ii) If the unit does require the diversion address then:
if it has received no previous response to its Include RQS, and has not sent the maximum number of transmissions of the RQS (see 11.2.1), it shall ignore the ACKT message;
otherwise it shall wait for a repeat ACKT, re-enabling user transmission if a time TB elapses (in which case, it may indicate the failure to the user).

If ACK(QUAL=0) is received, the unit shall re-enable user transmission and may indicate to the user that the called party is being directed to the traffic channel.

After receiving ACKX, ACKV or ACK for its Include call, the unit shall not request on the traffic channel another transaction of any type to the same called ident (or gateway) for at least a time TB. After receiving ACKT for its Include call, the unit shall not request on the traffic channel another transaction of any type for at least a time TB.

11.2.5 Time-out after waiting for Include call

A radio unit waiting for further signalling for an Include call shall re-enable user transmission if a time TI has elapsed since the last message it sent for the transaction, viz.

It may also indicate to the user that the outcome of the transaction is unknown.

11.2.6 Cancelling Include

•

•

A radio unit may cancel an Include request (after sending an RQS and while still waiting to receive ACKX, ACKV, ACKT or ACK) by transmitting a cancellation request RQX (see 5.5.3.1.3) on the traffic channel. The unit shall then wait for a response from the TSC; for timing, see 6.2.2.2. The unit shall repeat its cancellation request, each time waiting for a response from the TSC, until one of the following occurs:

- a. It receives ACK(QUAL=1), with the same prefix and idents as the RQX, confirming cancellation of the Include call.
- b. It receives ACKX, ACKV, ACKT(QUAL=0) or ACK(QUAL=0) for the Include call it is attempting to cancel. See also 11.2.4.
- c. It has sent the maximum number of transmissions NI. In this case, it shall return to waiting for signalling for the Include call (see 11.2.4 and 11.2.5).

In cases a. and b., the unit shall re-enable user transmission.

Page 11-7

11.2.7 Other procedures

- a. A radio unit shall not attempt an Include call if user transmission has been inhibited (by the GTC message or by a MAINT(OPER='111') message; see 9.2.2.5, 9.2.3.3 and 9.2.3.4).
- b. If a radio unit requesting or attempting to cancel an Include call, or waiting for further signalling, receives a MAINT(OPER='111') message inhibiting user transmission (see 9.2.3.3), then it shall continue with the Include call but shall not re-enable user transmission at the end of the transaction.
- c. If a radio unit requesting or attempting to cancel an Include call, or waiting for further signalling, receives a GTC message allocating a replacement traffic channel, it shall perform actions i) and ii) as specified in section 9.2.3.4 and shall then continue with the Include call. At the end of the transaction, the unit shall re-enable user transmission only if permitted by action iii) of 9.2.3.4.

•

d. If a radio unit's user goes on-hook (or equivalent) while it is requesting or attempting to cancel an Include call, or waiting for further signalling, then the unit shall abandon the Include call and shall obey the procedures specified in section 9.2.3.5.

(If the user goes on-hook (or equivalent) after an Include call, then the unit shall obey the procedures specified in section 9.2.3.5. However, see also section 11.1.9.)

e. If a radio unit requesting or attempting to cancel an Include call, or waiting for further signalling, receives a MAINT(OPER='110') or CLEAR message terminating the call in progress, then it shall abandon the Include call and shall obey the procedures specified in sections 9.2.3.7 and 9.2.3.8 respectively. 11.3 Procedures for All Radio Units on an Allocated Traffic Channel

11.3.1 Instruction to send extended address information

This procedure shall be obeyed by all radio units that are equipped to request extended addressing Include calls.

If a radio unit on a traffic channel receives an AHYC message with PFIX/IDENT2 matching its individual address then it shall either send address information or transmit ACKX(QUAL=0), as indicated below. For timing, see section 6.2.2.2.

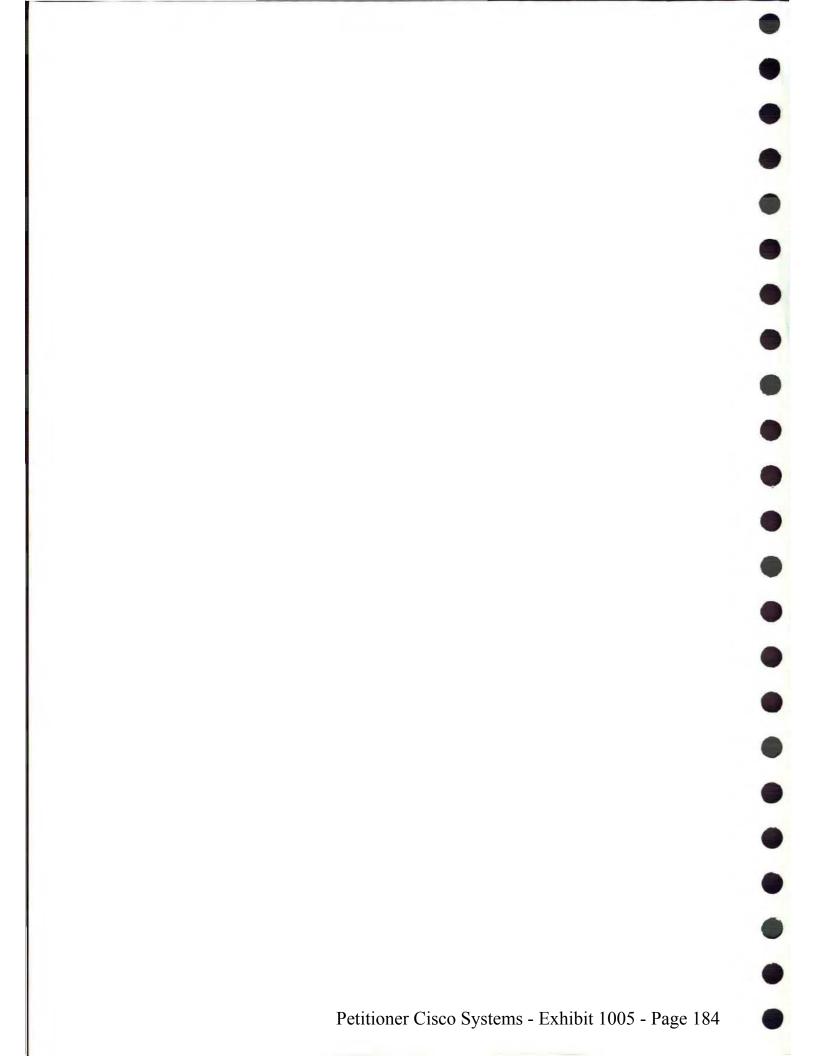

If

the unit has sent an extended addressing Include RQS and IDENT1 matches IDENT1 from the Include RQS and DESC is appropriate to IDENT1 (see 5.5.3.2.8) and SLOTS corresponds to the Include RQS (i.e. if IDENT1=PSTNGI and FLAG1=1 then SLOTS='10' else SLOTS='01')

then it shall transmit the full called address information, conforming to the codeword formats defined in section 5.6.1.2.2 (SAMIS, Mode 1).

Otherwise The unit shall transmit ACKX(QUAL=0), with the same prefix and idents as the AHYC.

Page 11-9

12. CALL DIVERSION PROCEDURES

This section defines the procedures for requesting and cancelling call diversion. Requests may apply to speech calls, data calls or both.

Two types of call diversion are provided:

i) Self-initiated diversion.

A radio unit may request that future calls addressed to it be redirected to a specified alternative destination.

ii) Third-party diversion.

A radio unit may request that future calls addressed to another subscriber unit (or group) be redirected to a specified alternative destination. For example, a despatcher unit may request diversion on behalf of a radio unit in its fleet.

In general, radio unit A (the requesting unit) may divert calls for address B (the blocked address) to alternative destination C (the diversion address); for self-initiated diversion, B = A. The procedures permit blocked address B to be a radio unit, line unit or group address. Destination C may be a radio unit, line unit or group address, a PABX extension or a PSTN number (short-form or general).

Three types of call diversion cancellation are provided:

- Self-initiated cancellation. A radio unit may request that its calls are no longer diverted.
- ii) Third-party cancellation. A radio unit may request that another subscriber unit's (or group's) calls are no longer diverted.
- iii) General cancellation by recipient.

A radio unit may request that any existing diversions to it be cancelled. (This is a general cancellation by the recipient of diversions; specific cancellation of diversions by the recipient is covered by third-party cancellation.)

It is recommended that requests for third-party diversion or thirdparty cancellation are accepted only from authorised units.

Call diversion is requested or cancelled using the Request Call Diversion Message RQT (see 5.5.3.1.4). In this message:

- PFIX/IDENT2 is the address of the requesting radio unit.
- For diversion requests, IDENT1 is the diversion ident C (or IPFIXI, PABXI or PSTNGI for an interprefix address, any PABX extension or a general PSTN number respectively).
 - For "self" or "third-party" cancellation of call diversion, IDENT1 specifies the unit or group whose calls should be returned (or IPFIXI for an interprefix address).

For general cancellation by a recipient, IDENT1 is set to DIVERTI.

Page 12-1

- Bit DIV indicates call diversion or cancellation.
- For call diversion, FLAG2 indicates "self" or "third-party" diversion.
- Field SD specifies the types of call (i.e. speech, data or both) to which the diversion or cancellation refers.

For diversion purposes, "speech" calls are defined as calls requested using RQS(DT=0), RQE(D=0), RQQ(STATUS='00000') or RQQ(STATUS='11111'). "Data" calls are defined as calls requested using RQS(DT=1), RQE(D=1), RQQ('00001' to '11110'), RQC or RQD.

For self-initiated diversion requests or any cancellation, two addresses (plus the other parameters) specify the requirement. However, for third-party diversion requests, address B (the blocked address) must be supplied.

The TSC uses the AHYC message to demand:

- a. extended address information for IDENT1
- b. blocked address B

as appropriate. If both a. and b. are needed, the TSC obtains the full information in two steps, each step using the AHYC message. The AHYCs are distinguished by the setting of IDENT1 (to IPFIXI, PABXI or PSTNGI for a., or to DIVERTI for b.), and so the order in which they are sent is not prescribed.

In the procedures, a request for call diversion or cancellation is defined as an extended addressing request if IDENT1 is set to IPFIXI, PABXI or PSTNGI. A request is defined as "complex" if it requires extended addressing or if three addresses must be provided; otherwise it is "simple".

Note that extended addressing procedures are used for requesting diversion to any PABX extension (with either a "long" or "short" extension number). The radio unit sets IDENT1 in the RQT message to PABXI, and then sends the PABX address information in response to an AHYC message with IDENT1 set to PABXI and DESC set to '010'. The unit sets bit SP in the SAMIS message to indicate whether it is sending BCD digits or a 13-bit extension number (plus 2-bit exchange number). See 5.5.3.2.8 and 5.6.1.2.2.

If the TSC accepts a diversion request and then a call to the blocked address is requested by a radio unit, the TSC indicates the diversion address to the calling radio unit using the ACKT(QUAL=0) acknowledgement. The unit then either retries on the diversion address or returns to the idle state. For example, see sections 9.1.1.4 and 9.2.1.4.

> Page 12-2 Petitioner Cisco Systems - Exhibit 1005 - Page 186

•

12.1 TSC Procedures for Call Diversion Requests

12.1.1 Responses to a simple diversion request

A radio unit requests simple call diversion by generating an RQT message (with FLAG2 = 0 and IDENT1 set to a valid called party ident or to DIVERTI), complying with the random access protocol. On receiving a simple RQT message, the TSC shall send one of the following responses, with the same prefix and idents as the RQT:

ACKI(QUAL=1), ACKX, ACKV(QUAL=0) or ACK(QUAL=0).

For acceptable delay, see 7.2.4. See also 12.1.5.

12.1.2 Responses to a complex diversion request

A radio unit requests complex call diversion by generating an RQT message (with FLAG2 = 1 and/or IDENT1 = IPFIXI, PABXI or PSTNGI), complying with the random access protocol. On receiving a complex RQT message, the TSC shall send one of the following responses:

- a. An acknowledgement ACKI(QUAL=1), ACKX or ACKV(QUAL=0), with the same prefix and idents as the RQT.
- b. For an extended addressing RQT: An AHYC message instructing the unit to send the full address information for IDENT1.
- c. For a request for 3-address diversion (i.e. RQT with FLAG2=1): An AHYC message instructing the unit to send the blocked address.

For acceptable delay, see 7.2.4. See also 12.1.3 to 12.1.5.

12.1.3 Instruction to send extended address information

After receiving an extended addressing RQT message, the TSC may demand the full address information for IDENT1 by sending the AHYC message, with:

- the same prefix and idents as the RQT
 - (i.e. IDENT1 set to IPFIXI, PABXI or PSTNGI as appropriate, and PFIX/IDENT2 set to the requesting unit's address)
- DESC set to indicate the appropriate gateway (see 5.5.3.2.8)
- SLOTS set to correspond to the RQT

(i.e. if IDENT1=PSTNGI and FLAG1=1 then SLOTS='10' else SLOTS='01').

The AHYC message instructs the requesting radio unit to send the full address information for IDENT1 in the following SLOTS slot(s) (see 9.2.2.1). If the TSC does not successfully decode the address information, it may repeat the AHYC message or transmit ACKV(QUAL=0) to indicate failure of the transaction.

Page 12-3

337

12.1.4 Instruction to send the blocked address

After receiving a request for 3-address diversion (i.e. FLAG2=1), the TSC may demand the blocked address by sending the AHYC message, with:

- IDENT1 set to DIVERTI
- PFIX/IDENT2 set to the requesting unit's address
- DESC set to '000'
- SLOTS set to '01'.

The AHYC message instructs the requesting radio unit to send the blocked address in the following slot (see 9.2.2.1). If the TSC does not successfully decode the address information, it may repeat the AHYC message or transmit ACKV(QUAL=0) to indicate failure of the transaction.

•

12.1.5 Acknowledgements sent to indicate progress of RQT transaction

The TSC may send the following acknowledgement messages, with the same prefix and idents as the RQT, to indicate to a radio unit the progress of its diversion transaction. (For a complex diversion request, ACK(QUAL=0) is not appropriate until the full diversion information has been obtained.)

ACKI	(QUAL=1)	-	Intermediate acknowledgement; more signalling to follow.
ACKX	(QUAL=0)	-	Invalid call e.g. unauthorised diversion request, or TSC does not provide call diversion.
ACKX	(QUAL=1)	-	System overload; request rejected.
ACKV	(QUAL=0)	-	Transaction abandoned.
ACK	(QUAL=0)	-	Call diversion or cancellation has been accepted.

