501 PHENYL CARBAMATES

The present invention relates to novel phenyl carbamates which are useful as pharmaceutical compositions. The invention further relates to pharmaceutical compositions having anticholinesterase activity.

Case 118-6848

Acetylcholine is a major neurotransmitter which is found in all parts of the body. Any reduction in its activity, either as a result of neuronal damage, degeneration etc. or as induced by drugs or toxins, causes marked changes in the function of the organism. Acetylcholine itself has an extremely short half life, since it is rapidly hydrolysed at its site of action and in plasma by specific cholinesterase enzymes. Drugs that inhibit acetylcholine, thereby enhancing cholinergic transmission. Three such agents are used clinically, i.e., physostigmine, a naturally occurring alkaloid, and two synthetic analogues, neostigmine and pyridostigmine. The latter two agents are strongly ionised at physiological pH and therefore are only poorly absorbed from the gastro-intestinal tract, and do not penetrate the central nervous system to any significant extent. Physostigmine is absorbed after

- 5 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 5 of 372 oral administration and readily enters the brain. As a therapeutic agent it has several disadvantages. It is chemically unstable and must be prepared in solution with an antioxidant, and protected from light. It has a relatively short half-life
5 (20-40 mins) thereby necessitating frequent administration. The latter is of particular importance when the drug is to be administered chronically. It has a low therapeutic ratio, a value of 3-5 being reported in the majority of studies in laboratory animals, and a small therapeutic window, i.e. small range of dose in which it can be given without the accompaniment of side effects. Although physostigmine is absorbed from the gastro-intestinal tract, this is reported to be irregular and unpredictable, and therefore it is usually preferred to administer the drug pareenterally. This is a serious drawback if it is to be used chroni-15 cally on an outpatient basis.

14

4

118-6848

There are a number of clinical and pathological conditions which are associated with cholinergic under-activity which can be improved by the administration of an anticholinesterase agent. These include reduction in cholinergic transmission induced by a 20 variety of exogenous substances acting in the peripheral, or central nervous system. Peripherally acting agents are gallamine, d-tubocurarine and pancuronium, which are used as muscle relaxants. Their action can readily be overcome by an anticholinesterase drug. Drugs which interfere with central cholinergic. 25 transmission are numeroùs, anticholinergic, atropine-like drugs including antiparkinson drugs, tricyclic antidepressants, neuroleptics, opiate analgesics, benzodiazepines and some types of general anaesthetics. So far the only agent that has proved to be of any value in reversing the effects of the latter group of drugs is physostigmine. In all reported cases of drug overdose or 30 lack of recovery when the agent was used peri-operatively, physo-

- 6 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 6 of 372

118-6848

stigmine is usually administered parenterally, and administration is repeated every 20-30 minutes as required.

≟ 3

Chronic treatment with neuroleptics often results in tardive dyskinesias. The widespread use of agents having anticholinesterase activity for the treatment of schizophrenia makes this side effect an ever increasing possibility. Physostigmine injected intravenously produces a significant but short lived improvement in a proportion of patients.

A number of pathological and degenerative diseases has also been shown to be associated with a reduction or loss of cholinergic transmission. This includes myasthenia gravis and Eaton Lambert syndrome in which there is an interference with neuromuscular transmission.

10

15

20

25

3

A selective loss of choline acetyltransferase (the enzyme that synthesises acetylcholine) has been found in specific brain regions of patients with pre-senile dementia of the Alzheimer type. These include the frontal and temporal cortex, hippocampus, amygdala, caudate nucleus, substantia innominata. Degeneration of cholinergic neurons in some of these areas appears to be assoclated with the aphasia, apraxia, agnosia and loss of short term memory that occurs in Alzheimer's disease. A similar type of dementia is also found in patients with Down's syndrome that survive to the age of 40 years and show similar cholinergic deficits. There is also a loss of cholinergic transmission in the caudate nucleus and putamen of patients with Huntingdon's chorea: Physostigmine injections have also been of some benefit in this condition. Treatment with a centrally acting anticholinesterase should also prove to be beneficial in Friedrich's ataxia.

> NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 7 of 372

There are two major classes of potent inhibitors of the enzyme Cholinesterase. The first group was modelled primarily on the natural alkaloids physostigmine (a carbamate) and an inhibitor of cholinesterase, and d-tubocurarine, an antagonist of acetylcholine. The second group consists of various organophosphorus compounds, such as disopropylfluorophosphonate, paraxon etc. The vast majority of the compounds of both these series were designed primarily as insecticides. In the first group of carbamate derivatives, almost all of the potent insecticides are monomethyl carbamates lacking a charged nitrogen function. This enables the molecule to penetrate rapidly the insect cuticle and fatty nerve sheath. The dimethyl derivatives are slightly less potent but are particularly toxic to houseflies and aphids. The monomethyl derivatives tend to be unstable in solution and hydrolyse readily at physiological pH. This greatly limits their biological action in mammals and makes them less suitable as pharmaceutical or therapeutic agents.

10

15

20

25

1

The organo-phosphorus group of compounds causes irreversible inhibition of cholinesterase and other serine containing enzymes, which, together with their high relative toxicity, virtually precludes their use in pharmaceutical preparations. The only exception is echothiopate, a quaternary ammonium organophosphorus compound, employed in eye drops for the treatment of glaucoma.

The synthetic anticholinesterase agents currently employed as pharmaceuticals all contain a charged nitrogen function and can be broadly classified into 3 groups.

Reversible inhibitors which contain a charged nitrogen function attached to an aromatic ring, e.g. edrophonium.

8.

۸

20

5

3) Bisquaternary structures, e.g. Demacarium, Ambenonium. These agents tend to be more selective inhibitors of acetylcholinesterase than butyrylcholinesterase, compared with the monoquaternary molecules.

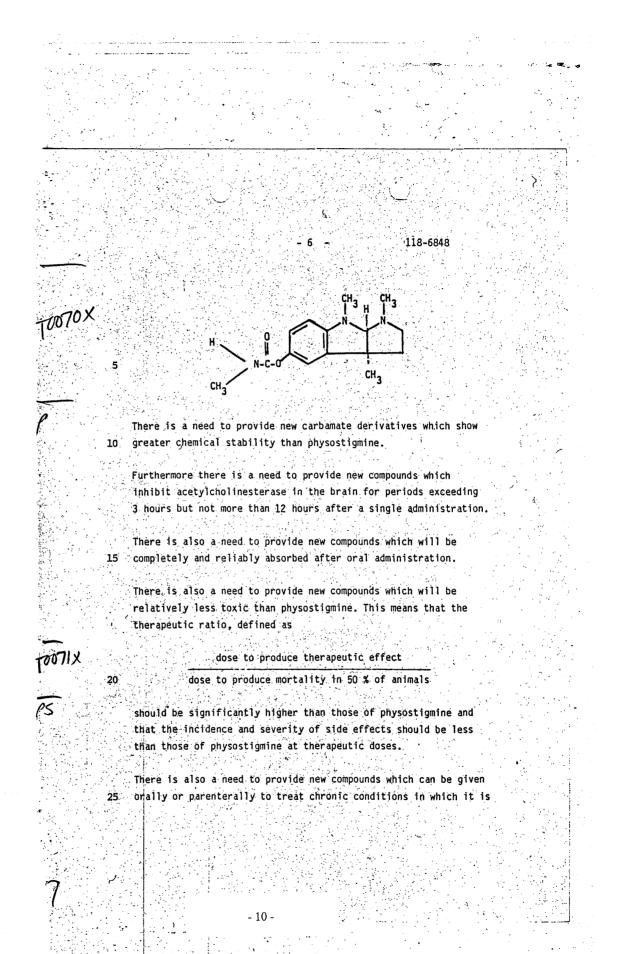

The pharmaceutical application of the quaternary anticholinesterase agents is limited because of their poor penetration through cell membranes. They are therefore used for actions outside the central nervous system, and are usually given parenterally, since they are not reliably absorbed from the gastrointestinal tract. Edrophonium, neostigmine and pyridostigmine and the bisquaternary analogues are used in anaesthetic practice for the reversal of the action of muscle relaxants. They are also used for the treatment of myasthenia gravis, and paralytic ileus.

Physostigmine is the only potent anti-cholinesterase agent which has been used clinically to treat conditions in which an elevation of brain acetylcholine activity is desired. These include, Alzheimer's disease, tardive dyskinesia, Down's syndrome and Huntingdon's chorea. Physostigmine is also used to reverse the effects of overdose of anticholinergic agents, anti-Parkinson drugs, benzodiazepines and opiate analgesics.

Physostigmine is a natural alkaloid extracted from calabar beans and the seeds of the vine Physostigma venenosum and has the formula

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 9 of 372

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 10 of 372

desired to raise cholinergic activity in the central nervous system. These include, Alzheimer's disease, Down's syndrome, Huntingdon's chorea, Friedrich's ataxia.

3

5

10

15

20

25

7

There is also a need to provide compounds that can be given parenterally at the end of operations, and anaesthetic procedures, to restore wakefulness, respiration and cardiovascular parameters to normal, after the use of anticholinergic, opiates, benzodiazepines, neuroleptics and general anaesthetics, thereby shortening the stay of patients in the recovery room.

There is also a need to provide compounds that can be given together with narcotic analgesics to patients suffering from severe pain, e.g. traumatic, post-operative, or due to carcinomatosis etc. in order to reduce the side effects (respiratory depression, somnolence, constipation and urinary retention) commonly encountered with narcotics, without impairing their analgesic potency.

There is also a need to provide compounds that can be given to _patients receiving antipsychotic drugs, which have developed tardive dyskinesias, in order to diminish or abolish the latter syndrome, without exascerbating the psychosis.

According to the present invention it has now been surprisingly found that certain novel and known phenyl carbamates also inhibit acetylcholinesterase in the mammalian brain after administration to provide systemic activity, e.g. oral or parenteral administration.

Thus according to the present invention there is now provided a pharmaceutical composition adapted to produce anticholinesterase

- 11 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 11 of 372

- 8 - 118-6848

activity in the central nervous system of mammals comprising a compound of the general formula I

wherein

10

15

20

7090X

R1 is hydrogen, lower alkyl, cyclohexyl, allyl or benzyl,

R2 is hydrogen, methyl, ethyl or propyl, or

 R_1 and R_2 together with the nitrogen to which they are attached form a morpholino or piperidino radical,

R3 is hydrogen or lower alkyl,

R4 and R5 are the same or different and each is a lower alkyl, and the dialkylaminoalkyl group is in the meta, ortho or para position,

or a pharmacologically acceptable salt thereof and a physiologically acceptable carrier therefor. Hereinafter these compounds are called compounds of the invention.

Especially preferred are pharmaceutical compositions having anticholinesterase activity in the central nervous system of mammals, 25 - wherein the dialkylaminoalkyl group is in the meta position, and R4 and R5 are both methyl.

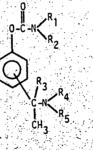

- 12 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 12 of 372

Certain compounds falling within the above formula have previously been described i.e. the m disubstituted compound in which R_1 and $R_3 = H$ and R_2 , R_4 and $R_5 =$ methyl which is known as Miotine(R) was claimed to be an insecticide and a myopic agent for use in eye drops. The m disubstituted compound in which R_1 and R_2 are methyl, R_3 is H and R_4 and R_5 are methyl has been described as an insecticide. The p and o disubstituted derivatives in which R_1 and $R_3 = H$ and R_2 , R_4 and $R_5 =$ CH₃ have been shown to inhibit a preparation of liver cholinesterase. The m disubstituted derivative in which $R_1 = H$ and R_2 , R_3 , R_4 and $R_5 =$ CH₃ has also been shown to inhibit liver cholinesterase.

q

The remaining compounds are believed to be novel and thus the present invention also provides novel phenyl carbamate derivatives of the general formula I'

and pharmacologically acceptable saits thereof, provided that for compounds wherein R4 and R5 are both methyl and having the dialkylamino group in the meta position, when R2 is methyl and R3 is hydrogen, R1 is neither hydrogen nor methyl, and when R2 and R3 are methyl, R1 is not hydrogen, and for compounds wherein R4 and R5 are both methyl and having the dialkylamino group in the ortho or para position when R1 and R3 are both hydrogen R2 is not methyl.

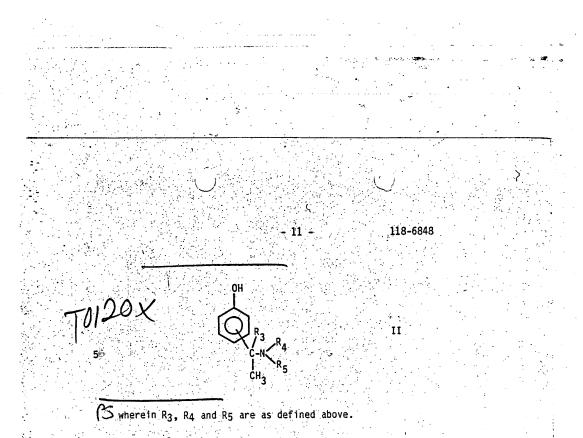

Preferred compounds of the above formula are N-ethyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-propyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N-allyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-ethyl, N-methyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N,N-diethyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N-butyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-methyl, N-propyl-3[1-(dimethylamino)ethyl]phenyl carbamate and N-ethyl, -N-methyl-3[1-(dimethylamino)isopropyl]phenyl carbamate.

As indicated, the invention also includes the pharmacologically acceptable salts of these compounds such as the acetate, salicylate, fumarate, phosphate, sulphate, maleate, succinate, citrate, tartrate, propionate and butyrate salts thereof.

The compounds of formula I can be prepared by amidating a compound of formula II

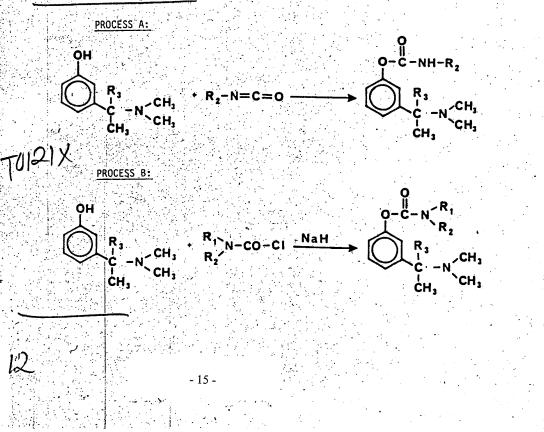

- 14

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 14 of 372

The process can be effected in conventional manner, e.g. by reacting the compound of formula II with an appropriate isocyanate if a compound wherein R_1 is hydrogen is desired, or with an appropriate carbamoyl halogenide, e.g. as described below in processes A and B.

10

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 15 of 372

12 - 118-6848

PROCESS A:

A stirred suspension of α -m-Hydroxyphenylethyldimethylamine or α -m-hydroxyphenylisopropyldimethylamine in benzene (0.2 -0.3 g/ml) is treated with 2.5 - 3 fold molar excess of the isocyanate. After stirring for 15 - 24 hours at ambient temperature the reaction mixture is connected to a rotovaporator (20 mm Hg). The residue obtained is dissolved in dry ether (25 ml) and the solution, which is ice cooled, is saturated with dry HCl (g). The formed precipitate (the anticipated carbamate) is filtered off, washed with dry ether (25 ml) and dried to constant weight in a dessicator over KOH pellets under high vacuum (0.1 mm Hg).

PROCESS B:

15

20

25

14

33

A solution of α -m-hydroxyphenylethyldimethylamine or α -m-hydroxyphenylisopropyldimethylamine in dry acetonitrile (0.1 - 0.5 M) is reacted with 50 - 70 % molar excess of the corresponding carbamoyl chloride in the presence of 200 % molar excess of NaH dispersion (50 - 80 % in mineral oil). The reaction mixture is left to stir at ambient temperature for 15 - 24 hours. Removal of the acetonitrile under reduced pressure (20 mm Hg) is followed by the addition of water (10 - 25 ml). The pH of the aqueous solution is adjusted to pH = 11 by the addition of the appropriate amount of NaOH 0.1 N followed by extraction with ether (3 x 25 ml). The combined organic phases are washed with brine (25 ml) dried over MgSO4. anhydride which is then filtered off. The ice cooled etheral filtrate is saturated with a stream of HCl (g) resulting in the formation of a heavy precipitate (the anticipated carbamate) which is collected by filtration, washed with dry ether (20 ml) and dried to constant weight in a desiccator under high vacuum (0.1 mm Hg) over KOH pellets.

- 16 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 16 of 372

The compounds of the invention e.g. in free form or salt form can be utilized by formulating one or more of them in compositions such as tablets, capsules or elixirs for oral administration or in sterile solutions or suspensions for parenteral administration. A compound or mixture of compounds of formula (I) or physiologically acceptable salt(s) thereof is compounded with a physiologically acceptable vehicle, carrier, excipient, binder, preservative, stabilizer, flavor, etc., in a unit dosage form as called for by accepted pharmaceutical practice. The amount of active substance in these compositions or preparations is such that a suitable dosage is obtained.

10

15

20

30

13

Illustrative of the adjuvants which may be incorporated in tablets, capsules and the like are the following: a binder such as gum tragacanth, acacia, corn starch or gelatin; an excipient such as dicalcium phosphate; a disintegrating agent such as corn starch, potato starch, alginic acid and the like; a lubricant such as mangnesium stearate; a sweetening agent such as sucrose, lactose or saccarin; a flavoring agent such as peppermint, oil of wintergreen or cherry. When the dosage unit form is a capsule, it may contain in addition to materials of the above type a liquid carrier such as a fatty oil. Various other mterials may be present as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets may be coated with shellac, sugar or both. A syrup or elixir may contain the active 25 compound, sucrose as a sweetening agent, methyl and propyl parabens as preservatives, a dye and a flavoring such as cherry or orange flavour.

Sterile compositions for injection can be formulated according to conventional pharmaceutical practice by dissolving or suspending the active substance in a vehicle such as water for injection.

- 17 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 17 of 372

Buffers, preservatives, antioxidants and the like can be incorporated as required.

- 14

Preferred antioxidants for use with the compounds of the present invention include sodium metabisulphite, and ascorbic acid.

5 While the invention will now be described in connection with certain preferred embodiments in the following examples, it will be understood that it is not intended to limit the invention to these particular embodiments. On the contrary, it is intended to cover all alternatives, modifications and equivalents as may be included within the scope of the invention as defined by the appended claims. Thus, the following examples which include preferred embodiments will serve to illustrate the practice of this invention, it being understood that the particulars described are by way of example and for purposes of illustrative discussion of preferred embodiments of the present invention only and are presented in the cause of providing what is believed to be the most useful and readily understood description of procedures as well as of the principles and conceptual aspects of the invention.

Tests for anticholinesterase activity

A solubilized preparation of acetylcholinesterase was prepared from mouse whole brain (minus cerebellum). The brain was homogenized with (100 mg/ml) phosphate buffer; pH 8.0, centrifuged, the supernatant discarded, and the pellet mixed with a similar volume as above of buffer pH 8.0 plus 1 % Triton; mixed, centrifuged and the supernatant which contained most of the solubilized enzyme, was used for the subsequent determinations of anticholinesterase activity.

- 20 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 20 of 372

The activity of the enzyme (rate of hydrolysis of substrate, acetylthiocholine) was measured using at least 4 different concentrations of substrate, and at least 3 different concentrations of each inhibitor. The enzyme was incubated with inhibitor for periods ranging for 2 - 180 mins. at 37 °C, substrate was then added, and its rate of hydrolysis measured by the spectrophotometric method of Ellman et al. (1961).

The molar concentration of each agent that inhibited the activity of the enzyme by 50 % (IC₅₀) at the peak time of activity (15 -60 min) was calculated from this data and recorded in Table 1 hereinafter. The compounds in general produce a significant inhibition from about 10^{-5} to about 10^{-8} molar. IN VIVO EXPERIMENTS:

a) Assessment of acetylcholinesterase inhibition

#14

IΨ

UL

10

15

20

25

The effect of each compound on brain acetylcholinesterase in vivo was measured, after subcutaneous or oral administration to mice. Animals were sacrificed, at different times ranging from 0.25 - 8 hours after drug administration. The brain was rapidly removed, and the enzyme acetylcholinesterase extracted and solubilized with 0.1 % Triton, and its ability to hydrolyse acetylthiocholine assessed as described above (in vitro experiments), in comparison with the enzyme removed from mice injected with normal saline. The compounds have in general a potency of from about 2% to about 90% that of physostigmine. Assessment of acute toxicity

Mice were given one of at least three different doses of each compound, orally or subcutaneously, a minimum of 10 mice allotted to each dose. The number of animals which died at

- 21 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 21 of 372

each dose within 3 hours was determined. From these data, the LD_{50} (dose in mg/kg which was lethal to 50 % of the mice) was computed.

This experiment was repeated after the animals had been pretreated with atropine sulphate, which blocks both peripheral and central muscarinic receptors. The data from these experiments enabled the assessment of the relative degrees of toxicity of the carbamates which result from excessive activation of muscarinic receptors, and from respiratory muscle paralysis, which is insensitive to this blocking agent.

The incidence and degree of side effects was noted for each dose of drug, starting with the lowest that caused any significant (> 20 %) inhibition of whole brain acetylcholinesterase.

Antagonism of the somnolent and respiratory depressant effects of opiates

Different doses of the carbamate compounds were injected intravenously with morphine in rabbits. Respiration rate, arterial blood gas tensions and pH were monitored continuously before and after drug administration for 4 -5 hours. In another series of experiments the effect of the anticholinesterase drugs was assessed on the analgesic effect of opiates in rabbits after application of a nociceptive stimulus, i.e. electrical stimulation of the sciatic nerve.

All specific examples of formula I' mentioned hereinbefore, e.g. on specification page 10, and after especially Tables 1 to 3, are prepared in analagous manner to Example 1 when R_1 and R_2 are each other than hydrogen and Example 2 when one of R_1 and R_2 are hydrogen. They are thus obtained as hydrochloride salts (except where otherwise specified). The specific compounds have metal substitutions.

The data in Tables 1 and 2 demonstrate that somewhat larger quantities are required of all the drugs of the RA series than of physostigmine to inhibit the enzyme acetylcholinesterase. However, a comparison of the data in Table I with that in 5 Table 2, shows that compounds RA5, RA6, RA15, RA14, RA10, RA7 and RA8 are all relatively more active <u>in vivo</u> compared to physostigmine than one would expect from the <u>in vitro</u> data. This greater <u>in vivo</u> potency is particularly marked when the drugs are administered orally. This relatively greater <u>in vivo</u> activity may 10 be due to:

22

a) greater chemical stability

0

15

b) a slower metabolic degradation or/and excretion

c) a higher lipid solubility, enabling a greater proportion of the drug to gain access to the enzyme in the central nervous system

d) more efficient absorption from gastro-intestinal tract.

For the purposes of their therapeutic application it is of little importance if one needs to give the drug (to human subjects) at a dose of 1 - 2 mg (physostigmine) or 2 - 50 mg that may be 20 required of the compounds of the RA series. What is important is the safety of the drugs and the presence and severity of side effects that may occur at therapeutic doses. A commonly-used measure of drug safety is the therapeutic index - or LD50/ED50

Dose to kill 50 % of animals

Dose to cause the desired therapeutic effect

- 26 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 26 of 372

It is assumed that the therapeutic effect of these anticholinesterase agents results from an elevation of brain cholinergic activity. This in turn, should be related to the degree of Inhibition of acetylcholinesterase. For the purpose of the compu-5 tation of the denominator of the therapeutic ratio, there is used the dose of drug that inhibits the activity of acetylcholinesterase by 50 %. This is based on the observation by Thal et al. (Ann. Neurology 13: 491, 1983) that the maximum improvement in . short term memory obtained in a series of patients with 'Alzheimer's disease was achieved with a dose of physostigmine which blocked the acetylcholinesterase in the cerebro-spinal fluid by 50 %. The numerator is the dose found to kill 50 % of the animals within 4 hours of a subcutaneous injection.

3

10

20.

25

23

The therapeutic ratios of compounds RA4, 5, 6, 7, 8, 10, 14 and 15 15 are all significantly higher than of physostigmine (see Table 3). This indicates that all these compounds have a wider margin of safety than that of physostigmine. Moreover, these RA compounds do not produce any significant undesirable side effects such as defaecation, lachrymation, fasciculations or tremor at the doses which inhibit the brain enzyme by 50 %, while the former 3 side effects are clearly evident when physostigmine is given at the appropriate dose (ED50).

The data in Table 3 show that atropine can afford considerably greater protection against the lethality of the derivatives RA4. 5, 7, 10, 13 and 14. This is particularly important in the treatment of drug overdose since the respiratory muscle paralysis which is not affected by atropine and which is the cause of death induced by excess drug administration in the presence of atropine cannot be satisfactorily reversed by specific antidotes.

