in EDIT/FDL and can be added to an FDL file. The FDL run-time options can be implemented within program control at run time by calling the FDL$PARSE routine. This routine also returns to higher-level languages the address of the record access block (RAB) to allow a program to subsequently change RAB values. Certain RAB options are not available in FDL and can be set only by direct manipulation of RAB fields and subfields at run time.

RMS RUN-TIME OPTIONS AVAILABLE THROUGH THE FDL ADD FUNCTION

```
(Add Delete Exit Help Invoke Modify Quit Set View)

MODULE 12
CALLING RMS SERVICES DIRECTLY FROM MACRO AND HIGHER-LEVEL LANGUAGES

Major Topics

- VAX/VMS procedure calling standard
- Reporting success or failure of call
  - Calling as a function
  - RMS completion status codes
  - Testing completion status
- Passing arguments to RMS procedures

Source

BASIC — User's Guide, Chapter 9

COBOL — User's Guide, Part IV

FORTRAN — User's Guide, Chapter 4

PASCAL — User's Guide, Chapter 4

MACRO — RMS Reference, Chapters 3 and 4

THE VAX/VMS PROCEDURE CALLING STANDARD

To eliminate duplication of programming and debugging, VAX/VMS provides a set of rules specifying the interface between a calling program and a called procedure. These rules are known as the VAX/VMS Procedure Calling Standard. If this standard is followed, a procedure written in any VAX/VMS native-mode language can be called from a program written in any other native-mode language. These languages include FORTRAN, MACRO, BASIC, COBOL, and PASCAL.

The VAX/VMS Procedure Calling Standard is followed by all VAX high-level languages. It permits interlanguage calls among all VAX languages. The VAX/VMS Procedure Calling Standard specifies:

1. how to save the state of the calling program and transfer control to the called procedure,

2. how to restore the state of the calling program and return control to it,

3. how to pass arguments between the calling program and the called procedure,

4. how to report the success or failure of the called procedure to the calling program.

REPORTING SUCCESS OR FAILURE OF A CALL

Calling as a Function

- The VAX/VMS Procedure Calling Standard requires that a procedure report success or failure to the calling program in a status longword.

- For most system-supplied procedures, the program must test the status longword to detect an error. The status longword is returned to the program in two ways.

  1. As the function result in high-level languages, if the procedure is called as a function.

  2. In RO in MACRO.

- When calling RMS procedures (or any system service), even if a fatal error is encountered, it will return by default to the next instruction in the user code.

- Before returning to user program from a file or record operation, RMS also writes the condition value in the completion status code field (_STS) of the associated control block (FAB or RAB). For certain completion values, RMS returns additional information in the status value field (_STV) of the control block. The description of the RMS completion status codes in Appendix A of the RMS Reference Manual indicates which codes return information in the STV field.

RMS Completion Status Codes

The following symbolic names are associated with the numeric constant:

RMS$_fff[...f]

Refer to the RMS Reference Manual for more information. Appendix A, Table A-2 lists the symbolic names for the completion codes alphabetically. Appendix A, Table A-1 lists the completion codes by number.

Example

```
RMS$_EOF          0001827A  (Hex)
                    98938   (Decimal)
```

The symbolic names and associated numeric values are defined in an $RMSDEF module, the location of which varies among the programming languages.

Location $RMSDEF Module

Language	SYS$LIBRARY:	External Reference to Symbolic Name Resolved at
BASIC	STARLET.OLB(1)	Link — for V3.0 and above use: SYS$LIBRARY:BASIC$STARLET.TLB
COBOL	STARLET.OLB(1)	Link
FORTRAN	FORSYSDEF.TLB(2)	Compile
PASCAL	STARLET.PEN(3)	Compile
MACRO	STARLET.MLB(1)	Assemble

Use the following DCL library utilities to extract a listing from one of these libraries.

(1) $LIBRARY/EXTRACT = $RMSDEF/OUT=filespec -

SYS$LIBRARY:STARLET.MLB

(2) $LIBRARY/EXTRACT=$RMSDEF/OUT=filespec -

SYS$LIBRARY;FORSYSDEF.TLB

(3) The source for the PASCAL environment file is in SYS$LIBRARY:STARLET.PAS. This is not a library output file. Use EDIT to locate and extract module $RMSDEF.

```
$LIBRARY/EXTRACT=$RMSDEF/OUT=RMSDEF.DEF   SYS$LIBRARY:STARLET.MLB

Testing Completion Status -- Calling RMS Procedures

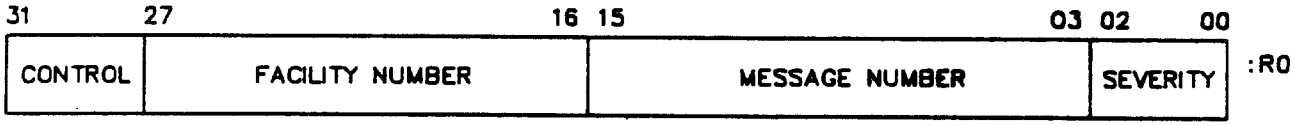
	BASIC	COBOL	FORTRAN	PASCAL
1. Call procedure as	Function	Function	Function	Function
2. Declare function name	EXTERNAL LONG function name	--	INTEGER*4 name	[INHERIT ('SYS$LIBRARY:STARLET')]
3. Declare variable to receive status code as function result	LONG STAT	01 STAT COMP PIC S9(9)	INTEGER*4 STAT	STAT : INTEGER;
4. If you wish to test for specific status code (optional)	EXTERNAL LONG CONSTANT symbol_name	01 symbol_name PIC S9(9) COMP VALUE IS EXTERNAL symbol_name	INCLUDE '($RMSDEF)'	[INHERIT ('SYS$LIBRARY:STARLET')]

A programmer can test for:

1. Success or failure <--- overall test -- binomial evaluation

2. Specific conditions <--- test of specific condition codes (symbolic names)

Format of Status Value



Severity Codes

Severity	Meaning
0	Warning
1	Success
2	Error
3	Information
4	Severe Error
5-7	Reserved for Future Use

Example 1. Testing Specific Condition Codes

(Sheet 1 of 2)

BASIC

```
01      EXTERNAL LONG FUNCTION SYS$GET
02      EXTERNAL LONG CONSTANT RMS$_EOF
03      DECLARE LONG STAT
04      .
05      .
06      STAT = SYS$GET(...)
07      handle error IF (STAT = RMS$_EOF)
08      .
09      .
```

COBOL

```
10      DATA DIVISION.
11      WORKING_STORAGE SECTION.
12        01  STAT       PIC S9(9)       COMP.
13        01  RMS$_EOF   PIC S9(9)       COMP    VALUE EXTERNAL RMS$_EOF.
14      PROCEDURE DIVISION.
15      BEGIN.
16      .
17      .
18      CALL 'SYS$GET' USING ... GIVING STAT.
19      IF STAT IS EQUAL TO RMS$_EOF THEN  handle error.
20      ...
```

FORTRAN

```
21      INTEGER*4         SYS$GET, STAT
22      INCLUDE           '($RMSDEF)'
23      .
24      .
25      STAT = SYS$GET(...)
26      IF (STAT .EQ. RMS$_EOF) THEN
27              handle error
28      END IF
29      .
30      .
```

Example 1 (Sheet 2 of 2)

PASCAL

```
31      [INHERIT ('SYS$LIBRARY:STARLET')] PROGRAM GO_GET_IT;
32      VAR
33         STAT : INTEGER;
34      ...
35      BEGIN
36      ...
37      STAT := $GET(...);
38      IF (STAT = RMS$_EOF) THEN handle error;
39      ...
40      END.
```

MACRO

```
41      $GET    ...
42      CMPL    #RMS$_EOF, R0
43      BEQLU   handle_error
44      ...
```

Example 2. Testing Overall Error -- Test of Low-Order Bit in STATUS Returned

(Sheet 1 of 2)

BASIC

```
01      EXTERNAL LONG FUNCTION SYS$GET
02      .
03      DECLARE LONG STAT
04      .
05      .
06      STAT = SYS$GET(...)
07      handle error IF (STAT AND 1%) = 0%
08      .
09      .
```

COBOL

```
10      DATA DIVISION.
11      WORKING_STORAGE SECTION.
12        01  STAT       PIC S9(9)        COMP.
13      .
14      PROCEDURE DIVISION.
15      BEGIN.
16      .
17      .
18      CALL 'SYS$GET' USING ... GIVING STAT.
19      IF STAT IS FAILURE THEN  handle error.
20      ...
```

FORTRAN

```
21      INTEGER*4        SYS$GET, STAT
22      .
23      .
24      .
25      STAT = SYS$GET(...)
26      IF (.NOT.STAT) THEN
27              handle error
28      END IF
29      .
30      .
```

Example 2 (Sheet 2 of 2)

PASCAL

```
31      [INHERIT ('SYS$LIBRARY:STARLET')] PROGRAM GO_GET_IT;
32      VAR
33         STAT : INTEGER;
34      ...
35      BEGIN
36      ...
37      STAT := $GET(...);
38      IF NOT ODD (STAT) THEN handle error;
39      ...
40      END.
```

MACRO

```
41      $GET    ...
42      BLBC    R0, handle_error
43      .
44      ...
```

RMS services are considered system services for the purpose of generating system service exceptions on errors. You can choose whether to test and handle errors in your program or set the system service failure exception mode (using the Set System Failure Exception Mode system service, SYS$SETSFM) to have failures automatically signaled. For most applications, especially if a high-level language is used, testing and handling errors in your program are the preferred method. If you test for error conditions in your program, be sure to disable any unwanted system service exception generation.

Three general SS$_ condition codes may be encountered.

SS$_INSFARG	Insufficient # arguments in call
SS$_ILLSER	Nonexistent service called
SS$_ACCVIO	Argument list cannot be read

Note that if the FAB or RAB is invalid or inaccessible, then the error completion routine will not attempt to store the error code in the STS field of an invalid control block structure. The following errors can be detected only by testing the completion code returned by the function call (or by enabling system service failure exception mode), following the completion of an RMS operation (even if an error completion AST has been specified):

RMS$_BLN	Invalid block length field (either FAB or RAB)
RMS$_BUSY	User structure (FAB/RAB) still in use
RMS$_FAB	FAB not writeable or invalid block ID field
RMS$_RAB	RAB not writeable or invalid block ID field
RMS$_STR	User structure (FAB/RAB) became invalid during operation

These completion codes indicate that the FAB or RAB is invalid or inaccessible. These completion codes are usually rare and, if they occur at all, would most likely occur during initial program debugging and testing. Examine the completion value in R0 or returned by the function call (instead of the STS field of the FAB or RAB) for the completion codes listed above.