For maximum acceptable delay of repeats of acknowledgements ACKX, ACKV and ACK, see time-out TB in 12.2.4.

12.1.6 Aborting the transaction

A radio unit may abort its diversion transaction by generating an RQX message (see 5.5.3.1.3), complying with the random access protocol. On receiving an RQX message aborting a diversion transaction, the TSC shall send a response: ACK(QUAL=1) with the same prefix and idents as the RQX.

12.1.7 TSC time-out

The TSC may instruct a radio unit to restart its waiting timer TJ, by sending the AHY message with bit POINT set to '1' (and the same prefix and idents as the RQT); see 9.1.1.7 and 9.2.2.3. If a time TJ, minus the tolerance on the radio unit's timer, elapses since the last message it received for a diversion transaction, the TSC shall not send any further signalling for the transaction. See also 12.2.5.

12.2 Procedures for Radio Units Requesting Call Diversion

A radio unit shall make only one call attempt at a time (except in emergency); while attempting access or waiting for a terminating (i.e. endof-transaction) acknowledgement to a diversion request, the unit shall not request another non-emergency call of any type (unless the user first aborts the original transaction).

12.2.1 Diversion request

A radio unit requests or cancels call diversion by transmitting an RQT message on a control channel, complying with the random access protocol (see 7.3). The fields in the RQT message shall be set appropriately (see 5.5.3.1.4); however, note particularly that:

- a. Bit DIV specifies whether the unit is requesting call diversion or cancellation of call diversion.
- b. Bit FLAG2 specifies whether or not three addresses must be provided.
- c. An extended addressing diversion request is indicated by setting IDENT1 in the RQT message to the appropriate gateway ident viz. IPFIXI, PABXI or PSTNGI. (Note that extended addressing procedures are used for requesting diversion to a PABX extension with either a "short" or "long" extension number.)

The unit shall attempt access until it receives a valid response (see 12.2.2/3), or until its user aborts the transaction (see 12.2.6), or until the access attempt fails (i.e. the unit has sent the maximum number of transmissions NR and received no response, or its access time-out TC has expired (see 7.3.8)). In the case of access failure, if the unit has not sent a request, it shall return to the idle state (and may indicate the failure to the user); otherwise, it shall wait for further signalling for the transaction - see 12.2.4 and 12.2.5.

12.2.2 Responses to simple diversion request

For a simple diversion request, the radio unit shall accept the following messages (with the same prefix and idents as the RQT) as a valid response to its RQT and send no more requests:

ACKI (QUAL=1), ACKX, ACKV (QUAL=0) or ACK (QUAL=0).

For other actions on receiving these messages, see section 12.2.4.

12.2.3 Responses to complex diversion request

For a complex diversion request, the radio unit shall accept the following messages as a valid response to its RQT and send no more requests:

- a. ACKI(QUAL=1), ACKX or ACKV(QUAL=0), with the same prefix and idents as the RQT.
- For an extended addressing RQT: AHYC, with the same prefix and idents as the RQT.

Page 12-5

c. For a request for 3-address diversion (i.e. RQT with FLAG2=1): AHYC, with PFIX/IDENT2 as its individual address and IDENT1 as DIVERTI.

For other actions on receiving these messages, see 12.2.4 and 9.2.2.1.

12.2.4 Acknowledgement received

If a radio unit attempting access or waiting for further signalling for a diversion transaction receives an appropriate acknowledgement (with the same prefix and idents as the RQT) then it shall take action as indicated below. For a complex diversion request, ACK(QUAL=0) is not appropriate until the full diversion information has been sent.

ACKI	(QUAL=1)	-	Intermediate acknowledgement; more signalling to
			follow.
ACKX	(QUAL=0)	-	Invalid call; request rejected.
ACKX	(QUAL=1)	-	System overload; request rejected.
ACKV	(QUAL=0)	-	Transaction abandoned.
ACK	(QUAL=0)	-	Call diversion or cancellation has been accepted.

If ACKI(QUAL=1) is received, the unit shall wait for further signalling for the transaction.

If ACKX or ACKV(QUAL=0) is received, the unit shall return to the idle state and may indicate to the user that the transaction has failed.

If ACK(QUAL=0) is received, the unit shall return to the idle state and may indicate to the user that the request for call diversion or cancellation has been accepted.

After receiving ACKX, ACKV or ACK for its diversion request, the unit shall not request another non-emergency call of any type to the same called ident (or gateway) for at least a time TB.

12.2.5 Time-out after waiting

A radio unit waiting for further signalling for a diversion transaction shall return to the idle state if a time TJ has elapsed since the last message it sent for the transaction, viz.

It may also indicate to the user that the outcome of the transaction is unknown.

Page 12-6

13. STATUS MESSAGE PROCEDURES

This section defines the procedures for status messages. Status messages may be sent to the TSC or to a radio or line unit.

A radio unit sends status information using message RQQ - see 5.5.3.1.7. The status field in an RQQ message consists of 5 bits, allowing 32 different status values. Two of these values have been predefined.

a) For status sent to the TSC:

.00000.	indicates that the unit is ready to receive a call (i.e. it indicates "off-hook" or equivalent).
'00001' to '11110'	are system-defined status values.
·11111·	indicates that the unit is no longer ready to receive a call (i.e. it indicates "on-hook" or equivalent).

RQQ('00000') and RQQ('11111') are used for the "Called Party Answer" mechanism - see section 9.2.2.2. If a radio unit receives AHY(CHECK=1) alerting it for an incoming call and responds with ACKI(QUAL=0), it may attempt random access with RQQ('00000') when its user/ data equipment is ready to receive the call. Then, if the user no longer wishes to receive the call, the unit may inform the TSC using RQQ('11111').

The other 30 status values may be used to send status information, as previously arranged with the system.

- b) For status sent to a radio unit or line unit:
 - '00000' requests that the addressed unit call back with a speech call.

'00001' to '11110' are user-defined status values.

'11111' cancels a previous speech call request.

For example, RQQ('00000') may be used to request a "despatcher-queued call". In this type of call, a radio unit sends RQQ('00000') to request that the addressed despatcher be informed that the unit's user wishes the despatcher to call him (for a speech call). The TSC routes the information to the despatcher unit, which keeps a list of requested calls. The despatcher may then request each call at his convenience in the usual way; for example, if his unit is a radio unit, it sends a Simple call request RQS (see 5.5.3.1.1 and 9.2.1).

RQQ('11111') is used to withdraw a previously requested call from the addressed unit's call queue. This may be used for cancellation either:

- i) after the called unit has accepted an RQQ('00000') message, or
- ii) after the called unit in an RQS or RQE call has accepted the call for call-back (by sending ACKB(QUAL=0) in response to the availability check); see 9.2.1.4 and 9.2.2.2.

Page 13-1

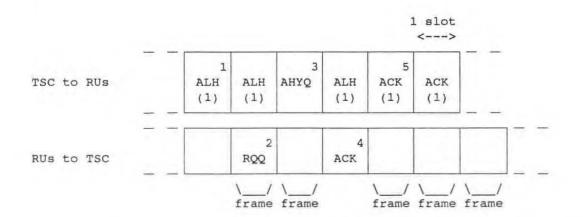

The other 30 status values may be used to send status information, as previously agreed between the requesting user and the called user.

The TSC informs a called radio unit of status information using message AHYQ - see 5.5.3.2.7. The status message may have originated from the TSC itself, from another radio unit (using RQQ etc.) or from a line unit.

The procedures for status messages addressed to the TSC are similar to a subset of the procedures for status messages addressed to radio units or line units. However, for clarity, they are specified separately:

- Section 13.1 specifies the procedures for status messages addressed to the TSC.
- Section 13.2 specifies the procedures for status messages addressed to radio units or line units.

A typical message sequence for a radio unit sending a status message to another radio unit (with the same prefix) is illustrated in the example below.

Example A message sequence on a control channel for a radio unit sending a status message to a radio unit with the same prefix.

- 1. ALH : General Aloha invitation (single-slot frame).
- RQQ : Random access request that status information be relayed to the called unit.
- 3. AHYQ : Status Ahoy message
 - acknowledges the RQQ message
 - relays the information to the called radio unit and demands a response.
- ACK : Acknowledgement ACK(QUAL=0) from the called radio unit - information accepted.

5. ACK : Acknowledgement ACK(QUAL=0) sent to the calling unit to indicate that the called unit has accepted the information. In this example the TSC immediately repeats the ACK message, for added reliability.

13.1 Procedures for Status Messages Addressed to the TSC

13.1.1 TSC Procedures for Status Messages Addressed to It

13.1.1.1 Responses to an RQQ message addressed to the TSC

A radio unit sends status information to the TSC by generating an RQQ message (with IDENT1 = TSCI), complying with the random access protocol. On receiving an RQQ message addressed to it, the TSC shall send one of the following responses:

- a. ACK(QUAL=0), ACKI(QUAL=1) or ACKX, with the same prefix and idents as the RQQ.
- b. For STATUS = '00000' or STATUS = '11111':
 - an AHYX message with the same prefix and idents as the "alerting AHY"
 - a GTC message for the original call (i.e. GTC with the same prefix, idents and bit D as the alerting AHY).

For acceptable delay, see 7.2.4. See also 13.1.1.2, 9.1.1.8 and 9.1.1.12.

13.1.1.2 Acknowledgements sent to indicate progress of RQO transaction

The TSC may send the following acknowledgement messages (with the same prefix and idents as the RQQ) to indicate to a radio unit the progress of its status transaction:

ACKI	(QUAL=1)	-	Intermediate acknowledgement; more signalling to
			follow.
ACKX	(QUAL=0)	-	Invalid call; message rejected.
ACKX	(QUAL=1)	-	System overload; message rejected.
ACK	(QUAL=0)	-	Transaction has been successfully completed
			i.e. the TSC has accepted the status information.

For maximum acceptable delay of repeats of acknowledgements ACKX and ACK, see time-out TB in 13.1.2.4.

13.1.1.3 Aborting the transaction

A radio unit may abort its status transaction by generating an RQX message (see 5.5.3.1.3), complying with the random access protocol. On receiving an RQX message aborting a status transaction, the TSC shall send a response: ACK(QUAL=1) with the same prefix and idents as the RQX.

13.1.1.4 TSC time-out

The TSC may instruct a radio unit to restart its waiting timer TJ, by sending the AHY message with bit POINT set to '1', PFIX/IDENT2 set to the unit's individual address and IDENT1 set to TSCI; see 9.1.1.7 and 9.2.2.3. If a time TJ (minus the tolerance on the radio unit's timer) elapses since the last message it received for the status transaction, the TSC shall not send any further signalling for the transaction. See also 13.1.2.5.

See also sections 9.1.1.5, 13.1.2.7 and 13.1.2.8.

Page 13-3

13.1.2 Procedures for Radio Units Sending Status Messages to the TSC

A radio unit shall make only one call attempt at a time (except in emergency); while attempting access or waiting for a terminating (i.e. endof-transaction) acknowledgement to a status message addressed to the TSC, the unit shall not request another non-emergency call of any type (unless the user first aborts the original transaction). •

• • •

•

• • •

13.1.2.1 Criteria for sending "off-hook" or "on-hook" message

If a radio unit on a control channel has been alerted for an incoming traffic channel call (see 9.2.2.2A), it may initiate the Called Party Answer mechanism, i.e. attempt random access with RQQ(STATUS='00000') addressed to the TSC, if:

- Its response to the last alerting AHY was ACKI(QUAL=0), and
- Its user/ data equipment is now ready to receive the call, and
- It is still waiting for the incoming call, i.e. the call has not taken place or been cancelled (by AHYX or by an AHY for a different call) and not more than a time TA has elapsed since receipt of the last AHY for the call; see 9.2.2.2A and 9.2.2.4.

If a radio unit has been alerted for an incoming traffic channel call and its user then indicates that he no longer wishes to receive the call (e.g. he wishes to initiate a call of his own), the unit may attempt to reject the call as follows:

- a. If it is currently attempting access or waiting for signalling for an "off-hook" RQQ, it attempts to send RQX (see 13.1.2.6).
- b. Otherwise, if the unit is still waiting for the incoming call, it attempts random access with RQQ(STATUS='11111') addressed to the TSC.

(Throughout these procedures, the unit responds to AHY messages and obey GTCs as specified in section 9.2.2. See also sections 13.1.2.7 and 13.1.2.8.)

13.1.2.2 Request for a status transaction to the TSC

A radio unit requests a status transaction by sending an RQQ message on a control channel, complying with the random access protocol (see 7.3). The fields in the RQQ message shall be set appropriately (see 5.5.3.1.7).

The unit shall attempt access until it receives a valid response (see 13.1.2.3), or until its user aborts the transaction (see 13.1.2.6), or until the access attempt fails (i.e. the unit has sent the maximum number of transmissions NR and received no response, or its access time-out TC has expired (see 7.3.8)). In the case of access failure, if the unit has not sent a request, it shall return to the idle state (and may indicate the failure to the user); otherwise, it shall wait for further signalling for the transaction - see 13.1.2.4, 13.1.2.5 and 13.1.2.7.

13.1.2.3 Valid responses to an RQQ addressed to the TSC

A radio unit shall accept the following messages as a response to its RQQ to the TSC, and send no more requests:

- a. An acknowledgement ACK(QUAL=0), ACKI(QUAL=1) or ACKX, with the same prefix and idents as the RQQ.
- b. For STATUS = '00000' or STATUS = '11111':
 - an AHYX message with the same prefix and idents as the "alerting AHY", or
 - a GTC message with the same prefix, idents and bit D as the alerting AHY.

For other actions on receiving these messages, see sections 13.1.2.4 and 13.1.2.7. See also section 13.1.2.8.

13.1.2.4 Acknowledgement received

If a radio unit attempting access or waiting for further signalling for a status transaction to the TSC receives one of the following acknowledgements (with the same prefix and idents as the RQQ), then it shall take action as indicated below.

ACKI	(QUAL=1)	-	Intermediate acknowledgement; more signalling to
			follow.
ACKX	(QUAL=0)	-	Invalid call; message rejected.
ACKX	(QUAL=1)	-	System overload; message rejected.
ACK	(QUAL=0)	-	Transaction has been successfully completed
			i.e. the TSC has accepted the status information.

If ACKI(QUAL=1) is received, the unit shall wait for further signalling for the transaction.