- 27 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 27 of 372

ĉ

The duration of significant brain enzyme inhibition (> 30 %) induced by physostigmine (ED50 dose) is less than 2 hours. Compounds RA4, 5, 6, 7, 8, 12, 14, 15 all act for more than 3 hours at their respective ED50 doses and RA6 and RA7 still causes significant inhibition (36 %) after 7 hours. Since none of these drugs caused noticeable side effects at the ED50 doses, an even longer duration of action may be achieved by giving between 50 and 100 % larger doses. The longer duration of action is a distinct advantage, particularly if the drugs are to be administered chronically to subjects suffering from neurological and behavioural conditions associated with a deficit in cholinergic transmission in the central nervous system, e.g. Alzheimer's disease, tardive dyskinesias, Huntingdon's chorea, Down's syndrome and Friedrich's ataxia.

24

22

333

H

14

10

15

20

25

The better the absorption of the drug after oral administration the more closely the LD50 given by this route resembles that after subcutaneous injection. Table 3 shows that RA6, 13, 7 and 4 are more efficiently absorbed from the gastro-intestinal tract than is physostigmine. The ED50 of RAg after oral administration is the same as that after S.C. injection, indicating a much better oral bioavailability than that of physostigmine. The higher oral bioavailability of these compounds may be a considerable advantage for their clinical use.

RA10, RA6, RA14 and RA15 produce significant antagonism of the respiratory depressant effects of morphine in rabbits for periods lasting between 3 - 5 hours depending on the drug and the dose administered. The analgesic activity of morphine is not reduced by the RA compounds. Muscle fasciculations are not evident at the doses of drugs administered. Physostigmine (0.1 - 0.2 mg/kg) 30 antagonizes the respiratory depressant effect of morphine for

28 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 28 of 372

30,-60 mins only and fasciculations are marked at the higher dose.

25

These findings show that the RA compounds may be given together with morphine to obtain adequate analgesia without significant degrees of respiratory depression.

The most preferred compounds of the RA series are RA4, RA5, RA6, RA15, RA14, RA7 and RA8, all of which produce inhibition of brain acetylcholinesterase after parenteral administration of significantly longer duration than that induced by physostigmine or miotine. These compounds also have a greater safety margin (therapeutic ratio) than physostigmine. RA4, 6, 7 and 8 also show better bioavailability after oral administration than physostigmine. In addition, the acute toxicity (lethality) induced by RA7 can be decreased more than 10-fold and that of RA14 more than 8-fold by the antidote atropine, compared to only a 3-fold decrease for physostigmine and miotine.

10

20

25

ŀ

(3)

26

The compounds of the invention are therefore useful for the treatment of senile dementia, Alzheimer's disease, Huntingdon's chorea, tardive dyskinesias, hyperkinesia, mania, acute confusion disorders, Down's syndrome and Friedrich's ataxia.

For these indications, the exact dosage will of course vary depending upon the compound employed, mode of administration and treatment desired. The compounds may be administered by any conventional route, non-oral or preferably orally.

In general, satisfactory results are obtained when administered at a daily dosage of from about 0.05 to 10 mg/kg animal body weight. For the larger mammals, an indicated total daily dosage

- 29

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 29 of 372

is in the range from about 0.5 to about 25 mg of the compound, conveniently administered in divided doses 2 to 4 times a day in unit dosage form containing for example from about 0.1 to about 12 mg of the compound or in sustained release form.

26 (-

The compounds may be administered in similar manner to known standards for use in these utilities. The suitable daily dosage for a particular compound will depend on a number of factors such as its relative potency of activity.

The compounds according to the invention may be administered in free base form or as a pharmaceutically acceptable acid addition salt. Such salts may be prepared in conventional manner and exhibit the same order of activity as the free forms.

10

It will be evident to those skilled in the art that the invention is not limited to the details of the foregoing illustrative 15 embodiments and examples and that the present invention may be embodied in other specific forms without departing from the essential attributes thereof, and it is, therefore, desired that the present embodiments and examples be considered in all respects as illustrative and not restrictive, reference being 20 made to the appended claims, rather than to the foregoing description, and all changes which come with the meaning and range of equivalency of the claims are, therefore, intended to be embraced therein.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 46 of 372

Serial No.	835466
Art Unit	126

The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless-

(b) the invention was patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of application for patent in the United States.

-2-

Claims 1 rejected under 35 U.S.C. 102(b) as being

anticipated by Meltzer, Gange and Berry .

The claimed composition useds as the prior art com-

positions and/or reaction mixtures regardless of

intended use.

The following is a quotation of 35 U.S.C. 103 which forms the basis for all obviousness rejections set forth in this Office action:

A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

Subject matter developed by another person, which qualifies as prior art only under subsection (f) and (g) of section 102 of this title, shall not preclude patentability under this section where the subject matter and the claimed invention were, at the time the invention was made, owned by the same person or subject to an obligation of assignment to the same person.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 47 of 372

Serial No.	835466
Art Unit	126

Claims 1,3-8 and 11-13 rejected under 35 U.S.C. 103 as being unpatentable over Aeschlimann (USP1,905,990), meltzer, Lange or Berry .

The deschlimann reference generically teaches the claimed compunds undering them obvious. The references discloses benologous and/or is empiric compounds that are so structurally similar that are would expect them to possess a community of properties in common.

Claim 2 rejected under 35 U.S.C. 103 as being unpatentable over Berry and Aeschlimann (USP 1,905,990) opinally in view of Aeschlimann (UPS 2,493,710.

Berry and Aeschlimann (USP 1,905,990) teach that it is known that the compounds possess anticholinesterase activity, applicants admit that it is known to use anticholinesterase agents in the treatment of the recited disarders, see lines 12-16 of pages 1; lines 16-18 of page 2; and lines 16-22 of page 5 of the specification. Accordingly, it is considered obvious to use these known anticholinesterase agents for the treatment of the recited disorders. Aeschlimann (USP 2,493,710) is cited to show that the various R_1 and R_2 of the instant claims are recognized to be functionally equivalent in analogous compounds rendering such a modification of the primary reference are cited as of interest.

FILED :	03/03/86	EXAMINER: M. SHIPPEN
FOR :	PHENYL CARBAMATES	· .

AMENDMENT

Honorable Commissioner of Patents and Trademarks Washington, D.C. 20231

Sir:

This is in response to the Official Action of January 23, 1987.

Please amend the above identified application as follows: /

In the Claims:

Cancel claim 1 in its entirety.

Amend the claims as follows:

Claim 2, fast line, after "thereof" and before the period, insert the following

 μ , provided that for compounds wherein R₄ and R₅ are both methyl and having the dialkylamino group in the meta position, when R₂ is methyl and R₃ is hydrogen, R₁ is neither

> NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 52 of 372

- 52 -

S/N 835,466

Page 2

hydrogen nor methyl, and when R_2 and R_3 are methyl, R_1 is not hydrogen, and for compound, wherein R_4 and R_5 are both methyl and having the dialk planing group in the ortho or para position when R_1 and R_3 are both hydrogen R_2 is not methyl--

REMARKS

The claims in the application are claims 2 to 13. Claim 2 was amended so that it is directed to the same group of compounds as claim 3.

For the information of the Examiner, some of the compounds claimed in this application were disclosed after the priority date at the 3rd OHOLO Biol. conference in Eilat, Israel held in November of 1985, a copy of the publication is attached hereto as Exhibit "A". Subsequent to this, workers at Warner-Lambert synthesized some of the compounds, a copy of the publication is attached hereto and marked as Exhibit "B".

It is noted that claims 9 and 10 were not rejected on any basis.

Reconsideration is requested of the rejection of claims 3-8 and 11-13 under 35 USC 103 as being unpatentable over Aeschlimann 1,905,990; Meltzer, Lange or Berry in that the

- 53 -

S/N 835,466

Page 3

5

references disclose homologous and/or isomeric compounds that , are so structurally similar that it would be expected they would possess a community of properties in common.

The Meltzer article discloses two compounds with the code numbers KD 1207 and 1261 which fall under formula I, but not under formula I', and provides results as to their insecticidal activity. There is also a general statement mentioning that the anticholinesterase activity of alkylphenyl N-methylcarbamates can be improved by introducing a p-dimethylaminomethyl group. There is however no alkyl group in addition to the dialkylaminoalkyl group in the compounds disclosed. Meltzer concerns a different art, that of killing insects whereas the present invention is for treating patients to save their lives.

The Lange article discloses one compound (table II, No. 37) which is Miotine, falling under formula I, as an inhibitor of coagulation factors. Lange in page 338, 3rd paragraph indicates that other compounds are preferred. There is no motivation to modify compound 37 to a compound such as now embraced by the claims.

The Berry article discloses the acetylcholinesterase

- 54 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 54 of 372

S/N 835466

Page 4

activity of 6 carbamates including one of formula I, which is Miotine. Berry is an academic work and does not come to any conclusion and does not suggest structural changes for any purpose.

Aeschlimann 1,905,990 generically covers Ndisubstituted carbamates of formula I, assuming the alkyl chain in the dialkylaminoalkyl group may be branched. However no compound having a dialkylaminoalkyl group is disclosed and there is no mention of any advantage of the compounds over physostigmine. In fact, Aeschlimann having prepared no compound with a dialkylaminoalkyl substituent could, of course, not have noticed the advantages bond to the alkyl bridge.

Applicants have now combined the two features of the alkyl bridge and tertiary nitrogen, and discovered further, unexpected advantages over physostigmine, comprising CNS selectivity, little side effects and low toxicity. These advantages are essential for the use of the compounds in senile mental decline.

Reconsideration is also requested of the rejection of claim 2 under 35 USC 103 as being unpatentable over Berry and Aeschlimann 1,905,990 or in view of Aeschlimann

- 55 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 55 of 372

s/N 835,466

Page 5

2,493,710. The claim has been amended to limit it to the compounds of claim 3. The rejection is based on the allegation that the references teach the compounds of the references possess anticholinesterase activity and that applicants admit it is known to use such agents in the treatment of the recited disorders. As indicated above the basic references do not disclose the subject compounds. They also do not suggest that the claimed compounds have the recited activity. Accordingly, it is submitted that the recited method is novel and is not suggested. As to Aeschlimann 2,493,710, it discloses carbamic acid esters including compounds presenting the alkyl bridge, but wherein the nitrogen in the alkylamine radical is either primary or secondary, but not tertiary like in the compounds of the present invention. Thus he noticed some advantages over physostigmine like a good p.o. bioavailability and a certain specificity but no details are given. However, there was no incentive to improve the activity by preparing tertiary amine homologues, and this was not done until the present invention.

The other references have been considered but since they are only recited as of interest a detailed discussion

- 56 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 56 of 372

S/N 835,466

Dated: 7/17/87

Page 6

appears unnecessary. The references however do not disclose , the claimed compounds.

For the reasons given hereinabove reconsideration of the rejection of the claims is respectfully requested.

Respectfully submitted, M.W. Rosin et. By: Richard T. Laughoin

3rd OHOLO Wyhann وينته 1. Conference Elat no feard. đ 1985 PHARMACOLOGICAL ACTIVITY OF NOVEL ANTICHOLINESTERASE AGENTS OF POTENTIAL USE IN TREATMENT OF ALZHEIMER'S DISEASE M. Weinstock, M. Razin and M. Chorev. Depts. of Pharmacology and Pharmaceutical Chemistry. Hebrew Univ. Medicine & Pharmacy Jerusalem, Israel Alzheimer's disease has been associated with degeneration of cholinergic neurones in the hippocampus and cerebral cortex. Physostigmine has some beneficial effect in this condition, but its short half life, low therapeutic ratio and irregular intestinal absorption limit its usefulness to hospitalized patients. We have prepared and tested 10 novel anticholinesterase agents in a variety of preparations in vitro and in vivo. Several of these compounds were found to have obvious advantages over physostigmine. In vitro activity was assessed on a solubilized preparation of mouse brain acetylcholinesterase (AChE). In vivo activity and acute toxicity were assessed at various times efter s.c. or oral administration to mice or rats. Five of the compounds. RA6,7,12,14 & 15 produced 50% AChE inhibition in mouse brain lasting 3-17 hours, while that of physostigmine lasted only 2 hours. The therapeutic ratio LD50/FD50 for physostigmine in mice was 5.6 after s.c. and <3.0 after oral administration, while those of five RA compounds ranged from 6.6-12. The maximum inhibition in AChE after oral or s.c. physostigmine in rats was only 31% in the cortex but reached 46% in the medulla, at doses which caused obvious fasciculations. In contrast, RA6,7,14 & 15 inhibited AChE in cortex by more than 50%, but that in the medulla by 1 25-45% at doses which did not cause signs of peripheral cholinergic overactivity. These drugs are currently being compared with physostigmine for their ability to restore memory in rats with lesions of the nucleus basalis. In view of their lower relative toxicity, longer duration of action, better oral bioavailability, and relatively greater 2.... inhibition of AChE in cortex than in medulla, these compounds may be superior to physostigmine in the treatment 130 of Alzheimer's disease. . 43 140 EXHIBIT "A"

CENTRAL CHOLINERGIC PHARMACOLOGY OF A SERIES OF CHOLINESTERASE IN-HIBITORS, R.E. Davis, L.L. Coughenour, J.G. Merriott, W.H. Moos, R.D. Schwerz, J.P. Symons, and A.J. Ihomas, Varner-Lambert/ Parke-Davis Pharmacoutical Research, Ann Arbor, HI (8105) The short duration of action and poor therapeutic ratio of the anticholinesterage, physostigmine, has limited its utility in treating patients suffering from cholinergic deficiencies. Recently, a series of acetylcholinesterase inhibitors (ACHG-I) has been described by Weinstock-Rosen (RA series) with a potential for decreased toxicity and increased duration of action relative to physostigmine. We have examined the effects of this series in a variety of 'in vitro' blochemical and 'in vivo' behavioral tests which are designed to characterize central cholinergic function. All compounds from the RA series exhibit higher affinity for muscarinic cholinergic agonist sites labeled by the muscarinic satagonist. OH8. The IC-50's of these compounds for displacing H-OPO is directly cogralated to their potency for inhibiting cholinesterase activity (r = 0.92). CPO displacement and cholinesterase activity of this series also are directly related to bulk parameters such as lipophilicity and molar refractivity. A similar relationship

as lipophilicity and molar refractivity. A similar relationship as lipophilicity and molar refractivity. A similar relationship holds with respect to the ability of these compounds to decrease the K+-stimulated presynaptic release of acetylcholine from brain slices. However, these RA series compounds do not stimulate the turnover of phosphoinositides (PI). The order of potency for displacing CPO, inhibiting cholinesterase activity and decreasing ACH release is RA-2 > RA-10 > RA-6 > RA-7 > RA-8. A similar order of potency holds Tor the ability of these compounds to decrease spontaneous subming and to reverse scopolamine-induced increases in swimping activity of rats. However, RA-6 does not reverse scopolamine-induced increases in swimming activity. Taken together these data suggest that the ability of these compounds to displace CPO binding but not Q48 binding may be

Taken together these data suggest that the ability of these compounds to displace CPO binding but not QHS binding may be related to their ability to inhibit cholinesterase activity. ACHE-I activity also is directly related to the ability of these compounds to decrease the presynaptic release of ACH from brain slices, decrease spontaneous swimeing activity and reverse scopolawine-induced swimming activity. This pattern of effects also is seen with the known anticholinesterase, physostimine.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 60 of 372

Serial No.	835466
Art Unit	126

Claims 3-8 and 11-13 are rejected under 35 U.S.C. 103 as being unpatentable over Aeschlimann (USP 1,905,990), Meltzer, Lange or Berry for reasons of record.

-2-

Applicants state that Aeschlimann (USP 1,905,990) does not disclose a compound having a "dialkylaminoalkyl" group and there is no mention of any advantage over physostigmine. The fact is that the product of example 2 has a "dialkylaminoalkyl" groups which is an adjacent homologue to the compounds instantly claimed, As to advantages of the prior art compounds, there is no requirement that the prior art disclose advantages over physostigmine. There is no evidence of the instant compounds possessing unexpected properties over the compounds of Aeschlimann (USP 1,905,990), note In re Hoch, 166 USPO 406. The fact that Meltzer does not teach "treating patients" is of no moment, In re Hoch, supra. The fact that compound 37 of Lange may not be the most preferred agent disclosed is of no moment, see In re Mills, 176 USPQ 196. Applicants suggestion that Berry does not suggest structural changes is of no moment because one of ordinary skill in the art would recognize the obviousness of homologous or isomeric compounds without the reference suggesting such changes.

Claim 2 is rejected under 35 U.S.C. 103 as being unpatentable over Berry and Aeschlimann (USP 1,905,990) optionally in view of Aeschlimann (USP 2,493,710) for reasons of record.

- 61 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 61 of 372

Serial No.	835466
Art Unit	126

Applicants arguments as to Berry and Aeschlimann (USP 1,905,990) that are the same as presented in response to the preceding rejection are not persuasive for the reasons given.

-3-

Claims 9 and 10 objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

Applicant information about "some of the compounds claimed" being disclosed after the priority date is noted. It is pointed out to applicants from the information provided by applicants it is not possible to determine what compounds were actually disclosed making an evaluation of such information impossible. It is further pointed out to applicants that they are not entitled to their priority date unless it is actually prefected in accordance with 35 USC 119 (also see MPEP 201.15). If the disclosure raises issues under 35 USC 102 or 35 USC 103, such a determination cannot be made with the information provided, see 37 CFR 1.56.

THIS ACTION IS MADE FINAL.

Applicant is reminded of the extension of time policy set forth in 37 CFR 1.136(a). The practice of automatically extending the shortened statutory period an additional month upon the filing of a timely first response to a final rejection has been discontinued by the Office. See 1021 TMOG 35.

- 62 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 62 of 372

Serial No.	835466
Art Unit	126

A SHORTENED STATUTORY PERIOD FOR RESPONSE TO THIS FINAL ACTION IS SET TO EXPIRE THREE MONTHS FROM THE DATE OF THIS ACTION. IN THE EVENT A FIRST RESPONSE IS FILED WITHIN TWO MONTHS OF THE MAILING DATE OF THIS FINAL ACTION AND THE ADVISORY ACTION IS NOT MAILED UNTIL AFTER THE END OF THE THREE-MONTH SHORTENED STATUTORY PERIOD, THEN THE SHORTENED STATUTORY PERIOD WILL EXPIRE ON THE DATE THE ADVISORY ACTION IS MAILED, AND ANY EXTENSION FEE PURSUANT TO 37 CFR 1.136(a) WILL BE CALCULATED FROM THE MAILING DATE OF THE ADVISORY ACTION. IN NO EVENT WILL THE STATUTORY PERIOD FOR RESPONSE EXPIRE LATER THAN SIX MONTHS FROM THE DATE OF THIS FINAL ACTION.

<u>Case 118-6848</u>

 $\{ \}$

SD PHENYL CARBAMATES

The present invention relates to novel phenyl carbamates which are useful as pharmaceutical compositions. The invention further relates to pharmaceutical compositions having anticholinesterase activity.

Acetylcholine is a major neurotransmitter which is found in all parts of the body. Any reduction in its activity, either as a result of neuronal damage, degeneration etc. or as induced by drugs or toxins, causes marked changes in the function of the organism. Acetylcholine itself has an extremely short half life, since it is rapidly hydrolysed at its site of action and in plasma by specific cholinesterase enzymes. Drugs that inhibit acetylcholinesterase, markedly increase and prolong the action of acetylcholine, thereby enhancing cholinergic transmission. Three such agents are used clinically, i.e., physostigmine, a naturally occurring alkaloid, and two synthetic analogues, neostigmine and pyridostigmine. The latter two agents are strongly ionised at physiological pH and therefore are only poorly absorbed from the gastro-intestinal tract, and do not penetrate the central nervous system to any significant extent. Physostigmine is absorbed after

()

oral administration and readily enters the brain. As a therapeutic agent it has several disadvantages. It is chemically unstable and must be prepared in solution with an antioxidant, and protected from light. It has a relatively short half-life (20-40 mins) thereby necessitating frequent administration. The latter is of particular importance when the drug is to be administered chronically. It has a low therapeutic ratio, a value of 3-5 being reported in the majority of studies in laboratory animals, and a small therapeutic window, i.e. small range of dose in which it can be given without the accompaniment of side effects. Although physostigmine is absorbed from the gastro-intestinal tract, this is reported to be irregular and unpredictable, and therefore it is usually preferred to administer the drug parenterally. This is a serious drawback if it is to be used chronically on an outpatient basis.

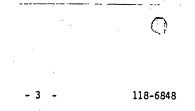

ł

There are a number of clinical and pathological conditions which are associated with cholinergic under-activity which can be improved by the administration of an anticholinesterase agent. These include reduction in cholinergic transmission induced by a variety of exogenous substances acting in the peripheral, or central nervous system. Peripherally acting agents are gallamine, d-tubocurarine and pancuronium, which are used as muscle relaxants. Their action can readily be overcome by an anticholin-. esterase drug. Drugs which interfere with central cholinergic transmission are numerous, anticholinergic, atropine-like drugs including antiparkinson drugs, tricyclic antidepressants, neuroleptics, opiate analgesics, benzodiazepines and some types of general anaesthetics. So far the only agent that has proved to be of any value in reversing the effects of the latter group of drugs is physostigmine. In all reported cases of drug overdose or lack of recovery when the agent was used peri-operatively, physo-

4

- 94 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 94 of 372

stigmine is usually administered parenterally, and administration is repeated every 20-30 minutes as required.

Chronic treatment with neuroleptics often results in tardive dyskinesias. The widespread use of agents having anticholinesterase activity for the treatment of schizophrenia makes this side effect an ever increasing possibility. Physostigmine injected intravenously produces a significant but short lived improvement in a proportion of patients.

A number of pathological and degenerative diseases has also been shown to be associated with a reduction or loss of cholinergic transmission. This includes myasthenia gravis and Eaton Lambert syndrome in which there is an interference with neuromuscular transmission.

A selective loss of choline acetyltransferase (the enzyme that synthesises acetylcholine) has been found in specific brain regions of patients with pre-senile dementia of the Alzheimer type. These include the frontal and temporal cortex, hippocampus, amygdala, caudate nucleus, substantia innominata. Degeneration of cholinergic neurons in some of these areas appears to be associated with the aphasia, apraxia, agnosia and loss of short term memory that occurs in Alzheimer's disease. A similar type of dementia is also found in patients with Down's syndrome that survive to the age of 40 years and show similar cholinergic deficits. There is also a loss of cholinergic transmission in the caudate nucleus and putamen of patients with Huntingdon's chorea. Physostigmine injections have also been of some benefit in this condition. Treatment with a centrally acting anticholinesterase should also prove to be beneficial in Friedrich's ataxia.

 \bigcirc

There are two major classes of potent inhibitors of the enzyme cholinesterase. The first group was modelled primarily on the natural alkaloids physostigmine (a carbamate) and an inhibitor of cholinesterase, and d-tubocurarine, an antagonist of acetylcholine. The second group consists of various organophosphorus compounds, such as diisopropylfluorophosphonate, paraxon etc. The vast majority of the compounds of both these series were designed primarily as insecticides. In the first group of carbamate derivatives, almost all of the potent insecticides are monomethyl carbamates lacking a charged nitrogen function. This enables the molecule to penetrate rapidly the insect cuticle and fatty nerve sheath. The dimethyl derivatives are slightly less potent but are particularly toxic to houseflies and aphids. The monomethyl derivatives tend to be unstable in solution and hydrolyse readily at physiological pH. This greatly limits their biological action in mammals and makes them less suitable as pharmaceutical or therapeutic agents.

The organo-phosphorus group of compounds causes irreversible inhibition of cholinesterase and other serine containing enzymes, which, together with their high relative toxicity, virtually precludes their use in pharmaceutical preparations. The only exception is echothiopate, a quaternary ammonium organophosphorus compound, employed in eye drops for the treatment of glaucoma.

The synthetic anticholinesterase agents currently employed as pharmaceuticals all contain a charged nitrogen function and can be broadly classified into 3 groups.

 Reversible inhibitors which contain a charged nitrogen function attached to an aromatic ring, e.g. edrophonium.

()

 Dimethyl carbamates with an aromatic or heterocyclic ring containing a charged nitrogen, neostigmine, pyridostigmine.

i(

16

5

3) Bisquaternary structures, e.g. Demacarium, Ambenonium. These agents tend to be more selective inhibitors of acetylcholin-esterase than butyrylcholinesterase, compared with the mono-quaternary molecules.

The pharmaceutical application of the quaternary anticholinesterase agents is limited because of their poor penetration through cell membranes. They are therefore used for actions outside the central nervous system, and are usually given parenterally, since they are not reliably absorbed from the gastrointestinal tract. Edrophonium, neostigmine and pyridostigmine and the bisquaternary analogues are used in anaesthetic practice for the reversal of the action of muscle relaxants. They are also used for the treatment of myasthenia gravis, and paralytic ileus.