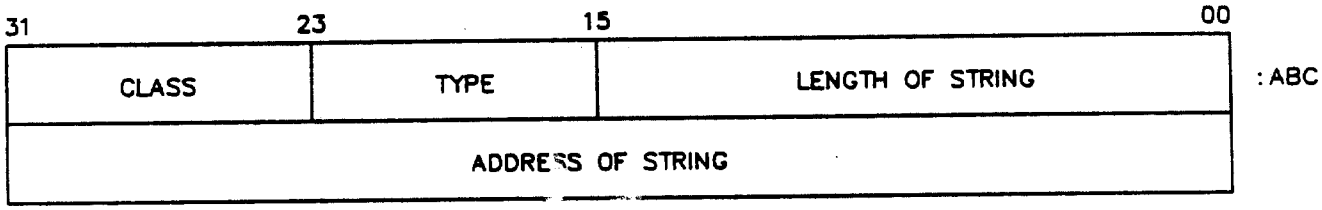
When signaling RMS errors, both the STS and STV fields of the appropriate structure (FAB or RAB) should be supplied. This will cause all relevant information to be displayed in the error message text, including additional information regarding the error status in the STV field. For the file processing and file naming services, use the STS and STV fields of the specified FAB (use the old FAB for the Rename service). For record processing and block I/O processing services, use the STS and STV fields of the corresponding RAB.

The recommended way to signal RMS errors is to provide both the STS and STV fields of the RAB or FAB as arguments to the Run-Time Library (RTL) routine LIB$SIGNAL (or LIB$STOP). Certain VAX languages provide a built-in means of signaling errors, such as by providing a system-defined function. For a more detailed explanation of condition signaling and invoking RTL routines, see the VAX/VMS Run-Time Library Routines Reference Manual.

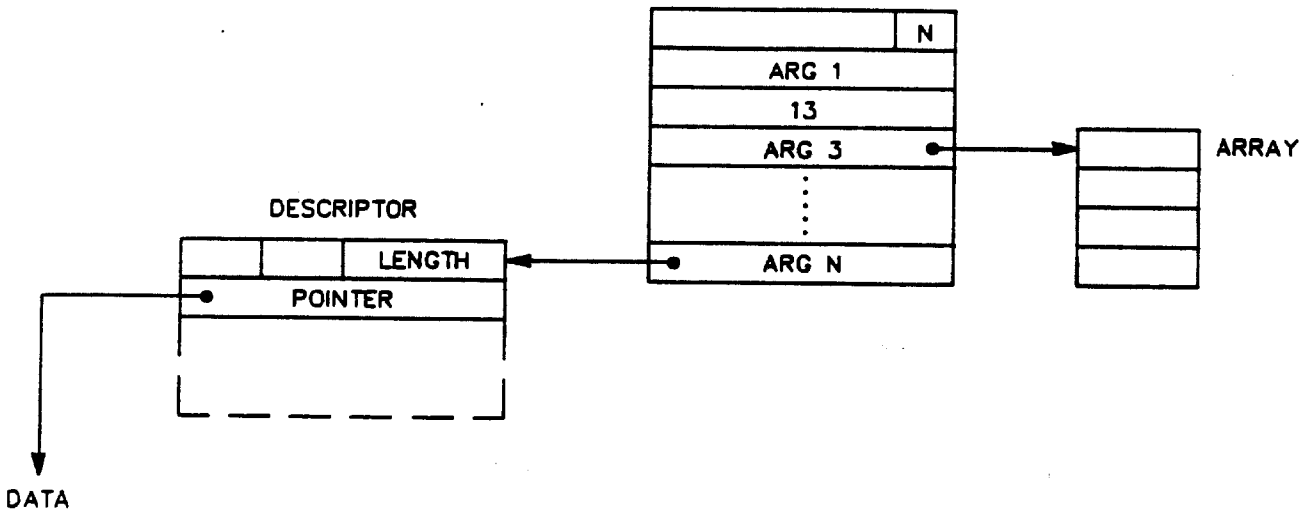
PASSING ARGUMENTS TO PROCEDURES

- Arguments are passed to procedures by an argument list.
- The VAX/VMS Procedure Calling Standard requires all arguments to be passed as longwords.
- Arguments may be passed by:
  - Value -- the actual data is placed in the argument list.
  - Reference -- passing the address of the argument.
  - Descriptor -- passing the address of a descriptor containing information about the data and a pointer to the data.
- The format of passed arguments must match the format expected by the called procedure.
  - In calls to user-written procedures, arguments should match the default for the language in which the procedure is written.
  - In calls to system-supplied procedures, arguments should match the format specified by the VAX/VMS documentation.

Layout of the String Descriptor for ABC



Format of an Argument List



BU-2485

Default Argument Passing and Receiving Mechanisms

Language	Numeric	Character	Array
BASIC	Reference	Descriptor	Descriptor
COBOL	Reference	Reference	N/A
FORTRAN	Reference	Descriptor	Reference
MACRO	No Default	No Default	No Default
PASCAL	Reference	Reference	Reference*

* Except conformant arrays

Argument Passing Specifiers

	Mechanism Specifier			
Description	BASIC	COBOL	FORTRAN	PASCAL
Passed by Value	BY VALUE	BY VALUE	%VAL	%IMMED
Passed by Reference	BY REF	BY REFERENCE or BY CONTENT	%REF	%REF
Passed by Descriptor	BY DESC	BY DESCRIPTOR	%DESCR	%DESCR
Passed by String Descriptor	BY DESC	BY DESCRIPTOR	%DESCR	%STDESCR

Example 3. Passing BY VALUE

BASIC:

```
DECLARE LONG abc
 .
 .
 .
abc = 35
 .
 .
 .
stat = SUB1 (abc BY VALUE)
```

COBOL:

```
...
01 abc PIC 9(5) VALUE is 35.
 .
 .
 .
CALL SUB1 USING BY VALUE abc
            GIVING STAT.
```

FORTRAN:

```
INTEGER*4 abc/35/
 .
 .
 .
stat = SUB1 (%VAL(abc))
```

PASCAL:

```
...
VAR
   abc : INTEGER := 35;
...
FUNCTION SUB1 (%IMMED xyz:INTEGER):
            INTEGER; EXTERN;
 .
 .
 .
STAT := SUB1 (abc);
```

MACRO:

```
abc: .LONG 35

 .
 .
PUSHL abc
CALLS #1, SUB1
```

Example 4. Passing BY REFERENCE

BASIC:

```
DECLARE LONG abc
 .
 .
 .
abc = 35
 .
 .
 .
stat = SUB1  (abc BY REF)
                 or
              (abc)
```

COBOL:

```
01 abc PIC 9(5) VALUE is 35.
 .
 .
 .
CALL SUB1 USING BY REFERENCE abc
                          or
                         abc
          GIVING STAT.
```

FORTRAN:

```
INTEGER *4  abc/35/
 .
 .
 .
STAT = SUB1 (%REF(abc))
                 or
              (abc)
```

PASCAL:

```
VAR
abc : INTEGER := 35;
...
FUNCTION SUB1 (%REF xyz: INTEGER): INTEGER;
                                    EXTERN;
                        or
                 (xyz : INTEGER);
 .
 .
 .
STAT := SUB1 (abc);
```

MACRO:

```
abc: .LONG 35
 .
 .
 .
PUSHAL abc
CALLS  #1, SUB1
```

Example 5. Passing BY DESCRIPTOR

BASIC:

```
DECLARE STRING abc
 .
 .
 .
abc = '35'
 .
 .
 .
STAT = SUB1 (abc BY DESC)
                or
             (abc)
```

COBOL:

```
01 abc PIC x(2) VALUE is '35'.
 .
 .
 .
CALL SUB1 USING BY DESCRIPTOR abc
          GIVING STAT.
```

FORTRAN:

```
CHARACTER*2 abc /'35'/
 .
 .
 .
STAT = SUB1 (%DESCR(abc))
                or
             (abc)
```

PASCAL:

```
VAR
abc : PACKED ARRAY [1..2] OF CHAR;
 .
 .
 .
FUNCTION  SUB1 (xyz:[CLASS_S] PACKED ARRAY [1..u:
           INTEGER] of CHAR): INTEGER; EXTERN;
 .
 .
 .
abc  = '35';
STAT. = SUB1 (abc);
```

MACRO:

```
abc: .ASCID /35/
 .
 .
 .
PUSHAQ      abc
CALLS       #1, SUB1
```

RMS routines -- The passing mechanism is identified in the second sentence of the argument description.

Passing Method	Description
Immediate Value	"The value of" or omission of the word "address"
Reference	"Address of"
Descriptor	"Address of a descriptor"

Example 6. Passing Mechanism for SYS$SETDDIR Arguments

Arguments	Passing Mechanism
new_dir_addr	_____
length_addr	_____
cur_dir_addr	_____

BASIC	Include commas as placeholders for each omitted argument.
COBOL	BY VALUE 0 for each omitted argument.
FORTRAN	Include commas as placeholders for each omitted argument.
PASCAL	Positional syntax: If default value is declared in formal declaration, then commas are not needed. Keyword syntax is allowed for PASCAL.
MACRO	For most RMS calls, MACROS exists to assist in the construction of the argument list. However, in a few cases (for example, SYS$SETDDIR), RMS procedures are called without an RMS MACRO and a zero should be passed for the optional argument. Keyword syntax is allowed for MACRO.

Example 7. Program Calling RMS Procedure SYS$SETDDIR

(Sheet 1 of 2)

BASIC

SETDDIR.BAS

```
1       10  !
2           !
3           !     This program calls the RMS procedure $SETDDIR to
4           !     change the default directory for the process.
5           !
6               EXTERNAL INTEGER FUNCTION SYS$SETDDIR

MODULE 13
ALTERNATE APPROACHES TO ACCESSING RMS CONTROL BLOCKS DIRECTLY — LANGUAGE EXAMPLES

Major Topics

- USEROPEN function supported by some higher-level languages
- Call FDL$PARSE to set up and initialize control blocks

Source

RMS Reference Manual — Chapter 5 (FAB), Chapter 7 (RAB)

USEROPEN FUNCTION OR REGULAR I/O

The USEROPEN function is an alternative approach to accessing RMS control blocks directly. The USEROPEN function is called as part of the OPEN command. Thereafter, regular language I/O is used.

Language	Open Keyword	Value	Language Function May Be Written In
BASIC	USEROPEN	function-name	BASIC
COBOL	not available	--	--
FORTRAN	USEROPEN	function-name	FORTRAN
PASCAL	USER_ACTION	function-name	PASCAL

The USEROPEN function has three arguments:

1. Arg 1 -- FAB address
2. Arg 2 -- RAB address

} passed to user by RMS

3. Arg 3 -- File # - BASIC
   Unit # - FORTRAN
   Filename identifier - PASCAL

} user defined

The Run-Time Library sets up the following VAX-11 RMS control structures before calling the USEROPEN function:

FAB File Access Block
RAB Record Access Block
NAM Name Block
XAB FHC Extended Attributes Block
. .
. } Any key XABs specified for index files
.

For BASIC and FORTRAN USEROPEN functions, only the RAB structure remains allocated after the OPEN. Therefore, do not store the addresses of the FAB, XAB, or NAM blocks for later use.

The PASCAL USER_ACTION parameter differs from the BASIC/FORTRAN USEROPEN keyword in that you may include user-written procedures with either OPEN or CLOSE or both, while USEROPEN is limited to OPEN. Further, the USER_ACTION function may be written in PASCAL and is allowed to up-level address. The RMS RAB, FAB, and NAM blocks are allocated dynamically and remain defined as long as the file is opened. Therefore, your program may store the addresses of these structures for later use.

To assign values to a field or read values in a field in the RMS control block (FAB, RAB), the user needs to be able to declare a structure in the programming language to match that of RMS.

BASIC

None provided in system library. Set up your own and 'include' it in the source file.