If ACKX is received, the unit shall return to the idle state and may indicate to the user that the transaction has failed.

If ACK(QUAL=0) is received, the unit shall consider the transaction successfully completed and may indicate this to the user.

After receiving ACKX or ACK for the transaction, the unit shall not request another non-emergency call of any type to the TSC for at least a time TB.

13.1.2.5 Time-out after waiting

A radio unit waiting for further signalling for a status transaction to the TSC shall return to the idle state if a time TJ has elapsed since the last message it sent for the transaction, viz.

RQQ, requesting the transaction (see 13.1.2.2) or ACK(QUAL=0), sent in response to an AHY message with bit POINT = 1 and IDENT1 set to TSCI (see 9.2.2.3).

It may also indicate to the user that the outcome of the transaction is unknown.

Page 13-5

13.1.2.6 Aborting the transaction

If the user wishes to abort the transaction after the unit has sent an RQQ and while it is still waiting for a terminating acknowledgement, the unit shall attempt to send an abort transaction request RQX (see 5.5.3.1.3), complying with the random access protocol. It shall attempt access until one of the following occurs:

- a. It receives ACK(QUAL=1) with the same prefix and idents as the RQX.
- b. It receives ACK(QUAL=0) or ACKX for the transaction it is attempting to abort. See also 13.1.2.4.

•

•

- c. It has sent the maximum number of transmissions NR and received no response, or its access time-out TC has expired (see 7.3.8). In this case, it shall return to waiting for signalling for the status transaction (see 13.1.2.4, 13.1.2.5 and 13.1.2.7).
- d. The conditions specified in 13.1.2.7 or 13.1.2.8 occur (applicable only for STATUS = '00000' and '11111').

In cases a. and b., the unit shall return to the idle state.

13.1.2.7 Receiving AHYX or GTC for the incoming call

If a radio unit:

- attempting access or waiting for a terminating acknowledgement to an "off-hook" or "on-hook" RQQ message (STATUS = '00000' or '11111'), or
- b. attempting to abort an "off-hook" or "on-hook" RQQ transaction

receives AHYX with the same prefix and idents as the alerting AHY, it shall respond with ACK(QUAL=1), stop its alerting signal (if appropriate) and return to the idle state; see also 9.2.2.4. If it receives a GTC message with the same prefix, idents and bit D as the alerting AHY, it shall obey the procedures in 9.2.2.5 and then revert to the idle state at the end of the call.

13.1.2.8 Receiving AHY for a different incoming call

If a radio unit:

- a. attempting access or waiting for a terminating acknowledgement to an "off-hook" or "on-hook" RQQ message (STATUS = '00000' or '11111'), or
- b. attempting to abort an "off-hook" or "on-hook" RQQ transaction

receives an AHY message checking its availability for a different incoming traffic channel call (i.e. bit D and/or bit E and/or the calling address is different from the alerting AHY), then the unit shall assume that the original call will not take place and shall abandon the RQQ transaction (without sending RQX). It shall also obey the procedures in 9.2.2.2A for the new call.

13.2 Procedures for Status Messages Addressed to Radio or Line Units

13.2.1 TSC Procedures for Status Messages to Radio or Line Units

13.2.1.1 Responses to a short addressing RQQ message

A radio unit requests that status information be relayed to a unit with the same prefix by generating an RQQ message, complying with the random access protocol. On receiving a common-prefix RQQ message, the TSC shall send one of the following responses:

- a. ACK(QUAL=0), ACKI(QUAL=1), ACKQ, ACKX or ACKV, with the same prefix and idents as the RQQ.
- b. ACKT(QUAL=0), with PFIX/IDENT2 as the calling unit's individual address.
- c. An AHYQ message for this transaction.

For acceptable delay, see 7.2.4. See also 13.2.1.4 and 13.2.1.5.

13.2.1.2 Responses to an extended addressing RQQ message

A radio unit requests that status information be relayed to a unit with a different prefix by generating an RQQ message (with IDENT1 = IPFIXI), complying with the random access protocol. On receiving an interprefix RQQ message, the TSC shall send one of the following responses, with the same prefix and idents as the RQQ:

a. An acknowledgement ACKI(QUAL=1), ACKX or ACKV(QUAL=0).

b. AHYC (i.e. an instruction to send the called unit's address).

For acceptable delay, see 7.2.4. See also 13.2.1.3 and 13.2.1.4.

13.2.1.3 Instruction to send extended address information

After receiving an interprefix RQQ message, the TSC may demand the called unit's address from the calling radio unit by sending the AHYC message (with the same prefix and idents as the RQQ, field DESC set to '000' and field SLOTS set to '01').

The AHYC message instructs the calling unit to send the called address in the following slot (see 9.2.2.1). If the TSC does not successfully decode the address information, it may repeat the AHYC message or transmit ACKV(QUAL=0) to indicate failure of the transaction.

Page 13-7

13.2.1.4 Acknowledgements sent to indicate progress of RQQ transaction

The TSC may send acknowledgement messages to indicate to a calling radio unit the progress of its status message - for idents, see 5.5.2.1. (For interprefix RQQs, only ACKI(QUAL=1), ACKX and ACKV(QUAL=0) are appropriate until the full address information has been obtained.)

	ACKI	(QUAL=1)	 Intermediate acknowledgement; more signalling to follow.
1	ACKQ	(QUAL=0)	- System is busy. Wait for further signalling.
	ACKQ	(QUAL=1)	- Called unit engaged. Wait for further signalling.
	ACKX	(QUAL=0)	 Invalid call e.g. TSC does not support status messages, or called address is a group address, or called unit is not equipped to accept the information.
	ACKX	(OUAL=1)	- System or called unit overload; message rejected.
	ACKV	(QUAL=0)	 Called unit not in radio contact or transaction abandoned.
	ACKV	(QUAL=1)	 Called unit engaged (and TSC will not hold the request), or called unit does not wish to accept the information.
-	ACKT	(QUAL=0)	- Called unit's calls have been diverted.
	ACK	(QUAL=0)	 Transaction has been successfully completed i.e. the called unit has accepted the status information.

For maximum acceptable delay of repeats of acknowledgements ACKX, ACKV, ACKT and ACK, see time-out TB in 13.2.2.4.

13.2.1.5 Informing a called radio unit

The TSC informs a called radio unit of status information by sending the AHYQ message (see 5.5.3.2.7). The status message may have originated from the TSC itself, or from a radio unit (using RQQ etc.) or a line unit.

For an interprefix status message, IDENT2 in the AHYQ address codeword is set to IPFIXI and a data codeword is appended containing the calling unit's address.

The AHYQ message demands a response from the called unit (see 13.2.3). If the response is ACK(QUAL=0), ACKX or ACKV(QUAL=1), the TSC may send appropriate acknowledgement(s) to a calling radio unit (see 13.2.1.4). If the TSC does not successfully decode a response, or if the response is ACKB(QUAL=1), it may repeat the AHYQ message. If the called unit cannot be contacted, the TSC may indicate the failure to the calling unit by sending ACKV(QUAL=0).

13.2.1.6 Aborting the transaction

A calling radio unit may abort its status transaction by generating an RQX message (see 5.5.3.1.3), complying with the random access protocol. On receiving an RQX message aborting a status transaction, the TSC shall send a response: ACK(QUAL=1) with the same prefix and idents as the RQX.

If the RQX is aborting a speech call request (i.e. RQQ(STATUS='00000')) and the TSC has already informed the called unit of the call request, it may inform the called unit of the abortion by sending AHYQ with STATUS='11111'.

13.2.1.7 TSC time-out

The TSC may operate a time-out on the maximum time for which it holds a status message request (for example, waiting for the called unit to be free).

The TSC may instruct a calling radio unit to restart its waiting timer TW, by sending the AHY message with bit POINT set to 'l'; see 9.1.1.7 and 9.2.2.3. If a time TW, minus the tolerance on the radio unit's timer, elapses since the last message it received for the status transaction (from the calling unit), the TSC shall not send any further signalling for the transaction. See also 13.2.2.5.

13.2.2 Procedures for Radio Units Sending Status Messages to Radio or Line Units

A radio unit shall make only one call attempt at a time (except in emergency); while attempting access or waiting for a terminating (i.e. endof-transaction) acknowledgement to a status message request, the unit shall not request another non-emergency call of any type (unless the user first aborts the original transaction).

13.2.2.1 Request for a status transaction to a radio or line unit

A radio unit requests a status transaction by sending an RQQ message on a control channel, complying with the random access protocol (see 7.3). The fields in the RQQ message shall be set appropriately (see 5.5.3.1.7); however, note particularly that an interprefix request is indicated by setting IDENT1 to IPFIXI. (Note also that status messages cannot be sent to a group.)

The unit shall attempt access until it receives a valid response (see 13.2.2.2/3), or until its user aborts the transaction (see 13.2.2.6), or until the access attempt fails (i.e. the unit has sent the maximum number of transmissions NR and received no response, or its access time-out TC has expired (see 7.3.8)). In the case of access failure, if the unit has not sent a request, it shall return to the idle state (and may indicate the failure to the user); otherwise, it shall wait for further signalling for the transaction - see 13.2.2.4 and 13.2.2.5.

13.2.2.2 Valid responses to a short addressing RQQ

For a common-prefix RQQ, the calling unit shall accept the following messages as a response to its RQQ and send no more requests:

- a. An acknowledgement ACK(QUAL=0), ACKI(QUAL=1), ACKQ, ACKX or ACKV, with the same prefix and idents as the RQQ message.
- b. An acknowledgement ACKT(QUAL=0) with PFIX/IDENT2 as its individual address. See also 13.2.2.4.
- c. An AHYQ message with the same prefix, idents and STATUS field as the RQQ message.

For other actions on receiving these messages, see section 13.2.2.4.

Page 13-9

13.2.2.3 Valid responses to an extended addressing RQQ

For an interprefix RQQ, the calling unit shall accept the following messages (with the same prefix and idents as the RQQ) as a response to its RQQ and send no more requests:

a. An acknowledgement ACKI(QUAL=1), ACKX or ACKV(QUAL=0).

b. AHYC (i.e. an instruction to send the called unit's address).

For other actions on receiving these messages, see 13.2.2.4 and 9.2.2.1.

13.2.2.4 Acknowledgement received

If a radio unit attempting access or waiting for further signalling for a status transaction receives an appropriate acknowledgement then it shall take action as indicated below. For interprefix RQQs, only ACKI(QUAL=1), ACKX and ACKV(QUAL=0) are appropriate until the full address information has been sent. For idents, see 5.5.2.1.

ACKI	(QUAL=1)	-	Intermediate acknowledgement; more signalling to follow.
ACKQ	(QUAL=0)	-	System is busy. Wait for further signalling.
ACKQ	(QUAL=1)	-	Called unit engaged. Wait for further signalling.
ACKX	(QUAL=0)	-	Invalid call; message rejected.
ACKX	(QUAL=1)	-	System or called unit overload; message rejected.
ACKV	(QUAL=0)	÷	Called unit not in radio contact or transaction abandoned.
ACKV	(QUAL=1)	-	Called unit engaged (and TSC will not hold the request), or called unit does not wish to accept the information.
ACKT	(QUAL=0)	-	Called unit's calls have been diverted.
ACK	(QUAL=0)	-	Transaction has been successfully completed i.e. the called unit has accepted the status information.

If ACKI(QUAL=1) or ACKQ is received, the unit shall wait for further signalling and may indicate to the user the progress of the transaction.

If ACKX or ACKV is received, the unit shall return to the idle state and may indicate to the user the reason for the failure of the transaction; it is recommended that receipt of ACKX(QUAL=0) be indicated in a distinct manner.

If a complete ACKT(QUAL=0) message is received, the unit shall either:

- return to the idle state (and may indicate to the user that the called unit's calls have been diverted), or
- b. attempt a new status transaction to the diversion address given in the ACKT message.
 Note that, if IDENT1 = IPFIXI in the ACKT address codeword and bit GF = 1 in the appended data codeword, then the diversion address is a group address; in this case, a status transaction to the diversion address would be an invalid call.

If an incomplete ACKT(QUAL=0) message is received, then:

Page 13-10

•

- If the unit does not require the diversion address, it shall return to the idle state (and may give an indication to the user).
- ii) If the unit does require the diversion address then:
 - if still attempting access for the transaction, it shall ignore the message and continue to attempt access;
 otherwise it shall wait for a repeat ACKT, returning to the idle state if a time TB elapses (in which case, it may indicate the failure to the user).

If ACK(QUAL=0) is received, the unit shall return to the idle state and may indicate to the user that the transaction has been successfully completed i.e. that the called unit has accepted the information. (Note that this does not imply user acceptance.)

After receiving ACKX, ACKV or ACK for the transaction, the unit shall not request another non-emergency call of any type to the same called ident (or gateway) for at least a time TB. After receiving ACKT for the transaction, the unit shall not request another non-emergency call of any type for at least a time TB.

13.2.2.5 Time-out after waiting

A calling radio unit waiting for further signalling for a status transaction to a radio or line unit shall return to the idle state if a time TW has elapsed since the last message it sent for the transaction, viz.

```
RQQ, requesting the transaction (see 13.2.2.1)
or SAMIS, providing extended address information for the call (see
9.2.2.1)
```

or ACK(QUAL=0), sent in response to an AHY message with bit POINT = 1 and IDENT1 as the called ident or gateway (see 9.2.2.3).

It may also indicate to the user that the outcome of the transaction is unknown.

13.2.2.6 Aborting the transaction

....

If the user wishes to abort the transaction after the unit has sent an RQQ and while it is still waiting for a terminating acknowledgement, the unit shall attempt to send an abort transaction request RQX (see 5.5.3.1.3), complying with the random access protocol. It shall attempt access until one of the following occurs:

- a. It receives ACK(QUAL=1) with the same prefix and idents as the RQX. In this case, it may indicate to the user that the outcome of the transaction is unknown.
- b. It receives ACK(QUAL=0), ACKX, ACKV or ACKT(QUAL=0) for the transaction it is attempting to abort. See also 13.2.2.4.
- c. It has sent the maximum number of transmissions NR and received no response, or its access time-out TC has expired (see 7.3.8). In this case, it shall return to waiting for signalling for the status transaction (see 13.2.2.4 and 13.2.2.5).

In cases a. and b., the unit shall return to the idle state.

Page 13-11

13.2.3 Procedures for All Radio Units on a Control Channel

The procedures in this section shall be obeyed by all radio units that are equipped to recognise a received AHYQ address codeword. (The requirement to recognise AHYQ will be system-dependent.)