Physostigmine is the only potent anti-cholinesterase agent which has been used clinically to treat conditions in which an elevation of brain acetylcholine activity is desired. These include, Alzheimer's disease, tardive dyskinesia, Down's syndrome and Huntingdon's chorea. Physostigmine is also used to reverse the effects of overdose of anticholinergic agents, anti-Parkinson drugs, benzodiazepines and opiate analgesics.

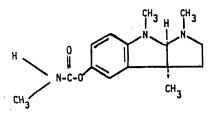

Physostigmine is a natural alkaloid extracted from calabar beans and the seeds of the vine Physostigma venenosum and has the formula

?∕、

There is a need to provide new carbamate derivatives which show greater chemical stability than physostigmine.

Furthermore there is a need to provide new compounds which inhibit acetylcholinesterase in the brain for periods exceeding 3 hours but not more than 12 hours after a single administration.

There is also a need to provide new compounds which will be completely and reliably absorbed after oral administration.

There is also a need to provide new compounds which will be relatively less toxic than physostigmine. This means that the therapeutic ratio, defined as

dose to produce therapeutic effect

dose to produce mortality in 50 % of animals

should be significantly higher than those of physostigmine and that the incidence and severity of side effects should be less than those of physostigmine at therapeutic doses.

There is also a need to provide new compounds which can be given orally or parenterally to treat chronic conditions in which it is

4

- 98 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 98 of 372

118-6848

ني)

desired to raise cholinergic activity in the central nervous system. These include, Alzheimer's disease, Down's syndrome, Huntingdon's chorea, Friedrich's ataxia.

 \cap

771

There is also a need to provide compounds that can be given parenterally at the end of operations, and anaesthetic procedures, to restore wakefulness, respiration and cardiovascular parameters to normal, after the use of anticholinergic, opiates, benzodiazepines, neuroleptics and general anaesthetics, thereby shortening the stay of patients in the recovery room.

There is also a need to provide compounds that can be given together with narcotic analgesics to patients suffering from severe pain, e.g. traumatic, post-operative, or due to carcinomatosis etc. in order to reduce the side effects (respiratory depression, somnolence, constipation and urinary retention) commonly encountered with narcotics, without impairing their analgesic potency.

There is also a need to provide compounds that can be given to patients receiving antipsychotic drugs, which have developed tardive dyskinesias, in order to diminish or abolish the latter syndrome, without exascerbating the psychosis.

According to the present invention it has now been surprisingly found that certain novel and known phenyl carbamates also inhibit acetylcholinesterase in the mammalian brain after administration to provide systemic activity, e.g. oral or parenteral administration.

Thus according to the present invention there is now provided a pharmaceutical composition adapted to produce anticholinesterase

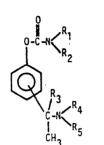

1

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 99 of 372

I

activity in the central nervous system of mammals comprising a compound of the general formula I

wherein

TICCX

H

1

- R1 is hydrogen, lower alkyl, cyclohexyl, allyl or benzyl,
- R₂ is hydrogen, methyl, ethyl or propyl, or
- R_1 and R_2 together with the nitrogen to which they are attached form a morpholino or piperidino radical,
- R₃ is hydrogen or lower alkyl,
- R4 and R5 are the same or different and each is a lower alkyl, and the dialkylaminoalkyl group is in the meta, ortho or para position,

or a pharmacologically acceptable salt thereof and a physiologically acceptable carrier therefor. Hereinafter these compounds are called compounds of the invention.

Especially preferred are pharmaceutical compositions having anticholinesterase activity in the central nervous system of mammals, wherein the dialkylaminoalkyl group is in the meta position, and R_4 and R_5 are both methyl.

Certain compounds falling within the above formula have previously been described i.e. the m disubstituted compound in which R_1 and $R_3 = H$ and R_2 , R_4 and $R_5 =$ methyl which is known as Miotine(R) was claimed to be an insecticide and a myopic agent for use in eye drops. The m disubstituted compound in which R_1 and R_2 are methyl, R_3 is H and R_4 and R_5 are methyl has been described as an insecticide. The p and o disubstituted derivatives in which R_1 and $R_3 = H$ and R_2 , R_4 and $R_5 = CH_3$ have been shown to inhibit a preparation of liver cholinesterase. The m disubstituted derivative in which $R_1 = H$ and R_2 , R_3 , R_4 and $R_5 =$ CH_3 has also been shown to inhibit liver cholinesterase.

The remaining compounds are believed to be novel and thus the present invention also provides novel phenyl carbamate derivatives of the general formula I'

e

and pharmacologically acceptable salts thereof, provided that for compounds wherein R4 and R5 are both methyl and having the dialkylamino group in the meta position, when R2 is methyl and R3 is hydrogen, R1 is neither hydrogen nor methyl, and when R2 and R3 are methyl, R1 is not hydrogen, and for compounds wherein R4 and R5 are both methyl and having the dialkylamino group in the ortho or para position when R1 and R3 are both hydrogen R2 is not methyl.

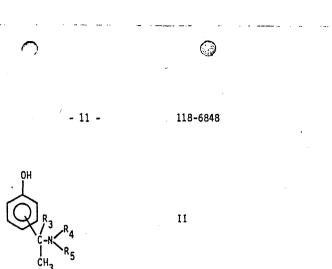

Preferred compounds of the above formula are N-ethyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-propyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N-allyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-ethyl, N-methyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N,N-diethyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N-butyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-methyl, N-propyl-3[1-(dimethylamino)ethyl]phenyl carbamate and N-ethyl, N-methyl-3[1-(dimethylamino)isopropyl]phenyl carbamate.

As indicated, the invention also includes the pharmacologically acceptable salts of these compounds such as the acetate, salicylate, fumarate, phosphate, sulphate, maleate, succinate, citrate, tartrate, propionate and butyrate salts thereof.

The compounds of formula I can be prepared by amidating a compound of formula II

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 102 of 372

- 102 -

wherein R₃, R₄ and R₅ are as defined above.

The process can be effected in conventional manner, e.g. by reacting the compound of formula II with an appropriate isocyanate if a compound wherein R_1 is hydrogen is desired, or with an appropriate carbamoyl halogenide, e.g. as described below in processes A and B.

 \bigcirc

PROCESS A:

A stirred suspension of α -m-Hydroxyphenylethyldimethylamine or α -m-hydroxyphenylisopropyldimethylamine in benzene (0.2 - 0.3 g/ml) is treated with 2.5 - 3 fold molar excess of the iso-cyanate. After stirring for 15 - 24 hours at ambient temperature the reaction mixture is connected to a rotovaporator (20 mm Hg). The residue obtained is dissolved in dry ether (25 ml) and the solution, which is ice cooled, is saturated with dry HCl (g). The formed precipitate (the anticipated carbamate) is filtered off, washed with dry ether (25 ml) and dried to constant weight in a dessicator over KOH pellets under high vacuum (0.1 mm Hg).

PROCESS B:

ĹÅ

14

î

14

ᡪъ

1

A solution of α -m-hydroxyphenylethyldimethylamine or α -m-hydroxyphenylisopropyldimethylamine in dry acetonitrile (0.1 - 0.5 M) is reacted with 50 - 70 % molar excess of the corresponding carbamoyl chloride in the presence of 200 % molar excess of NaH dispersion (50 - 80 % in mineral oil). The reaction mixture is left to stir at ambient temperature for 15 - 24 hours. Removal of the acetonitrile under reduced pressure (20 mm Hg) is followed by the addition of water (10 - 25 ml). The pH of the aqueous solution is adjusted to pH = 11 by the addition of the appropriate amount of NaOH 0.1 N followed by extraction with ether (3 x 25 ml). The combined organic phases are washed with brine (25 ml) dried over MgSO4 anhydride which is then filtered off. The ice cooled etheral filtrate is saturated with a stream of HCl (g) resulting in the formation of a heavy precipitate (the anticipated carbamate) which is collected by filtration, washed with dry ether (20 ml) and dried to constant weight in a desiccator under high vacuum (0.1 mm Hg) over KOH pellets.

٢

The compounds of the invention e.g. in free form or salt form can be utilized by formulating one or more of them in compositions such as tablets, capsules or elixirs for oral administration or in sterile solutions or suspensions for parenteral administration. A compound or mixture of compounds of formula (I) or physiologically acceptable salt(s) thereof is compounded with a physiologically acceptable vehicle, carrier, excipient, binder, preservative, stabilizer, flavor, etc., in a unit dosage form as called for by accepted pharmaceutical practice. The amount of active substance in these compositions or preparations is such that a suitable dosage is obtained.

Illustrative of the adjuvants which may be incorporated in tablets, capsules and the like are the following: a binder such as gum tragacanth, acacia, corn starch or gelatin; an excipient such as dicalcium phosphate; a disintegrating agent such as corn starch, potato starch, alginic acid and the like; a lubricant such as mangnesium stearate; a sweetening agent such as sucrose. lactose or saccarin; a flavoring agent such as peppermint, oil of wintergreen or cherry. When the dosage unit form is a capsule, it may contain in addition to materials of the above type a liquid carrier such as a fatty oil. Various other mterials may be present as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets may be coated with shellac, sugar or both. A syrup or elixir may contain the active compound, sucrose as a sweetening agent, methyl and propyl parabens as preservatives, a dye and a flavoring such as cherry or orange flavour.

Sterile compositions for injection can be formulated according to conventional pharmaceutical practice by dissolving or suspending the active substance in a vehicle such as water for injection.

Buffers, preservatives, antioxidants and the like can be incorporated as required.

Preferred antioxidants for use with the compounds of the present invention include sodium metabisulphite and ascorbic acid.

While the invention will now be described in connection with certain preferred embodiments in the following examples, it will be understood that it is not intended to limit the invention to these particular embodiments. On the contrary, it is intended to cover all alternatives, modifications and equivalents as may be included within the scope of the invention as defined by the appended claims. Thus, the following examples which include preferred embodiments will serve to illustrate the practice of this invention, it being understood that the particulars described are by way of example and for purposes of illustrative discussion of preferred embodiments of the present invention only and are presented in the cause of providing what is believed to be the most useful and readily understood description of procedures as well as of the principles and conceptual aspects of the invention.

EXAMPLE 1

0.5 g (3.03 mmole) of α -m-hydroxyphenylethyldimethylamine are dissolved in 15 ml of dry acetonitrile and 0.70 g (5.2 mmole) of diethylcarbamylchloride are added to the mixture with stirring. This is followed by NaH 150 mg (50 %) of dispersion. The reaction mixture is stirred overnight at 25 - 30 ° C. Removal of acetonitrile under reduced pressure is followed by addition of water (10 ml) and adjustment of the pH to 11. The product is extracted in ether, which is washed by brine, dried over MgSO4 and filtered. Upon addition of HCl (g) precipitation occurs immediately, the product is filtered off, washed by dry ether and dried in a desiccator under high vacuum over KOH pellets.

The carbamate is obtained as a white powder 640 mg (80 %) mp. 137 - 138 $^{\circ}$ and identified as N,N-diethyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, having the formula

 $-\frac{\|}{C} - N(Et)_2$ H-N(Me ĊH,

EXAMPLE 2

0.75 g (4.55 mmol) of α -m-hydroxyphenylethyldimethylamine are suspended in benzene (3 ml) and 0.898 g of ethylisocyanate are added to the mixture with stirring. After stirring 12 hours at room temperature the solvent is removed under reduced pressure.

Ĺ

ß

Tests for anticholinesterase activity

A solubilized preparation of acetylcholinesterase was prepared from mouse whole brain (minus cerebellum). The brain was homogenized with (100 mg/ml) phosphate buffer; pH 8.0, centrifuged, the supernatant discarded, and the pellet mixed with a similar volume as above of buffer pH 8.0 plus 1 % Triton; mixed, centrifuged and the supernatant which contained most of the solubilized enzyme, was used for the subsequent determinations of anticholinesterase activity.

13

- 108 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 108 of 372 - 17 -

118-6848

The activity of the enzyme (rate of hydrolysis of substrate, acetylthiocholine) was measured using at least 4 different concentrations of substrate, and at least 3 different concentrations of each inhibitor. The enzyme was incubated with inhibitor for 5 periods ranging for 2 - 180 mins. at 37 ° C, substrate was then added, and its rate of hydrolysis measured by the spectrophotometric method of Ellman et al. (1961).

The molar concentration of each agent that inhibited the activity of the enzyme by 50 % (IC₅₀) at the peak time of activity (15 -10 60 min) was calculated from this data and recorded in Table 1 hereinafter. The compounds in general produce a significant inhibition from about 10⁻⁵ to about 10⁻⁸ molar. IN VIVO EXPERIMENTS:

a) Assessment of acetylcholinesterase inhibition

14

15

20

25

The effect of each compound on brain acetylcholinesterase <u>in vivo</u> was measured, after subcutaneous or oral administration to mice. Animals were sacrificed, at different times ranging from 0.25 - 8 hours after drug administration. The brain was rapidly removed, and the enzyme acetylcholinesterase extracted and solubilized with 0.1 % Triton, and its ability to hydrolyse acetylthiocholine assessed as described above (in vitro experiments), in comparison with the enzyme removed from mice injected with normal saline. The compounds have in general a potency of from about 2% to about 90% that of physostigmine. Assessment of acute toxicity

Mice were given one of at least three different doses of each compound, orally or subcutaneously, a minimum of 10 mice allotted to each dose. The number of animals which died at

ÌÌ

- 109 -

- 18 -

I. 118-6848

each dose within 3 hours was determined. From these data, the LD₅₀ (dose in mg/kg which was lethal to 50 % of the mice) was computed.

This experiment was repeated after the animals had been pretreated with atropine sulphate, which blocks both peripheral and central muscarinic receptors. The data from these experiments enabled the assessment of the relative degrees of toxicity of the carbamates which result from excessive activation of muscarinic receptors, and from respiratory muscle paralysis, which is insensitive to this blocking agent.

5

10

20

.2

- 2

+

The incidence and degree of side effects was noted for each dose of drug, starting with the lowest that caused any significant (> 20 %) inhibition of whole brain acetylcholinesterase.

15 c) Antagonism of the somnolent and respiratory depressant effects of opiates

Different doses of the carbamate compounds were injected intravenously with morphine in rabbits. Respiration rate, arterial blood gas tensions and pH were monitored continuously before and after drug administration for 4 -5 hours. In another series of experiments the effect of the anticholinesterase drugs was assessed on the analgesic effect of opiates in rabbits after application of a nociceptive stimulus, i.e. electrical stimulation of the sciatic nerve.

All specific examples of formula I' mentioned hereinbefore, e.g. on specification page 10, and after especially Tables 1 to 3, are prepared in analagous manner to Example 1 when R₁ and R₂ are each other than hydrogen and Example 2 when one
of R₁ and R₂ are hydrogen. They are thus obtained as hydrochloride salts (except where otherwise specified). The specific compounds have metal substitutions.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 113 of 372

118-6848

The data in Tables 1 and 2 demonstrate that somewhat larger quantities are required of all the drugs of the RA series than of physostigmine to inhibit the enzyme acetylcholinesterase. However, a comparison of the data in Table 1 with that in Table 2, shows that compounds RA5, RA6, RA15, RA14, RA10, RA7 and RAg are all relatively more active <u>in vivo</u> compared to physostigmine than one would expect from the <u>in vitro</u> data. This greater <u>in vivo</u> potency is particularly marked when the drugs are administered orally. This relatively greater <u>in vivo</u> activity may be due to:

- 22 -

a) greater chemical stability

ł

ζ

(

(

(

^

b) a slower metabolic degradation or/and excretion

c) a higher lipid solubility, enabling a greater proportion of the drug to gain access to the enzyme in the central nervous system

d) more efficient absorption from gastro-intestinal tract.

For the purposes of their therapeutic application it is of little importance if one needs to give the drug (to human subjects) at a dose of 1 - 2 mg (physostigmine) or 2 - 50 mg that may be required of the compounds of the RA series. What is important is the safety of the drugs and the presence and severity of side effects that may occur at therapeutic doses. A commonly-used measure of drug safety is the therapeutic index - or LD50/ED50

Dose to kill 50 % of animals

Dose to cause the desired therapeutic effect

24

- 114 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 114 of 372

118-6848

It is assumed that the therapeutic effect of these anticholinesterase agents results from an elevation of brain cholinergic activity. This in turn, should be related to the degree of inhibition of acetylcholinesterase. For the purpose of the computation of the denominator of the therapeutic ratio, there is used the dose of drug that inhibits the activity of acetylcholinesterase by 50 %. This is based on the observation by Thal et al. (Ann. Neurology 13: 491, 1983) that the maximum improvement in short term memory obtained in a series of patients with Alzheimer's disease was achieved with a dose of physostigmine which blocked the acetylcholinesterase in the cerebro-spinal fluid by 50 %. The numerator is the dose found to kill 50 % of the animals within 4 hours of a subcutaneous injection.

- 23 -

The therapeutic ratios of compounds RA4, 5, 6, 7, 8, 10, 14 and 15 are all significantly higher than of physostigmine (see Table 3). This indicates that all these compounds have a wider margin of safety than that of physostigmine. Moreover, these RA compounds do not produce any significant undesirable side effects such as defaecation, lachrymation, fasciculations or tremor at the doses which inhibit the brain enzyme by 50 %, while the former 3 side effects are clearly evident when physostigmine is given at the appropriate dose (ED₅₀).

1

The data in Table 3 show that atropine can afford considerably greater protection against the lethality of the derivatives RA4, 5, 7, 10, 13 and 14. This is particularly important in the treatment of drug overdose since the respiratory muscle paralysis which is not affected by atropine and which is the cause of death induced by excess drug administration in the presence of atropine cannot be satisfactorily reversed by specific antidotes.

- 115 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 115 of 372 - 24 -

118-6848

The duration of significant brain enzyme inhibition (> 30 %) induced by physostigmine (ED₅₀ dose) is less than 2 hours. Compounds RA4, 5, 6, 7, 8, 12, 14, 15 all act for more than 3 hours at their respective ED₅₀ doses and RA6 and RA7 still causes significant inhibition (36 %) after 7 hours. Since none of these drugs caused noticeable side effects at the ED₅₀ doses, an even longer duration of action may be achieved by giving between 50 and 100 % larger doses. The longer duration of action is a distinct advantage, particularly if the drugs are to be administered chronically to subjects suffering from neurological and behavioural conditions associated with a deficit in cholinergic transmission in the central nervous system, e.g. Alzheimer's disease, tardive dyskinesias, Huntingdon's chorea, Down's syndrome and Friedrich's ataxia.

2

4

31

3

Ť

H

H

14

14

The better the absorption of the drug after oral administration the more closely the LD_{50} given by this route resembles that after subcutaneous injection. Table 3 shows that RA6, 13, 7 and 4 are more efficiently absorbed from the gastro-intestinal tract than is physostigmine. The ED₅₀ of RA8 after oral administration is the same as that after S.C. injection, indicating a much better oral bioavailability than that of physostigmine. The higher oral bioavailability of these compounds may be a considerable advantage for their clinical use.

 RA_{10} , RA_6 , RA_{14} and RA_{15} produce significant antagonism of the respiratory depressant effects of morphine in rabbits for periods lasting between 3 - 5 hours depending on the drug and the dose administered. The analgesic activity of morphine is not reduced by the RA compounds. Muscle fasciculations are not evident at the doses of drugs administered. Physostigmine (0.1 - 0.2 mg/kg) antagonizes the respiratory depressant effect of morphine for

- 116 -

26

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 116 of 372

- 25 -

118-6848

30 - 60 mins only and fasciculations are marked at the higher dose.

1

1

2

These findings show that the RA compounds may be given together with morphine to obtain adequate analgesia without significant degrees of respiratory depression.

The most preferred compounds of the RA series are RA4, RA5, RA6, RA15, RA14, RA7 and RAg, all of which produce inhibition of brain acetylcholinesterase after parenteral administration of significantly longer duration than that induced by physostigmine or miotine. These compounds also have a greater safety margin (therapeutic ratio) than physostigmine. RA4, 6, 7 and g also show better bioavailability after oral administration than physostigmine. In addition, the acute toxicity (lethality) induced by RA7 can be decreased more than 10-fold and that of RA14 more than 8-fold by the antidote atropine, compared to only a 3-fold decrease for physostigmine and miotine.

The compounds of the invention are therefore useful for the treatment of senile dementia, Alzheimer's disease, Huntingdon's chorea, tardive dyskinesias, hyperkinesia, mania, acute confusion disorders, Down's syndrome and Friedrich's ataxia.

For these indications, the exact dosage will of course vary depending upon the compound employed, mode of administration and treatment desired. The compounds may be administered by any conventional route, non-oral or preferably orally.

In general, satisfactory results are obtained when administered at a daily dosage of from about 0.05 to 10 mg/kg animal body weight. For the larger mammals, an indicated total daily dosage

- 117 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 117 of 372

118-6848

is in the range from about 0.5 to about 25 mg of the compound, conveniently administered in divided doses 2 to 4 times a day in unit dosage form containing for example from about 0.1 to about 12 mg of the compound or in sustained release form.

- 26 -

The compounds may be administered in similar manner to known standards for use in these utilities. The suitable daily dosage for a particular compound will depend on a number of factors such as its relative potency of activity.

The compounds according to the invention may be administered in free base form or as a pharmaceutically acceptable acid addition salt. Such salts may be prepared in conventional manner and exhibit the same order of activity as the free forms.

It will be evident to those skilled in the art that the invention is not limited to the details of the foregoing illustrative embodiments and examples and that the present invention may be embodied in other specific forms without departing from the essential attributes thereof, and it is, therefore, desired that the present embodiments and examples be considered in all respects as illustrative and not restrictive, reference being made to the appended claims, rather than to the foregoing description, and all changes which come with the meaning and range of equivalency of the claims are, therefore, intended to be embraced therein.

3. A phenylcarbamate of formula I

wherein

 R_1 is hydrogen, lower alky, cyclohexyl, allyl or benzyl,

- 29 -

1

R2 is hydrogen, methyl styler propyl, or

ċнз

Ö

- R1 and R2 together with the nitrogen to which they are attached form a morphonino or piperidino radical,
- R3 is hydrogen or 1
- R4 and R5 are the same of different and each is a lower alkyl, and the transmission alkyl group is in the meta, ortho or paraposition,

and pharmacologically acceptable salts thereof, provided that for compounds wherein R4 and R5 are both methyl and having the dialkylamino group in the meta position, when R_2 is methyl and R3 is hydrogen, R1 is neither hydrogen nor methyl, and when R_2 and R3 are methyl, R1 is not hydrogen, and for compounds wherein R4 and R5 are both methyl and having the dialkylamino group in the ortho or para position when R1 and R2 are both hydrogen R2 is not methyl.

ECLARATION AND POWER OF ATTORNEY ORIGINAL APPLICATION

As a below named inventor, I declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and joint inventor of the subject matter which is claimed and for which a patent is sought on the invention entitled PHENYL CARBAMATES the specification of which is

_

TANE

X	was filed	on Marc	h 3,	1986	as
	Applicatio	on Serial	No.	835 466	and
	was amende	ed on			

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims.

/1 acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, \$1.56(a).

I hereby claim foreign priority benefits under Title 35, United States Code, \$119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign applications for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Anticipated Classification of this application:

Class 560 Subclass 136

Prior Application: 06/835,466

Examiner: Michael C. Shippen

Art Unit: 126

THE COMMISSIONER OF PATENTS AND TRADEMARKS Washington, D. C. 20231

Sir: This is a request for filing a

[X] Continuation

application under 37 CFR 1.60, of pending
[] Divisional

prior application serial no._____, filed on ______ of

for

1. [X] Enclosed is a copy of the prior application, including the oath or declaration as originally filed and an affidavit or declaration verifying it as a true copy. (See 8 and 8a for drawing requirements.)

2. [] Prepare a copy of the prior application.

3. [X] The filing fee is calculated below:

CLAIMS AS FILED IN THE PRIOR APPLICATION, LESS ANY CLAIMS CANCELLED BY AMENDMENT BELOW

For	Number filed	Number extra	Rate		Basic Fe \$340.00			
Total Claims	10-20 <i>±</i>	0	x	\$10.00	=	0		
Independent Claims	4-3 =	1	x	\$34.00	-	34.00		
Total filing f	ee				=	\$374.00		

- 128 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 128 of 372 4. [] The Commissioner is hereby authorized to charge any fees which may be required, or credit any overpayment to Account No. . A duplicate copy of this sheet is enclosed.

5. [X] A check in the amount of \$374.00 is enclosed.

6. [] Cancel in this application original claims

of the prior art application before calculating the filing fee. (At least one original independent claim must be retained for filing purposes.)