```
%INCLUDE 'FABRABDEF.BAS'
```

FAB$TYPE
RAB$TYPE

FORTRAN

```
INCLUDE '($FABDEF)'
INCLUDE '($RABDEF)'
```

SYS$LIBRARY: FORSYSDEF.TLB

PASCAL

```
[INHERIT ('SYS$LIBRARY: STARLET')]
```

FAB$TYPE
RAB$TYPE

Now included in BASICSTARTLET.TLB

Example 1. USEROPEN Alternative (if available) or Regular I/O

Entry Points to PASCAL Utilities

This section describes the entry points to utilities in the VAX Run-Time Library that can be called as external routines by a VAX PASCAL program. These utilities access VAX PASCAL extensions that are not directly provided by the language.

1. PAS$FAB(f)

   The PAS$FAB function returns a pointer to the RMS File Access Block (FAB) of file f. After this function has been called, the FAB can be used to get information about the file and to access RMS facilities not explicitly available in the PASCAL language.

   The component type of file f can be any type; the file must be open.

   PAS$FAB is an external function that must be explicitly declared by a declaration such as the following:

```
TYPE
   Unsafe_File = [UNSAFE] FILE OF CHAR;
   Ptr_to_FAB  = ^FAB$TYPE;

FUNCTION PAS$FAB
   (VAR F : Unsafe_File) : Ptr_to_FAB;
   EXTERN;
```

   This declaration allows a file of any type to be used as an actual parameter to PAS$FAB. The type FAB$TYPE is defined in the VAX PASCAL environment file STARLET.PEN, which your program or module can inherit.

2. PAS$RAB(f)

   The PAS$RAB function returns a pointer to the RMS Record Access Block (RAB) of file f. After this function has been called, the RAB can be used to get information about the file and to access RMS facilities not explicitly available in the PASCAL language.

   The component type of file f can be any type; the file must be open.

PAS$RAB is an external function that must be explicitly declared by a declaration such as the following:

```
TYPE
   Unsafe_File = [UNSAFE] FILE OF CHAR;
   Ptr_to_RAB  = ^RAB$TYPE;

FUNCTION PAS$RAB
   (VAX F : Unsafe_File) : Ptr_to_RAB;
   EXTERN;
```

This declaration allows a file of any type to be used as an actual parameter to PAS$RAB. The type RAB$TYPE is defined in the VAX PASCAL environment file STARLET.PEN, which your program or module can inherit.

You should take care that your use of the RMS RAB does not interfer with the normal operations of the Run-Time Library. Future changes to the Run-Time Library may change the way in which the RAB is used, which may in turn require you to change your program.

FDL$PARSE ALTERNATIVE

Call FDL$PARSE to set up and initialize RMS control blocks and thereafter direct calls to RMS services must be used.

1. Opens up FDL file (specified as arg 1 in call).

2. Allocates necessary RMS control blocks and initializes permanent file attributes set in FDL file and any run-time characteristics indicated in the FDL file.

3. Returns address of FAB (arg 2) and address of RAB (arg 3) to the calling program. Subsequently, can be used by the calling program to access and change settings in FAB and RAB.

NOTE

- FDL$PARSE may be called from all higher-level languages including COBOL (and DIBOL).

- Once FDL$PARSE is called the rest of the I/O must be done by calling RMS services directly. There is no way to connect the file channel in the FAB obtained by FDL$PARSE with the regular higher-level language I/O. Note that this channel could be used in QIOs.

- The following warning applies to programmers used to accessing the RMS control blocks using a USEROPEN routine supported by their higher-level language.

WARNING

When you call FDL$PARSE you are responsible for enabling any file or record options you wish to use. They must be either explicitly specified in the FDL or directly set in the program. The defaults usually enabled by your compiler will not be set. Thus, if your compiler had usually enabled DEFERRED WRITE, you will now have to do it.

4. To access RMS control blocks and set them, most higher-level languages have to pass the FAB or RAB pointer to a routine. In the routine the FAB or RAB RECORD is specified as the receiving parameter.

IMPORTANT

The calling routine must pass the FAB or RAB pointer BY VALUE (even though the called routine expects to receive it by reference). We are deliberately tricking the compiler.

FDL$PARSE Routine

The FLD$PARSE routine parses an FDL specification, allocates RMS control blocks (FABs, RABs, or XABs), and fills in the relevant fields.

Format

```
FDL$PARSE fld_spec, fdl_fab_pointer
          ,fdl_rab_pointer [,flags]
          [,dflt_fdl_spc] [,stmnt_num]
```

Arguments

fdl_spec

The fdl_spec argument is the name of the FDL file or the actual FDL specification to be parsed. It is the address of a character string descriptor pointing to either the name of the FDL file or the actual FDL specification to be parsed. If the FDL$V_FDL_STRING flag is set in the flags argument, FDL$PARSE interprets this argument as an FDL specification in string form. Otherwise, FDL$PARSE interprets this argument as a file name of an FDL file.

fdl_fab_pointer

Address of an RMS file access block (FAB). The fdl_fab_pointer argument is the address of a longword which receives the address of an RMS file access block (FAB). FDL$PARSE both allocates the FAB and fills in its relevant fields.

fdl_rab_pointer

Address of an RMS record access block (RAB). The fdl_rab_pointer argument is the address of a longword which receives the address of an RMS record access block (RAB). FDL$PARSE both allocates the RAB and fills in its relevant fields.

flags

The flags (or masks) argument controls how the dflt_fdl_spc argument is interpreted and how errors are signaled. It is the address of a longword containing the control flags. If this argument is omitted or is specified as zero, no flags are set. The flags and their meanings are described below.

Flag	Description
FDL$V_DEFAULT_STRING	Interprets the dflt_fdl_spc argument as an FDL specification in string form. By default, the dflt_fdl_spc argument is interpreted as a file name of an FDL file.
FDL$V_FDL_STRING	Interprets the fdl_spec argument as an FDL specification in string form. By default, the fdl_spec argument is interpreted as a file name of an FDL file.
FDL$V_SIGNAL	Signals any error. By default, the status code is returned to the calling image.

This argument is optional. By default, an error status is returned rather than signaled.

dflt_fdl_spc

The dflt_fdl_spc argument is the name of the default FDL file or specification. It is the address of a character string descriptor pointing to either the default FDL file or the default FDL specification. If the FDL$V_DEFAULT_STRING flag is set in the flags argument, FDL$PARSE interprets this argument as an FDL specification in string form. Otherwise, FDL$PARSE interprets this argument as a file name of an FDL file.

This argument allows you to specify default FDL attributes. In other words, FDL$PARSE processes the attributes specified in this argument, unless you override them with the attributes you specify in the fdl_spec argument.

The FDL defaults can be coded directly into your program, typically with an FDL specification in string form.

This argument is optional.

stmnt_num

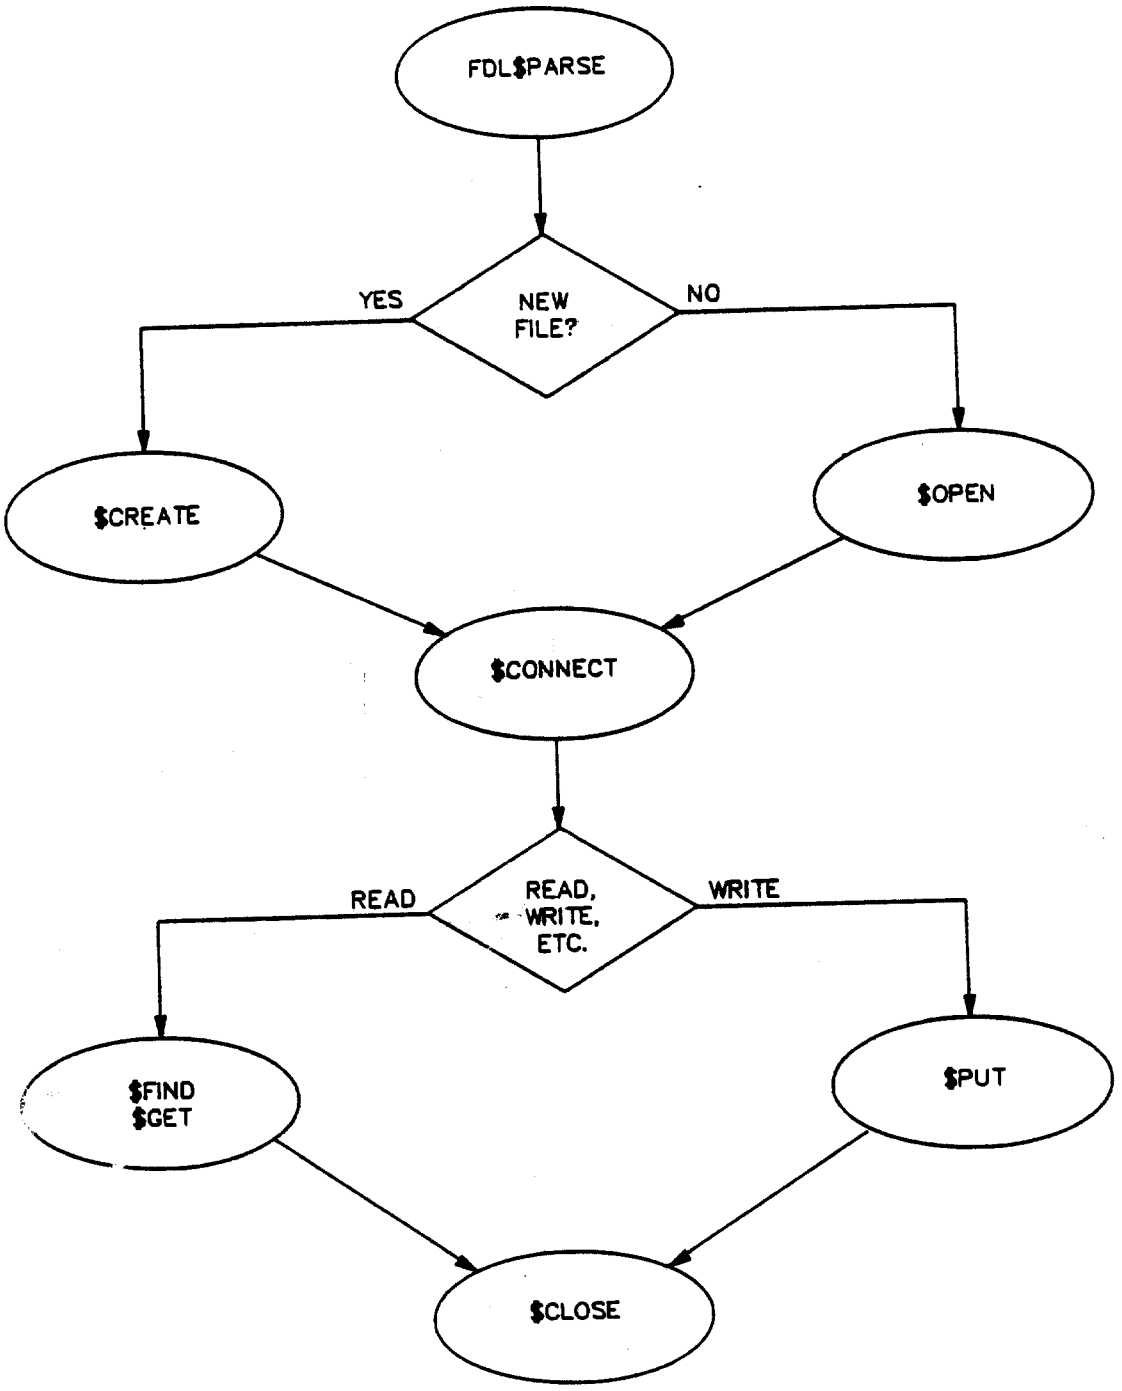
The FDL statement number. The stmnt_num argument is the address of a longword that receives the FDL statement number. If the routine completes successfully, the stmnt_num argument is the number of statements in the FDL specification. If the routine does not complete successfully, the stmnt_num argument receives the number of the statement that caused the error. In general, however, line numbers and statement numbers are not the same.

This argument is optional.

Condition Values Returned

SS$_NORMAL	Normal successful completion.
LIB$_BADBLOADR	Bad block address.
LIB$_BADBLOSIZ	Bad block size.
LIB$_INSVIRMEM	Insufficient virtual memory.
RMS$_DNF	Directory not found.
RMS$_DNR	Device not ready or mounted.
RMS$_WCC	Invalid wildcard context (WCC) value.

Typical Sequence of RMS Calls Initiated by FDL$PARSE



RMS services typically have three arguments:

1. RMS control block address (FAB or RAB)
2. Error completion AST routine
3. Success completion AST routine

Fields in RAB Defining User Record Buffers

Input Buffers

RAB$L_UBF — The user-specified address of a buffer in the program to hold the record (or block) as a result of a $GET or $READ operation (block-IO).

RAB$W_USZ — The user-specified length in bytes of record/block to be transferred to the input buffer.

NOTE

RMS on a $GET or $READ operation does not return the number of bytes written into the UBF buffer in this field. Instead, the number of bytes transferred on a $PUT or $READ operation is returned to the RAB$W_RSZ field.

Output Buffers

RAB$L_RBF — The user-specified address of a buffer in the program that contains the record/block to be written to the file.

When the user issues a $PUT or $WRITE operation (block-IO), this field must contain the address of the record/block to be written to the file.

NOTE

Supplementary use of this field for locate mode: RMS returns RMS buffer address of record just read at the end of a $GET operation.

RAB$W_RSZ The user-specified length, in bytes, of the output buffer.

NOTE

Supplementary use of this field for variable-length fields. RMS returns the length of the record/block transferred by a $GET or $READ operation. In the case of VFC records, RMS returns the length of the variable portion.

BASIC