÷

•

13.2.3.1 Receiving status message (AHYQ)

If a radio unit on a control channel receives an AHYQ message with PFIX/IDENT1 matching its individual address then it shall respond with the appropriate acknowledgement (see below), with the same prefix and idents as the AHYQ. If IDENT2 / IPFIXI in the AHYQ message, the unit shall respond in the slot following the AHYQ; if IDENT2 = IPFIXI, a data codeword is appended (containing the calling address) and the unit shall respond in the slot following the data codeword. For timing, see 6.2.1.3.

- a. If the unit is not equipped to accept the information then it shall send ACKX (QUAL=0).
- b. Otherwise, the unit shall send one of the following acknowledgements:

ACKB (QUAL=1) if IDENT2 = IPFIXI in the AHYQ message but the appended data codeword was not decodeable and the unit requires the message to be retransmitted.

- or ACKV (QUAL=1) if it does not wish to accept status information from this calling party
- or ACK (QUAL=0) if it has accepted the information in the AHYQ message.

14. SHORT DATA MESSAGE PROCEDURES

This section defines the procedures for short data messages of up to 184 bits of free-format data, transmitted on a control channel. The data is contained in up to four data codewords, appended to an address codeword (HEAD).

A radio unit requests to send a short data message using the RQC message (see 5.5.3.1.8). The TSC then:

- instructs the unit to send the short data message
- (and extended address information if appropriate)
- forwards the message to the called party
- indicates the outcome of the transaction to the calling unit.

A radio unit may send a short data message to the TSC or to a radio unit, a line unit, a group of units, all units in the system, a PABX extension (short or extended addressing) or a PSTN number (short-form or general).

The TSC may also transmit short data messages (addressed to a radio unit, a group or all units in the system), originated from the TSC itself or from a line unit, a PABX extension or the PSTN.

For calls from radio units, the TSC uses the AHYC message to demand:

- a. the called address information, for calls to:
 - interprefix addresses
 - (if appropriate: see below)
 - general PSTN destinations
 - "long" PABX extension numbers
- b. the short data message.

If both a. and b. are needed, the TSC obtains the full information in two steps, each step using the AHYC message. The AHYCs are distinguished by the setting of IDENT1 (to IPFIXI, PSTNGI or PABXI for a., or to SDMI for b.), and so the order in which they are sent is not prescribed.

Note that, when a radio unit sends its short data message, it supplies the address (prefix/ident) of the called party in the data message header. Therefore, for an interprefix call, the TSC need not demand the called address separately unless it is required for operational convenience.

The format for data within a short data message is not prescribed. Also, further (system-dependent) specifications may be required to define:

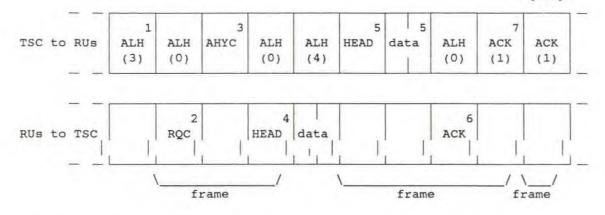

timings for repeat messages, and/or
 enumeration of data messages

to prevent duplicate messages (when a recipient accepts the repeat of a message as a new message).

A typical message sequence for a radio unit sending a short data message to another radio unit is illustrated in the example below.

Page 14-1

1 slot <--->

Example A message sequence on a control channel for sending a short data message from one radio unit to another radio unit on the same site. In this example, the data message comprises an address codeword and two appended data codewords.

- 1. ALH : General Aloha invitation (three-slot frame).
- 2. RQC : Random access request to transmit a short data message. (The request indicates the number of timeslots required for the data message: in this case, two slots.)
- 3. AHYC : Short data invitation message
 - acknowledges the RQC message
 - instructs the calling unit to send the data message in the next two slots
 - inhibits random access in the next slot.
- 4. HEAD + data : The calling radio unit sends its short data message to the TSC. In this example the message comprises an address codeword (HEAD) and two appended data codewords.
- HEAD + data : The TSC forwards the short data message to the called radio unit.

The second data codeword contains a flag (RSA) which is set to '0' to inhibit random access in the following slot, thus reserving the slot for a response from the called unit.

- ACK : Acknowledgement ACK(QUAL=0) from the called radio unit - data message accepted.
- 7. ACK : Acknowledgement ACK(QUAL=0) sent to the calling unit to indicate that the called unit has accepted the data message. In this example the TSC immediately repeats the ACK message, for added reliability.

14.1 TSC Procedures for Short Data Messages

14.1.1 Responses to a short addressing RQC message

A radio unit requests to send a short data message by generating an RQC message, complying with the random access protocol. On receiving a short addressing RQC message (with EXT = 1, or with EXT = 0 and IDENT1 set to a valid called party ident), the TSC shall send one of the following responses:

- a. ACKI(QUAL=1), ACKQ(QUAL=1), ACKX or ACKV, with PFIX/IDENT2 as the calling unit's individual address and IDENT1 as the called ident (or PABXI for a call to a PABX extension).
- b. ACKT(QUAL=0), with PFIX/IDENT2 as the calling unit's individual address.
- c. An AHYC message instructing the calling unit to send its data message.

For acceptable delay, see 7.2.4. See also 14.1.4 and 14.1.5.

14.1.2 Responses to an extended addressing RQC message

A radio unit requests to send a short data message by generating an RQC message, complying with the random access protocol. On receiving an extended addressing RQC message (with EXT = 0 and IDENT1 = IPFIXI, PSTNGI or PABXI), the TSC shall send one of the following responses:

- ACKI(QUAL=1), ACKX or ACKV(QUAL=0), with the same prefix and idents as the RQC.
- b. An AHYC message instructing the calling unit to send the full called address information.

c. An AHYC message instructing the calling unit to send its data message.

For acceptable delay, see 7.2.4. See also 14.1.3 to 14.1.5.

14.1.3 Instruction to send extended address information

After receiving an extended addressing RQC message, the TSC may demand the full called address (if appropriate), by sending the AHYC message with:

- the same prefix and idents as the RQC
 - (i.e. IDENT1 set to IPFIXI, PSTNGI or PABXI as appropriate, and PFIX/IDENT2 set to the calling unit's address)
- DESC set to indicate the appropriate gateway (see 5.5.3.2.8)
- SLOTS set to correspond to the RQC

(i.e. if IDENT1=PSTNGI and FLAG1=1 then SLOTS='10' else SLOTS='01').

The AHYC message instructs the calling unit to send the called party address information in the following SLOTS slot(s) (see 9.2.2.1). If the TSC does not successfully decode the address information, it may repeat the AHYC message or transmit ACKV(QUAL=0) to indicate failure of the transaction.

Page 14-3

Note that, when the radio unit sends its short data message, it supplies the called address (prefix/ident) in the data message header. Therefore, for an interprefix call, the TSC need not demand the called address separately unless it is required for operational convenience.

14.1.4 Instruction to send the short data message

After receiving an RQC message, the TSC may demand the short data message from the calling radio unit by sending the AHYC message, with:

- IDENT1 set to SDMI
- PFIX/IDENT2 set to the calling unit's address
- DESC set to '000'
- SLOTS equal to SLOTS from the RQC.

The AHYC message instructs the calling unit to send its short data message in the following SLOTS slots (see 9.2.2.1). If the TSC does not successfully decode the short data message, it may repeat the AHYC message or transmit ACKV(QUAL=0) to indicate failure of the transaction.

Note that AHYC bars random access only in the first following return slot. When demanding a short data message, the TSC shall take appropriate action to reserve the subsequent return slot(s) if they are within a frame (e.g. by sending the AHY message with both idents set to DUMMYI).

14.1.5 Acknowledgements sent to indicate progress of RQC transaction

The TSC may send acknowledgement messages to indicate to a calling radio unit the progress of its short data transaction - for idents, see 5.5.2.1. (For an extended addressing call, acknowledgements ACKQ, ACKV(QUAL=1), ACKT(QUAL=0) and ACK(QUAL=0) are not appropriate until the called address has been obtained. Acknowledgements ACKQ(QUAL=0) and ACK(QUAL=0) are not appropriate until the short data message has been obtained.)

ACKI	(QUAL=1)	-	Intermediate acknowledgement; more signalling to follow.
ACKQ	(QUAL=0)	-	System is busy. Wait for further signalling.
ACKQ	(QUAL=1)	-	Called party engaged. Wait for further signalling.
ACKX	(QUAL=0)	AL .	Invalid call e.g. TSC does not support short data messages, or called party is not equipped to accept the message.
ACKX	(QUAL=1)	-	System or called unit overload; message rejected.
ACKV	(QUAL=0)	-	Called unit not in radio contact or transaction abandoned.
ACKV	(QUAL=1)	-	Called party engaged (and TSC will not hold the request) or called unit does not wish to accept the message.
ACKT	(QUAL=0)	-	Called party's data calls have been diverted.
ACK	(QUAL=0)	-	Transaction has been successfully completed.

For maximum acceptable delay of repeats of acknowledgements ACKX, ACKV, ACKT and ACK, see time-out TB in 14.2.4.

14.1.6 Availability check on called radio unit

Before transmitting a short data message to a radio unit, the TSC may check that the unit is in radio contact (and suitably equipped). It uses the AHY message, with:

- bit POINT set to '0'
- bit CHECK set to '0'
- bit D set to '1'
- bit E set to '0'
- bit AD set to '0'
- PFIX/IDENT1 as the called unit's address
- IDENT2 set to SDMI.

The AHY message demands a response in the following slot from the called unit (see 9.2.2.2B).

The TSC may indicate the result of the availability check to a calling radio unit by sending appropriate acknowledgement(s) (see 14.1.5).

14.1.7 Informing called party

The TSC transmits a short data message to a radio unit, a group or all units in the system by sending the HEAD message on a control channel (see 5.6.2). The data message may have originated from the TSC itself, or from a radio unit (using RQC etc.), a line unit, a PABX extension or the PSTN.

The HEAD address codeword indicates the number of appended data codewords (up to four), and contains two 20-bit addresses: the called address and calling address (or gateway). The user data is contained in the data codewords. For an individually addressed short data message sent within a frame, the TSC shall set the RSA flag in the last data codeword (or in the "filler" data codeword) to '0', to inhibit random access in the next slot.

For an individually addressed short data message, the HEAD message demands a response from the called unit (see 14.3.1.1). If the response is ACK(QUAL=0), ACKX or ACKV(QUAL=1), the TSC may send appropriate acknowledgement(s) to a calling radio unit (see 14.1.5). If the TSC does not successfully decode a response, or if the response is ACKB(QUAL=1), it may repeat the HEAD message. If the called unit cannot be contacted, the TSC may indicate the failure to the calling unit by sending ACKV(QUAL=0).

For a short data message addressed to a group (or system-wide), the called units do not respond; the TSC may repeat the data message, to increase the probability of successful receipt. After transmitting the short data message, the TSC may send ACK(QUAL=0) to a calling radio unit.

14.1.8 Aborting the transaction

A calling radio unit may abort its short data transaction by generating an RQX message (see 5.5.3.1.3), complying with the random access protocol. On receiving an RQX message aborting a short data transaction, the TSC shall send a response: ACK(QUAL=1) with the same prefix and idents as the RQX.

Page 14-5

14.1.9 TSC time-out

The TSC may operate a time-out on the maximum time for which it holds a short data message (for example, waiting for the called party to be free).

ĩ,

The TSC may instruct a calling radio unit to restart its waiting timer TJ or TW, by sending the AHY message with bit POINT set to '1'; see 9.1.1.7 and 9.2.2.3. If a time TJ or TW, minus the tolerance on the radio unit's timer, elapses since the last message it received for a short data transaction (from the calling unit), the TSC shall not send any further signalling for the transaction. See also 14.2.6.

Page 14-6

14.2 Procedures for Radio Units Sending Short Data Messages

A radio unit shall make only one call attempt at a time (except in emergency); while attempting access or waiting for a terminating (i.e. endof-transaction) acknowledgement to a short data message request, the unit shall not request another non-emergency call of any type (unless the user first aborts the original transaction).

14.2.1 Request for a short data transaction

A radio unit requests to transmit a short data message by sending an RQC message on a control channel, complying with the random access protocol (see 7.3). The fields in the RQC message shall be set appropriately (see 5.5.3.1.8); however, note particularly that:

- a. Field SLOTS specifies the number of timeslots required for the data message (minimum two slots, maximum three slots).
- b. An extended addressing request is indicated by setting IDENT1 in the RQC message to the appropriate gateway (viz. IPFIXI, PSTNGI or PABXI).

The unit shall attempt access until it receives a valid response (see 14.2.2/3), or until its user aborts the transaction (see 14.2.7), or until the access attempt fails (i.e. the unit has sent the maximum number of transmissions NR and received no response, or its access time-out TC has expired (see 7.3.8)). In the case of access failure, if the unit has not sent a request, it shall return to the idle state (and may indicate the failure to the user); otherwise, it shall wait for further signalling for the transaction - see 14.2.4 to 14.2.6.

14.2.2 Valid responses to a short addressing RQC

For a short addressing RQC, the calling unit shall accept the following messages as a response to its RQC and send no more requests:

- a. ACKI(QUAL=1), ACKQ(QUAL=1), ACKX or ACKV, with PFIX/IDENT2 as its individual address and IDENT1 as the called ident (or PABXI for a PABX call).
- b. ACKT(QUAL=0) with PFIX/IDENT2 as its individual address.
- c. AHYC, with PFIX/IDENT2 as its individual address and IDENT1 as SDMI.

For other actions on receiving these messages, see 14.2.4 and 9.2.2.1.

14.2.3 Valid responses to an extended addressing RQC

For an extended addressing RQC, the calling unit shall accept the following messages as a response to its RQC and send no more requests:

- a. ACKI(QUAL=1), ACKX or ACKV(QUAL=0), with the same prefix and idents as the RQC.
- b. AHYC, with the same prefix and idents as the RQC.
- c. AHYC, with PFIX/IDENT2 as its individual address and IDENT1 as SDMI.

For other actions on receiving these messages, see 14.2.4 and 9.2.2.1.