7. [X] Amend the specification by inserting before the first line the sentence: - This is a [X] continuation, [] division, of application serial no \$35,466, filed March 3, 1986

8. [] Transfer the drawings from the prior application to this application and abandon said prior application as of the filing date accorded this application. A duplicate copy of this sheet is enclosed for filing in the prior application file. (May only be used if signed by person authorized by 1.138 and before payment of base issue fee.)

8a. [] New formal drawings are enclosed.

8b. [X] Priority of application serial no. 74497 filed on March 5, 1985 in Irael is claimed under 35 U.S.C. 119.

[] The certified copy has been filed in prior application serial no. , filed

9. [] The prior application is assigned of record to and the assignment is recorded in the U.S. Patent and Trademark Office at reel , Frame[s]

10. [X] The power of attorney in the prior application is to: 307 Richard T. Laughlin, Reg. No. <u>17,264</u>

a. [X] The power appears in the original papers in the prior application

- 129 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 129 of 372 b. [] Since the power does not appear in the original papers, a copy of the power in the prior application is enclosed.

c. [X] Address all future communications to:

()/Richard T. Laughlin, Esq.)JAUGHLIN, MARKENSOHN, LAGANI & PEGG 129 Headquarters Plaza)Morristown, New Jersey 07960

11. [X] A preliminary amendment is enclosed. (Claims added by this amendment have been properly numbered consecutively beginning with the number next following the highest numbered original claim in the prior application.

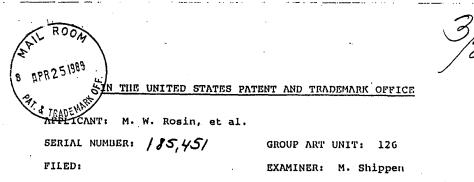

The undersigned declares further that all statements made herein of his or her own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application of any patent pending thereon.

FOR: PHENYL CARBMATES

MENDMEN'T

Nonorable Commissioner of Patents and Trademarks Washington, D.C. 20231

Sir:

Please amend the above-identified application as follows:

Cancel all of the claims and substitute the following claims:

14. A phenylcarbamate of formula

wherein

- R1 is hydrogen, lower alky, cyclohexyl, allyl or benzyl,
- R2 'is hydrogen, methyl, ethyl or propyl, or
- R1 and R2 Vogether with the nitroyen to which they are attached form a morpholino or piperidino radical,
- R3 is hydrogen or lower alkyl,
- R_4 and R_5 are the same or different and each is a lower alkyl, and the dialkylaminoalkyl group is in the meta,

/orthu or para position,

and pharmacologically acceptable safts thereon, provided that for compounds wherein R4 and R5 are both methyl and having the dialkylamino group in the meta position, when R2 is methyl and R3 is hydrogen, R1 is neither hydrogen normethyl, and when R2 and R3 are methyl, R1 is not hydrogen, and for compounds wherein R4 and R5 are both methyl and having the dialkylamino group in the ortho or para position when R1 and R3 are both hydrogen R2 is not methyl.

15.

16.

A compound of claim 14 wherein the dialkylaminoalkyl group is in meta position and R_4 and R_5 are both methyl. A compound of CTaim 14 which is N-ethyl-3-[1-

A compound of claim 14 which is N-ethyl, N-methyl-3[1-

(dimethylamino #ethyl]phenyl carbamate or a

(dimethylamino)ethyl phenyl carbamate or a pharmacologically acceptable salt thereof.

(dimethylamino)ethyl]phenyl carbamate or a pharmacologically acceptable salt thereof. A compound of claim 1A which is N.N-diethyl-3[1-

(dimethylamino)ethyl/phenyl carbamate or a pharmacologically acceptable salt thereof.

pharmacologically acceptable salt thereof. 17. A compound of claim 14 which is N-propy1-3[1-

18.

19.

20.

21.

22.

A compound of claim 14 which is N-buty1-3[1-(dimethylamino)-ethyl]phenyl carbamate or a pharacologically acceptable saft thereof. A compound of claim 3 which is N-methyl, N-propyl-3[1-

dimethylamino ethyl]phenyl carbamate or a pharmacologically acceptable salt thereof.

A compound of claim 3 which is N-methyl, N-ethyl-3[1dimethylamino) isopropyl] phenyl carbamate or a pharmacglogically acceptable salt thereof.

(Rewritten) N-cyclohexyl-3[1-(dimethylamino)ethyl] phenyl carbamate and pharmacologically acceptable salts thereof.

(Rewrittent N-ally1-3[1-(dimethylamino)ethyl]phenyl carbamate and pharmacologically acceptable salts thereof.

- 132 -

25.

A method of treating a subject suffering from senile dementia, Alzheimer's disease, Huntingdon's chorea, tardive dyskinesias, hyperkinesia, mania, acute confusion disorders, Friedrich's ataxia and Down's syndrome, which comprises administering a therapeutically effective amount of a compound of formula

wherein

- R1 is hydrogen,/lower alkyl, cyclohexyl, allyl or benzyl,
- R2 is hydrogen / methyl, ethyl or propyl, or
- R1 and R2 together with the nitrogen to which they are attached form a morpholino or piperidino radical,

Ċн₃

- R3 is hydrogen or lower alkyl,
- R4 and R5 fre the same or different and each is a lower alkyl, and the dialkylaminoalkyl group is in the meta, ortho or para position,

or a pharmacologically acceptable salt thereof.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 133 of 372

REMARKS

New claims 14 to 25 are presented. Claims 23 and 24 are identical to claims 9 and 10 which were allowed in the parent application.

Respectfully submitted,

Richard T. Laughlin

Attorney for Applicant

Laughlin, Markensohn, Lagani & Pegg 129 Headquarters Plaza Morristown, New Jersey 07960 (201) 539-0080

:

Serial No. 185451

Art Unit 126

The following is a quotation of 35 U.S.C. 103 which forms the basis for all obviousness rejections set forth in this Office action:

-2-

A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

Subject matter developed by another person, which qualifies as prior art only under subsection (f) and (g) of section 102 of this title, shall not preclude patentability under this section where the subject matter and the claimed invention were, at the time the invention was made, owned by the same person or subject to an obligation of assignment to the same person.

Claims 14 -22 are rejected under 35 U.S.C. 103 as being unpatentable over Aeschlimann (USP 1,905,990), Meltzer, Lange or Berry.

The Aeschlimann reference generically teaches the claimed compounds rendering them obvious. The references discloses homologous and/or isomeric compounds that are so structurally similar that are owe would expect them to possess a community of properties in common. Note the product of example 2 of Aeschlimann has a "dialkylaminoalkyl" group which is an adjacent homologue to the compounds instantly claimed. As to advantages of the prior art compounds, there is not evidence of the instant compounds possessing unexpected properties over the compounds of Aeschlimann (USP 1,905,990), note In re Hoch, 166 USPQ 406. The fact that Meltzer does not teach "treating patients is of no moment, In re Hoch, <u>Supra</u>.

- 137 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 137 of 372 Serial No. 185451 Art Unit 126

The fact that compound 37 of Lange may not be the most preferred agent disclosed is of no moment, see In re moment, see In re Mills, 176 USPQ 196. Assertions that the prior art does not suggest structural changes is of μ 0 moment because one of ordinary skill in the art would recognize the obviouness of homologous or isomeric compounds without the reference suggesting such changes.

-3-

Claim 25 Årejected under 35 U.S.C. 103 as being unpatentable over Berry and Aeschlimann (USP 1,905,990) optionally in view of Aeschlimann (USP 2,493,710).

Berry and Aeschlimann (USP 1,905,990) teach that it is known that the compounds possessing anticholinesterase activity. Applicants admit that it is known to use anticholinesterase agents in the treatment of the recited disorders, see lines 12-16 of page 1; lines 16-18 of page 2; and lines 16-22 of page 5 of the specification. Accordingly, it is considered obvious to use these known anticholinesterase agents for the treatment of the recited disorders. Aeschlimann (USP 2,493,170) is cited to show that the various R₁ and R₂ of the instant claims are recognized to be functionally equivalent in analogous compounds rendering such a modification of the primary reference compounds obvious.

Claims 23 and 24 are allowed.

It unclear what is meant by "(Rewritten)" in claims 23 and 24. It is suggested that such be deleted from the claims.

- 138 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 138 of 372 Serial No. 185451

Art Unit 126

The remaining references are cited as of interest. This is a continuation of applicant's earlier application S.N. 835,466. All rejected claims are drawn to the same invention claimed in the earlier application and could have been finally rejected on the grounds or art of record in the next Office action if they had been entered in the earlier application. Accordingly, THIS ACTION IS MADE FINAL even though it is a first action in this case. See MPEP 706.07(b).

Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a). The practice of automatically extending the shortened statutory period an additional month upon the filing of a timely first response to a final rejection has been discontinued by the Office. See 1021 TMOG 35.

A SHORTENED STATUTORY PERIOD FOR RESPONSE TO THIS FINAL ACTION IS SET TO EXPIRE THREE MONTHS FROM THE DATE OF THIS ACTION. IN THE EVENT A FIRST RESPONSE IS FILED WITHIN TWO MONTHS OF THE MAILING DATE OF THIS FINAL ACTION AND THE ADVISORY ACTION IS NOT MAILED UNTIL AFTER THE END OF THE THREE-MONTH SHORTENED STATUTORY PERIOD, THEN THE SHORTENED STATUTORY PERIOD WILL EXPIRE ON THE DATE THE ADVISORY ACTION IS MAILED, AND ANY EXTENSION FEE PURSUANT TO 37 CFR 1.136(a) WILL BE CALCULATED FROM THE MAILING DATE OF THE ADVISORY ACTION. IN NO EVENT WILL THE STATUTORY PERIOD FOR RESPONSE EXPIRE LATER THAN SIX MONTHS FROM THE DATE OF THIS FINAL ACTION.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Examiner Shippen whose telephone number is (703) 557-0805.

Any inquiry of a general nature or relating to the status of this application should be directed to the Group receptionist whose telephone number is (703) 557-3920.

Inhibition of Activated Factors II, VII, IX, and X by Synthetic Organic Compounds Directed against the Active-Site Seryl Residue¹

J.A. v.d. Woerd-de Lange, M.C.E. van Dam-Mieras, H.C. Hemker Department of Biochemistry, State University of Limburg, Maastricht, The Netherlands

Key Words. Thrombin + Factor VII, + Factor IX, + Factor X, + Inhibition + Organic compounds

2Ľ

Abstract. A series of 53 organic chemicals belonging to the groups of organic phosphates, sulforyl derivatives and carbamates were screened for their activity against the coagulation factors II, (thrombin), VII, IX, and X, Relatively specific inhibitors for the factors II, VII, and X, were found.

Introduction

In the past decade, much progress has been made in the characterization of the molecular processes underlying blood coagulation (table I). The activation reactions occurring in the coagulation pathways are highly specific, limited proteolysis reactions; the activated coagulation factors with the exception of factors V_a and VIII, belong to the class of the serine proteases. When comparing the amino acid sequences around the active-site serine residues of the coagulation factors with those of the pancreatic enzymes chymotrypsin, trypsin and elastase, it can be seen that a high degree of sequence homology exists among these proteins [4]. Furthermore, thrombin and factor X_a contain histidine and asparagin residues present in trypsin and chymotrypsin. In the case of thrombin and factor X_a ,

 1 This work has been described in full detail in the PhD thesis of the first author (Leyden University, 1976).

almost

acid facto acid the amino acid sequence of the active-site-bearing chain shows about 40– 45% sequence homology with trypsin. These data strongly suggest a close analogy between the coagulation factors and the pancreatic enzymes with respect to the activation of the zymogen and the catalytic mechanism of the active enzyme. Most likely, the substrate-binding pocket of the coagulation proteases will resemble that of trypsin because all coagulation proteases are specific towards basic amino acids (table I).

317

ê?

のないないないないである

Dick

The main differences between the coagulation factors and the digestive enzymes are the presence of a second protein chain in the coagulation factors not involved in the catalytic reaction per se and, perhaps as a consequence of the occurrence of this additional protein part, the higher substrate specificity of the coagulation factors.

Of course, the tertiary structure of the coagulation factors can only be proven by crystallographic studies of these enzymes and their (natural) substrates, but valuable information can be obtained from work with model substrates. In these studies, small changes in the substrate structure can be introduced, and the effects on the enzyme-substrate interaction brought about by these small changes can give useful information about the substrate-binding site and the catalytic site of the enzymes. The same holds true for inhibitors.

The aim of the work presented here was to find specific inhibitors for the different coagulation factors. The availability of such specific inhibitors would be useful for the study of the mechanism of blood coagulation and for the chemical determination of the coagulation factors. The stereochemistry of the specific inhibitors could contribute to our knowledge of the structure of the active site of the coagulation factors, and finally, the specific inhibitors might possibly be used therapeutically. In the experiments described here, the inhibitory capacity towards the activated coagulation factors was checked for a series of organic compounds belonging to the organic phosphates, the sulfanyl derivatives and the carbamates. Other groups have used the same approach, but the families of inhibitors investigated here have, to our knowledge, not been screened before [13, 16, 30, 31].

Materials and Methods

Isolation and Purification of the Factors $II_{\omega} VII_{\omega} IX_{\varepsilon}$ and X_{ε} [see also 40] As starting material, a coagulation factor concentrate containing the factors II, VII, IX, and X was prepared according to Swart [37]. The coagulation factor concentrate was activated with thromboplastin and Ca²⁺; the activated coagulation factors were separated

- 145

v.d. Woerd-de Lange/van Dam-Mieras/Hemker

by chromatography on a Whatman DE 32 column. (For the factors II, and VII, the best results were obtained when the isolation was carried out at 4 °C; for factor X₈ the best results were obtained when the isolation occurred at room temperature.) It was not possible to obtain factor IX, by this procedure, presumably because the starting material did not contain a sufficient amount of this factor. However, when the coagulation factor concentrate was activated with contact product, a factor IX, preparation could be obtained. This preparation always contained factor XI, (from the contact product) and was only used in preliminary experiments. It was also possible to isolate a factor VII, $-IX_{*} - X_{*}$ concentrate from serum and to isolate the factors VII, and X_{*} from this concentrate by chromatography on Sephadex G-100.

No attempt was made to obtain preparations that contained clotting factors that could be considered pure by the usual physicochemical criteria. Preparations that contained one coagulation factor in excess and no or trace activities of the others were considered sufficiently pure for our purposes. This is because the inhibitors are added in large molar excess anyhow, and the tests employed are sufficiently specific not to be influenced by trace amounts of inhibited or uninhibited coagulation factors other than the one under investigation.

Coagulation Factor Reagents

These reagents were prepared according to Koller et al. [20] and Loeliger and Koller [23] (factor II); according to Borchgrevink et al. [1] (factor V); according to Hernker et al. [12] (factor SVII and X); according to Denson [5] (factor VIL/X reagent). The factor VIII and factor IX reagents were obtained from a patient with a severe deficiency of the respective coegulation factor (<1 % activity) (440 ml blood collected in a siliconized glass vessel containing 60 ml ACD solution; storage at -20 °C). Factor XI reagent was obtained from congenital factor XI deficient plasma.

Thromboplastin was prepared from human brain according to Owren and Aas [32]. Contact product was prepared according to Niewiarowski et al. [29].

Determination of Coagulation Factors

For the estimation of the factors II, V, VII and X, one-stage estimations were carried out as described by van der Meer et al. [26]; the factors VIII and IX were estimated according to Veltkamp et al. [42]; factor XI was estimated according to Horowitz et al. [14].

Determination of the Activated Coagulation Factors

Factor II, was determined according to *Hemker* et al. [11]; factor VII, in the same system as factor VII [26] but with phospholipids instead of thromboplastin; the factors VIII, and IX (at the same system as used for factors VIII and IX (42] except that no kaolin was added to the test system and the incubation time of sample and reagent prior to recalcification was 1 min instead of 30 min; factor X₄ was determined in a one-stage test with a factor VII and X deficient reagent and phospholipid [26].

Inhibitors were the same as described by Meyers [27] and Meyers et al. [28].

Inhibition Experiments

The cosgulation factor (concentration about $10^{-4}-10^{-7}$ mol/l) was incubated with the inhibitor (concentration about $10^{-2}-10^{-4}$ mol/l) at pH 7.4, 37 °C, in siliconized glass or in plastic during 30 min (the concentrations of the coagulation factors were: thrombin,

12.5 NIH U/ml; factor VIIa, 0.4-0.6 U/ml; factor IXa, 0.15-0.25 U/mi; factor Xa, 0.5-0.75 U/ml; the final inhibitor concentration is given in tables II-V. If there was no or only a slight inhibition after 30 min, the enzymatic activity was tested again after 1, 2, 3 or, sometimes, 18 h.

All chemicals were p.a. grade from Merck. Protein concentrations were determined by measuring $E_{240\,nm}$ in a Zeiss PM Q 11 spectrophotometer. It was assumed that for prothrombin and thrombin, 1 extinction unit at 280 nm corresponds with 1.6 mg protein/ml [17, 37] and for all other protein mixtures with 1 mg protein/ml [36].

For a number of compounds the nuclear magnetic resonance (NMR) spectra were recorded in a Jeol PS 100 NMR apparatus; sweep time 250 s, sweep with 1,080 Hz (×0.01 ppm). The organic compounds were dissolved in CDCl₃; with the compounds No. 1, 7, 13, and 30, a little deuterated aceton was added.

Results and Discussion

Within a series of related inhibitors that are all able to react with an active-site serine residue, the actual course of the reaction is determined by the stereochemistry of the enzyme around the active-site residue [21]. Therefore, it can be expected that the differences between the coagulation factors will be reflected in their susceptibility towards related inhibitors with varying chemical structure. As far as small substrates are considered, this is the same phenomenon that accounts for substrate specificity. For this reason, the interaction of series of serine esterase inhibitors with the factors II_a, VII_a, IX_a, and X_a has been investigated.

The evaluation of the kinetic constants of the inhibition process was based on the following general scheme for the reaction of serine proteases with irreversible inhibitors.

 $E+1 \stackrel{k_{+1}}{\rightleftharpoons} E \cdot I \stackrel{k_{+2}}{\rightarrow} E_{inhibited} + P$

For this situation the steady-state approximation yields

 $\frac{d[E \cdot I]}{d_1} = k_{+1} ([E] [I] - K_i [E \cdot I]) = 0$

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 148 of 372 Inhibition of Activated Clotting Factors

321

If $[E_{tt}]$ stands for $[E] + [E \cdot I]$, the total amount of uninhibited enzyme, it can be deduced that the formation of the irreversibly inhibited enzyme proceeds with the velocity

 $v = \frac{-d[E_{aki}]}{dt} = k_{+2} \frac{[I]}{[I] + [K_i]} [E_{aki}].$

Integration of this differential equation yields

 $[E_{aki}]_i = [E_{aki}]_0 \exp(-k_{+2} \frac{[1]}{[1] + K_i} t).$

When the residual activity $([E_{akt}]/[E_{akt}]_0)$ after the incubation time t is plotted on semilogarithmic paper against the incubation time, a straight line is obtained. The slope of this line gives the apparent reaction constant (k_{app}) of the inactivation process. In formula:

 $k_{app} = -k_{+2} \frac{[1]}{[1] + K_i}$

hosphate

1 mmol

zyl-phos-

The values of k_{*2} and K_i can be obtained in the usual way by plotting $1/k_{spp}$ against 1/[1]. An example of this approach is given in figures 1 and 2.

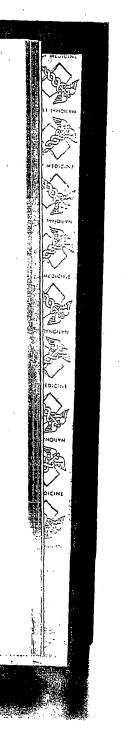

The inhibitors used in this study were first described by Myers and co-workers [26, 27] who tested their inhibitory activity towards acetylcholine esterases; their chemical structure is given in table II. Table II summarizes the results of a first screening of the inhibitory activity of the tested compounds towards the factors II_a, VII_a, IX_a and X_a. The k₃₀ values given in table II were calculated after a fixed constant time interval (30 min) without a control of the actual time course of the inactivation and, therefore, must be considered as a rough estimation of the inhibitory capacity of the compounds under consideration.

The compounds that seemed to be good and/or specific inhibitors during this first screening were tested again with the factors Π_{a} , $\nabla \Pi_{a}$, IX_{a} , and X_{a} , but this time the inhibitor concentration was the same with all four coagulation factors. The purity of the compounds used for this second screening was also checked by NMR spectroscopy. All compounds except compounds No. 13, 16, and 35 had a purity of at least 97%; the compounds No. 13, 16, and 35 seemed to be partially degraded. The results of this second screening are shown in italics in table II.

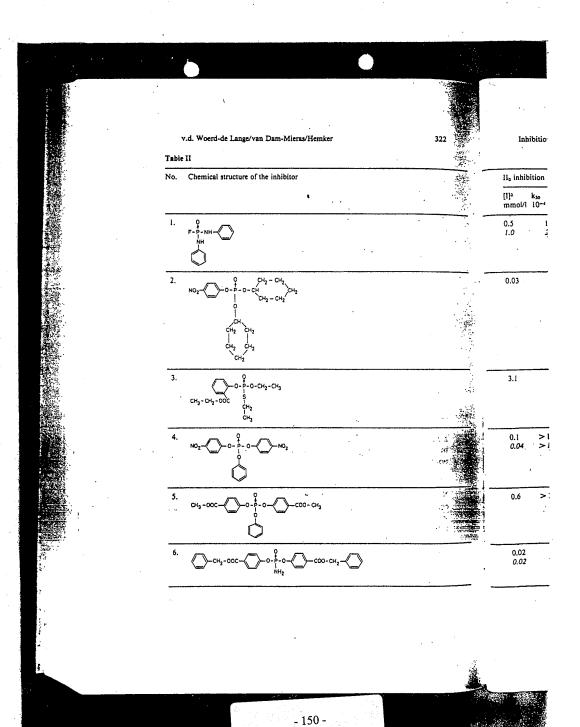

In order to facilitate the evaluation of the inhibitory capacity of the compounds tested, the k_{app} values for the inhibition of the coagulation factors with diisopropylfluorophosphate (DFP) are given in table III.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 165 of 372 v.d. Woerd-de Lange/van Dam-Mieras/Hemker Table III. Inhibition of the coagulation factors Π_a , VII_a , IX_a , and X_a by DFP

Coagulation factor	[DFP] mmol/i	k _{app} 10 ⁻⁴ min ⁻¹	-11-
11,	0.2	3,600	•
VII	6.9	60 .	
IX.	4.2		
X.	50 .	300.	

As judged from table II, there seem to occur rather specific inhibitors for the different coagulation factors among the organic compounds tested. The inhibitors that gave k_{30} values of 50×10^{-4} min⁻¹ in these screenings were used further to determine the k_{*2} and K_1 values of the inactivation processes (see below). As the data on the ineffective inhibitors gave information on the active site as well, we did not omit the negative results.

Tables IV-VI give the kinetic constants of the interaction of the factors II_4 , VII_4 , and X_4 , respectively, with their more or less specific inhibitors. For the determination of the $k_{\star 2}$ and K_4 values given in these tables, samples were taken from the incubation mixture at different times and the residual activity was measured. $k_{\star 2}$ and K_4 values were calculated as described above. By sampling from the incubation mixture and dilution with the substrate, the velocity of the inhibition reaction decreases and competition between the inhibitor and natural substrate occurs. Because of this dilution, and because the clotting times are short compared to the incubation times, it can be assumed that the inactivation reaction does not proceed further during the clotting test. For the same reasons, the inhibition of thromboplastin and of the coagulation factors in the reagent by the inhibitor during the activity determination can be neglected.

As can be deduced from table II, among the rather specific irreversible thrombin inhibitors, compounds No. 7 and 19 are the most promising. Furthermore, it can be seen in this table that compound No. 31 inhibits preferentially factor VII_a and compound No. 1 inhibits preferentially factor X_a. Compound No. 17 inhibits strongly all three factors, thrombin, VII_a and X_a. Of course, it should be kept in mind that table II shows the results of a rough first screening and gives no real kinetic constants.

When comparing the tables IV, V, and VI, it is striking that the 'specific' inhibitors all belong to the class of the organic phosphorus com-

irreversible promising. 31 inhibits ntially facombin, VII_a he results of

at the 'spe-

pounds. Moreover, all the irreversible thrombin inhibitors except compound No. 30 have the structure:

339

while compound No. 30 has the structure:

As can be seen in the general scheme for the reaction of serine proteases with irreversible inhibitors given above, the inhibitor first forms a reversible complex with the enzyme $[E \cdot I]$ which is further converted into an irreversible complex $[E_{inhibited}]$. K_1 reflects the affinity of the enzyme for the substrate, and k_2 is the reaction velocity of the irreversible step. As can be seen in table IV, the compounds with a

≻or ()--- CH2-

group in the R_2 position give relatively large k_2 values; the smallest K_4 values are found with the compounds which do not have aromatic groups in the R_2 portion.