```
DECLARE LONG X-ptr
  .
  .
  .
X-ptr = LOC (     )
```

COBOL

```
01 x-ptr     USAGE IS POINTER
                 VALUE REFERENCE _____________.
                                 variable-name
```

FORTRAN

```
INTEGER*4     x-ptr
  .
  .
  .
X-ptr = %LOC (      )
```

PASCAL

Alternative 1 (New Pascal V3.0)

VAX

```
x-ptr : INTEGER;
  .
  .
  .
x-ptr : = IADDRESS (      );
```

Alternative 2

```
TYPE          {real    }
  ptr-type = {integer;}

VAR
 x-ptr : ^ptr-type;
  .
  .
  .
x-ptr : = ADDRESS (      );
```

MACRO

```
label:
  .
  .
  .
MOVAL     label
```

VAX Language I/O Operations and RMS Services

This section consists of tables showing how each language's statements relate to RMS services.

BASIC I/O Statements and RMS Routines

BASIC Statement	RMS Routines
GET	$GET
PUT	$PUT
FIND	$FIND
DELETE	$DELETE
UPDATE	$UPDATE
RESTORE	$REWIND
SCRATCH	$TRUNCATE
FREE	$FREE
UNLOCK	$RELEASE

NOTE

1. The first PRINT or INPUT statement to channel 0 causes an $OPEN and $CONNECT operation to SYS$INPUT and SYS$OUTPUT.

2. If a $DELETE, $FIND, $FREE, $GET, $PUT, or $UPDATE operation fails because the record stream is active, the function is retried after a $WAIT.

COBOL I/O Statements and RMS Routines

COBOL Statement	RMS Routine
ACCEPT	$GET
CLOSE	$CLOSE, $DISCONNECT, $NXTVOL
DELETE	$FIND, $DELETE (See Note)
OPEN	$OPEN or $CREATE, $CONNECT
READ	$GET
REWRITE	$FIND, $UPDATE (See Note)
WRITE	$PUT
DISPLAY	$PUT
START	$FIND
UNLOCK	$RELEASE, $FREE

NOTE

$FIND is done only when the DELETE or REWRITE is being performed during random access.

FORTRAN I/O Statements and RMS Routines

FORTRAN Statement	RMS Routine	See Note Number:
ACCEPT	$GET	5
BACKSPACE	$REWIND, followed by one or more $GET operations if target record is not the first record	
CLOSE	$CLOSE	
DEFINE FILE	None	
DELETE(u)	$DELETE	5
DELETE(u, REC = r)	$FIND, $DELETE	5
ENDFILE	$PUT	2,5
FIND	$FIND	1,5
INQUIRE (by file)	$PARSE, $SEARCH, $OPEN, $CLOSE	
INQUIRE (by unit)	None	
OPEN	$OPEN or $CREATE, $CONNECT	
OPEN (with USEROPEN)	None	
OPEN (on connected unit)	$PARSE, $SEARCH, $CLOSE, $OPEN or $CREATE, $CONNECT	8
PRINT	$PUT	4,5
READ	$GET	1,5,7
READ (internal file)	None	
REWIND	$REWIND	
REWRITE	$UPDATE	5
TYPE	$PUT	4,5
UNLOCK	$FREE	5
WRITE	$PUT	2,5,7
WRITE (internal file)	None	

NOTES

1. If the unit is not already open, the first READ or FIND statement on a logical unit invokes an $OPEN and a $CONNECT.

2. If the unit is not already open, the first WRITE or ENDFILE statement on a logical unit causes a $CREATE and $CONNECT.

3. The first ACCEPT statement in a program causes an $OPEN and $CONNECT.

4. The first PRINT statement in a program and the first TYPE statement in a program each cause a $CREATE and $CONNECT.

5. If a $DELETE, $FIND, $FREE, $GET, $PUT, or $UPDATE fails because the record stream is active, the function is retried after a $WAIT.

6. If RECORDTYPE is explicitly or implicitly 'SEGMENTED', an unformatted sequential READ statement can cause more than one $GET.

7. If RECORDTYPE is explicitly or implicitly 'SEGMENTED', an unformatted sequential WRITE statement can cause more than one $PUT.

8. If the specified file name is the same as the name of the currently open file, only the BLANK= parameter is changed; otherwise, the current file is closed and the new file opened.

PASCAL I/O Statements and RMS Routines

PASCAL Statement	RMS Routine	See Note Number:
CLOSE	$CLOSE	1,3
DELETE	$DELETE	1
EOF	None	1,2
EOLN	None	1,2
FIND	$GET	1
FINDK	$GET	1
GET	$GET	1,2
LINELIMIT	None	1,2

LOCATE	None	1
OPEN	$OPEN or $CREATE, $CONNECT	4
PAGE	$PUT	1,2
PUT	$PUT	1,2
READ	$GET	1,2
READLN	$GET	1,2
RESET	$REWIND, $GET	4,5
RESETK	$REWIND, $GET	1
REWRITE	$REWIND, $GET, $TRUNCATE	4,5
STATUS	None	1,2
TRUNCATE	$TRUNCATE	1,2
UFB	None	1,2
UNLOCK	$RELEASE	1
UPDATE	$UPDATE	1
WRITE	$PUT	1,2
WRITELN	$PUT	1,2

NOTES

1. May implicitly open file INPUT or OUTPUT. See OPEN for RMS operations.

2. If delayed device access (lazy lookahead) is in progress on the file, a $GET will be done, and all open text files for which prompting is enabled may have a $PUT performed for them.

3. If the file is in Generation mode, a $PUT may also be performed.

4. If the file is a text file opened on a terminal, and if the carriage control is LIST and no USER-ACTION procedure was specified, the file is closed and reopened with two-byte VFC record type and PRN carriage control to allow prompting.

5. Opens file if it is not already open. See OPEN for RMS operations.

Summary of FAB Fields and Options

Field	Name
FAB$L_ALQ	Allocation quantity
FAB$B_BKS	Bucket size
FAB$W_BLS	Block size for tape
FAB$L_CTX	Context
FAB$W_DEQ	Default file extension quantity
FAB$L_DEV	Device characteristics
FAB$L_DNA	Default file specification string address
FAB$L_DNS	Default file specification string size
FAB$B_FAC	File access
FAB$L_FNA	File specification string address
FAB$L_FNS	File specification size
FAB$L_FOP	File processing options
FAB$V_CBT	Contiguous best try
FAB$V_CIF	Create if nonexistent
FAB$V_CTG	Contiguous allocation
FAB$V_DFW	Deferred write
FAB$V_DLT	Delete on close service
FAB$V_MXV	Maximize version number
FAB$V_NAM	Name block inputs
FAB$V_NEF	Not position at end of file (tape)
FAB$V_NFS	Not file structured
FAB$V_OFP	Output file parse
FAB$V_POS	Current position (after closed file) (tape)
FAB$V_RCK	Read check
FAB$V_RWC	Rewind on close service (tape)
FAB$V_RWO	Rewind on open service (tape)

Field	Name
FAB$L_FOP (Cont.)	
FAB$V_SCF	Submit command
FAB$V_SPL	Spool to printer
FAB$V_SQO	Sequential only
FAB$V_SUP	Supersede
FAB$V_TEF	Truncate at end-of-file
FAB$V_TMD	Temporary, marked for delete
FAB$V_TMP	Temporary (file with no directory entry)
FAB$V_UFO	User file open or create file only
FAB$V_WCK	Write check
FAB$B_FSZ	Fixed control area size
FAB$W_GBC	Global buffer count
FAB$W_IFI	Internal file identifier
FAB$L_MRN	Maximum record number
FAB$W_MRS	Maximum record size
FAB$L_NAM	Name block address
FAB$B_ORG	File organization
FAB$B_RAT	Record attributes
FAB$V_FTN	FORTRAN carriage control
FAB$V_CR	Print LF and CR
FAB$V_BLK	Do not cross block boundaries
FAB$B_RFM	Record format
FAB$B_RTV	Retrieval window size
FAB$L_SDC	Spooling device characteristics
FAB$B_SHR	File sharing
FAB$L_STS	Completion status code
FAB$L_STV	Status value (if any)
FAB$L_XAB	Extended attribute block address

Summary of RAB Fields and Options

Field	Name
RAB$L_BKT	Bucket code
RAB$L_CTX	Context
RAB$L_FAB	FAB address
RAB$W_ISI	Internal stream ID
RAB$L_KBF	Key buffer address
RAB$B_KRF	Key of reference
RAB$B_KSZ	Key size
RAB$B_MBC	Multiblock count
RAB$B_MBF	Multibuffer count
RAB$L_PBF	Prompt buffer address
RAB$B_PSZ	Prompt buffer size
RAB$B_RAC	Record access mode
RAB$C_SEQ	
RAB$C_KEY	
RAB$C_RFA	
RAB$L_RBF	Record address
RAB$W_RFA	Record's file address
RAB$L_RFA0	VBN #
RAB$W_RFA4	Byte offset or ID #
RAB$L_RHB	Record header buffer
RAB$L_ROP	Record processing options
RAB$V_ASY	Asynchronous
RAB$V_BIO	Block I/O
RAB$V_CCO	Cancel CTRL/O
RAB$V_CVT	Convert to uppercase
RAB$V_EOF	End-of-file
RAB$V_ETO	Extended terminal operation
RAB$V_FDL	Fast delete

Field	Name
RAB$L_ROP (Cont.)	
RAB$V_KGE	Key greater than or equal to
RAB$V_KGT	Key greater than
RAB$V_LIM	Limit
RAB$V_LOA	Load according to fill factor
RAB$V_LOC	Locate mode
RAB$V_NLK	No lock
RAB$V_NXR	Nonexistent record
RAB$V_PMT	Prompt
RAB$V_PTA	Purge type-ahead
RAB$V_RAH	Read-ahead
RAB$V_REA	Lock record for read (others can read)
RAB$V_RLK	Lock record for write (others can read)
RAB$V_RNE	Read no echo
RAB$V_RRL	Read regardless of lock
RAB$V_RNF	Read no filter
RAB$V_TMO	Timeout
RAB$V_TPT	Truncate put
RAB$V_UIF	Update if
RAB$V_ULK	Manual unlocking
RAB$V_WAT	Wait if record currently locked
RAB$V_WBH	Write-behind
RAB$W_RSZ	Record size
RAB$L_STS	Completion status code
RAB$L_STV	Status value (if any)
RAB$B_TMO	Timeout period
RAB$L_UBF	User record area address
RAB$W_USZ	User record area size
RAB$L_XAB	Next XAB address

Current Record Context

For each RAB connected to a FAB, RMS maintains current context information, identifying where each RAB is positioned at any given moment. RMS modifies the current context as your program performs record operations.

At any point, the current record context is represented by, at most, two records: the current record or the next record.

The context of these two records is internal to RMS; you have no direct contact with them. However, you should know what the context is to access the desired record using the appropriate RMS record service.

Record Access Stream Context

Record Operation	Record Access Mode	Current Record	Next Record
Connect	Does not apply	None	First record
Connect with RAB$L_ROP RAB$V_EOF bit set	Does not apply	None	End of file
Get, when last service was not a Find	Sequential	Old next record	New current record+1
Get, when last service was a Find	Sequential	Unchanged	Current record+1
Get	Random	New	New current record+1
Put, sequential file	Sequential	None	End of file
Put, relative file	Sequential	None	Next record position
Put, indexed file	Sequential	None	Undefined
Put	Random	None	Unchanged
Find	Sequential	Old next record	New current record+1
Find	Random	New	Unchanged
Update	Does not apply	None	Unchanged
Delete	Does not apply	None	Unchanged

Record Access Stream Context (Cont.)

Record Operation	Record Access Mode	Current Record	Next Record
Truncate	Does not apply	None	End of file
Rewind	Does not apply	None	First record
Free	Does not apply	None	Unchanged
Release	Does not apply	None	Unchanged

NOTES

1. Except for the Truncate service, RMS establishes the current record before establishing the identity of the next record.

2. The notation +1 indicates the next sequential record as determined by the file organization. For indexed files, the current key of reference is part of this determination.

3. The Connect service on an indexed file establishes the next record to be the first record in the index represented by the RAB key of reference (RAB$B__KRF) field.

4. The Connect service leaves the next record as the end of file for a magnetic tape file opened for Put services (unless the FAB$V__NEF option in the FAB$L__FOP is set).

Example 2. FDL$PARSE Alternative

BASIC (Sheet 1 of 7)