Page 14-7

14.2.4 Acknowledgement received

If a radio unit attempting access or waiting for further signalling for a short data transaction receives an appropriate acknowledgement then it shall take action as indicated below. (ACKQ, ACKV(QUAL=1), ACKT(QUAL=0) and ACK(QUAL=0) are not appropriate until the called address information has been sent - in the RQC, as extended address information or in the short data message. ACKQ(QUAL=0) and ACK(QUAL=0) are not appropriate until the short data message has been sent.) For idents, see 5.5.2.1. •

•

ACKI	(QUAL=1)	-	Intermediate acknowledgement; more signalling to follow.
ACKQ	(QUAL=0)	-	System is busy. Wait for further signalling.
ACKQ	(QUAL=1)	-	Called party engaged. Wait for further signalling.
ACKX	(QUAL=0)	-	Invalid call; message rejected.
ACKX	(QUAL=1)	-	System or called unit overload; message rejected.
ACKV	(QUAL=0)	-	Called unit not in radio contact or transaction abandoned.
ACKV	(QUAL=1)	-	Called party engaged (and TSC will not hold the request) or called unit does not wish to accept the message.
ACKT	(QUAL=0)	-	Called party's data calls have been diverted.
ACK	(QUAL=0)	-	Transaction has been successfully completed.

If ACKI(QUAL=1) or ACKQ is received, the unit shall wait for further signalling and may indicate to the user the progress of the transaction.

If ACKX or ACKV is received, the unit shall return to the idle state and may indicate to the user the reason for the failure of the transaction; it is recommended that receipt of ACKX(QUAL=0) be indicated in a distinct manner.

If a complete ACKT(QUAL=0) message is received, the unit shall either:

- return to the idle state (and may indicate to the user that the called party's data calls have been diverted), or
- b. attempt a new short data transaction to the diversion address given in the ACKT message.

If an incomplete ACKT(QUAL=0) message is received, then:

 If the unit does not require the diversion address, it shall return to the idle state (and may give an indication to the user).

ii) If the unit does require the diversion address then:

- if still attempting access for the transaction, it shall ignore the message and continue to attempt access;
- otherwise it shall wait for a repeat ACKT, returning to the idle state if a time TB elapses (in which case, it may indicate the failure to the user).

If ACK(QUAL=0) is received, the unit shall return to the idle state and may indicate to the user that the transaction has been successfully completed i.e. that:

- for an individual call, the called unit has accepted the short data message; (note that this does not imply user acceptance);

 for a group (or system-wide) call, the short data message has been sent to the group.

After receiving ACKX, ACKV or ACK for the transaction, the unit shall not request another non-emergency call of any type to the same called ident (or gateway) for at least a time TB. After receiving ACKT for the transaction, the unit shall not request another non-emergency call of any type for at least a time TB.

14.2.5 Sending the short data message

The calling unit shall transmit its short data message (a HEAD address codeword and appended data codeword(s) - see 5.6.2) on receipt of an appropriate AHYC from the TSC; see section 9.2.2.1.

14.2.6 Time-out after waiting

A calling radio unit waiting for further signalling for a short data transaction shall return to the idle state if a time TJ (for a data message addressed to the TSC) or TW (for other destinations) has elapsed since the last signalling message it sent for the transaction, viz.

RQC, requesting the transaction (see 14.2.1)
or SAMIS, providing extended address information for the call (see
 9.2.2.1)
or HEAD, containing the short data message (see 14.2.5 and 9.2.2.1)
or ACK(QUAL=0), sent in response to an AHY message with bit POINT = 1

It may also indicate to the user that the outcome of the transaction is unknown.

and IDENT1 as the called ident or gateway (see 9.2.2.3).

14.2.7 Aborting the transaction

A radio unit may abort a short data transaction (after sending an RQC and while still waiting to receive ACKX, ACKV, ACKT or ACK) by transmitting an abort transaction request RQX (see 5.5.3.1.3), complying with the random access protocol. It shall attempt access until one of the following occurs:

- a. It receives ACK(QUAL=1) with the same prefix and idents as the RQX. In this case, it may indicate to the user that the outcome of the transaction is unknown.
- b. It receives ACK(QUAL=0), ACKX, ACKV or ACKT(QUAL=0) for the transaction it is attempting to abort. See also 14.2.4.
- c. It has sent the maximum number of transmissions NR and received no response, or its access time-out TC has expired (see 7.3.8). In this case, it shall return to waiting for signalling for the short data transaction (see 14.2.4 to 14.2.6).

In cases a. and b., the unit shall return to the idle state.

Page 14-9

14.3 Procedures for All Radio Units on a Control Channel

The procedures in this section shall be obeyed by all radio units that are equipped to recognise a received HEAD address codeword. (The requirement to recognise HEAD will be system-dependent.)

14.3.1 Receiving short data message (HEAD)

14.3.1.1 Individually addressed HEAD message

If a radio unit on a control channel receives a HEAD message with PFIX1/IDENT1 matching its individual address then it shall respond with the appropriate acknowledgement (see below), with PFIX/IDENT1 as its individual address and IDENT2 set to IDENT2 from the HEAD. The HEAD address codeword contains a field (LEN) which indicates the number of appended data codewords; the unit shall respond in the slot following the last data codeword. For timing, see 6.2.1.3.

- a. If the unit is not equipped to accept the data message then it shall send ACKX (QUAL=0).
- b. Otherwise, the unit shall send one of the following acknowledgements:

ACKB (QUAL=1) if not all the appended data codewords were decodeable and the unit requires the message to be retransmitted

- or ACKX (QUAL=1) if it cannot accept the message at this time (e.g. its data store is full)
- or ACKV (QUAL=1) if it does not wish to accept a data message from this calling party

or ACK (QUAL=0) if it has accepted the data message.

14.3.1.2 HEAD message addressed to a group

If a radio unit on a control channel receives a HEAD message with PFIX2/IDENT2 not matching its individual address, and

PFIX1/IDENT1 matching one of its group addresses for this system or

IDENT1 set to the system-wide all-call ident ALLI,

then it may accept the information contained in the HEAD address codeword and the appended data codewords, but shall transmit no response.

Page 14-10

15. DATA INTERROGATION PROCEDURES

......

This section defines data interrogation procedures, which allow the TSC to demand that an addressed radio unit transmits a data message of a prescribed type. This demand is an interrogation by the TSC, not part of the signalling for a call requested by the radio unit. It may be sent on either a control channel or an allocated traffic channel.

The TSC interrogates the radio unit by sending message AHYC, Mode 2 (see 5.5.3.2.8). In this message, PFIX/IDENT1 is set to the radio unit's individual address and IDENT2 is the ident of the interrogator (a non-radio-unit ident). The type of data to be transmitted by the radio unit is indicated by the descriptor field DESC and the non-radio-unit ident.

The TSC does not acknowledge receipt of the radio unit's data message (though it may take appropriate action as a result of the received data).

Currently, for data interrogation, only one value of the data message descriptor field DESC has been assigned. This value is used for implementing serial number checks: the TSC may at any time, on a control channel or traffic channel, instruct a radio unit to send its 38-bit serial number. Comparison of the received serial number with the expected value (held in store at the TSC) will assist in the detection of fraudulent users.

Page 15-1

15.1 Data Interrogation Procedures for TSC

15.1.1 Data interrogation on a control channel

The TSC may demand that a radio unit on a control channel transmits a data message of a prescribed type, by sending the AHYC message with:

- PFIX/IDENT1 set to the individual address of the radio unit
- IDENT2 set to the ident of the interrogator (for example, for a serial number check, IDENT2 = TSCI)
- DESC set to indicate the type of data message required; see 5.5.3.2.8 (for example, for a serial number check, DESC = '000')
- SLOTS set appropriately; see 5.5.3.2.8 (for example, for a serial number check, SLOTS = '01').

The AHYC message instructs the addressed radio unit to transmit a data message in the following SLOTS slot(s) (see 15.2.1). If the TSC does not successfully decode a reply, it may repeat the AHYC message when convenient. (The TSC does not acknowledge receipt of the data message).

Note that AHYC bars random access only in the first following return slot. When demanding a multi-codeword data message, the TSC shall take appropriate action to reserve the subsequent return slot(s) if they are within a frame (e.g. by sending the AHY message with both idents set to DUMMYI).

15.1.2 Data interrogation on a traffic channel

The TSC may demand that a radio unit on an allocated traffic channel transmits a data message of a prescribed type, by sending the AHYC message with:

- PFIX/IDENT1 set to the individual address of the radio unit
- IDENT2 set to the ident of the interrogator
- DESC set to indicate the type of data message required; see 5.5.3.2.8
- SLOTS set appropriately; see 5.5.3.2.8.

The AHYC message instructs the addressed radio unit to transmit a data message (see 15.2.2). If the TSC does not successfully decode a reply, it may repeat the AHYC message.

Petitioner Cisco Systems - Exhibit 1005 - Page 214

Page 15-2

•

15.2 Procedures for All Radio Units

The procedures in this section shall be obeyed by all radio units that are equipped to recognise a received Mode 2 AHYC message. (The requirement to recognise AHYC, Mode 2 will be system-dependent.)

15.2.1 Data interrogation message (AHYC, Mode 2) on a control channel

If a radio unit on a control channel receives an AHYC message with PFIX/IDENT1 matching its individual address then it shall either send a data message in the following SLOTS slot(s), or transmit ACKX(QUAL=0), as indicated below. For timing, see section 6.2.1.3.

If

IDENT2 is set to TSCI and DESC is set to '000' and SLOTS is set to '01' and the unit is equipped to transmit its serial number on interrogation

then it shall transmit its serial number, conforming to the codeword format defined in section 5.6.1.2.2 (SAMIS, Mode 2, DESC='000'). (The form of the serial number is system-dependent.)

Otherwise The unit shall transmit ACKX(QUAL=0), with the same prefix and idents as the AHYC.

15.2.2 Data interrogation message (AHYC, Mode 2) on an allocated traffic channel

If a radio unit on a traffic channel receives an AHYC message with PFIX/IDENT1 matching its individual address then it shall either send a data message or transmit ACKX(QUAL=0), as indicated below. For timing, see section 6.2.2.2.

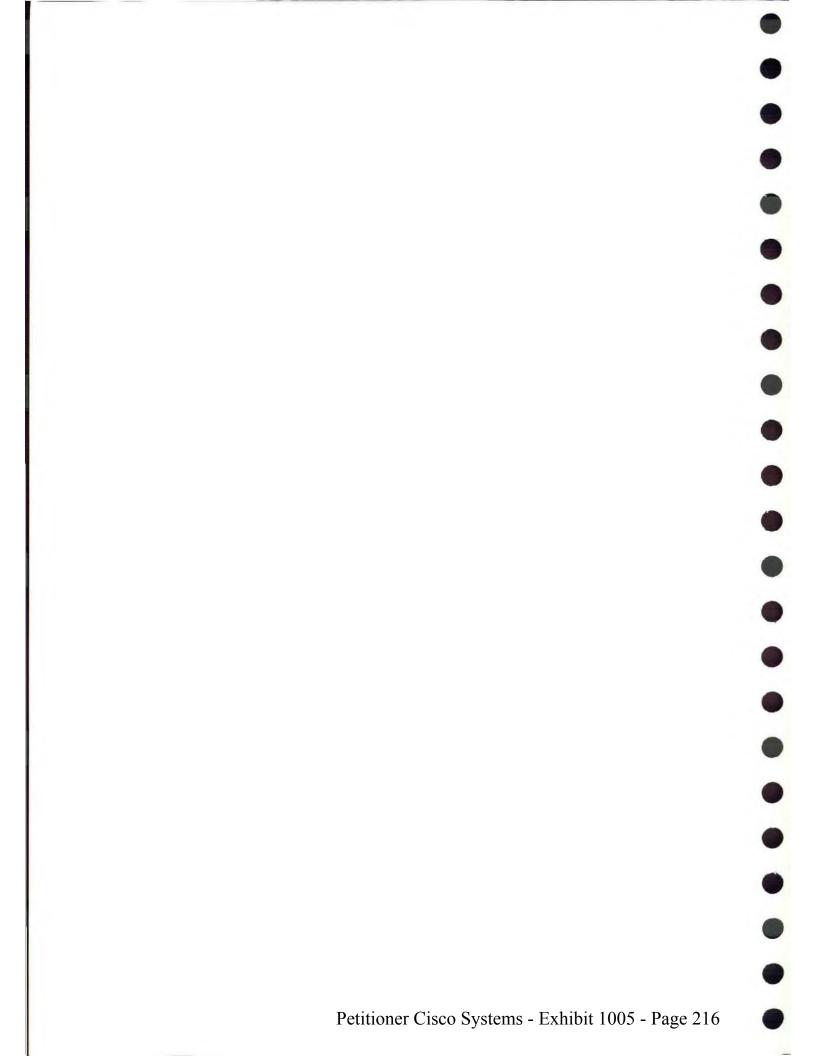

If

IDENT2 is set to TSCI and DESC is set to '000' and SLOTS is set to '01' and the unit is equipped to transmit its serial number on interrogation

then it shall transmit its serial number, conforming to the codeword format defined in section 5.6.1.2.2 (SAMIS, Mode 2, DESC='000').

Otherwise The unit shall transmit ACKX(QUAL=0), with the same prefix and idents as the AHYC.