From the results presented above it is clear that also small synthetic compounds can discriminate between the closely related compounds thrombin, factor VII, and factor X. The same conclusion was reached by other groups. Okamoto et al. [30] studied a series of thrombin inhibitors belonging to No-naphtalenesulfonyl-L-argine derivates. The structure of these inhibitors is characterized by three entities: a positively charged group (the amino acid argine), an aromatic group (the dansyl group, attached to the α -NH₂ group of arginine), and a hydrophobic carbon chain (attached to the carboxyl group of arginine; optimal chain length 3 or 4 C-atoms). These authors reported I_{50} values for these compounds in the range from 0.03 to 2 µmol/l when fibrinogen (3 µmol/l) or Na-benzoyl-L-phenylalanyl-L-valyl-L-arginine-p-nitroanilide (100 µmol/l) is used as a substrate. These values are of the same order of magnitude as the K_I values described in this article. Kettner and Shaw [16] reported inactivation experiments of thrombin by tetra- and tripeptide argine chloromethyl ketones. The peptide part of these substrates contains the amino acid sequence at the site cleaved by thrombin in its physiological substrates. The compounds Val-Pro-Arg-CH₂Cl (analog of the factor XIII cleavage site) and Ile-Pro-Arg-CH2Cl (analog of the pro-

thrombin cleavage site) inactivate thrombin by 50% in less than 25 min at a concentration of 7.5 \times 10⁻⁸ M. The compound Gly-Val-Arg-CH₂Cl [analog of the cleavage site in the fibrinogen A (a) chain] was effective at a concentration of 2 \times 10⁻⁶ mol/l. The authors reported that the compounds with the proline residue in the P₂ composition were markedly more reactive with thrombin than with plasma kallikrein, plasmin, urokinase, and factor X₄. Markwardt [25] described irreversible thrombin inhibitors derived from the competitive inhibitors benzylamine and benzamidine by introduction of a reactive fluorosulfonyl moiety at the aromatic ring. These compounds, aminomethyl and amidinofluorosulfonylbenzenes, possessed an inhibitory effect towards thrombin that surpassed that of DFP and phenylmethyl sulfonylfluoride (PMSF).

INSECTICIDAL ACTIVITY OF SUBSTITUTED PHENYL NMETHYLCARBAMATES

BY

J. MELTZER and H. B. A. WELLE*

N.V. Philips-Duphar, 's-Graveland and Institute for Organic Chemistry T.N.O., Utrecht, The Netherlands, respectively

The insecticidal and the acaricidal activities of a number of substituted phenyl N-methylcarbamates have been determined on the housefly (Musca domestica), the black bean aphid (Aphis fabae), the Colorado potato beetle (Leptinotarsa decemilneata), the cabbage worm (Pieris brassicae) and the carmine spider mite (Tetranychus cinnabarinus).

It is demonstrated that the thesis of Kolbezen, Metcalf & Fukuto (1954), Metcalf, Fukuto & Winton (1962) and Kohn, Ospenson & Moore (1965), that the meta-isomers of alkylphenyl N-methylcarbamates are the most active, has to be restricted to some insect groups (e.g. flies and caterpillars). In the case of the Colorado potato besite the o- and m-isomers were equally active; for aphids the o-isomer was the most toxic one.

This fact as well as the different responses of the test insects if the compounds are further alkylated indicate that various carbamates exhibit more or less selective activities. Most striking was the high level of activity in the new group of p-dimethylaminomethylphenyl N-methylcarbamates on most of the insects, in combination with a complete lack of toxicity to houseflies.

As previously pointed out by Kolbezen et al. (1954) and Metcalf et al. (1962), it was found that lengthening of the N-methyl group or N_iN -dialkylation resulted in loss of insecticidal activity.

The most active dimethylaminophenyl compounds were those with a p-dimethylamino group in combination with alkyl substituents in the 2,5- and 3,5-positions. Several p-dimethylaminomethylphenyl N-methylcarbamates with two or three alkyl substituents (except the 2,6combination) proved to be highly active, except on flies, to which they were virtually nontoxic. Greatest broad-spectrum activity was shown by 2,3-dimethyl-4-dimethylaminomethylphenyl N-methylcarbamate. It is demonstrated that by introducing a p-dimethylamino- or a p-dimethylaminomethyl group in alkylphenyl N-methylcarbamates a considerable gain in anticholinesterase and insecticidal activity is obtained.

1. Introduction

During the last 15 years a considerable number of carbamates have been investigated in respect of insecticidal activity. The compounds presented here include several members of a new class of carbamates, viz. the *p*-dimethylaminomethyl substituted phenyl-*N*-methyl carbamates. All these carbamates were synthesized by

the second author, while he was connected with the Institute for Organic Chemistry T.N.O.

Although many papers on carbamates have been published, so far no comparison of the action on four insect orders and Acarina has been made. The compounds were examined by using houseflies (Musca domestica L.), black bean aphids (Aphisfabae Scop.), larvae of the Colorado potato beetle (Leptinotarsa decemlineata Say), caterpillars of the large cabbage white (*Pieris brasicae* (L.)) and females of the carmine spider mite (*Tetranychus cinnabarinus* Boisd.),

人の方法語をいう考試へのでは認知を必く

このであるというということの

The synthesis and the physical data of most of the carbamates used in this study are described in the thesis of Welle (1964). Since then, several new 4-dimethylaminomethylphenyl N-methyl carbamates (Table I) have been synthesized by the method first published by him for the preparation of ring-alkylated 4-dimethylaminomethylphenyl N-methyl carbamates. The new N,N-dimethyl carbamate KD 1490 was prepared by condensing 2,3-dimethyl-4-dimethylaminomethyl phenol with dimethylcarbamoyl chloride in excess pyridine. The intermediate 2,6-dimethyl-4dimethylaminomethyl phenol could also be prepared by refluxing for 5 hours equimolecular quantities of 2,6-dimethyl phenol, dimethylamine and formaldehyde in water.

The carbamates were recrystallized from light petroleum b.p. 60-80°, with the exception of KD 1446, which was recrystallized from a methanol-ethanol mixture and of KD 1413 and 1435, which were used without purification. All boiling points and melting points are uncorrected.

3. Methods

3.1. Musca domestica

One ml of an acetonic solution of the test compound was poured into a Petri dish of 9 cm diameter. The dish was gently shaken, in order to distribute the substance evenly over the surface. The acetone was allowed to evaporate for exactly 10 minutes, after which the dish was closed. In the meantime a disc of filter paper of 2.5 cm diameter, soaked in water, was placed on the inner surface of the lid. Then the dishes were placed upside down, and provided with five male and five female flies. The experiments were carried out with at least three replicates. The dishes were kept at room temperature. Final mortality counts took place after 21 hours.

3.2. Aphis fabae

Potted seedlings of broad bean (Vicia faba L.) with two well-developed leaves were dipped in emulsions or solutions prepared by pouring an acetonic solution of the test compound into the appropriate amount of water. If necessary, an emulsifying agent was added. After the plants had been dried, they were placed in plexiglass

cylinders and infested with ten young adult aphids. Subsequently the cylinders were covered with lens paper and incubated in climatically conditioned racks at 24° C and 60—70% R.H. The racks were illuminated by tubular fluorescent lamps for 16 hours per day. Final mortality counts took place after 5 days.

3.3. Leptinotarsa decemlineata

Potato haulms were dipped in emulsions or solutions and placed in flasks filled with tap water. They were further treated like the broad-bean plants mentioned under 3.2, with the exception that the plants were infested with ten third-stage larvae of the Color do potato beetle and that the cylinders were left uncovered.

3.4. Pieris brassicae

172

人のなみとうとしていた。

Potted cauliflower seedlings were treated in the same manner as for the broad beans described above. The plants were infested with 10 third-stage caterpillars, and further treated like the broadbean plants mentioned under 3.2. Final mortality counts took place after 5 days.

3.5. Tetranychus cinnabarinus

Potted French beans were dipped like the other plants referred to above. After the plants had been dried, the leaves were provided with plexiglass cages of 2.5 cm diameter, in which ten young female mites were placed. Then the plants were incubated in the climatically conditioned racks and treated like the others mentioned Final mortality counts took place after 5 days.

3.6. Determination of anticholinesterase activity

Inhibition of fly head cholinesterase by the compounds involved was determined as follows. From frozen flies the heads were separated by sieving, and homogenized at 0° by means of an Ultraturrax homogenizer using 7.5 ml of 0.05 M tris-HCI buffer of pH 7.5 per gram of fly heads. The homogenate was sonicated during 3 \times 10 minutes, using a cooling bath at -10° . The resulting homogenate was passed through cheese cloth and the filtrate was centifuged at 25000 g and 4° for 60 minutes. The clear supernatant with an average cholinesterase activity of 4 μ moles of acetylthicocholine per ml per minute was used as the enzyme preparation. It was usually diluted 100-fold with cold 0.05 M tris HCI-buffer of pH 7.5.

Incubation with the inhibitors was effected by adding 0.3 ml of inhibitor solution in 0.05 M tris HCl, containing 5% ethanol, to 0.3 ml of the diluted cholinesterase preparation. After 30-minutes incubation at 25° the remaining cholinesterase activity was determined according to Ellman. Courtney, Andres & Featherbone (1961) by adding 0.3 ml of buffer solution, 0.3 ml of 5.5'-dithio-bis-(2-mitrobenzoate) reagent and 0.3 ml of acetylthiocholine solution, to a final concentration of 1 mmole/1 and measuring the optical density at 412 nm during 6 minutes, using a Unicam SP 600 spectrofotometer. The increase in optical density with time followed a linear course with all the inhibitors tested at all relevant concentrations. The

K mar Loch

The alkoxy compounds, however, were most active on all insects examined when the alkoxy group was in o-position. This is in agreement with the results of Metral & Fukuto (1965).

With the dimethylaminophenyl N-methylearbamates there was no significant difference between the activities of the o- and the *m*-isomers on aphids, beet and caterpillars. In this case, however, the o-isomer was the most active one on flies and spider mites. With the dimethylaminomethylphenyl N-methylcarbamater there was no significant difference between the activities of the o- and the *m*-isomer on flies, aphids and beetles. In this case, however, the *m*-isomer was the most active one on caterpillars.

In general we can see from the results in Table II that the o- and m-isomers are superior to the p-isomer. The superiority of o- or m-position depends on the test insect, however.

4.2. Insecticidal activity of mono- and dialkyl substituted compounds

Table III illustrates the influence of further alkylation by starting from either o- or m-isopropylphenyl N-methylcarbamates. In the case of the o-isomer, introduction of a methyl group in position 5 annihilated insecticidal activity; introduction of another isopropyl group in the 5-position resulted in loss of activity on aphids and beetles, but not on flies.

Finally, introduction of a methyl group in the 6-position dramatically reduced the toxicity to flies. Also the activity on aphids and caterpillars was lessened, but there was no adverse effect on the activity on beetles and spider mites.

From Tables II and III it is apparent that the response of the various test insects to the substituents and their positions is different and therefore more or less selective activities might be expected within the group of carbamates.

4.3. Insecticidal activity of phenyl N-alkyl and N,N-dialkylcarbamates

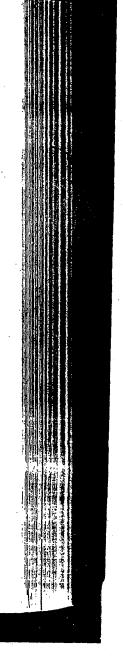

Several derivatives are listed in Tables IV & V. It is apparent that N-methylation of the carbamic ester enhanced toxicity, but that lengthening of the N-alkyl group ubolished toxicity. This is in agreement with the findings of Kolbezen *et al.* (1954). Furthermore the N-N-dimethyl compounds were less active than their corresponding N-methyl derivatives. In some cases this decrease in activity was found rather dramatic, as is illustrated in Table V. This is in accordance with analogous results of Metcalf *et al.* (1962).

4.4. Insecticidal activity of dimethylaminophenyl N-methylcarbamates

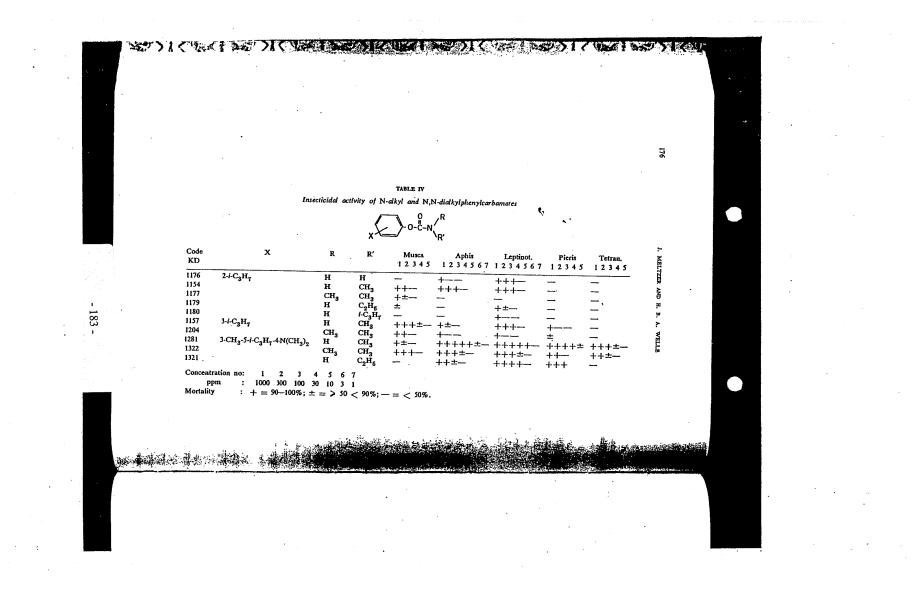

In Table VI the results obtained with the dimethylamino group in respectively the o- and m-positions are listed. Of the ortho-compounds the 4- and 5-alkyl derivatives were the most active. The meta-derivatives showed less activity.

Far greater insecticidal activities were encountered with the compounds that have the dimethylamino group in p-position, as can be seen in Table VII. Introduction of all alkyl groups shown in the table resulted in a gain of insecticidal activity, if they were introduced into the 2-, 3-, or 5-position. It seems that *m*-substitution produces insecticides that are superior to the o-substituted ones. This is in agreement with Kaeding, Shulgin & Kenaga (1965). The high toxicity of most of the listed compounds to aphids and beetles is in sharp contrast to the weak activity on flies. In the case of spider mites, too, these compounds showed only little activity, except the 3-isopropyl-5-methyl derivative. The weak action on flies may be caused by a lack of contact activity, or it may be the result of the capability of flies to decompose the compounds rapidly. In the case of the spider mites decomposition seems more likely, for the compounds concerned possess systemic properties and, if

Greatest broad-spectrum activity was shown by the 2,3-dimethyl derivative. In comparison with this substance the 2-isopropyl, the 2-methyl-5-isopropyl and the 2-isopropyl-5-methyl derivatives were equally toxic to aphids. On Colorado potato beetles the 2,3,5-trimethyl compound was even better; the 3,5-dimethyl and the 3methyl-5-ethyl derivatives were equal in activity. On spider mites the 2,3-dimethyl compound was superior to all others, though the 2,3,5-trimethyl and the 3-methyl-5-ethyl derivatives also showed considerable acaricidal activity.

4.6. Effect of the introduction of a p-dimethylamino and a p-dimethylaminomethyl group on the insecticidal and the anticholinesterase activities of some alkylphenyl N-methylcarbamates

When comparing the N-methyl carbamic esters of the alkyl phenols with their corresponding p-dimethylamino and p-dimethylaminomethyl derivatives, we observe the important effect on toxicity obtained by the introduction of the latter groups.

All cases listed in Table IX show a considerable gain in insecticidal activity by the introduction of the *p*-dimethylamino or the *p*-dimethylaminomethyl groups into the corresponding alkyl phenols, except on flies. In Table IX are also listed the cholinesterase inhibition values expressed as the negative logarithms of the dilutions required for 50% inhibition of fly-head cholinesterase. These values show clearly that the anticholinesterase activities also are enhanced as a result of the introduction of a dimethylamino or a dimethylaminomethyl group at the *p*-position.

Acknowledgements

The authors are much indebted to Drs. W. H. Dekker, and Messrs. J. D. van Beek, and W. A. Bosboom for assistance in the preparation of the compounds; to Dr. L. C. Post for the determination of the anticholinesterase activities of the compounds; and to Messrs. K. Olivier, B. J. van der Kolk, and A. H. Adriaansen for the execution of the entomological evaluation tests.

résumé ··

ACTIVITÉ INSECTICIDE DE N-MÉTHYLCARBAMATES DE PHÉNYLE SUBSTITUÉS

L'activité insecticide et acaricide de plusieurs N-méthylcarbamates de phényle substitués a été examinée sur la mouche domestique (Musca domestico), le puceron noir (Aphis fabae), le doryphore (Leptinotara decemilineata), la chenille de la piéride du chou (Pieris brassicae) et l'araignée rouge des serres (Tetranychus cinnabarinus). Les N-méthylcarbamates de phényle monosubstitués ne présentent qu'une faible activité acaricide. Les substances avec des substitutions en position méta ou ortho montrent une meilleure activité insecticide que celles avec la substitution en position para. Pour les mouches domestiques l'alcoylation en position méta se trouve donner les composés les plus actifs; pour les puerons l'alcoylation en position ortho était la plus efficace et pour les doryphores les combinaisons o- et m-étaient d'une activité égale. Les isomères ortho des dérivés alcoxylés étaient plus efficaces.

En cas de substitution par un groupe diméthylamino îl n'y a pas de différence importante quant à l'activité insecticide entre les positions ortho ou méta. En général il en est de même pour les substitutions par diméthylaminométhyle, bien que le m-isomère soit le plus efficace sur les chenilles.

L'introduction d'un deuxième groupe alcoyle dans un N-méthylcarbamaté de o- ou m-isopropylphényle change le spectre d'action. Un groupe 5-méthyle diminue beaucoup l'activité de l'o-isomère. Un groupe 5-siopropyle diminue l'activité sur les pucerons, mais pas sur les mouches. Quand un groupe 5-méthyle ou 5-isopropyle est introduit dans un N-méthylearbamate de m-isopropyl-phényle l'activité est généralement augmentée. L'introduction d'un groupe

- 188 -

J. MELTZER AND H. B. A. WELLE

182

くのないです。そのことのないというというというという。

6-méthyle diminue toutefois l'activité sur les mouches, les pucerons et les chenilles, mais pa sur les Coléoptères et les araignées rouges. Les N-méthylcarbamates de phényle s'avèrent posséder une meilleure activité que les com

Les N-méthylcarbamates de phényle s'avèrent possèder une meilleure activité que les combinaisons N,N-diméthylcarbamates correspondantes. Une prolongation du groupe N-alcoyité diminue également l'activité.

Les dérivés de N-méthylearbamates de 2-diméthylamino-phényle ont une plus grande activité que les isomères méta correspondants. On trouve toutefois la meilleure activité dans les Nméthylearbamates de 4-diméthylamino-phényle alcoylés. Tout groupe alcoyle à condition d'être introduit en fosition 2-, 3-, ou 5-augmente l'activité insecticide. Les composés métic substitués semblent encore un peu plus actifs que les dérivés d'o-alcoyle. La grande activité sur les pucerons contrasie nettement avec la faible activité sur les mouches et les araignées rouges. Le seul dérivé présentant une bonne activité sur les araignées rouges est le N-méthylcarbamate de 3-isopropyl-4-diméthylamino-5-méthylphényle.

Les N-méthylcarbamates de p-diméthylaminométhyl-phényle alcoylés présentent également une forte action insecticide, sauf sur les mouches. Le N-méthylcarbamate de 2, 3-diméthyldiméthylaminométhyl-phényle présente la plus grande activité et le plus large spectre d'action

A partir des N-méthylcarbamates d'alcoylphényle l'introduction d'un groupe p-diméthylamino ou p-diméthylamino-méthyle augmente considérablement l'activité anticholinestérasique aussi bien que l'activité insecticide.

(3)

(1), using the inverse variances as weighting factors.⁵ Thus estimates of k_1 , k_r and their standard errors are found. Rates of spontaneous reactivation of inhibited particulate AChE preparations were also measured by washing off the surplus inhibitor, analogous to the method of great dilution employed for studies on highly purified solubilized preparations. The estimates were found to differ significantly from those calculated by the first method, as will now be described. Particulate AChE was prepared from disphragm muscle by the "short method" of Berry and Rutland⁶ and the activity was determined by automatic continuous titration, using a twin-syringe assembly to keep the substrate econcentration constant. The saline medium was 0-15M KCl, pH 7+42, 38°, and the substrate was 55 mM acstylcholine. A typical progress curve of an inhibition experiment is illustrated. The normal velocity was first recorded (AB), the slope of AB giving a measure of ν_{-} A small volume of carbanate solution was added at B. The trace became curved as inhibition progressed, and it was ultimately recognized that a steady rate had been reached, the straight line CD providing a measure of ν_{-} . Any intermediate velocity ν_{-} is measured by the slope of the trace IIX, defined by the point J. To avoid the difficulty of drawing tangents, each short portion of the trace IIX, the alone of a trace to a circle of large radius, the point J beins, with sufficient accuracy, the midpoint of the arce IX. The tangent at J is parallel to the chord IX, the slope of which is the required measure of ν_{-} . Lo control experiments is which no carbanate was dided, the traces remained linear during the consumption of more titrants than was consumed during an inhibition run: no corrections for dilution were therefore required. Direct measurement of spontaneous reactivation was made by incubating a portion of preparation for 30 min at room temperature with enough carbamate to give 95-100 per cent inhibition. Thee

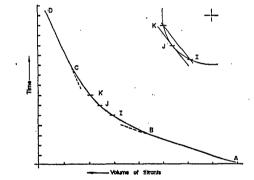

Fig. 1. Copy of trace of representative inhibition experiment. *AB*, normal velocity; *BC* diminishing velocity during approach to the steady "equilibrium" velocity *CD*. Inset, method of drawing tangent at *J* parallel to the chord *IK*. The curvature has been exaggerated to show clear separation of chord and tangent. See description in text.

portion was then washed three times by centrifugation, each with 30-40 vol. of 0-15M KCl. Since in earlier experiments with intact red cells such washing had caused complete reactivation of physo-stigmine-inhibited AChE⁷ it was assumed that washing had effectively removed free carbamate. In the present experiments washing caused only a lithe reactivation, which could be accounted for as the result of the time taken to wash. The washed inhibited preparation was then put up for assay with acetylcholine and the rate of recovery observed for 1:5-2 hr. Reactivation was assumed to be first order with respect to (v_-0), using a washed uninhibited portion to estimate p... In all cases the data were graphed to verify that the appropriate first-order equation was obeyed, before computing the results. before computing the results.

HEC 13 AMILIN GROUP 120 Dear Sir: This is in reply to the final rejection of October 11, 1988. (Please amend the application as follows: IN THE CLAIMS

Claims 23 and 24 line 1 cancel -- (Rewritten) --

REMARKS

45

The claims in the application are claims 14 to 25. The allowance of claims 23 and 24 is appreciated.

Attached hereto is a copy of a portion of Volume 29 of Advances in Behavioral Biology pages 539 to 549. This article sets forth the unexpected advantages of the compounds covered by the claims.

It is true, as the Examiner pointed out, that Aeschlimann 1,905,990 has prepared a compound with a dialkylaminoalkyl substituent, but he disclosed no such compound wherein, as in all the compounds of the present application, the alkyl between the

- 193 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 193 of 372

phenyl and the amino is <u>branched</u>. Although according to U. S. patent 2,493,710 he prepared at a later date a compound with such a branched alkyl, this was not a dialkylamino compound. Thus present inventor has combined the features of the branched alkyl bridge and the tertiary nitrogen.

Two

Second, though it is true that miotine as well as the Meltzer compound (identified in the present application under the code number RA₁₀) both do present the branched alkyl bridge and the tertiary nitrogen, and thus are structurally closer to the new compounds than the Aeschlimann compounds, it is stressed that by introducing for the first time high alkyl substituents than methyl on the nitrogen of the carbamate moiety, the applicant has prepared high homologues of miotine (which bears a hydrogen and a methyl) and the Meltzer compound (which bears two methyls), which surprisingly exhibit very significant advantages not only over physostigmine and the Aeschlimann art, but also over miotine and the Meltzer compound. It was totally unexpected that the mere substitution of a methyl by a higher alkyl would significantly improve the pharmacological profile of these compounds.