```
10 OPTION  TYPE = EXPLICIT                                    BASPARSE_INDX.BAS
    !
    !
    !   NOTE:  $LINK BASPARSE_INDX,BAS_SETRMS
    !
    !          BAS_SETRMS.BAS contains two external routines:
    !
    !                   SETFAB
    !                   SETRAB
    !
    !   This BASIC program uses FDL$PARSE to set up RMS structures
    !   for accessing an indexed file rather than using a USEROPEN
    !   function.  In addition, all access to the INDEXED file is done
    !   using RMS services rather than regular BASIC I/O.
    !   User is prompted for key value for random retrieval of
    !   records and given option to delete any record retrieved.
    !
    !   Program assumes FILE SHARING and RECORD LOCKING
    !
    ON ERROR GO TO err_check

MODULE 14
ADVANCED USE OF FILE SPECIFICATIONS

Major Topics

- Search lists and wildcards
- RMS procedures — $PARSE and $SEARCH

Source

Guide to VAX/VMS File Applications — Chapter 5

SEARCH LISTS AND WILDCARDS

Full file specification:

```
NODE::DEVICE:[root.][DIRECTORY]filename.type;version-no
```

NOTE

Node and root are optional in the full file specification.

Defaults or Logical Names

Only node, device, or, if only a file name is specified, filename, may be a logical name. The translation may contain any filename element.

In addition to applying the process-default device and directory, RMS allows an application program to specify defaults for the device and directory components, as well as other components, of a file specification. The method that RMS uses to apply defaults and translate any logical names present is called file parsing. In effect, RMS merges the various default strings (after translating any logical names) to generate the file specification used to locate the file.

Search List

A search list is a logical name that contains more than one file specification.

Example

```
$ASSIGN   [SMITH]Test1.DAT,
            [SMITH]DATA2.DAT     SEARCH
```

A search list should be used when a predefined group of files is processed by a program that is not intended to be interactive. Using a search list is particularly desirable if the files have unrelated file names or if they are located on different directories or devices. A search list also minimizes processing time by searching for a definite group of files. If the search line does not contain any wildcards and the user wishes to process only the first match found, no special processing is required.

Wildcards

The following wildcards can be used with search lists or file specifications:

*, %, or ellipsis (...)

Example

```
$Assign [WOODS]TEST*.DAT    WILD
```

RMS DEFAULT FILE-PARSING ACTIVITIES

An RMS file service that operates on an unopened file (such as the Create and Open services) will perform the following file-parsing activity by default:

- Examine a file specification for validity
- Translate any logical names present
- Apply defaults
- Attempt to locate the file

If a name block is present, additional file-parsing activities can occur by default.

- Return the actual complete file specification used to access the file and its associated file identifier.
- Return the length of each component of a file specification, as well as other information about the file specification.

RMS FILE-PARSING ACTIVITIES NOT DONE BY DEFAULT

Certain RMS file services, including the Open and Create services, cannot process a file specification that contains a wildcard character. Therefore, these RMS file services must be preceded by another RMS file service called the Parse service. (If a search list with no wildcards is present, the Parse service is usually not needed.) The Parse service can be used to determine whether wildcards or search lists are present. It also initializes control block fields that are necessary to search for multiple files using the RMS Search service. To use the Search service, a name block must be present when the Parse service is invoked.

If a file specification contains one or more wildcards, it must be preprocessed using the Parse and Search services before the file can be located. The Parse service sets certain bit values in a name block field called the file name status bits field (NAM$L_FNB) that can be tested to determine whether a wildcard or a search list logical name is present. The Search service locates a file and specifies its name (without wildcards). If wildcards are present, you must first invoke the Search service before processing (opening or creating) the file. If wildcards are not present, the file can be processed without invoking the Search service, with one exception. If the user wishes more than one file in a search list to be processed, the Search service must be invoked as many times as needed to return the next file specification to be processed.

The sequence of special file processing steps required involves one call to the Parse service followed by one or more calls to the Search service prior to each file open. To process a single file, invoke the Search service only once; to process many files, invoke the Search service as many times as needed to return the next qualified file specification to be processed. When no more files match the file specification, the Search service returns a "no-more-files-found" message (RMS$_NMF). Two Run-Time Library routines, LIB$FIND_FILE and LIB$FILE_SCAN, perform functions that are similar to the Parse and Search services.

For general-purpose applications, the programmer may test for wildcards and/or search lists by invoking the Parse service and testing the appropriate bits in the NAM$L_FNB field. In cases where the program assumes only a single file, the results of this test may be used to explicitly disallow wildcards or search lists.

NAM$L_FNB Status Bits

Field Offset	Description
NAM$V_CNCL_DEV	Device name is a concealed device.
NAM$V_DIR_LVLS	Number of subdirectory levels (value is 0 if there is a user file directory only), a 3-bit field.
NAM$V_EXP_DEV	Device name is explicit.
NAM$V_EXP_DIR	Directory specification is explicit.
NAM$V_EXP_NAME	File name is explicit.
NAM$V_EXP_TYPE	File type is explicit.
NAM$V_EXP_VER	Version number is explicit.
NAM$V_GRP_MBR	Directory specification is in the group/member number format.
NAM$V_HIGHVER	A higher-numbered version(s) of the file exists (output from Create and Enter services).
NAM$V_LOWVER	A lower-numbered version(s) of the file exists (output from Create and Enter services).
NAM$V_NODE	File specification includes a node name.
NAM$V_PPF	File is indirectly accessed process permanent file.
NAM$V_QUOTED	File specification includes a quoted string; indicates that the file name length and address field contains a quoted string file specification. Applies to network operations or magnetic tape devices only.*
NAM$V_ROOT_DIR	Device name incorporates a root directory.

* To distinguish network quoted string file specifications from quoted strings containing ASCII "a" file names (supported for ANSI-labeled magnetic tapes), both the NAM$V_QUOTED and NAM$V_NODE bits will be set.

NAM$L_FNB Status Bits (Cont.)

Field Offset	Description
NAM$V_SEARCH_LIST	A search list logical name is present in the file specification.
NAM$V_WILDCARD	File specification string includes a wildcard; returned whenever any of the other wildcard bits are set.
NAM$V_WILD_DIR	Directory specification includes a wildcard character(s).
NAM$V_WILD_GRP	Group number contains a wildcard character(s).
NAM$V_WILD_MBR	Member number contains a wildcard character(s).
NAM$V_WILD_NAME	File name contains a wildcard character(s).
NAM$V_WILD_SFD1 to NAM$V_WILD_SFD7	Subdirectory 1 through 7 specification includes a wildcard character(s).
NAM$V_WILD_TYPE	File type contains a wildcard character(s).
NAM$V_WILD_UFD	User file directory specification includes a wildcard character(s).
NAM$V_WILD_VER	Version number contains a wildcard character(s).

Example 1. Processing Filename(s) With Wildcards Using LIB$FIND_FILE

(Sheet 1 of 2)

```

82      GO TO 100
83
84  300         CALL EXIT
85      END
```

LIB$FIND_FILE -- FIND FILE

LIB$FIND_FILE is called with a wildcard file specification for which it searches. LIB$FIND_FILE returns all file specifications that satisfy that wildcard file specification.