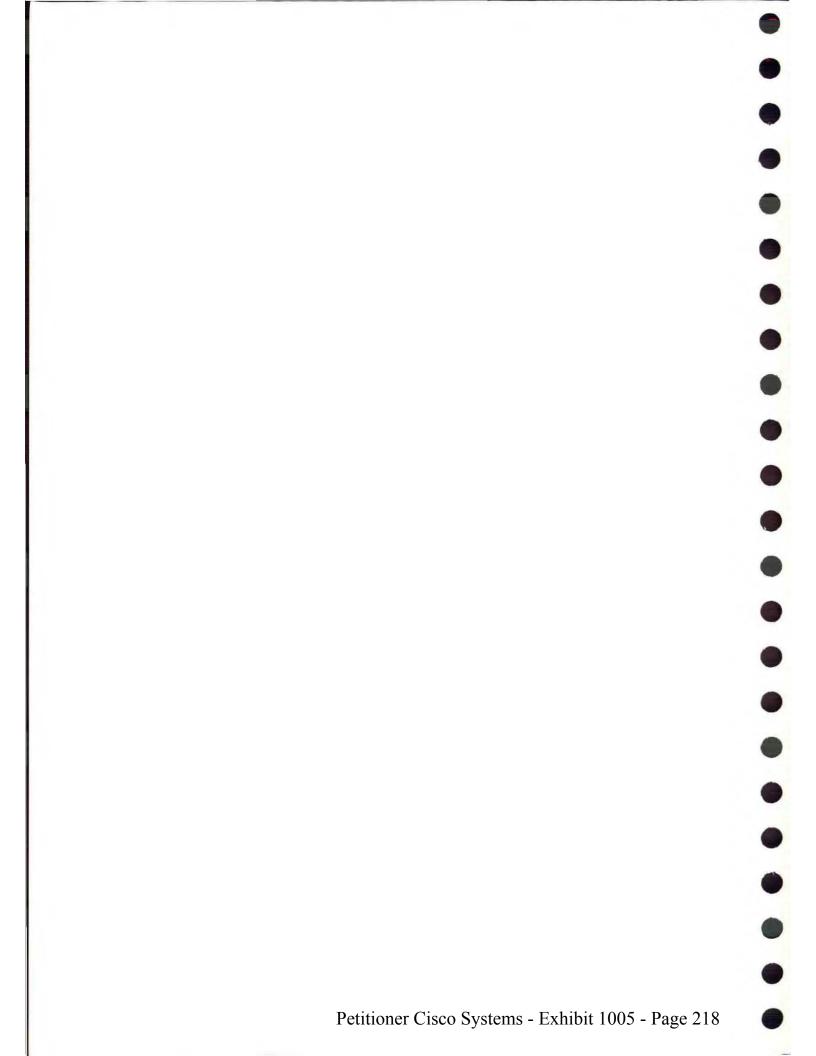

Page 15-3

16. ADDITIONAL SHORT DATA PROCEDURES e.g. SAMs

Additional short data procedures are not included in this issue.

Page 16-1

17 STANDARD DATA PROCEDURES

17.0 Introduction

This section defines the procedures for setting up data calls and then transmitting Tmessages (see 2) in a standard manner on a standard data traffic channel (the data channel). A base station may include several data channels.

Data may be transferred between the following parties:

radio unit ---> TSC, line unit, radio unit or group radio unit ---> all standard data equipped (SDE) units in system radio unit ---> PABX extension (short or long extension number) radio unit ---> PSTN destination (prearranged or general) radio unit ---> Public Data Network (PDN) subscriber TSC ---> radio unit, group or all SDE units in system line unit ---> radio unit, group or all SDE units in system PABX extn. ---> radio unit, group or all SDE units in system PSTN terminal-> radio unit, group or all SDE units in system PDN user ---> radio unit, group or all SDE units in system

Set-up of a new data call is initiated by the RQD request transmitted on either the control or data channel. For this and other purposes the data channel has random access frames interspersed with the user data being conveyed.

The data channel provides a link between the TSC and radio unit for the purposes of a data call. For an individual link with the TSC, errors on the data channel are corrected as necessary by automatic request for repetition (ARQ) before the data is passed on to any other data link or equipment, i.e. operation is "store and forward". The TSC may limit the time for which it will store a call if it finds difficulty in forwarding it. For a call between radio units at least two links are necessary.

One data channel at a base station may be shared at one time by up to 1023 links, several of which may be concurrently active, although the mean data transfer rate experienced by each active radio unit is liable to reduce as the total activity increases. The TSC is the master station and controls all transmissions on the data channel so as to avoid any simultaneous transmissions (except random access ones) from radio units on the return channel.

17.0.1 Facilities offered by the Standard Data Procedures

Facilities offered by these procedures are:

- radio units operate in a half-duplex mode with bidirectional Tmessage transmission facility,
- b) for group calls the data in the link from the TSC to the group is not corrected by automatic request for repetition but may be repeated up to a prearranged number of times to increase the probability of successful reception by all group members,
- c) a data call may be conducted with an individual radio unit or transmitted to a group of radio units, and in the latter case responses may be obtained either by separate polling of each radio unit in the group or by inviting random access from group members,
- d) the calling party may request that a call shall be directed to any one of 8 sub-addresses (PORTs), e.g. to call a particular receiving terminal configuration,
- e) an end-to-end high accuracy data transfer (HADT) mode may be invoked,
- f) a calling radio unit may request priority for resources for a data call,
- g) a calling radio unit may make a request for an interactive data exchange with the called party so that the TSC will test whether a suitable radio channel is available and the called party is ready to exchange data,
- h) urgent calls may be requested,
- j) a suitably equipped radio unit may engage in more than one data call concurrently,
- any called party can be informed of the identity of the calling party,
- 1) the calling party is given a reason for any call set-up failure,
- m) a data call may consist of a single Tmessage (see NOTE 1), or may include a response or a number of data interchanges with pauses between the various Tmessages,
- n) each link provided via a data channel is bit-transparent (see NOTE 2),
- p) the standard data signalling rate is 1200 bit/s, with provision for a customised rate (see NOTE 3), and

- q) radio units may be transferred individually or in groups from one data channel to another so that relief data channels may be created and brought into use when a data traffic overload occurs and can be taken out of use when the overload subsides. Also a radio unit on a data channel may be transferred collectively to another data channel.
- NOTE 1. No specific "mail-box" facility is listed but all the ingredients necessary to provide that facility are available.
- NOTE 2. Users concerned about unauthorised reception may wish to take advantage of this facility by encrypting their data.
- NOTE 3. The individual links of a call may transmit at different rates because of the storage provided by the TSC. No customised rate is prescribed by this standard.

17.0.2 Guide to Some Key Protocol Aspects

17.0.2.1 Data Channel Addressing

On the data channel it would be wasteful of time always to use address codewords including the full identity of both the sender and recipient of a transmission dataitem. Moreover, if two radio units are involved they each have their own link with the TSC(s), and these links often act at different times because of the store and forward nature of the facility. Therefore on the data channel, instead of Prefixes and Identities, each radio unit uses a 10-bit transaction number termed a "TRANS" which identifies that link during that call and is assigned by the TSC in a "Go-to-TRANS" (GTT) message sent during the call set-up phase. The TRANS validity ceases when the link closes, and the TRANS value may then be reused for a new link. A dummy TRANS value '000000000' is reserved for use in messages whenever no allocated value is appropriate.

Apart from the use of TRANS, the use of certain addresswords containing a PFIX and IDENT(s) also is valid on a data channel in appropriate circumstances.

17.0.2.2 Data channel format

All messages on the data channel conform to the traffic channel format described in section 3. On the forward channel preamble and SYNT are found in the last half of a Data Channel System Codeword (DCSC), equivalent to the CCSC of a control channel but with SYNC replaced by SYNT, see 5.1.

The standard allows for two possible transmission rates, viz 1200 bit/s and a customised one. Only one rate is used on any one channel. All stations must be able to utilize the 1200 bit/s rate, but use of the customised one is optional. A calling or individually called radio unit states whether it could operate at the customised rate in its respective RQD or acknowledgement message. The TSC specifies the rate for each TRANS in the relevant GTT message, but must not specify the customised rate unless both TSC and radio unit can use it. At 1200 bit/s the timing of a radio unit message relative to the TSC "invoking message" is as described in 6.2.1.3, but for any customised rate this timing is specified elsewhere. Some timing criteria are outlined in Appendix 6.

The data channel format is similar to a control channel in some ways, consisting of random and non-random transactions with radio units. However, because the transactions are often lengthy, differences between data and control channel are:

- a) because of the long messages a TSC may transmit, on the forward channel DCSCs are infrequent compared to CCSCs,
- b) the concept of time-slots only applies within random access frames,
- c) the Aloha function which introduces a random access frame does not require a whole codeword and frequently shares a codeword with another function,
- d) the list of codewords on the forward channel which withdraw slots from a random access frame is different,

- e) the WAIT parameter is replaced by a 3-bit frame count parameter, WF. If a random access attempt has not been acknowledged before WF frames have been received then the access attempt may be repeated,
- f) in the Aloha function there is a frame length (slots) field ND which has 5 bits to give a wide range of frame lengths,
- g) a 10-bit TRANS field replaces the PFIX and IDENT fields found in frame marking codewords, and
- h) there is no equivalent of the modifier M field in frame marking codewords (a TRANS value of '0000000000' permits any radio unit to attempt access, otherwise only the radio unit(s) assigned to the specified TRANS can attempt access).

17.0.2.3 Access on the data channel

Random access opportunities are provided on the data channel for radio units to make various data service requests. A frame marking function states the number of slots in an access frame, and radio units attempt access by transmitting a one-codeword message in a random slot within that frame. At 1200 bit/s each slot consists of two codewords, but slots at the customised rate may differ. The access frame has a maximum length of 31 slots. The frame marking function occupies half a codeword, the other half often being used for an acknowledgement.

Three types of frame marking function are provided, viz:

- DAL, a general Aloha,

- DALG, which limits requests to urgent calls or those for repeat of a group Tmessage, and

- DALN, which invites any requests except those for a repeat of a non-urgent group Tmessage.

Five types of request may be sent by radio units, viz:

- RQD to request a data call (which may be a concurrent call), (RQD with urgency bit E set to '1' is sent in any random access frame)

- DRUGI to request resumption of data transmission or reception in a given TRANS after a period of inactivity,

- DRQG to request repeat of the whole of a group Tmessage,

- DRQZ to request transmission of expedited data, and

- DRQX to request that a TRANS be closed. If the TRANS value in DRQX is the dummy, '0000000000', then it requests that all TRANS assigned to that radio unit be closed.

Permitted responses to these requests are detailed in 17.2.2.

A parameter, NDR, limits the number of random access tries in any one access attempt, and a time-out, TDC, limits the duration of a random access attempt. These parameters are pre-set. If either is exceeded then the

Page 17-5

random access attempt is abandoned.

The AHYD message contains bit E to signal an urgent call. As well as the AHYD message, the TSC may send other data aboy type messages to addressed radio units, viz:

- DAHY to check whether a particular TRANS is still active,

- DAHYZ to inform a radio unit of expedited data, e.g. to reset the link to a known state, and

- DAHYX to demand that a specific (or all) TRANS are closed.

17.0.2.4 Call Set-up

The call set-up procedures are similar whether initiated on the control or data channel.

To make a data call the radio unit transmits an RQD message. This includes PFIX and IDENT information and the called PORT, priority or urgency required, whether real-time data exchange with the recipient is required, whether high accuracy data transfer (HADT) is required, and whether the customised transmission rate can be used. The TSC grants the Request by sending a GTT message which includes the calling identity, the designation of the data channel to be used, the TRANS to be used for that call (or TRANS can be allocated on the data channel), and the designated link transmission rate.

To call a radio unit(s) the TSC sends an AHYD (POINT=0) message containing calling and called identities, whether HADT will be used, and the called PORT. In an individual call, if the radio unit can satisfy the call requirements it acknowledges this with a message which includes an indication of whether the customised rate can be used. A GTT message from the TSC, including the called identity, channel number, TRANS for that link (usually), and transmission rate, then instructs the radio unit to go to the data channel.

A call to or from a prearranged destination on any network can be set up using a special Ident, e.g. NETSIj or one of the spare Ident's. Calls to general PSTN and PABX destinations require extended addressing which is achieved in the normal manner. General calls to or from a PDN destination use the gateway "DNI", and then are switched to the data channel so that the addressing can be completed in gateway dependent format.

For a group call no response is made to the AHYD message. The group link then is announced by a GTT message. Usually the group transmission rate is prearranged. Any unit which cannot cope with the announced transmission rate or HADT, or accept the PORT ignores that message (but radio units may use a fall-back PORT). Although no reply to the Tmessage is possible within the call, a radio unit may note the caller's address in the AHYD, and, after the call, if it wishes to respond it sets up (e.g. on the data channel) a new call to the noted originator's address. The amount of data which can be conveyed in one group call is limited to a maximum of 11994 bits.

17.0.2.5 The ARQ scheme and related matters

Apart from the above, as well as the forward error correction possibilities offered by each codeword, an ARQ scheme is included in links with individual radio units. The descriptions given in this subsection apply only to individual links.

ARQ is not provided for a transmission to a group but, by prearrangement, the Tmessage may be transmitted automatically more than once, and individual radio units can request a repeat.

On any link no dataitem may contain more user data than that found in the address word plus 62 data codewords. Tmessages needing more than this are sent by dividing them into a number of dataitems. The maximum number of data codewords in any dataitem is controlled by the receiving station (or the TSC for a first dataitem) and in no case exceeds 62. Initially a dataitem is sent in one user data message but a fragment of a dataitem can also constitute a user data message.

The number of data codewords in any user data message is stated in a FRAGL field in its address codeword (SITH, see 5.8.12), and the position of the last bit of user data in the final codeword is given in the LASTBIT field of SITH. In a dataitem, user data starts in the 10-bit USER DATA field of SITH and continues with 47 bits of user data in every appended data codeword until the final codeword in the dataitem. In the user data field of that codeword (including SITH if it has no appended data codeword) the end of the user data is followed by a '1' to confirm the end of the user data. Any space left in the field is filled with '0's (unless HADT is used, see below). If it happens that the last user data bit occupies the final bit in the user data field of a codeword the end of user data is still confirmed, which gives rise to an appended data codeword containing a '1' and 46 '0's in its information field.

If HADT is invoked, the last 15 information bits in the message are a checksum on the data in the dataitem, and may replace 15 filler '0's. See 17.2.3.1.4.2.

In response to a faulty user data message the receiver may send a selective acknowledgement (SACK) to request retransmission of a fragment of a dataitem. Alternatively the receiver may request complete retransmission of the dataitem by sending a negative acknowledgement (NACK).

If HADT is invoked, when an apparently entire dataitem has been received the checksum is used to decide whether the dataitem is incorrect, and if so a NACK message is sent.

When the entire dataitem has been correctly received, a positive acknowledgement (PACK) is sent. Only then may the next dataitem be embarked upon. PACK and NACK only differ in 1 bit, and are known collectively as DACK.

As a precaution against lost or duplicated messages every header and acknowledgement contain the TRANS and a 1-bit dataitem number (ITENUM). The dataitem number remains constant for one dataitem and any repeat fragments but differs between any two adjacent dataitems.

DACK occupies only about half a codeword (a submessage) and the remaining submessage is used for data channel access (see 17.0.2.3 and

17.0.2.6). In contrast a SACK message includes one assigned EFLAG bit for every dataword in the dataitem. An assigned EFLAG which is set to 'l' indicates that the relevant data codeword must be repeated. The leading EFLAG represents the leading data codeword in the dataitem, and so on (see 5.8.11 for rules governing the use of the EFLAGS' field).