It was our intention to file an affidavit under Rule 132 attesting to the superiority of the claimed compounds. It was just realized that all the data available for this showing are already disclosed in the patent or specifications and in a publication of the inventors, which appeared in the priority year. This data,

- 194 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 194 of 372

Three

2

summarized below, appears to be adequate for establishing superiority not only of RA_7 versus RA_{10} but also of all the higher alkyl homologues of the present invention versus RA_{10} or miotine.

As mentioned in the description or the publication, physostigmine has serious disadvantages such as a low therapeutic ratio and a short duration of action which necessitates frequent dosing. The known carbamates have similar disadvantages and thus have never been used as acetylcholinesterase inhibitors: miotine (used as miotic) has a low therapeutic ratio and a short duration of action.

The new carbamates with at least one alkyl higher than methyl on the N of the carbamate unexpectedly exhibit a higher therapeutic ratio than miotine and a longer duration of action than miotine and RA_{10} . This can be seen in Table 3 of the patent application specification and Table 4 of the publication as regards the therapeutic ratio and in Table 2 of the patent application specification and table 3 of the publication (% inhibited by ED_{10} after 3 hours) as regards the duration of action.

The longer duration of action seems to be an advantage shared by all the higher homologues of RA_{10} as defined above. This is very important and totally unexpected.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 195 of 372 Page Four

It is believed that based on this showing the compounds defined by the claims are patentable over the references. For the reasons given hereinabove reconsideration of the rejection of the claims is respectively requested.

Respectfully submitted,

Richard T. Laughlin Attorney for Applicant Laughlin, Markensohn, Lagani & Pegg 129 Headquarters Plaza

Morristown, New Jersey 07960 (201)-539-0080

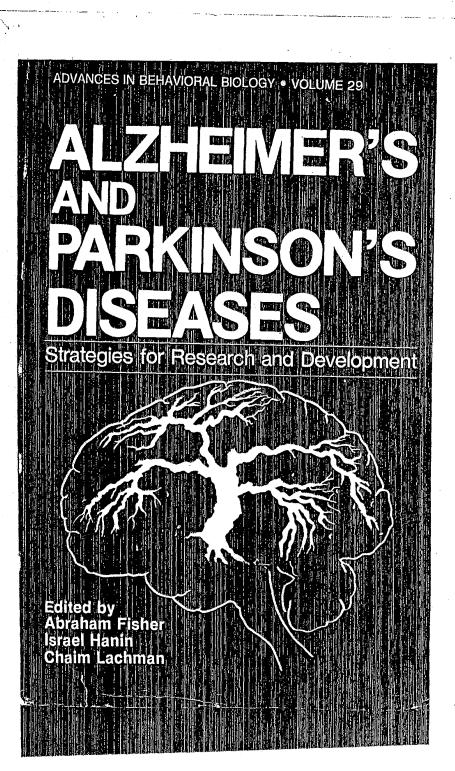

CERTIFICATE UNDER 37 CFR 1.8 (a)

I hereby certify that this amendment is being deposited with the United States Postal Service First class postage prepaid in an envelope addressed to: Commissioner of Patents and Trademarks, Washington, D. C. 20231, on December 9, 1988.

INTRODUCTION

In dementia of the Alzheimer type there is a selective loss in the cerebral cortex of choline acetyltransferase (CAT), the enzyme that synthesizes acetylcholine $(ACh)^{1/2}$. The degree of dementia and memory impairment that occurs in this condition is yell correlated with the decrement in cortical cholinergic transmission². Horeover, scoolamine, a cholinergic antagonist, can cause memory impairment in normal individuals similar to that in aging⁴. These findings suggest that impaired cortical cholinergic transmission may be at least in part responsible for the symptomatology of Alzheimer disesse. In support of this suggestion it was found that physostigmine, which prevents the destruction of ACh, can cause memory improvement in Alzheimer patients⁵. The extent of improvement of the symptomatology was closely related to the degree of inhibition of acetylcholinesterase (AChE) in the spinal fluid, and thus to the amount of physostigmine reaching the contral nervous system⁵.

As potential therapy for dementia, physostigmine has a number of disadvantages, the most serious of which is its low therapeutic ratio. In most studies in which any improvement in symptomatology was reported, the dose range in which this occurred was very narrow $(1-2.5_{\rm mod}, 1.5_{\rm mod}, 1.5_{\rm mod})$, with higher doses causing a decrement in performance or distressing side effects due to peripheral cholinergic overactivity. Another disadvantage is its low chemical stability⁵ and short duration of action, which necessitate frequent dosing. Its oral bioavailability is also unpredictable, and it only appears to produce improvement in Alzheimer symptomatology by this route if it is given with lecithin⁹.

The purpose of the present study was to synthesize anticholin-esterase agents which readily reach the CNS after parenteral and oral administration; which have a higher therapeutic ratio than that of phy-sostigmine, greater chemical stability, and a longer duration of action. These advantages should make them more suitable than physostigmine for the long term treatment of conditions associated with a deficit in cholinergic transmission in the central nervous system.

Apart from physostigmine, all of the carbemate anticholinesterases which are used medicinally, have a quaternary N-function and thus do not

539

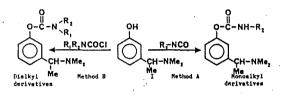

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 199 of 372

penetrate the CNS to any significant extent¹⁰. Almost all the synthetic carbamates with a tertiary N were designed as insecticides, and have a monomethyl substituent on the N of the carbamate. They are thus relatively unstable at physiological pH and of short duration¹⁰. One such carbamate, mictine, has only been used clinically as a mictic¹¹. The dimethyl analogue, has only been used as an insecticide¹². The effect of other mono or dialkyl substitution on the N of the carbamate of this structure on AChE activity <u>in vitro</u> or <u>in vivo</u> does not appear to have been studied. Accordingly we prepared and tested a series of mono and alkyl derivatives of mictine, the activities of some of which are described. (A patent has been applied for the novel structures). Particular emphasis is placed on their abilities to inhibit brain AChE and on their relative toxicities.

METHODS

Preparation of mono- and di-substituted phenyl carbamates

The N-monoalkyl and N,N-dialkyl substituted phenyl carbamates were synthesized from d-m-hydroxyphenylethyl-dimethylamine (I), which was itself prepared according to the procedure described by Stedman' with minor modifications, as shown in the scheme below:

For the synthesis of the monoalkylphenyl carbamates, a 2-3 fold molar excess of the alkyl isocyanate was reacted with phenol I in dry benzene at room temperature overnight (see Scheme 1 method A). For the benzene at room temperature overnight (see Scheme 1 method A). For the synthesis of the N,N-dialkyl-substituted phenyl carbamates, 1.5-2 fold molar excess of the corresponding carbamayl chloride was allowed to react with phenol I in dry acetonitrile in the presence of a similar excess of sodium hydride (see Scheme 1 method B). The weak acidity of phenol I required the use of a strong base such as sodium hydride to produce the phenolate which acts as the nucleophile.

All carbamates were obtained as hydrochloride salts by saturating their etheral solutions with HCl(g). These salts were purified by re-orystallization from ethanol-ether. Furity was assessed by t.l.c. on precoated silica gel plates, reversed-phase HPLC, elemental microchem-ical analysis and H-n.m.r.

Measurement of antiAChE activity in vitro

Male mice (Sabra strain) weighing 30-40g were sacrificed by cervical dislocation and the whole brain minus cerebellum rapidly removed and weighed. The brains from 10 mice were homogenized in 1ml/ 100g wet weight phosphate buffer 0.1M pH 8.0, centrifuged at 12.000 rpm and the supernatant, discarded. The pellet was mixed with a similar volume as above of buffer 0.1M pH 8.0 containing 1% Triton using a Yortex Genie at maximum speed for 1 min. The mixture was centrifuged and the supernatant which contained most of the solubilized AChE was used for subsequent determinations of anticholinesterase activity. for subsequent determinations of anticholinesterase activity.

The effect of at least three different concentrations of each inhibitor was measured on the rate of hydrolysis of 20 µl of 0.075M acetylthiocholine iodide by 25 µl of solubilized AChE. The enzyme was incubated with the inhibitor for periods ranging from 2-180 mins at $37^{\circ}C$ before the addition of the substrate. The rate of hydrolysis was measured by the spectrophotometric method of Ellman et al.¹³. From these data the molar concentration of each agent that inhibited the activity of the enzyme by 50% (IC50) at the time of peak activity (30-120 min) was calculated.

Measurement of antiAChE activity in vivo

At least three doses of each drug were administered subcutaneously (s.c.) or orally to mice. Animals were sacrificed at different times ranging from 0.25 to 7 hours after drug administration. The presence or absence of side effects reminiscent of cholinergic hyperactivity (tremors, salivation, defecation, fasciculations, difficulty in breathing) were noted for each drug. The brain was rapidly removed at the given times stated above and the enzyme AChE extracted and solubilized as described in the previous section. The activity of the enzyme removed from drug treated mice was measured as described above and compared with that of mice given saline (control).

Assessment of scute toxicity

1. Relationship

Table

Male mice were given one of at least three different doses of each drug orally or s.c., a minimum of 10 mice being alotted to each dose. The number of animals that died in each group within 3 hours was determined, and from these data the LD50 (dose in umoles/kg which was lethal to 50% of the mice) was computed.

relative

between

Capacity factor defined as ratio of difference between retention time of the compound and that of the unretained solute to that of the unretained solute on a reversed phase (C18) HFLC column (solvent; 70% of 0.1% aqueous TFA soln. + 30% methanol). This factor is a measure of the relative hydrophobicity of the compound.

541

- 201 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 201 of 372 This experiment was repeated in animals which had been pretreated 15 mins previously with either atropine methylnitrate (ATNN 5mg/kg) which block only peripheral muscarinic receptors¹⁴ or atropine sulphate, (5mg/kg) which blocks both central and peripheral muscarinic receptors, and the anticholinesterase agents were injected s.c.

Measurement of antiAChE activity in different areas of rat brain

Male and fomale Sabra rats weighing 150-350g were injected s.c. with either saline, physostigmine 0.15mg/kg, RA6 1.0mg/kg. RA7 0.5mg/kg or RA15 0.5mg/kg (six animals were used for each treatment group). The cerebral cortex, hippocampus, corpus striatum and medulla oblongata were rapidly dissected on ice, weighed individually, homogenized in phosphate buffer and extracted and solubilized as described above for mouse brain. The activity of the enzyme from treated and control rats was also measured as described above.

The percent inhibition of AChE by each drug was computed for the different brain areas by comparison with the pooled mean of the control values (n=12) for each area.

Statistical analyses. Data from the experiment on the effects of drugs on AChE in different areas of rat brain were analysed by 2-way analysis of variance, followed by Neuman Keul's post hoc comparisons.

RESULTS

- - -

The relationship between the N alkyl substituents, relative hydrophobioity and molar refractivity is shown in Table 1. In general both the latter parameters increased as the size of the mono or disubstituted alkyl groups became larger.

Table 2. The effect of the novel compounds on AChE activity in mouse brain in vitro and in vivo

AntiAChE activity in mouse brain

The inhibitory activities of the novel carbamates and physostigmine on a solubilized preparation of AChE of mouse whole brain in vitro are summarized in Table 2. The monomethyl substituted derivative, R42, (miotine), was found to be the most potent inhibitor of brain AChE, both in vitro and in vivo. It has a rapid onset of action which is of a relatively short duration (90-120 min in vivo) like that of physo-stigmine (Table 3). Increase in the size of the alkyl radical to sthyl (RA6), resulted in a large reduction (>30 fold) in <u>in vitro</u> activity, but only a 6-fold decrease, in vivo. Larger substituents, n-propyl, and c-hexyl proved to be more potent inhibitors than N-ethyl, or N-allyl, but less so, than N-methyl, while introduction of an i-propyl group resulted in a 1000-fold decrease in AChE activity. In general, all the novel monosubstituted carbamates were more active <u>in vivo</u> by factors of 2-20 times, then one would have expected from the activities on the isolated enzyme when compared to physostigmine or miotine. [Table 2].

Comparison of the data in Tables 1 and 2, reveals that there is no correlation between in vitro anticholinesterase activity (IC50) of the monosubstituted carbamates and any of the physical parameters examined, e.g. chain length in extended conformation, methyl (RA2), <ethyl (RA6), (RA12); which we can be conformation in the conformation of the comparameters of

The disubstituted carbamates were generally less active in vitro than the corresponding monosubstituted derivatives. Among the three analogues there appeared to be a negative correlation between inhibitory potency, and both hydrophobicity and molar refractivity volume.

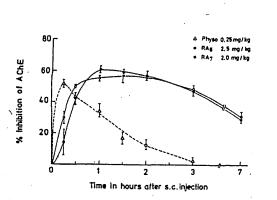

Introduction of a second methyl group on the N of the carbamate caused only a small reduction in inhibitory activity. However, when one group was substituted by ethyl, (RA7) <u>in vitro</u> activity fell by 2 orders of magnitude. Surprisingly, this compound was considerably more potent than one would have expected from the <u>in vitro</u> data when it was injected into the whole animal Under these conditions its activity was only reduced to 1/3rd of that of the dimethyl derivative.

- 203 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 203 of 372

The diethyl substituted compound, RA8, proved to be a weak inhibitor, with an IC50 of only 35 μ K. All the compounds having a substitutent larger than methyl, had a slower onset of action, both on the isolated solubilized enzyme and in the whole enimel, and a longer duration of action in vivo, than methyl derivatives and physostignine (Table 3). The latter drugs ceased to inhibit brain AChE 2-3 hours after injection, while all the novel compounds with alkyl substituents larger than methyl caused significant inhibition for 3-7 hours [Fig. 1].

The maximum inhibition of the brain AChE after oral administration of any dose of physostigmine, did not exceed 50%. This was achieved at about a 4 times larger dose than the ED50 after s.c. injoction [Table 3]. Higher doses, caused marked respiratory distress, fasciculations and tremors. With the possible exception of RA10, a greater than 70% inhibition of brain AChE was obtained after oral administration of all the other compounds. The incidence of untoward symptoms due to cholinergic overactivity was also much lower with these compounds.

Acute toxicity

The acute toxicity of the anticholinesterase agents is shown in Table 4, when these were given alone or after pretreatment with ATMN or atropine. The therepeutic ratios, defined as the LD50/ED50, of all the compounds except RA2 were about 3 times greater than that of physostigmine, which was only 3.5. Blockade of peripheral muscarinic receptors by ATMN, caused a similar increase in LD50 (1.5-2.2 fold) in all the compounds. When muscarinic receptors in the CNS were also blocked by

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 204 of 372 atropine, the LD50 of physostigmine and the majority of the compounds rose by 2.2-3.5 fold. The disubstitued compounds, RA10 and RA7, however, showed a 6-11 fold increase in LD50.

AntiAChE activity in different areas of rat brain

The AChE activity of different areas of rat brain is shown in Table 5. While the cerebral cortex, hippocampus and medulla showed approximately similar amounts of enzyme activity, that in the striatum was about 10-fold higher.

Fig. 2 shows the effect of physostigmine and three novel carbamates on AChE activity in 4 areas of rat brain. The doses of the 4 drugs were chosen which gave the same degree of inhibition of AChE in the cerebral cortex. At these doses, RAG, RA7 and RA15 caused significantly less inhibition in the medulla (PC0.05) and RA7 caused a lower effect in the striatum, than in the cortex. RA6 and RA7 also produced significantly less inhibition in the medulla than did physostigmine. The effect of RA15 in the hippocampus was significantly greater than that of all the other drugs when given at a dose that inhibited the enzyme in the cortex to a similar extent.

DISCUSSION

In the present series of carbamate derivatives in vitro inhibition (IC50) of brain AChE varied 3000-fold from the most to least potent drug. In the mono-alkylated derivatives, no correlation was found between the IC50 values and hydrophobicity, molar refractivity, or length of the most extended conformation of the carbamate moiety. Thus, the largest substituent, o-hexyl, showed a much smaller decrease in inhibitory potency compared to mictime, than did the monoethyl derivative. On the other hand, introduction of an i-propyl resulted in a 1000-fold decrease in activity, while n-propyl, which has the same molar refractivity and hydrophobicity, was only 10 times less potent than mictime. miotine.

Medulla (12)	5.55+0.27
Corpus striatum (11)	27.10 <u>+</u> 1.10

Furthermore, no clear correlation could be demonstrated between anti AChE activity of the carbamates on the isolated enzyme taken from mouse brain and that obtained <u>ex vivo</u> after injection of the drug into mice. All the novel carbamates were relatively much more active in vivo in relation to physostigmine or miotine, than <u>in vitro</u>. This discrepancy was especially evident in the disubstituted analogues, RA7 and RA8. These compounds were 50-60 times more effective <u>in vivo</u> than one would have predicted from the data on the isolated enzyme.

The relatively greater activity of the larger monoalkyl and dialkyl substituted drugs in the whole animal may be due to a greater chemical stability. It has previously been shown that monomethyl carbamates are much less stable that dimethyl derivatives at physiolgical μ ^{HO}. The relatively long duration of enzyme inhibition (>7 hours) of all the larger alkyl derivatives <u>in vivo</u>, (compared with about 2 hours for physostigmine) suggests that they are chemically more stable at body pH and are more slowly metabolized.

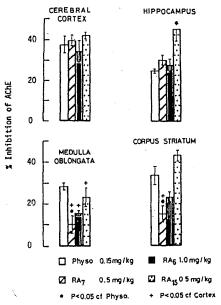

Another reason for the greater in vivo activity of the RA compounds may be their higher lipid solubility, which should enable a greater proportion of the drug to reach the central nervous system. This property could also explain the more efficient absorption from the gastro-intestinal tract of several of these carbamates, particularly RA7 and RA8.

and RA8. Comparison of the soute toxicity of the RA compounds with that of physostigmine in mice, showed the former to have considerably higher therapeutic ratios, 10-12, compared with 3.5 for physostigmine and 4.5 for miotime. Furthermore, signs of cholinergic overactivity, fasciculations, tremore, salivation and defecation were seen at the ED50 dose (which caused 50% inhibition of the whole brain enzyme) of physostigmine but not of the other carbamates. The greater therapeutic ratios of the RA compounds appears at first sight to be surprising since the mortality is a direct result of AChE inhibition, and is due to the presence of excess AChE in the present study by pretreating the animals with atropine which prevents the centrally induced respiratory depression⁴, and which raises the LD50 of all the monosubstituted carbamates by a factor of about 3. In the presence of such muscarinic blockade, deeth from overdose then results from respiratory muscle paralysis due to excess ACh at the neuronuscular junction. At this stage, no antidotes are effective and only artificial ventilation can prevent loss of life. The fact that the LD50 of RA7 can be increased 11-fold by muscarinic receptor blockade, demonstrates a relative lack of effect of this drug on somatic muscle. This is a distinct advantage in terms of its therapeutic potential.

2. Inhibition of AChE in different areas of rnt brain by physostigmine and 3 novel carbamates
* Significantly different from physostigmine in same brain area P<0.05
+ Significantly different from value in cortex for same drug P<0.05 Fig.

In order to explain the lower toxicity of the RA compounds an attempt was made to determine whether they have a selective effect in different brain areas. It was found that physostigmine inhibited AChE to the same extent in four areas in the rat brain in spite of the fact that these areas contain different amounts of enzyme. In contrast, RA6, RA7 and RA15 given in dozes which blocked AChE in the cerebral cortex by 35-40%, caused significantly less inhibition in the medulla. The most striking difference was seen with RA7 which only reduced AChE in the medulla by 10%. Since the ED50 was determined in whole brain, of which the cerebral cortex contributes a major portion compared to the medulla, this differential effect of the drugs serves to explain their higher therapeutic ratio. therapeutic ratio.

547

- 207 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 207 of 372

The selective effect may result from a difference in the distribution of the drugs to these brain areas. Alternatively, it may be due to the presence of AChE iscenzymes, which could have different affinities for the inhibitors. Such a differential sensitivity of multiple forms of AChE has been demonstrated for organophosphates¹⁰. It remains to be determined whether multiple forms of AChE are present in rat brain, and whether they are selectively inhibited by RA compounds.

The data from this study show that larger monoalkyl or dialkyl derivatives of miotine, possess several advantages over physostigmine for potential therapeutic application in conditions involving reduced cholinergic transmission in the cerebral cortex. If the therapeutic effect of these agents results from inhibition of AChE in this brain area, compounds RA6, RA15, RA14, RA12, RA10, RA7 and RA6 all have considerably higher therapeutic ratios than physostigmine and show fever side effects at ED50 doses. This may be due to a selective inhibition al advantage in the fact that the lethal effects of drug overdose can be prevented by atropine. While the duration of significant enzyme inhibition after physostigmine is less than 2 hours, all the above drugs (except RA10) act for periods of 7 hours or more after a single injection. The longer duration is a distinct advantage in the treatment of chronic conditions such as Alzheimer's disease. Furthermore, RA6, RA7 and RA8 show a significantly more efficient oral absorption since their potencies when given by this route closely resemble those after parenteral administration. The data from this study show that larger monoalkyl or dialkyl

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 210 of 372

Serial No. 185,451 Art Unit 126

Applicants' evidence ("Advances in Behavioral Biology," Vol. 29, pages 539-549) has not been considered since a good and sufficient reason has not been presented why the evidence could not have been presented earlier. Moreover, it does not appear that such evidence would put the application in condition for allowance. Also, note MPEP 609.

The evidence presented in the specification has been considered but not found persuasive of patentability. Fisrt, while Aeschlimann (USP 1,905,990) refers to physostigamine, this compound is not representative of the compounds of the reference, e.g., compound of example 2. As such, it is considered that the compounds of Aeschlimann have not been compared. Second, it is not seen that miotine and the compound of Meltzer are structurally closer than the compounds of Aeschlimann. Third, the showing is not commensurate in scope with the claims. While compound RA6 is a homologue of miotine, the claims still read on other compounds that are just as structurally close or closer to the prior art compounds. For example, homologues and isomers of the Aeschlimann compounds wherein R1 and R2 are methyl, R3 is hydrogen and R4 and R5 are ethyl; the homologues of miotine wherein one or both of R4 and R5 is ethyl or R3 is methyl; and homologues and isomers of the Meltzer compound wherein R1, R2, R4 or R5 is ethyl or R3 is methyl. Fourth, the evidence of Talbe 3 would suggest that the Meltzer compound are comparable to the instantly claimed compounds. Fifth, the method claims read on the use of the prior art compounds represented by applicants to be inferior or

AMENDMENT UNDER RULE 115

Hon. Commissioner of Patents and Trademarks Washington, D.C. 20231

12×

SIR:

This is in response to the Office Action mailed on October 11, 1988 and setting a shortened statutory period for response of three months to expire on January 11, 1989. Applicants petition that, if required, the time for response be extended and the corresponding fee be charged. The Commissioner is hereby authorized to charge any additional fees which may be required to Acct. No. 11-0224. Applicants further respectfully request that this response be accepted as a bona fide effort to meet any potential response requirements outstanding and due in the above

captioned matter.

01313189

Please amend the application as follows:

1

- 216 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 216 of 372 IN THE CLAIMS:

Please cancel claims 14 to 17 without prejudice to their reintroduction at a later point in time.

/ le. (amended) [A compound of claim 14 which is] Nethyl,N-methyl-3[1-(dimethylamino)ethyl]phenyl carbamate and [or] pharmacologically acceptable salts thereof.

Please cancel claims 19 to 22 and 25 without prejudice to their reintroduction at a later point in time.

REMARKS

Claims 14 to 25 were in the case. The present amendment cancels claims 14 to 17, 19 to 32 and 25 without prejudice to their reintroduction at a later point in time.

Applicants' attorney thanks the Examiner Michael L. Shippen for the interview kindly granted on February 22, 1989. The courtesies exchanged during the interview are very much appreciated. During the interview the claims and the references of record were considered. Applicants' attorney presented arguments distinguishing the composition disclosed in claim 18 of the instant application from the teachings of the references substantially as set forth below.

2

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 217 of 372 It appeared that the application provided some statements, which indicate that the N-ethyl,N-methyl-3[l-(dimethylamino)ethyl]phenyl carbamate of claim 18 is patentably distinguished over the art of record.

It was noted during the interview that the closest art of record appeared to be the compound code 1207 on page 177, first item of Table V of the journal article "Insecticidal Activity of Substituted Phenyl N-Methylcarbamates" by J. Meltzer and H. B. A. Welle in Ent. exp. & appl. 12 (1969), 169 -172. This conpound is N-methyl-3(1-(dimethylamino)ethyllphenyl carbamate. Whereas this reference compound has an active hydrogen atom left at the nitrogen of the carbamate group, the present invention has this hydrogen atom substituted by ethyl.