Format

```
LIB$FIND_FILE  file-spec,result-spec,context
               [,default-spec][,related-spec]
               [,stv-addr][,user-flags]
```

Arguments

File-spec

```
type:         character string
access:       read only
mechanism:    by descriptor
```

The file specification may contain wildcards that LIB$FIND_FILE uses to search for the desired file. The file-spec argument is the address of a descriptor pointing to the file specification. The maximum length of a file specification is 255 bytes.

The file specification used may also contain a search list logical name. If present, the search list logical name elements can be used as accumulative to related file specifications, so that unspecified portions of file specifications will be inherited from previous file specifications.

result-spec

```
type:         character string
access:       modify
mechanism:    by descriptor, dynamic string
```

The result-spec argument is the address of the resultant file specification that LIB$FIND_FILE returns when it find a file that matches the specification.

context

```
type:         longword integer (signed)
access:       modify
mechanism:    by reference
```

The context argument is a zero or an address of an internal FAB/NAM buffer from a previous call to LIB$FIND_FILE. It is a signed longword integer containing the address of the context. LIB$FIND_FILE uses this argument to retain the context when processing multiple input files. Unspecified portions of file specifications are inherited from the last files processed because the file contexts are retained in this argument.

default-spec

type: character string
access: read only
mechanism: by descriptor

The default-spec argument is the default file specification. It is the address of a descriptor pointing to the default file specification.

related-spec

type: character string
access: read only
mechanism: by descriptor

The related-spec argument is the related file specification containing the context of the last file processed. It is the address of a descriptor pointing to the related file specification.

stv-addr

type: longword integer (signed)
access: write only
mechanism: by reference

The stv-addr argument is the RMS secondary status value from a failing RMS operation. It is a signed longword integer containing the address of a longword-length buffer to receive the RMS secondary status value (usually returned in the file access block field, FAB$L_STV).

user-flags

type: longword (unsigned)
access: read only
mechanism: by reference

The user-flags argument is the address of an unsigned longword containing the user flags.

The flag bits, their corresponding symbols, and descriptions are described below.

Bit	Symbol	Description
0	NOWILD	If set, LIB$FIND_FILE returns an error if a wildcard is input.
1	MULTIPLE	If set, this performs temporary defaulting for multiple input files and the related-spec argument is ignored. See the description of context in LIB$FILE_SCAN. Each time LIB$FIND_FILE is called with a different file specification, the specification from the previous call is automatically used as a related file specification. This allows parsing of the elements of a search list logical name such as DISK2:[SMITH] FIL1.TYP,FIL*2.TYP, and so on. Use of this feature is required to get the desired defaulting with search list logical name. LIB$FIND_FILE_END must be called between each command line in interactive use or the defaults from the previous command line will affect the current file specification.

Condition Values Returned

RMS$_NORMAL	Routine completed successfully.
SHR$_NOWILD	LIB facility code. A wildcard was present in the file specification parsed and the wildcard flag bit was set to "no wildcard."

Any condition value returned by RMS Parse and Search services, LIBGET_VM, LIBFREE_VM, or LIB$SCOPY_R_DX.

Example 2. Processing Filename(s) With Wildcards or Search Lists Using RMS $PARSE and $SEARCH

(Sheet 1 of 4)

```
 1  {                                                        PASSEARCH.PAS  }
 2
 3  {   NOTE:  Test data for this program  ------>   INTER*.DAT              }
 4
 5  {   In PASCAL you do not have to call FDL$PARSE to set up
 6      RMS structures.  You are able to set them up and
 7      initialize them directly in PASCAL.
 8
 9      This PASCAL program sets up the RMS structures and does
10      all access to a sequential file using RMS services
11      rather than using any regular PASCAL I/O.
12
13      It also checks whether a wild card is used in the file
14      spec. or a logical name search list by calling $PARSE.
15      If either is used then $SEARCH is called repeatedly until
16      there are no further file name translations.             }

MODULE 15
PROCESS QUOTAS AND LIMITS

Source

Guide to VAX/VMS File Applications — Chapter 1 (Sections 1.6-1.7)

PROCESS AND SYSTEM RESOURCES FOR FILE APPLICATIONS

To use RMS files efficiently, your application requires certain resources that are defined for the system or each process. Specific resources and quotas may need to be adjusted for the process running a file application. Coordinate process and system requirements with your system manager during the application design (or redesign) procedure before implementing the RMS options that require the additional resources for the application. In some cases, the system manager may want to order additional memory or disk drives to ensure that sufficient system resources are available.

Memory Requirements

One of the most important ways to improve application performance is to allocate larger buffer areas or more buffers for an application. The number of buffers and the size of buckets can be fine tuned on the basis of the way the file will be accessed (for indexed files, the index structure and other factors must also be considered).

RMS maintains not only the specified buffers when a file is opened (or created), but also control structures that are charged against process memory use. Memory use generally increases with the number of files to be processed at the same time. The amount of memory needed for I/O buffers can vary greatly for each file; the amount of memory needed for control structures is fairly constant for each file.

The memory use (working set) of a process is governed by three SYSGEN parameters. (Process quotas)

1. Working set default (WSDEFAULT) specifies the initial size of the working set, in pages (512 bytes).

2. Working set quota (WSQUOTA) specifies the maximum size, in pages, that the working set can grow to (unless physical memory pages are available and a larger working set extent value is specified).

3. Working set extent (WSEXTENT) specifies the maximum size, in pages, that the working set can grow to, including the use of free pages of physical memory.

These values can ensure that the process will have sufficient memory to perform the application with a minimum of paging.

Process Record-Locking Quota

When an application will access a shared file for which record modifications or additions are allowed, the process enqueue quota should be examined. The need to increase the process enqueue

quota (ENQLM) varies with the number of records that may be simultaneously locked, multiplied by the number of open files.

The enqueue quota (ENQLM) limits the number of locks a process (and its subprocesses) can own. VAX RMS uses the Lock Management Facility to synchronize shared file access, global buffers, and record locks. Because VAX RMS takes out one lock for every shared file, local buffer, global buffer section, and outstanding record lock, users who expect to perform large amounts of VAX RMS file sharing should have ENQLM set to a large value.

If your process performs extensive VAX RMS file sharing without a sufficient enqueue quota, you could receive the SS$_EXENQLM error message.

If your system performs extensive VAX RMS file sharing and the value of the LOCKIDTBL system parameter is too low, you could receive the SS$_NOLOCKID error message. Your system manager would need to increase both the value of LOCKIDTBL and the value of RESHASHTBL.

Estimate the number of locks per process per file as one per file, plus the multibuffer count for that file, plus the number of records locked (which is usually one unless manual locking is enabled). Use the DCL command SHOW RMS_DEFAULT to display the default multibuffer counts.

Other Limits

Other limits that should be examined are:

1. Process Open File Limit

   The number of files that a process will have open simultaneously is governed by the open file limit (FILLM).

2. Process Asynchronous I/O Limit

   If asynchronous record I/O will occur, the following limits should be examined.

   - Asynchronous system trap limit (ASTLM)
   - Buffered I/O limit (BIOLM)
   - Direct I/O limit (DIOLM)

The values suggested to the system manager for these and other limits are provided in the table below. For a complete description of these limits, see the Guide to VAX/VMS System ~~Management and Daily Operations.~~ Managers reference manual

Process Resource Limits, Suggested Values, Types, and Descriptions

Limit	Value	Type*	Description
ASTLM	24	N	AST queue limit
BIOLM	18	N	Buffered I/O count limit
BYTLM	8192	P	I/O byte count limit
CPU	0	D	CPU time limit (0 = no limit)
DIOLM	18	N	Direct I/O count limit
ENQLM	30	P	Enqueue quota
FILLM	20	P	Open file limit
JTQUOTA	1024	P	Initial byte quota for job-wide logical name table
MAXACCTJOBS	0	S	Maximum active processes for a single account (0 = no limit)
MAXDETACH	0	S	Maximum detached processes for a single username (0 = no limit)
MAXJOBS	0	S	Maximum active processes for a single username (0 = no limit)
PGFLQUO	12800	P	Paging file limit
PRCLM	2	P	Subprocess creation limit
SHRFILM	0	P	Maximum number open shared files (0 = no limit)
TQELM	10	P	Timer queue entry limit

Process Resource Limits, Suggested Values, Types, and Descriptions (Cont.)

Limit	Value	Type*	Description
WSDEF	300	N	Default working set size
WSEXTENT	700	N	Working set extent
WSQUO	350	N	Working set quota

* D = Deductible
N = Nondeductible
P = Pooled
S = System-wide

Source: VMS V4.0 System Management and Daily Operations (September 1984)

In addition to process requirements, a shared file may want to use the capabilities of global buffers to avoid needless I/O when the desired block is already in memory. The memory use of global buffers is governed by the following SYSGEN parameters.

1. The number of RMS global buffers (RMS_GBLBUFQUO) specifies the maximum number of RMS global buffers in use on a system simultaneously, regardless of the number of users or files.

2. The number of global sections (GBLSECTIONS) specifies the maximum number of global sections in use simultaneously on the system.

3. The number of global page table entries (GBLPAGES) specifies the number of global page table entries in use simultaneously on the system.

4. The number of system-wide pages allowed for global page-file sections or scratch global sections (GBLPAGFIL) specifies the number of system-wide pages allowed for global page-file sections, or scratch global sections, in use simultaneously on the system.

When DCL opens a file (a process-permanent file), RMS places internal structures for this file in a special portion of P1 space called the Process I/O Segment. The size of this segment is determined by the SYSGEN parameter PIOPAGES and cannot be expanded dynamically. If DCL tries to open a file and there is not enough space in the Process I/O Segment for the internal structures, you will receive an error message and the file will not be opened.

For a complete description of these parameters, see the description of the System Generation Utility (SYSGEN) in the VAX/VMS Utilities Reference Volume.

Also see all RMS_~ & ACP_~ parameters

MODULE 16
RMS Utilities

Major Topics

PART 6. ANALYZE/RMS/INTERACTIVE

- INTERACTIVE commands
- Sample interactive sessions
  - Exploring indexed file structures
  - Tracking a record from key value to data record

Source

Guide to VAX/VMS File Applications — Chapter 10

PART 6. ANALYZE/RMS/INTERACTIVE

ANALYZE/RMS_FILE Interactive Commands

Command	Function
AGAIN	Displays the current structure again.
DOWN [branch] DOWN AREA DOWN KEY DOWN DATA DOWN BYTES DOWN RRV DOWN SIDRS	Move the structure pointer down to the next level. If the current node has more than one branch, the branch keyword must be specified. If a branch keyword is required but not specified, the utility will display a list of possibilities to prompt you. You can also display the list by specifying "DOWN ?."
DUMP n	Displays a hexadecimal dump of the specified block.
EXIT	End the interactive session.
FIRST	Moves the structure pointer to the first structure on the current level. The structure is displayed. For example, if you are examining data buckets and want to examine the first bucket, this command will put you there and display the first bucket's header.
HELP [keyword...]	Displays help messages about the interactive commands.
NEXT	Moves the structure pointer to the next structure on the current level. The structure is displayed. Pressing the RETURN key is equivalent to a NEXT command.
REST	Moves the structure pointer along the rest of the structures on the current level, and each is displayed in turn.
TOP	Moves the structure pointer up to the file header. The file header is displayed.
UP	Moves the structure pointer up to the next level. The structure at that level is displayed.

New ANALYZE/RMS_FILE Interactive Commands as of VAX/VMS Version 4.4

Command	Function
BACK	Moves the structure pointer to the previous node if one exists within the current level, and displays that node. The number of structures that the pointer is to be moved can also be specified by using the optional parameter BACK n, where n is an integer.
NEXT	As of 4.4, will accept the optional parameter n (NEXT n) to specify the number of structures that the pointer is to be moved forward.
POSITION/BUCKET	Positions the pointer to a specific bucket of the file. This command can be used to bypass step-by-step positioning, and also to position the pointer at a bucket that would otherwise be inaccessible due to structural errors in the file.
POSITION/RECORD	Positions the pointer at a specific record in the current bucket, allowing subsequent structures to be accessed easier.

Guide to VAX/VMS File Applications — Chapter 10 (Section 10.1)

DETECTING PROBLEMS

Corrupted files are seldom encountered in a VAX environment. Programmers who work with indexed files on a daily basis month after month may eventually encounter a corrupted file due to a hardware problem, such as a power failure or disk head failure. In the event that a recent backup copy of the file does not provide a satisfactory solution, this module provides some tools for trying to salvage the data yourself. In some cases, particularly with serious hardware problems, the file may not be able to be recovered.

Some indicators of a possible data corruption problem are:

- Error message -- Bucket format check failed for VBN = #
- The file doesn't have as many records as it should

If the error was immediately preceded by a series of hardware errors, it may be best to restore a backup copy of the file, since there may be other problems that have not been encountered as yet.

The following utilities are tools for detecting problems and recovering data.

- COPY or BACKUP utility
- ANALYZE/RMS/CHECK utility
- DUMP utility
- CONVERT utility
- PATCH utility (in extreme cases)

Example 1. ANALYZE/RMS/CHECK Output For Corrupted File

***  VBN 8:  Index bucket references missing data bucket with VBN 200.
***  Drastic structure error precludes further analysis.

The analysis uncovered 2 errors.

ANALYZE/RMS/CHECK/OUT=CORRUPT1.CHECK CORRUPT1.DAT
```