In order to mark the last assigned data codeword in the SACK message the first non-assigned EFLAG is set to '1' and any remaining non-assigned EFLAGs are set to '0'. There are 23 EFLAGs in the SACK addressword. If the dataitem has more than 22 datawords the SACK has an appended data codeword with a 40-bit EFLAG field, as confirmed by an address codeword flag "AD". Security of the EFLAG information is enhanced by a 4-bit 'ONES' field in each SACK codeword. The value of ONES is set to the modulo-16 number of EFLAGs set to 1 in that codeword.

In response to a SACK message containing assigned EFLAGs which are set to '1' the data transmitter sends a fragment of the dataitem which consists of a new header and only the repeated relevant data codewords in the same order as in the dataitem. A radio unit sends this response immediately (see Figure 17.1 below). For procedures for the data sending station (DSS) see 17.2.3.1.

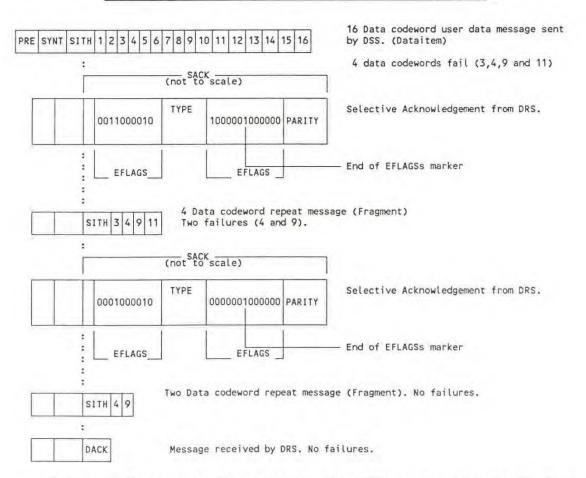

FIGURE 17.1 Use of EFLAGS in Selective Repeat of a user data message

After sending a user data message, if, within a set time limit, the sender does not recognize an acknowledgement then it may infer that either

the recipient failed to decode the SITH (and hence any appended datawords) or that an acknowledgement was sent but not decoded. If only the addressword of a two-word SACK is decoded then clearly the user data message was received but the SACK cannot be acted upon. The acknowledgement loss situation can be rectified by repeating the message, but this is wasteful if the message is a long one and only acknowledgement information has been lost. To reduce waste a Repeat Last Acknowledgement (RLA) message is specified so that a sending station can demand acknowledgement repetition instead of sending a message repetition. The sending station acts upon the information in the repeated acknowledgement.

An acknowledgement from a radio unit follows substantially immediately after the end of the message transmitted by the TSC but the acknowledgement sent by the TSC in response to a message from a radio unit may be delayed by up to a pre-set time limit after the end of the message. If the time limit is exceeded the radio unit may use random access to send a query to the TSC.

17.0.2.6 Data Traffic and Flow Control

• • • •

The TSC controls all data traffic on the data channel either by using a GO submessage to grant a dataitem transmission to the addressed radio unit or by using an aloha marker submessage to give a random access opportunity to radio units (see 5.8.2). A radio unit may indicate to the TSC in a GO submessage the length of the next dataitem it proposes to send. The TSC may grant a shorter dataitem length.

A field found both in SITH and DACK is "TNITEL" which informs the receiver of the proposed number of data codewords (0 to 62) in the next dataitem. The GO submessage (sent by a data receiving station) includes a 6-bit field, RNITEL, which defines the maximum number of data codewords that can be accepted in the next user data message.

Flow control at a link level is achieved by using the TNITEL and RNITEL fields. A data sending station must not send more data than is acceptable to the receiving station, as expressed in RNITEL. The TNITEL value found in SITH is advisory so that the receiver can check that it has sufficient storage.

When transmitted in a DACK submessage, if TNITEL has any value except the null value, 'llllll', that means the the acknowledging station intends or wishes to send user data, and hence bidirectional transmission is implied. If sent by a radio unit, TNITEL < 'lllll' can be acted upon by the TSC to invite user data. For example, bidirectional data flow in a TRANS may occur in the following recurrent order:

F'w'd Chan	DACK+TNITEL+GO	Message	DACK+TNITEL+GO
Ret'n "	Message	DACK+TNITEL+GO	
etc.			

A radio unit which finds it necessary to stop data reception completely for some time may cease to be offered more data by the TSC. In that case, when it is ready the radio unit may request resumption of data flow by using a random access opportunity.

17.0.2.7 RESET

The RESET function is employed by a receiving or sending station or by the TSC to reset the data to a known state. The RESET operated by the end users is usually combined with synchronisation points so that after a RESET operation data communication can restart from a known synchronisation mark. The synchronisation marking techniques of the network service user are not specified in this standard. Generally this involves more than one link but of course comprises a single link if the radio unit and TSC happen to be the two end parties.

The RESET operation discards all that data transmitted before initiation of the RESET but not yet delivered to the network service user.

If the TSC receives the RESET message (which may be sent in a random access frame or in place of an acknowledgement or instead of invited data) it firstly acknowledges the message and also transmits RESET to the other correspondent at the earliest opportunity, e.g. before sending a 'GO' message or other which would permit the correspondent to send or repeat data. If necessary the TSC repeats the RESET until it is acknowledged by the radio unit. The TSC sends no more data to the originator of the RESET until this acknowledgement has been received.

A data receiving or sending radio unit which receives a RESET message firstly removes all data from its receiving and sending buffers and acknowledges the (received) RESET and then sends a RESET to (its) data terminal equipment (DTE) and waits for DTE acknowledgement before resuming any data sending or receiving.

17.0.2.8 Demarcation of a Tmessage

A "MORE" bit is found in each SITH, "MORE" is used to indicate the conclusion of each Tmessage. It is the duty of each node in the communication chain to interpret the "MORE" bit in this protocol or its equivalent in any other protocol and pass its meaning on to the dependant link in the appropriate format and position within the data stream.

17.0.2.9 Closing a TRANS and Moving to another channel

A TRANS may be closed either by TSC demand (which may or may not also demand an acknowledgement) or by radio unit request or by expiry of the radio unit inactivity timer TDX or TDN for an individual or group call respectively. When all TRANS of a radio unit have been closed it returns to the control channel.

If a TSC finds it desirable to move a radio unit to another data channel, e.g. because the data channel it is on has become overloaded, it may do so without breaking down a data call. To do this the TSC first demands closure of any calls concurrent with the one to be preserved. Then, at a time when neither radio unit nor TSC are attempting to send a message it sends the radio unit a GTT message including a new channel and a new TRANS. The radio unit moves to the new channel and notes that the new TRANS replaces the preserved one for the continued call.

The TSC may simultaneously move all the radio units to a new data channel by addressing them with the ALLI ident.

Page 17-10

•

17.1 Procedures for Setting Up Standard Data Calls

This section contains the procedures for setting up standard data call links on either a control channel or a data channel. The procedures cover the following aspects:

a) Link with calling party

- call request procedures for standard data calls
- instruction to send extended address information
- call cancellation while waiting for a call
- establishment of calling party data link.
- b) Link with called party
 - availability/rate check on called radio units
 - establishment of called party data link.

Standard data calls from radio units are requested using the Standard Data Communication Request Message RQD (see 5.7.1). For an emergency standard data call, bit E in the RQD is set to '1'.

The RQD message contains all the information necessary to request a common-prefix call, a system-wide call or a call to a prearranged PSTN or PDN destination.

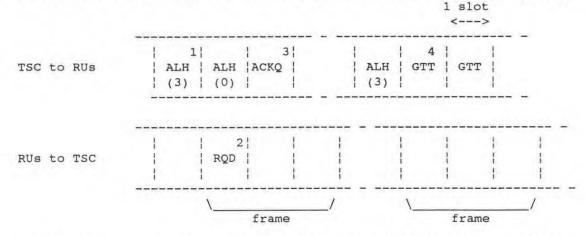

For an interprefix call, a general call to the PSTN or a call to any PABX extension, the call details cannot be accommodated in a single address codeword. For these calls, the RQD message requests entry into the extended addressing mode; the radio unit sets IDENT1 in the RQD to the appropriate gateway ident (viz. IPFIXI, DNI, PSTNGI or PABXI), and the TSC then demands the full called party information using the AHYC message.

Usually, if the TSC has a direct entry point to a data network then for a general call to a data network destination, the radio unit sets IDENT1 in the RQD message to DNI. After setting up the link, the radio unit is invited to supply the full destination address on the data channel using network layer procedures. Alternatively a radio unit may contact a distant data network entry point via the PSTN or a PABX, and when that contact has been established the full destination address is provided on the data channel as described above.

Note that extended addressing procedures are used for requesting a standard data call to any PABX extension (with either a long or short extension number). The unit sets IDENT1 in the RQD message to PABXI, and then sends the PABX address information in response to an AHYC message with IDENT1 set to PABXI and DESC set to '010'. The unit sets bit SP in the SAMIS message to indicate whether it is sending BCD digits or a 13-bit extension number (plus 2-bit exchange number). See 5.5.3.2.8 and 5.6.1.2.2.

Radio units requesting a 'general' PSTN call use the gateway ident, PSTNGI. In this case, units are requested to provide the full dialling information for the PSTN destination using extended addressing procedures. The FAD field in the RQD message performs the same function as FLAG1 in an RQC message.

The call set-up procedures are outlined in section 17.0.2, and typical message sequences for establishing standard data links are illustrated in the example below. The call shown is a common-prefix non-emergency call between two radio units, both of which are currently tuned to controlchannels. In this example, the calling unit is queued (to wait for a data channel or for the called party in an interactive call) otherwise the TSC could have sent the Go To Transaction message directly.

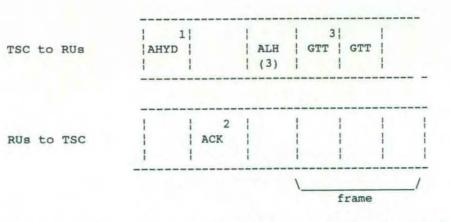

Example 1A A message sequence on a control channel for a calling radio unit requesting a common-prefix standard data call.

1.	ALH	General	Aloha	invitation	(three-slot	frame).	
	-	Contraction of				al and	

- RQD : Random access request for a Standard Data call.
- 3. ACKQ : The TSC acknowledges the RQD message, informing the calling unit that the call has been queued.
- 4. GTT : Go To Transaction message instructing the calling unit to switch to a designated data channel for the transaction. In this example, the GTT message is repeated, for added reliability.

(Note that the GTT message cannot mark an Aloha frame, but does not withdraw slots from an ongoing frame.)

Example 1B A message sequence on a control channel for a called radio unit in a common-prefix standard data call.

- AHYD : Availability/rate check message sent to called unit. Demands a response from the called unit.
- 2. ACK : Acknowledgement that the radio unit is available and indicates whether it can operate at the customised rate.
 - 3. GTT : Go To Transaction message instructing the called unit to switch to a designated data channel for the transaction. In this example, the GTT message is repeated, for added reliability.

As shown in the example, data links are established using the Go To Transaction message GTT. Note that the GTT message instructs only one radio unit or group. GTT messages are sent independently to establish links, for a particular call, between:

- a) calling radio unit and TSC,
- b) TSC and called radio unit (or group), as required. Note

that:

- these GTT messages may be sent on different sites;
- they may designate different data channels;
- the specified transmission rates may be different;
- there is no relationship between the transaction numbers (which will be different if both parties are directed to use the same data channel).

Page 17-13

Also, since all data is transferred via the TSC, it may not be necessary for the two parties to be on their data channels at the same time. Bit INTER in RQD indicates whether the calling party requires that the called party should be available to receive the data immediately (enabling a call where the parties appear to have interactive contact, achieved via the TSC's store-and-forward mechanism).

In the example, both radio units started the exchange tuned to control channels. More generally:

- a) The call request (and following message sequence) may be sent on either a control or data channel, as appropriate.
- b) The message sequence with the called party may take place on either a control or data channel, depending on where the called party is currently tuned.

The message sequences are similar whether they take place on a control or data channel. Where there are differences (for example, in the random access method) these are indicated in the procedures.

Note that high accuracy data transfer (HADT) may be invoked by setting the HADT bit of an RQD or AHYD message to '1'. When HADT is used in a call, it shall be applied to all links within the call which conform to this standard and, in an individual call, to both possible user data transmission directions. Parts of the call chain which do not conform to this standard are assumed here to be of adequate data transfer accuracy and are excluded from the rules laid down here. It is the user's responsibility to assure himself of the data transfer accuracy of these non-MPT 1327 parts of the chain.

17.1.1 TSC Procedures for Setting Up Standard Data Calls

This section describes facilities available for use by the TSC. However, note that the TSC is allowed a great deal of flexibility and it need not implement all these facilities.

Section 17.1.1.1 defines the basic procedures for setting up non-emergency standard data call links. Section 17.1.1.2 defines the procedures for emergency standard data calls.

17.1.1.1 TSC Procedures for Setting Up Non-Emergency Standard Data Call Links

17.1.1.1.1 Responses to a short addressing RQD(E=0) message

A radio unit requests a short addressing non-emergency standard data call by generating an RQD message (with E = 0 and IDENT1 set to a valid called party ident or short-form ident), on a control channel or data channel, complying with the appropriate random access protocol. On receiving a short addressing RQD(E=0) message, the TSC shall send one of the following responses (on the channel on which the RQD was received): (For acceptable delay, see 7.2.4 or 17.1.4.)

- a. ACKI(QUAL=1), ACKQ, ACKX or ACKV, with the same prefix and idents as the RQD.
- b. ACKT(QUAL=0), with PFIX/IDENT2 as the calling unit's individual address.
- c. A Go To Transaction message GTT for the calling unit see 17.1.1.1.7.

The response is thus a direct acknowledgement (as in a. and b.) or an indirect acknowledgement (as in c.). The acknowledgement messages may also be sent to the calling unit at appropriate times to indicate the progress of the call - see 17.1.1.1.4.

(Note that the above list of responses applies both to the first request received for a call and to any repeat requests that the radio unit may send if it fails to receive a response.)

17.1.1.1.2 Responses to an extended addressing RQD(E=0) message

A radio unit requests an extended addressing non-emergency standard data call by generating an RQD message (with E = 0 and IDENT1 = IPFIXI, PSTNGI or PABXI), on a control channel or data channel, complying with the appropriate random access protocol. On receiving an extended addressing RQD(E=0) message, the TSC shall send one of the following responses, with the same prefix and idents as the RQD:

- a. An acknowledgement ACKI(QUAL=1), ACKV(QUAL=0) or ACKX.
- b. AHYC (i.e. an instruction to send the full called address information).