The reference "Inhibition of Activated Factors 11, VII, IX, and X by Synthetic Organic Compounds Directed against the Active-Site Seryl Residue" by J. A. v. d. Woerdde Lange et al. in Haemostasis 10, 315 -347 (1981) also lists as compound #37 on page 332 the same compound as the above reference, that is N-methyl-3[l-(dimethylamino)ethyl]phenyl carbamate.

It is submitted that the compound of claim 18 is clearly distinguished from the compound recited in these two

3

- 218 -

references by the ethyl group substituting a hydrogen atom at the carbamate nitrogen atom.

This compound of the references is further recited in the specification of the applicants and listed in the tables of the present application as a reference compound labelled Miotine or Miotine HCl for the hydrochloric acid salt (compare Page 19, Table 1, second item; Page 20, Table 2, second item; and Page 21, Table 3, second item).

The same Tables contain the compound of claim 18 designated as RA7 HCl (Table 1) or RA7 (Tables 2 and 3). As stated on Page 17, lines 15 to 25, the acetylcholinesterase inhibition was determined after subcutaneous administration. While the potency of the reference compound miotine is 5 percent on a relative scale of 100 percent referring to the activity of physostigmine, the invention compound of claim 18 was found to have a potency of 41 or more than eight times as large.

Table 3 compares the acute toxicity of carbamates in mice. This toxicity was determined as set forth in the specification on page 17, line 26 to page 18, line 14. The first data column of Table 3 shows that the lethal dose of the reference compound Miotine was 4.5, whereas the invention compound of claim 18 exhibited a lethal dose of

- 219 -

46, which is more than ten times as large. Thus the side effects of the invention compound of claim 18 appear to be much less than those of the reference compound Miotine. Furthermore, data column 2 of Table 3 indicates that the degree of protection afforded by pretreatment with atropine has only a value of 2.4 for the reference compound Miotine, whereas the invention compound of claim 18 has a value of 10.4, which is more than four times as large. Data column 3 of Table 3 calculates the therapeutic ratio and finds that the reference compound Miotine has a therapeutic ratio of 4.9, whereas the invention compound of claim 18 has a therapeutic ratio of of 12.4, which is more than 2.5 times as high.

The applicants' specification provides on pages 22 to 26 a comparison of compounds according to the invention to reference compounds. The last two paragraphs on page 23 show a general superiority of certain compounds including the compound of claim 18 over the reference compound Miotine. Page 24, lines 4 and 5 demonstrates that the invention compound of claim 18 shows a longer time effectivenessas compared to other compounds considered including the reference compound Miotine. This leads to particular advantages in the treatment of certain diseases

5

- 220 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 220 of 372 as stated on page 24, lines 8 to 14. Furthermore, page 24, lines 15 to 23 discloses that there is a more effective absorption of the invention compound of claim 18 as compared to the reference compound Miotine.

In view of the clear structural difference of the invention compound of claim 18 as compared with what appears to be the closest reference Miotine, as well as in view of the advantageous pharmacological properties of the invention compound of claim 18 over the reference Miotine, it is respectfully submitted that the compound of claim 18 *A*ethyl,N-methyl-3[l-(dimethylamino)ethyl]phenyl carbamate is clearly patentable over Miotine and the art of record.

The present amendment is intended to present a claim which is deemed to be in better form for appeal.

It is submitted that a large part of the present submission is inherently contained in the application. Therefore, it was not appropriate to present this focused consideration prior to the cancellation of claims 14 to 17, 19 to 22 and 25.

The present amendments were not presented earlier since they are in response to the specific combination of references performed in the Final Rejection. The way of combination of references in the Final rejection is

б

- 221 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 221 of 372

unexpected and new to the Applicants.

The present amendment is deemed to remove and/or simplify issues which would otherwise require consideration in an appeal. The present amendment is further submitted to adopt suggestions gathered from the Office Actions.

The present amendment is believed not to present any new issues since the claim is substantially based on a previously presented claim and since the application provides clear support for particular advantages associated with the invention compound of claim 18.

The present amendment is cancelling the finally rejected claims 14 to 17, 19 to 22 and 25 in order to place the application in better condition for appeal.

It is submitted that the amendment is a bona fide attempt to advance the prosecution by amendments to the claims seeking to overcome rejections based on the applied prior art.

It is submitted that the present amendment. complies with observations made in the Final Rejection.

Reconsideration of all outstanding rejections is respectfully requested.

Thus, the Applicants believe that this case is now in condition for allowance and a Notice of Allowance is

7

- 222 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 222 of 372 solicited. If the Office in any respect finds that this amendment is not complete to place the application in condition for allowance, then an interview with Applicants' attorney is respectfully requested. It is submitted that such an interview would be particularly appropriate because applicants have narrowed the issues substantially during prosecution of this application.

Entry of the present amendment is respectfully requested. The claim as presently submitted is deemed to be in form for allowance and an early notice of allowance is earnestly solicited.

Respectfully submitted,

By: _

4,	<u> 59-102-1</u>	560-115.000	R05	UTILITY	NC)	\$560.00	06/14/89

The amount of the issue fee is specified in 37 C.F.R. 1.18. If the applicant qualified for and has filed a verified statement of small entity status in accordance with 37 C.F.R. 1.27, the issue fee is one-half the amount for non-small entities. The issue fee due printed above reflects applicant's status as of the time of malling this notice. A verified statement of small entity status may be filed prior to or with payment of the issue fee. However, in accordance with 37 C.F.R. 1.28, failure to establish status as a small entity prior to or with payment of the issue fee precludes payment of the issue fee in the amount so established for small entities and precludes a refund of any portion thereof paid prior to establishing status as a small entity.

THE ISSUE FEE MUST BE PAID WITHIN THREE MONTHS FROM THE MAILING DATE OF THIS NOTICE as indicated above. The application shall otherwise be regarded as ABANDONED. The issue fee will not be accepted from anyone other than the applicant; a registered attorney or agent; or the assignee or other party in interest as shown by the records of the Patent and Trademark Office. Where an authorization to charge the issue fee to a deposit account has been filed before the mailing of the notice of allowance, the issue fee is charged to the deposit account at the time of mailing of this notice in accordance with 37 C.F.R. 1.311. If the issue fee has been so charged; it is indicated above.

In order to minimize delays in the issuance of a patent based on this application, this Notice may have been mailed prior to completion of final processing. The nature and/or extent of the remaining revision or processing requirements may cause slight delays of the patent. In addition, if prosecution is to be reopened, this Notice of Allowance will be vacated and the appropriate Office action will follow in due course. If the issue fee has already been paid and prosecution is reopened, the applicant may request a refund or request that the fee be credited to a deposit account. However, applicant may request that the previously submitted issue fee be applied. If shandoned, applicant may request refund or credit to a deposit account.

In the case of each patent issuing without an assignment, the complete post office address of the inventor(s) will be printed in the petent heading and in the Official Gazette. If the inventor's address is now different from the address which appears in the application, please fill in the information in the spaces provided on PTOL-85b enclosed. If there are address changes for more than two inventors, enter the additional addresses on the reverse side of the PTOL-85b.

The appropriate spaces in the ASSIGNMENT DATA section of PTOL-85b must be completed in all cases. If it is desired to have the patent issue to an assignee, an assignment must have been previously submitted to the Patent and Trademark Office or must be submitted not later than the date of payment of the issue fee as required by 37 C.F.R. 1.334. Where there is an assignment, the assignee's name and address must be provided on the PTOL-85b to ensure its inclusion in the printed patent.

Advance orders for 10 or more printed copies of the prospective patent can be made by completing the information in Section 4 of PTOL-85b and submitting payment therewith. If use of a deposit account is being authorized for payment, PTOL-85c should also be forwarded. The order must be for at least 10 copies and must accompany the issue fee. The copies ordered will be sent only to the address specified in section 1 or 1A of PTØL-85b.

 \Box Note attached communication from the Examiner.

Patents issuing on applications filed on or after Dec. 12. 1980 may require payment of maintenance fees. See 37 CFR 1.20 (e) — (j).

CXLIII. STUDIES ON THE RELATIONSHIP BETWEEN CHEMICAL CONSTITUTION AND PHYSIOLOGICAL ACTION.

IV. THE INHIBITORY ACTION OF CERTAIN SYNTHETIC URETHANES ON THE ACTIVITY OF ESTERASES.

By EDGAR STEDMAN AND ELLEN STEDMAN.

From the Department of Medical Chemistry, University of Edinburgh.

(Received June 26th, 1932.)

PART III [Stedman and Stedman, 1931] of this series of communications was concerned with an examination of the action towards liver esterase of the group of urethanes which had previously been shown to behave pharmacologically as "parasympathetic stimulants," and it was demonstrated that, while such urethanes possessed the power of inhibiting the action of this enzyme to a very high degree, other urethanes and bases did not produce a similar effect. It was therefore concluded that a relationship between constitution and inhibitory action towards liver esterase existed analogous to that between constitution and physiological action in the same group. This result afforded exceedingly strong, if not conclusive, evidence in favour of Loewi and Navratil's [1926] views regarding the mechanism of the action of physostigmine on the heart, and further appeared to indicate the nature of the enzyme which, according to Engelhart and Loewi [1930] and to Matthes [1930], brings about the destruction of acetylcholine and of the vagus substance. It is clear from Locwi's work, however, that the liver is not normally directly responsible for the destruction of the vague substance, which, in his original experiments, was shown to be caused by aqueous extracts of the frog's heart. It therefore appeared to be desirable to examine the inhibitory action of the above group of urethanes towards serum esterase, particularly as Engelhart and Loewi, Matthes, and Plattner have shown that both whole blood and serum are capable of destroying acetylcholine. At the same time the actions of the urethanes on two other enzymes, namely pancreatic lipase and phosphatase, the normal substrates of which are esters, have been examined in order to determine the extent to which the inhibitory action of the urethanes is specific.

INHIBITION OF ESTERASES BY URETHANES 1215

PANCREATIC LIPASE.

Enzyme preparation. The pancreatic lipuse was prepared from pig's pancreas according to Willstätter and Waldschmidt-Leitz's method [1923]. The minced glands were desiccated by successive treatment with acctone and ether and the fibrous material was separated from the dry preparation by pounding it in a mortar and then shaking it through a fine sieve. The fine powder so obtained was extracted for 4 hours at 30° with 87 % glycerol (32 cc. for 2 g. of powder), centrifuged, and the extract stored in this form. Immediately before use, 15 cc. of this extract were diluted to 60 cc. with water, and again centrifuged to remove a fine precipitate which separated.

Hydrolysis of olive oil. The influence of miotine hydrochloride on the hydrolysis of olive oil by pancreatic lipase was first examined. Into each of two small stoppered bottles 2.5 g. of olive oil were weighed and 2 cc. of ammonia-ammonium chloride buffer ($p_{\rm II}$ 8.9) were then added. The contents of one bottle were now treated with 11 cc. of the above enzyme extract and those of the other with 11 cc. of the same extract containing 5 mg. of miotine hydrochloride which had been dissolved in it one hour previously. Each bottle was shaken for 3 minutes to emulsify the oil and then placed in a thermostat at 30° for one hour. The contents of each bottle were now washed with 100 cc. of rectified spirit into a flask, 20 cc. of ether added to dissolve the oil and the solutions titrated with 0.727N alcoholic potassium hydroxide, using thymolphthalein as indicator. In each case 0.8 cc. of the alkali were used. A control, using 11 cc. of water in place of the enzyme solution, required 2.4 cc. of the alkali. It is clear that miotine exerted no inhibitory action.

Hydrolysis of tributyrin. In order to follow the hydrolysis of tributyrin, the stalagmometric method described in Part III was employed. The above diluted extract (1 cc.) of pancreatic lipase was mixed with 2 cc. of phosphate buffer $(p_{11} 7 \cdot 9)$ and diluted to 10 cc. with water. One cc. of this preparation was treated with 12 mg, of miotine hydrochloride dissolved in 1 cc. of water and allowed to stand for one hour, when 1 cc. of the mixture was used in a hydrolysis experiment. For the control, 1 cc. of water was employed in place of the solution of miotine hydrochloride. The following figures represent the diminution in the drop number in successive periods of 20 minutes: control, 15, 23; in the presence of miotine, 14, 23. Miotine is thus without inhibitory action on the hydrolysis of tributyrin by pancreatic lipase.

Hydrolysis of melkyl butyrate. The method employed was at first identical with that used in Part III with liver esterase, except that the reaction mixture contained a high percentage of glycerol which activates as well as stabilises the lipase. Into a 100 cc. graduated flask were introduced 50 cc. of a 50 % solution of glycerol and 20 cc. of buffer (1 part $2 \cdot 5 N$ NH₃: 2 parts $2 \cdot 5 N$ NH₄Cl; p_{Π} 8.9) and the mixture was then warmed to 30° in a thermostat. One cc. of methyl butyrate was dissolved as completely as possible in this by shaking, when 20 cc. of the diluted extract of pancreatic lipase were added and the volume was

- 228 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 229 of 372

made up to 100 cc. with water. The flask was again placed in the thermostat, 20 cc. of the mixture being immediately withdrawn, run into a mixture of 25 cc. of 0.2 N hydrochloric acid with 20 cc. of water and titrated with 0.2 N sodium hydroxide, using bromocresol purple as indicator. Similar volumes of the mixture were withdrawn at intervals of 20 minutes and titrated in the same way. In the experiment designed to test the inhibitory action of miotine, 12 mg, of the hydrochloride were dissolved in 25 cc. of the diluted extract of the enzyme and allowed to stand for one hour; 20 cc. of this solution were then used in a hydrolysis experiment. The following results were obtained, the figures representing the number of cc, of 0.2 N alkali required to titrate the acid liberated in 20 cc. of the reaction mixture in 20, 40 and 60 minutes respectively: control, 1.75, 2.7, 3.4; in the presence of miotine, 1.15, 1.85, 2.35. A small inhibitory effect is apparent, although it is much smaller in magnitude than with liver esterase.

Willstätter and Memmen [1924] have shown that calcium oleate exerts a marked activating action on the hydrolysis of methyl butyrate by pancreatic lipase. Another experiment was therefore carried out in the presence of this activator. The procedure was identical with that outlined above except that 2 cc. each of 2 % sodium oleate and calcium chloride solutions were added to the reaction mixture after the addition of the enzyme but before making up to volume. In view of the activation caused by this addition, only 5 cc. of the diluted glycerol extract of lipase were used. Nevertheless the same amount of miotine was employed. The following figures are typical of the results obtained: control, 2-25, 4-1, 5-05; in the presence of miotine, 1-7, 3-15, 4-25. Owing to the fact that the hydrolysis of methyl butyrate by pancreatic lipase does not take a linear course, possibly because of the changes which occur in the $p_{\rm H}$ of the solution, it is not possible to calculate in a simple manner the percentage inhibition produced by the miotine. Nevertheless it is clear from the figures that the inhibition caused by the miotine in this experiment is of the same order of magnitude as that produced by the same quantity in the absence of calcium oleate, although only one fifth of the amount of enzyme was required in the latter experiment.

An experiment similar to that last described was also carried out with the hydrochloride of the methylurethane of *m*-dimethylaminophenol, this particular urethane being chosen because it had proved to be the most active of the urethanes examined in inhibiting the hydrolysis of methyl butyrate by liver esterase. About 10 mg. of the urethane were employed, the remaining details being identical with those described above. The results are shown by the following figures: control, 2-05, 3-9, 4-75; in the presence of the urethane, 1-45, 2-9, 3-85. A small inhibitory effect is again apparent.

In view of the possibility that the glycerol, necessarily present in the above solutions, might diminish the inhibitory action of the urethanes, the influence of glycerol on the inhibitory action of miotine towards liver esterase was examined. An acidified and dialysed extract of liver powder, similar to those

- 229 -

1216

INIÚBITION OF ESTERASES BY URETHANES

1217

described in Part III, was employed, the hydrolysis of methyl butyrate being followed under the conditions described in that paper with the modification that 50 cc. of water were replaced by 50 cc. of 50 % glycerol. As inhibitor, 0-01 mg, of miotine hydrochloride was employed. The following titration figures were obtained: control (without glycerol), 1-85, 3-8, 5-5; control (with glycerol), 1-85, 3-65, 5-15; in the presence of miotine (without glycerol), 0-55, 1-5, 2-2; in the presence of miotine and glycerol, 0-55, 1-4, 2-0. It is evident that the glycerol was without influence either on the activity of the estense or on the inhibitory activity of miotine. The experiment further serves to illustrate the much greater sensitivity of liver estense to miotine. With only a thousandth part of the amount used with pancreatic lipsase a greater inhibition was produced.

KIDNEY PROSPHATASE.

The preparation of kidney phosphatase employed was obtained by Erdtman's method [1927]. 600 g, of pig's kidneys were minced, suspended in 500 cc. of water to which much toluene had been added, and incubated for 2 days at 37° . The mixture was then filtered through a fine metal strainer, and the turbid filtrate treated with 1½ litres of rectified spirit. The precipitate so produced was filtered, stirred with 500 cc. of alcohol and again filtered, this process being repeated twice. It was then similarly treated with 500 cc. of ether, dried in the air and ground in a mortar. Extracts of the phosphatase were prepared by shaking 4 g, of this dry powder with 80 cc. of N/40 ammonia for 1½ hours and removing the solid material in the centrifuge.

The substrate employed was sodium glycerophosphate. To a mixture of 10 cc. of 5 % sodium glycerophosphate, 10 cc. of buffer (ammonia-ammonium chloride, p₁₁ 8.9) and 60 cc. of water, previously warmed to 30° in a thermostat, were added 10 cc. of the above solution of phosphatase. The total volume was then made up to 100 cc, with water and the solution replaced in the thermostat. 20 cc. of the mixture were immediately withdrawn and run into 10 cc. of 10 % trichloroacetic acid. The free phosphate was then estimated in 25 cc. of the filtrate by precipitating it as phosphomolybdic acid, dissolving the latter after filtration in 10 cc. of 0-21N NaOH and titrating the excess alkali with 0-0995 N nitric acid. Similar withdrawals and estimations were made at fixed intervals. A typical experiment will suffice to illustrate that miotine is without action on kidney phosphatase. 12 mg, of miotine hydrochloride were dissolved in 12 cc. of the enzyme solution and, after an interval of one hour, the phosphatase activity of 10 cc. of the solution was determined, a control being carried out simultaneously. The following figures represent the cc. of nitric acid required to neutralise the excess alkali in estimations on samples withdrawn immediately and after 80 minutes respectively: control, 18.2, 8.9; with miotine, 18.6, 8.9.

SERUM ESTERASE.

In order to examine the inhibitory action of the various urethanes towards serum esterase, the serum of the guinea-pig was chosen, since the blood of this

- 230 -

1218

animal is known to contain a relatively high amount of the enzyme. 2-3 co. of the serum, the exact volume depending upon the esterase activity of the sample employed, were treated with 2 cc. of phosphate buffer of $p_{\rm H}$ 7.9 and the mixture was diluted to 10 cc. with water. One cc. of this solution was mixed with 1 cc. of a solution of the urethane under examination and allowed to stand for about an hour, when the esterase activity of 1 cc. of the mixture was determined by the stalagmometric method described in Part III. In the control experiment, the solution of the urethane was replaced by an equal

INHIBITION OF ESTERASES BY URETHANES 1219

LIVER ESTERASE.

In view of the fact that serum from the guinea-pig was used in the above experiments it was thought that it would be of interest to examine the inhibitory actions of the various urethanes on the liver esterase from the same species. A preparation of this esterase was therefore made from a number of guinea-pig's livers using the same procedure as was employed in Part III in connection with liver esterase from the pig. The activity of the preparation towards methyl butyrate, however, proved to be much smaller than that from the pig and it was not, therefore, possible to follow the hydrolysis of simple esters by the technique employed in Part III. Despite its smaller activity towards methyl butyrate, this preparation nevertheless proved to be at least as active towards tributyrin as was the esternse from pig's liver. The experiments recorded in Table II were therefore carried out, using this substance as

substrate. The preparations of the esterase employed were obtained by extracting the desiccated liver powder with dilute ammonia, acidifying this extract with acid and, after removing the precipitate thus produced, dialysing for about 3 days in collodion membranes. In the various experiments recorded, Biochem, 1932 XXVI

78

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 233 of 372

1.5-3 co. of such an extract were mixed with 2 cc. of phosphate buffer of p_{11} 8-0 and the mixture was diluted to 10 cc. with water. One cc. of this solution was mixed with 1 cc. of water or of a solution of the urethane under examination, allowed to stand for about an hour, and 1 cc. of the mixture used in a hydrolysis experiment. The results obtained with the various urethanes are recorded in Table II.

SUMMARY AND DISCUSSION.

In so far as they show that the hydrolysis of tributyrin by the esterase from the liver of the guinea-pig is inhibited by small concentrations of the urethanes which have been shown to behave as parasympathetic stimulants, the above experiments constitute an extension to the liver esterase from a second species of the results obtained with the pig and reported in Part III of this series. While we have not carried out any extensive experiments with liver esterases from other species, we have nevertheless submitted those from a few to a preliminary examination and have found in each case that their activity is inhibited by miotine when present in concentrations of the same order of magnitude as employed in the above experiments. It would therefore appear legitimate to conclude that the urethanes of the type under consideration inhibit the activity of liver exterases in general and irrespective of the species from which they are derived.

Our experiments further demonstrate that the inhibitory action of the urethanes is not restricted to the liver enzyme but extends to the esterase which is present in the blood-serum of the guinea-pig and of certain other species. In view of the fact that it has been shown by the authors mentioned in the introduction that both whole blood and serum are capable of destroying small amounts of acetylcholine, a process which is inhibited by physostigmine, this result was, perhaps, to be expected. Nevertheless, it must be emphasised that the experiments here recorded have been carried out using tributyrin as substrate. While it would seem probable that the same enzyme is concerned in both processes, this cannot at present be regarded as definitely established. There exists, indeed, some evidence to the contrary. Thus, Takahashi [1930], has recently compared the lipolytic activities of the sera from a number of species, using tributyrin as substrate, and has found that they fall in the following order: rabbit > cat > horse > man > dog > cattle. This order is in general agreement with the results of earlier workers and also with some unpublished experiments which we have carried out. On the other hand, the order in which the defibrinated blood from a number of species destroys acetylcholine is, according to Galehr and Plattner [1927], man > pig \geq cattle > dog > horse > rabbit > cat. The latter series is practically the reverse of that which holds for the hydrolysis of tributyrin and hence suggests either that different enzymes are concerned in the two processes or that some other factor, hitherto unrecognised, is involved. It is unlikely that a solution of this aspect of the problem will be possible until the blood-enzymes have been purified and

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 234 of 372

1220

INHIBITION OF ESTERASES BY URETHANES 1221

concentrated. Unfortunately such purification is attended with considerable difficulty on account of the quantity and ready solubility of the serum proteins. We are nevertheless at present engaged in an attempt to effect this purification.

Although the possibility thus exists that the hydrolysis of tributyrin and the destruction of acetylcholine are brought about by different serum enzymes, our results appear quite definitely to indicate that the enzymes, if specifically different, are of the same general nature. We have now established that the activities of both liver and serum esterases are inhibited by small concentrations of urethanes of the miotine type. Nevertheless, the above results show that the activity of pancreatic lipase, an enzyme which, although it resembles liver esterase in hydrolysing simple esters, differs from the latter enzyme in attacking fats relatively more rapidly, is not inhibited by miotine when its substrate is either a fat, in the form of olive oil, or tributyrin. When, however, its substrate is methyl butyrate, a simple ester, its action is inhibited by miotine, although a concentration of the drug which is high compared with that required with serum or liver esterase is necessary. Similarly, the hydrolysis of glycerophosphoric acid by kidney phosphatase, a process involving an ester of a different type from that attacked by liver esterase, is unaffected by miotine. It thus appears that the inhibitory action of the urethanes with which we are concerned is directed mainly towards true esterases, and it is therefore probable that the destruction of acetylcholine is brought about by an enzyme of the same nature.

Regarding the nature of the inhibitory action of the drugs in question, there appears little to be added to our comments in Part III. It was pointed out in that communication that the urethanes are esters and that combination between them and the enzyme probably involves the same mechanism as with the normal substrate, in which case the resulting inhibition would be due to the inability of the enzyme to hydrolyse the urethane. Some chemical evidence which supports this view may be mentioned. In Part I [1920] of this series it was mentioned that when aqueous solutions of certain of the urethanes are boiled, decomposition occurs with the production of methyl isocynate. This decomposition was erroneously referred to as hydrolysis, but it is clear, as pointed out by Aeschlimann and Reinert [1931] in a paper concerned with the pharmacology of urethanes of the same type, that no hydrolytic process is involved. This can be seen from the following equation:

 $N(CH_{a})_{a}$. CH(CH_{a}). C₄H₄. O, CO. NHCH₃ = $N(CH_{a})_{a}$. CH(CH₃). C₄H₄. OH + CH₂CNO.