DUMP Utility

The DUMP command offers you various capabilities.

- DUMP/HEADER gives you a formatted printout of all the fields in the file header.

- DUMP/RECORDS dumps just the data records. This is very useful with files that contain a lot of overhead that does not interest you (such as indexes).

- DUMP can print your file (or its records) in a wide variety of formats: per byte, per word, or per longword; in octal, decimal, or hexadecimal.

- /BLOCKS[=(option[,...])]

  Specifies that the input medium be dumped one block at a time. This is the default for all devices except network devices. You cannot specify /BLOCKS for network devices.

  You can use one or more of the following options to select a range of blocks to be dumped:

  START:n — Specifies the number of the first block to be dumped. By default, the dump begins with the first block of the file or device.

  END:n — Specifies the number of the last block to be dumped. By default, the dump ends with the last block of the file or device. If the input is a disk file, the /ALLOCATED qualifier determines whether the last block is the end of file block or the last allocated block.

  COUNT:n — Specifies the number of blocks to be dumped. This option provides an alternate way to specify the last block to be dumped.

  If you specify only one option, you can omit the parentheses. You cannot specify both END and COUNT.

  Blocks are usually numbered beginning with 1. However, for a disk device that is mounted with the /FOREIGN qualifier, blocks are numbered beginning with 0.

  If you specify /BLOCKS, you cannot specify /RECORDS.

- /OUTPUT[=file-spec]

  Specifies that the DUMP output be written to the specified file. By default, the DUMP command writes output to SYS$OUTPUT. If you specify /OUTPUT without a file specification, the DUMP command writes output to a file with the same file name as the input file and the file type DMP.

Example 2. DUMP/BLOCKS Output

(Sheet 1 of 2)

```
$DUMP/BLOCKS=(START:1,END:4)/OUTPUT=DUMP_INTER11.LIS INTER11.DAT

GUIDELINES FOR RECOVERING DATA FROM CORRUPTED INDEXED FILES

1. Make a backup copy of the file immediately. In attempting to recover the data, use the backup copy.

2. Verify that the data file that may be corrupted is the correct data file. Use ANALYZE/RMS/INTERACTIVE or DUMP to check the file header, prologue, and key descriptors to make sure that there has not been a mixup in files. Possible areas to check out:

   - A logical name may be causing the program to use the wrong file.
   - If users are sharing an account, they sometimes decide to use the same file name for different data files.
   - Incorrect usage of DCL commands can make a copy of a file with different attributes from the original file. (For example, an indexed file input to EDIT/EDT is output as a sequential file.)

3. Determine whether the file is really corrupt using ANALYZE/RMS/CHECK. The /CHECK qualifier does not find all types of corruption.

   If the /CHECK qualifier detects any errors, the file has been corrupted. If you have had a hardware problem, such as a power failure or a disk head failure, then the hardware probably caused the corruption. If you have not had any hardware problems, then a software error may have caused the corruption.

   If the /CHECK qualifier indicates a number of severe errors, you should probably stop at this step and go back to the most recent backup copy that is uncorrupted.

4. If some particular virtual block is identified as having a problem by the /CHECK qualifier, get a dump of all the blocks in the index bucket or data bucket that begins with that virtual block.

   Before checking it against the internal layouts provided in Module 5, do the next step.

5. Use the CONVERT utility to try to restore the data.

   a. If none of the primary level 0 data buckets are corrupted, you will generally be able to recover the data as follows:

      $CONVERT/STAT corrupted_index_file new_index_file

   b. In general, if the corruption is associated with a primary index bucket or with any of the secondary index buckets then the convert in step (a.) should be successful. There is one exception to this: when the corruption involves one of the primary index buckets in the initial pathway down to the first level 0 data bucket, the CONVERT utility is not able to recover the data from the primary key. If you have at least one alternate key, attempt to convert the data by outputting a sequential version based on the alternate key sorted order as a first step and then convert the sequential file to an indexed one as a second step.

      Step 1.

      If you do not have an FDL file for the indexed file, you can obtain one from the corrupted file.

      $ANAL/RMS/FDL corrupted_index_file

      The FDL file produced by ANALYZE will have to be edited.

      $EDIT new_index.FDL

      - Delete the version number in the filename.

      Step 2.

      Produce an FDL file for the sequential file.

      $EDIT/FDL seq.FDL

Step 3.

```
$CONVERT/KEY=1/FDL=seq.FDL/STAT _____  _____
                                |      |
                  corrupted_index_file |
                                       |
                      good_sequential_file_output
```

Step 4.

```
$CONVERT/FDL=new_index.FDL/STAT _______________  _________
                                good_sequential  new_index
```

If you do not have an alternate key or the CONVERT utility using an alternate key is not successful, see Step 7.

6. If the CONVERT utility is not able to restore the data file, or is not able to restore all the data, examine the dump you obtained in Step 4.

   Are you able to identify what the problem is? For example, is the check byte at the beginning of the bucket equal to the one at the end of the bucket?

7. If you were able to identify what the problem is in Step 6, or if the corruption involves the initial pathway down through the primary index bucket and you have no alternate key, you may wish to try to patch the file.

   CAUTION

   Patching a corrupted data file is not encouraged. The recommended procedure is to use the CONVERT utility, or go to a backup copy. Patching is undertaken by users at their own risk. The ISAM structures are extremely fragile. If in patching a file, a byte or even a bit is misplaced, subsequent processing of the file may crash the system.

   You can attempt to patch the file if you are able to detect:

   - what the source of the corruption is
   - what value in a particular byte location is not what ISAM expects
   - what the value should be

Before undertaking this step, be sure you have a backup copy of the corrupted file as directed in Step 1. Also be sure you have a file copy in your directory of the DUMP (see Step 4) of the bucket in question.

You should not think of using the PATCH utility if there are a number of errors. It should only be used selectively.

The PATCH utility is primarily for patching "IMAGE" files, but it may be used to patch any kind of file by using the qualifier /ABSOLUTE. In addition, to do the patch in place use the qualifier /NONEW_VERSION; otherwise, in the case of an indexed file, it outputs a new SEQUENTIAL version.

The steps for using the PATCH utility are described at the end of this section.

IMPORTANT

The patched file definitely must be converted to produce a valid index structure (see Step 9).

8. If you used the PATCH utility in Step 7, rerun ANALYZE/RMS/CHECK on the patched data file.

9. If the data was recovered by the PATCH utility (even if no errors are now identified by /CHECK), make a new copy of the file using the CONVERT utility so that the index structures are rebuilt.

10. If the problem was with a data bucket (primary level 0 data buckets), use the dump obtained of the respective bucket (Step 4) to identify whether any data records in the bucket need to be updated or deleted.

    If the problem was with a primary index bucket or with a bucket in a secondary index tree, then the convert in Step 5 or in Step 9 reconstructed these buckets and no further action is required.

11. If the corruption appears to be due to something other than a minor hardware failure (such as a power failure in the middle of writing an updated bucket back to disk), try to find out what caused the corruption.

    You may be able to save yourself a lot of work in the future by trying to find out what happened to the file. If, for example, the file is always corrupted on Tuesday, it is worth investigating what is different on Tuesday.

12. In all cases, even if your data recovery was successful, if you believe that some DIGITAL software caused the error, submit a Software Performance Report (SPR). Always include the ANALYZE/RMS/CHECK report, a copy of the data file, and a description of what was done with the data file. If possible, also supply a version of the file prior to the corruption and the program or procedure which led to the corruption. Being able to reproduce the problem is of tremendous value.

Qualifiers

/ABSOLUTE
The /ABSOLUTE function allows a user to patch any file (not just image files) at absolute virtual addresses relative to the beginning of the file. This feature allows replacement of existing data with new data of the same length. If data is smaller than that of the original data, the PATCH utility uses the appropriate fill character for the mode in use. For example, if the current mode is data (numeric or ASCII) mode, a null is used for fill. Any patch operation that results in a data replacement longer than the length of the original data generates an error message and terminates the command in progress; either the PATCH utility prompt or DCL prompt is then displayed, whichever is appropriate.

/NEW_VERSION
The /NEW_VERSION qualifier is used in conjunction with the /ABSOLUTE qualifier to control whether a new version of the patched file is created or the contents of the existing file are modified in place. /NEW_VERSION is the default. If /NONEW_VERSION is selected, the PATCH command UPDATE will act as a checkpoint operation; all modifications made to the file are written back to the file instead of waiting until image exit. If /ABSOLUTE is not specified with /NONEW_VERSION, /NONEW_VERSION is ignored; a new version of the file will be created.

NOTE

If /NONEW_VERSION is specified, the file will be overwritten. No attempt on the part of the user, including pressing CTRL/Y, will prevent this result. Therefore, you should have a backup copy of the file before making any attempt to patch it.

There are only two PATCH commands appropriate for replacing data when the /ABSOLUTE qualifier is used.

1. The EXAMINE command for read operations.

2. The REPLACE command for write operations.

Commands that attempt to expand the file, such as ALIGN and INSERT, should be avoided because they will probably corrupt the file. (These commands will be trapped by the PATCH utility and an error message will be issued indicating that the replacement data must not exceed the length of the original data.)

EXAMINE
Displays the contents of the specified locations in terms of the current mode settings.