For acceptable delay, see 7.2.4 or 17.2.1.1.4. For the usage of these messages, see 17.1.1.1.3 and 17.1.1.1.4.

17.1.1.1.3 Instruction to send extended address information

After receiving an extended addressing RQD message, the TSC may demand the full called address by sending the AHYC message, with:

- The same prefix and idents as the RQD.
- DESC set to indicate the appropriate gateway (see 5.5.3.2.8).

Page 17-15

- SLOTS set to correspond to the request as follows:

For an interprefix or PABX call, SLOTS = '01' or For a general PSTN call, SLOTS = '01' or '10'

(The FAD field in the RQD message indicates if the number of dialled digits exceeds 9).

•

The AHYC message instructs the calling radio unit to send the called party address information in the following SLOTS slot(s) (see 17.1.2.1.5). If the TSC does not successfully decode the address information, it may repeat the AHYC message or transmit ACKV(QUAL=0) to indicate failure of the call.

After decoding the full address information successfully, the TSC may send appropriate acknowledgements to the calling unit (see 17.1.1.1.4).

Note that AHYC bars random access only in the first following return slot. For SLOTS = '01', this is sufficient for the radio unit's response; however, for SLOTS = '10', the TSC shall take appropriate action to reserve the second return slot if it is within a random access frame (e.g. by sending the AHY message with both idents set to DUMMYI in the slot following the AHYC).

17.1.1.1.4 Acknowledgements sent to indicate progress of a call set-up attempt

The TSC may send acknowledgement messages at appropriate times to indicate to a calling radio unit the progress of its standard data call. For idents, see 5.5.2.1. (For extended addressing calls, only ACKI(QUAL=1), ACKV(QUAL=0) and ACKX are appropriate until the full address information has been obtained.) Note that the criteria for setting the maximum delay of repeats of acknowledgements ACKX, ACKV and ACKT should take account of time-out TDB (described in 17.1.2.1.4).

The TSC may send ACKI(QUAL=1) or ACKQ to indicate to a calling radio unit the progress of the signalling for its data call:

ACKI (QUAL=1)	-	Intermediate acknowledgement; more signalling to follow.
ACKQ (QUAL=0)	÷	All data channels are busy. Wait for further signalling.
ACKQ (QUAL=1)	-	Called party is engaged (and calling party requires interactive contact). Wait for further signalling.

It may send ACKX or ACKV to indicate to the calling unit that its data call request will not be complied with:

ACKX (QUAL=0) -

Invalid call e.g. TSC or called party does not support standard data at least from this caller, or the radio unit is blacklisted, or called address is unobtainable.

ACKX	(QUAL=1)	-	System overload, or for INTER='1' the called party is engaged or will not interact at this time and the TSC has not queued the call; request rejected.
ACKV	(QUAL=0)	-	Called unit not in radio contact or call set-up abandoned.
ACKV	(QUAL=1)	-	Call not queued because the called party is unable to receive a call with the required facilities, e.g. the called radio unit does not support HADT or interaction or cannot accept the requested PORT.

If the TSC has previously accepted a diversion request RQT requesting that this type of call be redirected to another party, then it shall send ACKT(QUAL=0) with PFIX/IDENT2 as the calling unit's individual address and:

a. IDENT1 as the diversion ident, or

b. IDENT1 as a gateway (viz. IPFIXI, PSTNGI, or PABXI); in this case, the diversion address follows in concatenated data codeword(s); see 5.5.2.1.

(On receiving ACKT, the radio unit will either return to the idle state or re-attempt access by calling the diversion address - see 17.1.2.1.4.)

17.1.1.1.5 Call cancellation by calling party

A calling radio unit may cancel a requested standard data call by generating an RQX message (see 5.5.3.1.3), complying with the appropriate random access protocol. On receiving an RQX message cancelling a standard data call, the TSC shall send a response: ACK(QUAL=1), with the same prefix and idents as the RQX.

17.1.1.1.6 Queue time-out

.

The TSC may order its queue of standard data calls (non-priority and priority, between any parties) in any way acceptable to the system operator.

The TSC may operate a time-out on the maximum time for which it queues a standard data call. See also 17.1.2.1.7.

The TSC may instruct a calling radio unit to restart its waiting timer, by sending the AHY message with bit POINT set to '1'. If a time TW, (control channel) or TDW (data channel), minus the tolerance on the radio unit's timer, elapses since the last call set-up message it received for a standard data call (from the calling unit), the TSC shall not send on this channel any further call set-up messages to the calling unit for this call. (It may send AHYX to inform a called radio unit that the call will not take place - see 17.1.1.1.9.)

17.1.1.1.7 Establishing a data link with a calling party

A calling radio unit's request message indicates whether it is able to operate at the customised transmission rate. If the customised rate is not acceptable to both the calling unit and the TSC, then the TSC shall default to the standard rate. The TSC shall not specify a rate which is different from one in current use on the allocated channel.

For an interactive call, the TSC may establish the data link with the calling party only when it has ascertained that the called party or network gateway can accept the call (see 17.1.1.1.8 for checking call acceptance by a radio unit).

The TSC sends the Go To Transaction message GTT (on the channel on which the RQD was received). The TSC may repeat the GTT command.

The GTT message specifies:

i) The data channel number for the transaction.

For a call set-up GTT sent on a data channel, this shall be the number of that same data channel. (Whereas the TSC procedures for in-call transfer are specified in section 17.2.5.1.)

ii) The transmission rate to be used.

For a call set-up GTT sent on data channel, this shall specify the rate currently used on that channel.

iii) A transaction number TRANS for use on that data channel.

For GTT sent on a control channel, the TSC may set TRANS to a dummy value '0000000000'. In this case, it shall send further GTT message(s) on the specified data channel to designate a valid transaction number. The calling party will wait for a time TDG for a data channel GTT - see 17.1.2.3.4c. Accordingly, it is recommended that the TSC sends any data channel GTTs for the call within a period TDG (minus the tolerance on the radio unit's timer) following the first control channel GTT.

When establishing a data link with a calling radio unit, the TSC shall set bit O/R in the GTT message to '1'.

17.1.1.1.8 Availability/rate check on individually called radio unit

A TSC which wishes to set up a standard data call to a radio unit shall, before establishing the called party link, check whether the called unit can accept the call.

The TSC checks availability of a called radio unit for standard data, and asks whether the unit can accept the customised transmission rate, by sending the AHYD message. This message may be sent on either a control channel or data channel as appropriate. In the AHYD message:

- INTER indicates whether interactive contact is required,

- bit E indicates whether the call is urgent,

Page 17-18 Petitioner Cisco Systems - Exhibit 1005 - Page 236 •

- PORT is the called port,
- PFIX/IDENT1 is the called unit's individual address,
 - IDENT2 is the calling ident or short-form ident appropriate to the calling terminal or gateway, and
 - HADT is set as appropriate.

If IDENT2 = IPFIXI, the TSC may append a data codeword containing the calling unit's address; if so, it shall set bit AD in the AHYD to '1'.

The AHYD message demands a response from the called unit (see 17.1.2.3.1 or 17.1.2.4.3). If the response is ACKX or ACKV(QUAL=1), the TSC may send appropriate acknowledgement(s) to a calling radio unit (if the calling unit is still in the state of waiting for call set-up signalling for this call). If the TSC does not successfully decode a response, or if the response is ACKB(QUAL=1), it may repeat the AHYD message. If the called unit cannot be contacted, the TSC may indicate the failure to a waiting calling unit by sending ACKV(QUAL=0).

Acknowledgement ACK(QUAL=0) contains a bit, MODEM, which indicates whether the customised transmission rate is acceptable to the unit (see 5.5.2.2).

17.1.1.1.9 Informing called party of call cancellation

If an individual call is cancelled then the TSC may inform a called radio unit by sending the AHYX message with PFIX/IDENT1 as the called unit's address and IDENT2 as the calling ident or gateway. The TSC may repeat the AHYX message if it is not acknowledged by an ACK(QUAL=1) message from the called unit (see 17.1.2.3.2 or 17.1.2.4.4).

17.1.1.1.10 Sending AHYD to a group or ALLI

After receiving a request for a standard data call to a group (or to all units in the system), the TSC may send the AHYD message to announce:

- whether it is an emergency call (bit E),
- the called PORT,
- the calling or short-form ident or gateway (IDENT2), and
- whether HADT will be used.

For a request for a group call with INTER set to '1', or if PORT information is needed by called radio units, use of this message is recommended.

The AHYD message may be sent on either a control channel or data channel as appropriate. It may be repeated.

For an interprefix call, the TSC may append a data codeword containing the calling unit's address; if so, it shall set bit AD in the AHYD to '1'.

Page 17-19

On receipt of the AHYD message, group members do not respond but may wait for a time TA (on a control channel) or TDA (on a data channel) for the corresponding GTT message (see 17.1.2.3.3 or 17.1.2.4.5). Accordingly, it is recommended that, on this channel:

- a) The TSC sends any GTT messages for the call within a period TA/TDA (less the tolerance on the radio unit's timer) following the first transmitted AHYD message.
- b) The TSC does not send any GTT messages for a different call to the same group address within a period TA/TDA (plus tolerance) following the last AHYD for this call. (Note that some radio units may miss the GTT messages for this call.)

17.1.1.1.11 Establishing data link with called party

The TSC establishes a data call link with a called radio unit or group by sending the Go To Transaction message GTT with bit O/R set to '0'. It may repeat the GTT command.

The GTT message specifies:

i) The data channel number for the transaction.

For a call set-up GTT sent on a data channel, this shall be the number of that same data channel.

ii) The transmission rate to be used.

For a call set-up GTT sent on a data channel, this shall specify the rate currently used on that channel.

For GTT sent on a control channel to a group, the method for the TSC to choose an appropriate transmission rate is system-dependent.

iii) A transaction number TRANS for use on the data channel.

For GTT sent on a control channel, the TSC may set TRANS to a dummy value '0000000000'. In this case, it shall send further GTT message(s) on the specified data channel to designate a valid transaction number. Called party(ies) will wait for a time TDG for a data channel GTT (or for an AHYD for another call) - see 17.1.2.3.4c. Accordingly, it is recommended that the TSC sends any data channel GTTs for the call within a period TDG (minus tolerance) following the first control channel GTT; and does not send any data channel GTT messages for a different call to the same group address within a period TDG (plus tolerance) following the last control channel GTT. •

17.1.1.2 TSC Procedures for Setting Up Emergency Standard DataCall Links

17.1.1.2.1 Response to an emergency standard data request

A radio unit requests an emergency standard data call by generating an RQD(E=1) message, on a control channel or data channel, complying with the appropriate normal random access protocol (unless it has other arrangements with the system). On receiving an RQD(E=1) message, the TSC shall send a response: ACKE(QUAL=0) with the same prefix and idents as the RQD. For maximum permissible delay, see 7.2.4 or 17.2.1.1.4.

ACKE(QUAL=0) is sent only as a response to an RQE or RQD(E=1) message; it is an intermediate acknowledgement, indicating that further signalling will follow.

17.1.1.2.2 Signalling for previous call

After receiving an RQD(E=1) message, the TSC shall not send any further call set-up messages to the calling unit for any previous call requested by that unit (though, for a traffic channel or standard data call, it may send AHYX to inform a called radio unit that the call will not take place).

17.1.1.2.3 Obtaining extended address information

After receiving and responding to an extended addressing RQD(E=1) message, the TSC may demand the full called address information from the calling radio unit by sending the AHYC message (as in 17.1.1.1.3).

17.1.1.2.4 Acknowledgements sent to indicate progress of call

After receiving and responding to an RQD(E=1) message, the TSC may send acknowledgements ACKI(QUAL=1), ACKQ, ACKX, ACKV or ACKT(QUAL=0) to the waiting calling unit to indicate the progress of the call (as in 17.1.1.1.4).

17.1.1.2.5 Call cancellation by calling party

A calling radio unit may send an RQX message to cancel its emergency standard data call. The TSC procedures are as defined in 17.1.1.1.5.

17.1.1.2.6 TSC time-out

The TSC may instruct a calling radio unit to restart its waiting timer by sending the AHY message with bit POINT set to 'l' (and bit E set to 'l'). If a time TW/TDW, minus the tolerance on the radio unit's timer, elapses since the last call set-up message it received for an emergency data call (from the calling unit), the TSC shall not send on this channel any further call set-up messages to the calling unit for this call. (It may send AHYX to inform a called radio unit that the call will not take place.) See also 17.1.2.2.6.

17.1.1.2.7 Availability/rate check on individually called radio unit

This check shall be made as specified in 17.1.1.1.8.

17.1.1.2.8 Establishing data links

If all standard data channels (or transaction numbers) are fully occupied then the TSC may terminate another data call prematurely in order to establish.an emergency call.

The procedures for establishing data links are as detailed in sections 17.1.1.1.7 and 17.1.1.11.

17.1.2 Radio Unit Procedures for Establishing Standard Data Calls

Section 17.1.2.1 defines the procedures for requesting non-emergency standard data calls and section 17.1.2.2 defines the procedures for emergency standard data calls. Sections 17.1.2.3 and 17.1.2.4 define related procedures for all radio units on control and data channels.

17.1.2.1 Procedures for Radio Units Requesting Standard Data Calls

A radio unit shall use short addressing for calls to other radio units with the same prefix, or, by prearrangement with the system, to a limited number of PSTN and PDN destinations. A radio unit also shall use short addressing for general calls via any PDN gateway offered by the TSC, in which case the full addressing is then accomplished on the allotted data channel in the format appropriate to that gateway.

A radio unit shall make only one call set-up attempt at a time (except in emergency); while attempting access or waiting for further call set-up signalling for its standard data call, Unless the user first cancels the original call the unit shall not request another non-emergency call of any type.

17.1.2.1.1 Request for a non-emergency standard data call

A radio unit requests a non-emergency standard data call by sending an RQD(E=0) message, on a control channel or data channel, complying with the appropriate random access protocol (see 7.3 or 17.2.1.2). The fields in the RQD message shall be set appropriately (see 5.7.1); however, note particularly that:

a. An extended addressing request is indicated by setting IDENT1 in the RQD message to the appropriate gateway viz. IPFIXI, PSTNGI, and PABXI.

Note that:

extended addressing procedures are used for a call to a PABX extension. 'Short' PABX procedures are not supported for standard data calls, and

Page 17-22