```
PATCH> EXAMINE location [:location][,...]
```

location
Specifies one or more locations whose contents are to be displayed. Several locations can be specified in a comma-separated list or colon-separated range. Both lists and ranges can be specified in a single command.

The location parameter can also be represented by a backslash operator (\).

REPLACE
Replaces the contents of one or more locations with new instructions or data in terms of the current mode settings.

```
PATCH> REPLACE location =current-contents[,...] new-content...
```

location
Specifies either a single location whose contents are to be replaced or the starting address of a sequence of locations whose contents are to be replaced. The length of the sequence depends on the current mode settings (/BYTE, /WORD, or /LONG). The default length is a longword (4 bytes).

current-contents
Specifies one or more data entries to be replaced. The data specified must be the actual contents.

new-contents
Specifies one or more data entries that are to replace the current contents.

Do not specify conflicting data types within a single REPLACE command.

Use the REPLACE command to replace the contents of one or more locations with new data in terms of the current mode settings. Before performing the replacement, the REPLACE command confirms the contents of the specified locations.

When you replace ASCII or numeric data, the number of replacement entries cannot exceed the number of existing entries. For example, this means that if you confirm the contents of six consecutive locations, you can replace the contents of only those six locations. If the number of replacement entries is less than the number of existing entries, the remaining locations are filled with zeros.

In addition, the PATCH utility truncates replacement entries if they exceed the limit imposed on them by the current length mode. For ASCII characters, the right-most characters are discarded. For numeric data, the left-most digits are discarded.

Example

```
$ PATCH/ABSOLUTE/NONEW_VERSION LIN.COM
PATCH>EX/ASCII 57
00000057:  'MANA'
PATCH>REPLACE/ASCII 57='MANA'
NEW>  'mana'
NEW>  'test'
NEW>  exit
old:          00000057: 'MANA'
%PATCH-E-REPLACEERR, replacement value too large for location
PATCH>replace/ascii 57='MANA'
NEW>  'mana'
NEW>  exit
old:          00000057: 'MANA'
new:          00000057: 'mana'
```

Example 4. Data Recovery Lab for CORRUPT3.DAT

Problem observed with INTER11.DAT:

Data file had eleven records when last accessed. Today the file appears to have a total of two records.

Steps

1. $COPY INTER11.DAT CORRUPT3.DAT

2. $ANALYZE/RMS/INTER CORRUPT3.DAT

   Verified was INTER11.DAT format

3. $ANALYZE/RMS/CHECK/OUT=CORRUPT3.CHECK CORRUPT3.DAT

   $ANLRMS-I-ERRORS, DISK$INSTRUCTOR:[WOODS.RMS.COURSE]CORRUPT3.DAT;1
   1 error

   CHECK /OUTPUT identifies bucket format check
   failed for VBN = 6

   NOTE

   VBN 6 is a level 0 data bucket.

4. $DUMP/BLOCKS=(START:6,END:6)/OUTPUT=CORRUPT3.DUMP CORRUPT3.DAT

5. Bucket VBN 6 is a data bucket.

   $CONVERT/STAT CORRUPT3.DAT GOOD3.DAT

   %CONV-F-READERR, error reading
   DISK$INSTRUCTOR:[WOODS.RMS.COURSE]CORRUPT3.DAT;1
   -RMS-F-CHK, bucket format check failed for VBN = 6

   $DELETE GOOD3.DAT;1 < NULL FILE >

6. Examine output from CORRUPT3.DUMP

```
                          CHECK bytes

    VBN 6 - BYTE 0          02
            BYTE 511        01
```

NOTE

In this atypical case, bucket size happens to be one block.

7. Use the PATCH utility to change VBN 6 -- byte 511 to 02.

a. Location

```
    512 x 6 = 3072
              - 1 (backup one byte to byte 511 in VBN 6)
              ----
              3071
```

b. Calculate location in HEX

```
$ X == 3071
$ SH SYM X
  X = 3071   Hex = 00000BFF   Octal = 00000005777
```

c. Run PATCH

```
$ PATCH/ABSOLUTE/NONEW CORRUPT3.DAT
%PATCH-I-NOGBL, some or all global symbols not accessible
%PATCH-I-NOLCL, image does not contain local symbols

PATCH>EXAMINE/BYTE 00000BFF
00000BFF:  01

PATCH>REPLACE/BYTE 00000BFF = 01
NEW>  02
NEW>  EXIT
old:    00000BFF:  01
new:    00000BFF:  02

PATCH>EXIT

%PATCH-I-OVERLAY,DISK$INSTRUCTR:[WOODS.RMS.COURSE]CORRUPT3.DAT;1
        being overwritten
```

8. $RENAME CORRUPT3.DAT GOOD3.DAT

```
$ANALY/RMS/CHECK/OUT=GOOD3.CHECK  GOOD3.DAT
```

9. $CONVERT/STAT GOOD3.DAT INTER11_CONV.DAT

10. Check CORRUPT3.DUMP output to see whether any data records in VBN 6 need to be updated or deleted.

Example 5. Data Recovery Lab for CORRUPT4.DAT

Step 6 -- Identify nature of problem

The check bytes do not match in one of the index buckets (VBN 7) which lies on the initial path of the primary index. This index bucket is not the root primary index bucket (level 2), but a level 1 bucket.

Dump of VBN 7

```
Dump of file DISK$INSTRUCTOR:[WOODS.RMS.COURSE]CORRUPT4.DAT;1
File ID (37426,1,0)   End of file block 16 / Allocated 16

Virtual block number 7 (00000007), 512 (0200) bytes

 20202020 20202020 20202020 20204853 55420001 00000008 000100EA 00070004

 FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF
 00000000 00000000 00000000 00000000 00000000 00000000 0000FFFF FFFFFFFF
 0300001F7 00040006 0005000F 00000000 00000000 00000000 00000000 00000000
```

Check chars 1 Do not match

There are two alternative ways to recover the data for this example.

1. Use alternate key 1 to recover a sequential version of the data file. See Step 5(b.).

2. Patch the ending check byte to match the beginning check byte in bucket VBN 7. See Step 7.

The first alternative is the preferred one, but for illustration purposes both alternatives will be demonstrated.

Alternative 1 -- CORRUPT4.DAT

Step 5(b.) -- Use alternate key to convert

1. If you don't have an FDL file for the indexed version, obtain one.

   $ANAL/RMS/FDL CORRUPT4.DAT <-- outputs CORRUPT4.FDL

2. $EDIT CORRUPT4.FDL

   - Delete version number in filename.

3. Use EDIT/FDL to produce a sequential FDL specification for output file in Step 4.

```
$EDIT/FDL  seq4.fdl
```

4.
```
$CONVERT/KEY=1/FDL=seq4.fdl/STAT CORRUPT4.DAT seq4.dat
                                              |
                                      sequential output
```

5.
```
$CONVERT/FDL=corrupt4.fdl/STAT seq4.dat GOOD4.DAT
                          |                 |
                   FDL indexed       indexed output
```

Alternative 2 -- CORRUPT4.DAT

Step 7 -- Use the PATCH utility

1. Location

```
7 x 512 = 3584
           - 1 (backup one byte to byte 511 in VBN 7)
          ----
          3583
```

2. HEX location

```
$ X == 3583
$SH SYM X
X = 3583    Hex = 00000DFF  Octal = 00000006777
```

3. Patch

```
          $PATCH/ABSOLUTE/NONEW  CORRUPT4.DAT
          %PATCH-I-NOGBL, some or all global symbols not accessible
          %PATCH-I-NOLCL, image does not contain local symbols

          PATCH>EXAMINE/BYTE 00000DFF
          00000DFF:  03

          PATCH>REPLACE/BYTE 00000DFF = 03
          NEW>  04
          NEW>  EXIT
          old:    00000DFF:  03
          new:    00000DFF:  04

          PATCH>EXIT

%PATCH-I-OVERLAY, DISK$INSTRUCTR:[WOODS.RMS.COURSE]CORRUPT4.DAT;1
      being overwritten
```

Appendix A

APPENDIX A

Indexed files -- specific points in RMS-coded instructions when locking is done at record, bucket, or file level.

1. Record operations (assumes no bucket splits)

   - $PUT
     - Initialization/validation (if sequential access, is key value of new record greater (ascending primary key) or less (descending primary key) than that of last record, etc.)
     - Position to point of insert (involves positioning through the index structure by key, and leaves data bucket locked)
     - Adjust "high set" appropriately
     - Build record overhead fields in bucket; move in record itself
     - Lock new record
     - Update new record (if necessary)
     - Unlock bucket
     - Insert alternate keys (if any) extracted from user buffer
   - $DELETED (assumes previous $GET/$FIND and record locked)
     - Initialization/validation (is there a current record, etc.)
     - If RRV, position by RFA to record (leaves bucket locked)
     - Save record in internal buffer
     - Delete the RRV (if any)
     - Delete the primary record itself
     - Unlock bucket
     - Delete all alternate keys, plucking values from saved record (if FAST_DELETE option not specified)

- $UPDATE (assumes previous $GET/$FIND and record locked)
  - Initialization/validation
  - If RRV, position by RFA to record (leaves bucket locked)
  - If alternate keys will change, then:
    a. Save old record
    b. Unlock data bucket
    c. Insert new SIDR entries
    d. Reposition by RFA to record (leaves bucket locked again)
  - Is new record size less than or equal to old size?
    + YES (smaller or same as old record)
    a. Adjust high set appropriately
    b. Insert record
    + NO (larger than old record)
    a. Save record ID
    b. Perform "pseudo-$DELETE"
    c. Perform "pseudo-$PUT" (stuffing saved record ID)
  - Unlock bucket
  - Delete old SIDR entries (if any) using old record buffer

2. Record operations involving bucket split(s) (assume old bucket is currently locked)
   - Lock area
   - Enough space for a new bucket?
     + YES (a bucket's worth of blocks is available)
     - Allocate new bucket
     - Unlock area

+ NO (must do a $EXTEND)
  - Lock file to prevent file operations
  - Lock prolog
  - Do the $EXTEND
  - Allocate new bucket
  - Unlock area
  - Unlock prolog
  - Unlock file

- Format new bucket
- Set new bucket's next pointer to old bucket's next pointer
- Set old bucket's next pointer to the new bucket
- Move data into new bucket
- Scan old bucket for records past the split point that have RRVs, and keep in a table.
- Update free space in old bucket and unlock it
- Update RRVs in internal table to point to new location of records. This involves multiple positionings by RRV -- one for each RRV to be updated.

  Note that SIDRs are not updated. SIDR entries may point to an RRV, which in turn points to the real record. Because of the RRV updating process, this level of indirection never goes beyond one.