If, then, despite their structures as esters, these urethanes are not normally hydrolysed by ordinary chemical reagents but undergo a decomposition of a different nature, it is not difficult to understand the inability of esterases to bring about their destruction. The inhibitory action would be a direct consequence of this, provided the urethanes were endowed with high affinities for the enzyme.

78-2

- 234 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 235 of 372

The general relations between the nature of the urethane and its inhibitory activity towards liver esterase observed in Part III and discussed in that paper have again been encountered in the experiments described above and require no further comment. The order of activity of isomeric urethanes appears, however, to differ according to the source of the enzyme. While it would be in accordance with other observations that the enzymes from different species should exhibit differences in this respect, it is more difficult to understand why the esterases from the liver and serum of the same species should show similar differences. The obvious explanation, that the two latter enzymes are different substances, may be correct. We feel, however, that it would be wiser at the present time not to lay too much stress upon these small differences, which might conceivably be caused by impurities which are present in the enzyme solutions.

The authors desire to thank Dr C. P. Beattie of the Bacteriology Department of this University for providing them with the guinea-pig's serum and livers used in this work. The expense of this investigation has been largely defrayed by grants from the Earl of Moray Research Fund of this University.

CXXIX. STUDIES ON THE RELATIONSHIP BETWEEN CHEMICAL CONSTITUTION AND PHYSIOLOGICAL ACTION. III. THE INHIBITORY ACTION OF CERTAIN SYNTHETIC URETHANES ON THE ACTIVITY OF LIVER ESTERASE.

BY EDGAR STEDMAN AND ELLEN STEDMAN.

From the Department of Medical Chemistry, University of Edinburgh.

(Received June 27th, 1931.)

PARTS I and II [Stedman, 1926; 1929, 1] of this series of communications have dealt with a new relationship between chemical constitution and physiological action. It has been shown that certain synthetic urethanes possess in common with the alkaloid physostigmine, which is also a urethane, the power of producing a constriction of the pupil when instilled into the eye. As a result of this work, as well as of extensions thereof published elsewhere [Stedman and Stedman, 1929; 1931], it has been concluded that substances which can be classed as phenyl esters of carbamic acids and which possess a basic group will, in general, exhibit similar miotic properties. Constitutional factors which repress, or tend to repress, such properties have already been discussed. Until recently the pharmacological examination of the synthetic urethanes had not extended beyond their action on the eye and it was not therefore certain that they would resemble physostigmine in other physiological properties. One of the urethanes, namely, the methylurethane of a-m-hydroxyphenylethyldimethylamine, which had already been shown to possess marked miotic properties and had been named miotine [Stedman, 1929, 2] on that account, has, however, now been submitted to a complete, and three others to an extensive although less complete, pharmacological examination [White and Stedman, 1931]. Miotine has thus been shown to possess physiological properties which are qualitatively identical with those of physostigmine, and similar results have been obtained with the other urethanes as far as they have been examined. The above relationship between chemical constitution and physiological action is therefore not limited to miotic activity but embraces all the known physiological actions of physostigmine. Now, Loewi and Navratil [1926] have attributed the action of physostigmine on the heart to its power of inhibiting the destruction of acetylcholine by an agent which they have shown to be present in the heart and in aqueous extracts of this organ. A similar agent is present in the blood of certain species [Galehr and

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 237 of 372

1148

Plattner, 1927]. Loewi and Navratil consider this agent to be an esterase, a view which has been disputed by Plattner and Galehr [1928]. The arguments of Plattner have, however, been disposed of in a recent paper by Engelhart and Loewi [1930], who have brought forward convincing evidence of the enzymic nature of the substance causing the destruction of acetylcholine. Evidence leading to the same conclusion has also been published by Matthes [1930]. In view of the similarity between the actions of miotine and physostigmine on the heart, and in particular of the fact that miotine, like physostigmine, sensitises the vagus and potentiates the action of acetylcholine, it might be expected that miotine would also inhibit the destruction of acetylcholine by the agent in question. That this is actually the case has been shown by Dr Matthes, who kindly compared the action of miotine with that of physostigmine during his investigation of the inhibition by the latter of the destruction of acetylcholine by serum. The problem thus arises as to whether urethanes of the type discussed above, which have been shown to possess similar physiological properties, also share the property of inhibiting the action of the serum-enzyme. Another problem is, however, involved. In the investigations both of Loewi and his co-workers and of Matthes, the destruction of acetylcholine by the solutions under examination has been measured by biological methods, and no experiments appear to be recorded which indicate whether the enzyme which is responsible for this destruction will hydrolyse simple esters, or whether its action is specific towards acetylcholine. If the enzyme is a true esterase it should be capable of hydrolysing simple esters, in which case its activity, as well as the inhibition thereof by drugs, could be followed by titration methods. It appeared to us that these problems could be most conveniently, although indirectly, solved by examining the influence of the urethanes on the activity of the enzyme present in the liver and which is known to hydrolyse simple esters more readily than glycerides. The results of such an investigation are recorded in the present communication.

MATERIALS.

Esterase preparations. All the esterase solutions employed in these experiments have been prepared from pigs' livers by the method of Willstätter and Memmen [1924, 2]. The liver, obtained direct from the slaughter house, was finely minced, desiccated by successive treatment with acetone and ether, and the dry preparation powdered and sieved. Solutions of the enzyme were prepared, as required, by extracting 2 g. of this fine powder with 100 cc. of 0°020 N ammonia for 1 hour and removing the insoluble material in the centrifuge. In the earlier experiments no further purification of the esterase was attempted. In the later work, however, it was found to be advantageous carefully to acidify the ammoniacal extract with acetic acid, and, after removing the precipitate so produced, to dialyse the clear solution in collodion membranes for 3-4 days, a procedure similar to that first described by

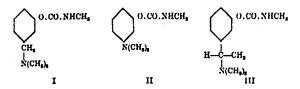

- 237 -

STRUCTURE & PHYSIOLOGICAL ACTION OF URETHANES 1149

Willstätter, Bamann and Waldschmidt-Graser [1928] and subsequently employed by other workers.

Substances examined for inhibitory action. The urethances with a pharmacological action similar to that of physostigmine which have been examined for inhibitory action comprise three series of isomeric compounds, namely, the methylurethances of o-, m- and p-hydroxybenzyldimethylumine, the o-, m- and p-dimethylaminophenyl esters of methylcarbamic acid, and the methylurethanes of the isomeric a-hydroxyphenylethyldimethylamines. The structures of the m-isomerides in these three series are represented in formulae I. II and III respectively. These compounds have been examined both in the

form of their hydrochlorides and methiodides, the preparation of which has been effected by the methods of Stedman [1926; 1929, 1] and Stedman and Stedman [1929]. In the case of the o-isomerides, the hydrochlorides of which are hygroscopic, the base was dissolved in the calculated quantity of hydrochloric acid immediately before use. It should be noted that the urethane represented by formula III is the substance which has been named miotine. As will be evident from the formula, miotine and its position isomerides contain an asymmetric carbon atom. Unfortunately attempts to resolve these compounds have not so far met with success; the examination of their inhibitory actions towards liver esterase has therefore necessarily been carried out with the racemic substances. It will be convenient in the following pages to refer to the isomeric compounds corresponding with formula III as o-, m- and p-miotine, and to those corresponding with formulae I and II as the methylurethanes of the benzyl and phenyl series respectively.

In addition to urethanes with a physostigmine-like action, the methylurethane of choline iodide, CH_NH.CO.OC_H_N(CH_)I [Stedman, 1929, 1], has been examined as an example of an aliphatic urethane. Some tests have also been made with the following alkaloids: pilocarpine, arecoline, ricinine. The two former were employed as nitrate and hydrobromide respectively, these salts being obtained from commercial sources. The ricinine was prepared from castor-oil seeds; since this alkaloid is soluble in water it was employed in the form of the free base.

Pilocarpine and arecoline were examined because the pharmacological actions of these alkaloids are similar to that of physostigmine. Ricinine does not exhibit such similarities. It occurs, however, in the castor-oil seed associated with a lipase, and since physostigmine also occurs in a seed, the Calabar

1150

bean, it was thought that if the two alkaloids were found to resemble one another with respect to their inhibition of the activities of enzymes, this might form the basis of an explanation of the functions of alkaloids in general. As will be shown below, ricinine does not inhibit the activity of liver esterase; its possible influence on the activity of ricinus lipase, the enzyme with which it is associated naturally, has not yet been investigated.

EXPERIMENTS WITH METHYL BUTYRATE AS SUBSTRATE.

Technique. The activity of the esterase preparations has been determined by a method essentially similar to that developed by Willstütter and Memmen [1924, 1] for pancreatic lipase and subsequently adapted by the same authors [1924, 2] for use with liver esterase. For convenience of measurement, 1 cc. of substrate (methyl butyrate) was used for each 100 cc. of reaction mixture, as recommended by Bamann [1929]. The general procedure was as follows: 20 cc. of ammonia-ammonium chloride buffer (1 part 2.5 N NH2 : 2 parts 2.5 N NH₄Cl; $p_{\rm H}$ 8.9) contained in a 100 cc. measuring flask were diluted with 65-70 cc. of water, the exact volume depending on the volume of enzyme solution subsequently added, and the mixture brought to 30° in a thermostat. 1 cc. of methyl butyrate was then added and the flask shaken vigorously until the ester had dissolved completely. To the clear solution a measured volume (5 or 10 cc.) of the enzyme preparation was added, the total volume of the mixture brought to 100 cc. by the addition of water, and the whole thoroughly mixed. 20 cc. of the mixture were immediately withdrawn, run into a mixture of 25 cc. of 0-2 N hydrochloric acid with 20 cc. of water, and titrated with approximately 0.2 N sodium hydroxide, using bromocresol purple as indicator. Similar titrations were made at intervals of 20 minutes. With this procedure and using a suitable quantity of ensyme the amount of hydrolysis was approximately proportional to the time.

The enzyme solution consisted, in the earlier experiments, when ammoniacal extracts of liver powder were employed, of 5 cc. of a mixture of 5 cc. of the extract with 1 cc. of water, the latter being replaced by 1 cc. of a solution of the substance under examination in the experiments designed to test the inhibitory action of this substance. In the later experiments, in which the acidified and dialysed esterase preparation was employed, 5 cc. of enzyme solution were mixed with 5 cc. of ammonia-ammonium chloride buffer (of above composition but diluted 1 in 10), 2 cc. of water or solution added, and 10 cc. of this mixture used for the hydrolysis.

Activity of esterase preparations. The activity of the esterase preparations made from different livers was fairly constant. The following figures, which represent the number of oc. of 0-194 N alkali required to titrate the acid liberated in 20 cc. of the reaction mixture in 20, 40 and 60 minutes respectively, using 4-17 cc. of an ammoniacal extract of liver powder in 100 cc. of reaction mixture, may be taken as typical: 2-3, 4-75, 7-25. This result was

- 239 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 240 of 372

STRUCTURE & PHYSIOLOGICAL ACTION OF URETHANES 1151

obtained on May 19th, 1930, with a fresh extract of a liver powder (L.P. 2) prepared on April 23rd, 1930, and almost identical values were obtained on June 10th, 1930, with a similar extract from the same powder. These facts are recorded in detail because of the following remarkable phenomenon which was observed with an extract of this powder but which has not so far been encountered with other preparations. On June 23rd, 1930, a fresh ammoniacal extract of L.P. 2 was rendered just acid to litmus by the addition of 0.5 N acetic acid. The precipitate, which formed slowly, was centrifuged off and the clear solution tested for activity under precisely the same conditions as those employed for the above ammoniacal extract, when the following figures were obtained: 4.45, 8.25, 8.95. Owing to the unexpectedly high activity of this extract the hydrolysis of the substrate was virtually complete in the experimental period of 1 hour, with the result that the reaction did not take the usual linear course. It is therefore not possible accurately to compare the activities of the different extracts of L.P. 2, but it is clear from the figures quoted that the activity of the acidified extract was at least twice as great as that of the ammoniacal extracts previously prepared from the same weight of the same powder. Dialysis of the acidified extract for 4 days was accompanied by an apparent slight diminution in activity, as is shown by the following titration figures: 3.4, 6.7, 8.35; this, however, was mainly due to the dilution which occurred during dialysis. The increase in activity observed on acidification can doubtless be explained by the removal of an inhibitory substance; from the difficulty in reproducing this experiment it appears that a very critical adjustment of conditions, probably of $p_{\rm H}$, is necessary for the precipitation of this inhibitor.

Influence of time of contact between inhibitor and enzyme on inhibitory action. Rona and Bach [1920], in their studies on the inhibitory action of atoxyl on various lipases, have shown that the maximum inhibitory effect of this substunce is not developed unless it is left for a certain period of time in contact with the enzyme before the addition of the substrate. A number of preliminary experiments having demonstrated that urethanes of the miotine type exert a pronounced inhibitory action on the hydrolysis of methyl butyrate by liver esterase, the influence of this time of contact of the inhibitor with the enzyme was investigated. For this purpose, 1 cc. of a solution of miotine hydrochloride, containing 1.2 mg./cc., was added to each of 7 test-tubes containing 5 cc. of an ammoniacal extract of liver powder. After varying intervals of time 5 cc. of the mixture were employed for a hydrolysis experiment. The results are given in Table I. The figures indicate that, under the conditions employed, the maximum inhibitory action of miotine hydrochloride is not exerted unless it has been in contact with the esterase for 2 hours prior to the addition of the substrate. The difference between the maximum inhibitory action and that produced after contact for 1 hour is, however, very small and almost falls within the limits of experimental error. It has therefore been considered sufficient, when comparing the inhibitory activities of the various

urethanes, to allow the inhibitor to stand in contact with the enzyme for 1 hour before use.

The figures in Table I give some further important information. Miotine is an ester of methylcarbamic acid and might therefore be expected to suffer, like other esters, a more or less rapid hydrolysis when in contact with liver esterase. In the above experiments, however, it is clear that no appreciable hydrolysis has occurred in a period of $5\frac{1}{2}$ hours. In this connection it should be mentioned that, although the hydrolysis experiments were carried out at 30°, the mixtures of miotine and esterase were allowed to stand at room temperature before addition to the reaction flask.

Some experiments on the influence of the time of contact of enzyme and inhibitor on the inhibitory action of the latter were also made under somewhat different conditions. Although the procedure employed in these experiments was not adopted in much of the subsequent work, the results are recorded here since they are not entirely without interest. In the preceding experiments the enzyme and inhibitor were in contact under conditions of concentration widely different from those obtaining in the final reaction mixture. In order to render these conditions more nearly comparable the following modified series of experiments was carried out. A solution of 1.2 mg. of miotine hydrochloride in 1 cc. of water was added to each of a series of flasks containing the diluted buffer mixture and enzyme (ammoniacal extract) previously warmed to 30°. After varying intervals of time, 1 cc. of methyl butyrate was added and rapidly dissolved by shaking, the volume adjusted to 100 cc., and the titrations were performed as before. The results are expressed in Table II. Unfortunately a quantitative comparison cannot be made between the results of Tables I and II since not only were different enzyme preparations employed but the amounts of inhibitor used were slightly different. Nevertheless it is evident that the inhibitory action of miotine hydrochloride is of the same order of magnitude in the two sets of experiments. The most striking point of difference is the definite indication of a destruction of the miotine in the second set after 4 hours' contact with the enzyme. We are inclined, however, to attribute this destruction to the alkalinity of the

In all these experiments the general technique described earlier was utilised, ammoniacal extracts of desiccated liver powder being employed as esterase solution in each case. Since this work was carried out over an extended period of time, different liver preparations, as indicated in Table III, were necessarily employed owing to the moderately rapid deterioration which such preparations undergo. The results demonstrate clearly the marked inhibitory action which urethanes of the type examined exert upon the activity of liver esterasc. A detailed comparison of the figures shows further that, in general, the inhibitory activity of the hydrochlorides of the tertiary bases is greater than that of the corresponding quaternary iodides. While this is not universally the case, particularly in the higher concentrations, the inhibitory activities of the methiodides consistently decrease, with increasing dilution of the inhibitor, at a much greater rate than do those of the hydrochlorides of the tertiary

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 244 of 372

STRUCTURE & PHYSIOLOGICAL ACTION OF URETHANES 1165

busce, with the result that at low concentrations the latter are uniformly more active. This difference between the two types of salts is emphasized because it is probably related to the mechanism of the inhibitory action.

Examination of other types of compounds for inhibitory activity. The following compounds were tested for inhibitory activity under conditions similar to those used in the preceding experiments: methylurethane of choline iodide, hydrochloride of a-m-hydroxyphenylethyldimethylamine, pilocarpine nitrate, arccoline hydrobromide, atropine hydrochloride and ricinine. The titration figures need not be recorded in detail since in no case was any inhibitory action observed in the highest concentrations examined, namely, 10 mg. per 100 cc. of reaction mixture.

Influence of p_H on inhibitory action. The technique adopted for the experiments in which methyl butyrate was employed as substrate is not very suitable for the investigation of p_{Π} effects. Even when relatively large amounts of buffer are employed, the acid liberated during the hydrolysis is sufficient to cause some change in p_{Π} ; if the solution is thereby brought to the acid side of neutrality, some loss in the activity of the esterase may occur with the result that the hydrolysis of the substrate will no longer proceed at a constant rate. This effect was actually observed in a number of experiments. In the experiment quoted in Table IV, which was carried out at $p_{\rm H}$ 6.8, proportionality between the amount of hydrolysis and the time was maintained;

		0-0013	1.85	3.6	5.45	5

this experiment therefore serves to illustrate the general influence of $p_{\rm H}$ on the inhibitory action of miotine hydrochloride. For comparison, the results of an experiment at $p_{\rm H}$ 8-9 carried out under similar conditions are included in the same table. The technique described in connection with the experiments quoted in Table II was employed for both experiments. The phosphate buffer used consisted of a mixture of equal parts of M/3 Na₂HPO₄ and M/3 NaH₄PO₄, 70 cc. being employed in each 100 cc. of reaction mixture. When this buffer was employed, phenolphthalein was used as indicator for the titrations.

Unfortunately the enzyme solutions employed in these experiments, although prepared from the same liver powder, were of different degrees of

- 244 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 245 of 372

1156

purity; the results are not therefore strictly comparable. Nevertheless, two important conclusions can be drawn from these experiments: firstly, the inhibitory action of miotine hydrochloride is smaller on the acid than on the alka line side of neutrality; secondly, the inhibitory action falls off with decreasing concentration of inhibitor much more rapidly in acid than in alkaline solution.

Comparison of the inhibitory activities of isomeric urethanes. The urethanes which have been shown above to inhibit the hydrolysis of methyl butyrate by liver esterase are members of three series of isomeric compounds, with their corresponding methiodides. The results do not, however, necessarily indicate the relative inhibitory activities of the position isomerides within a given series or even of members of different series, for, as previously mentioned, the inhibitory activities of the various compounds were examined on different esterase preparations, and since the latter were made from different liver powders at varying times after their preparation they possessed different activities and probably contained varying amounts of natural inhibitors. On the assumption that any natural inhibitors which may be present in the enzyme preparation enter into competition with the urethanes, it is clear that in experiments designed to compare the activities of different compounds it is not sufficient to employ the same esterase activity; the comparison can only be regarded as valid in those cases where the same esterase extract has been employed. Some experiments, recorded in Table V, have consequently been carried out in which a comparison has been made of the inhibitory activities of the members of each series of urethanes towards the same enzyme preparation. Finally, the hydrochlorides of the m-isomerides of the three series have been compared under the same conditions as a measure of the relative activities of the three series of compounds. In all cases the ammoniacal extracts of the liver powders were purified by acidification with acetic acid followed by dialysis.

From the magnitude of the titration figures it is evident that the percentage inhibition shown in the last column of Table V must be subject to su error of a few per cent. Bearing this in mind, the more significant results revealed by a study of this Table may be summarised as follows.

Miotine series. The inhibitory activities of the hydrochlorides of the mand p-isomerides are identical, that of the o-isomeride being considerably smaller; the inhibition produced by the latter is, in fact, slightly smaller than that caused by the two former when present in one-tenth of its concentration. No very great difference can be observed between the activities of the methiodides, the m- and p-isomerides showing about equal activity and the o-compound exhibiting a slightly greater effect. It is noteworthy and exceptional that the inhibitory activity of the hydrochloride of the o-isomeride is somewhat smaller than that of its methiodide in the same molar concentration.

Phenyl series. The activities of the hydrochlorides are definitely in the order m > p > o. The methiodides follow the same order; the *m*- and *p*-compounds show, however, practically identical activities.

Benzyl series. In this series the order for the hydrochlorides is m > p > o, and for the methiodides p > o > m.

Comparison of the three series. The inhibitory activities of the hydrochlorides of the *m*-isomerides in equimolar concentrations are definitely different, the order being phenyl > miotine > benzyl.

The results in Table V may be further utilised in order to direct attention to the varying activities of the urethanes with different esterase preparations. Thus, to take the most marked case, the concentrations of miotine hydrochloride required to inhibit the acidified and dialyzed extracts of two esterase preparations (L.P. 6 and L.P. 7) to exactly the same extent (30%) are in the ratio 1:10, the extract from L.P. 6 requiring a final concentration of 1/300,000 M and that from L.P. 7 one of 1/3,000,000 M. The different responses of these ensyme preparations are doubtless related to their histories, which are as follows: the liver powder L.P. 6 was prepared on January 9th,

- 246 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 247 of 372

1931. An animoniacal extract of this was made on January 14th and its activity tested by the standard procedure used in this investigation, when the following titration figures were obtained: 2.3, 4.6, 7.0. Practically identical values were obtained on the same day following the acetic acid treatment. The acid solution was then dialysed for 5 days, the dialysed solution giving, on January 19th, titration figures of 2.05, 4.05, 6.05. The diminution in activity shown by these figures is only apparent and can be accounted for by the slight dilution which the extract had undergone during dialysis. On the following day, however, the titration figures for the dialysed extract had fallen to 1.75, 3.5, 5.3. Thus, in 24 hours the activity had diminished about 12 %, and it was this extract with lowered activity which was employed for the comparison of the inhibitory activities of the urethanes of the miotine series. We are of opinion that this loss in activity can be attributed to the acidity caused by the relatively long period of dialysis, and we have found that, with the highly permeable collodion bags which we employ, such losses consistently occur when the process of dialysis is extended beyond 3 or, at most, 4 days.

The preparation L.P. 7 was made on February 18th, 1931. An ammoniacal extract was prepared on February 20th, and this was acidified and dialysed until February 23rd. In view of the fact that this extract, which was more sensitive to miotine hydrochloride than the one referred to above, proved to be stable, it appears probable that the presence of inactivated esterase in the enzyme solutions diminishes the inhibitory activity of urethanes of the type under discussion.

EXPERIMENTS WITH TRIBUTYRIN AS SUBSTRATE.

Technique. In order to follow the hydrolysis of tributyrin by liver esterase the stalagmometric method devised by Rona and Michaelis [1911] and subsequently employed by Willstätter and Memmen [1923] in connection with pancreatic lipase has been utilised. A straight stalagmometer with a water value of 81 at 20° was employed throughout the experiments.

In using this method it is frequently considered sufficient to work at room temperature without any special temperature control. At the time our experiments were carried out, however, the temperature of our laboratory fluctuated considerably and tended to be somewhat low, falling at times to below 10°. At such temperatures the activity of the enzyme is naturally considerably diminished, and it was therefore considered advisable to use a thermostat. The reaction mixture, contained in a small beaker, was placed in a bath at 20° and the stalagmometer supported directly over the beaker by means of a suitable stand. By raising the beaker and applying gentle suction at the top of the stalagmometer the mixture could be drawn into the latter. The beaker was then again lowered and the drops from the stalagmometer allowed to fall into it. By this arrangement fluctuations in the temperature of the liquid actually in the stalagmometer could not be prevented, but the

1158

STRUCTURE & PHYSIOLOGICAL ACTION OF URETHANES 1159

bulk of the reaction mixture was maintained constantly at 20°, thereby permitting a uniform action of the esterase.

The remaining procedure was as follows: 50 cc. of a saturated solution of tributyrin were mixed with 5 cc. of M/3 phosphate buffer (p_H 7.9 or 6.8) and the mixture brought to 20°. 1 cc. of a mixture of 1 cc. of esterase solution with 1 cc. of a solution of the urethane in the experiments designed to measure the inhibitory action of the latter, was then added and the drop number immediately measured. Two further counts were made at intervals of 20 minutes. As in the experiments with methyl butyrate, the enzyme was left in contact with the urethane for 1 hour before mixture with the substrate.

All the esterase solutions employed were prepared from ammoniacal extracts of liver powders acidified with acetic acid; in some cases the extracts were dialyzed. In each case, 1 to 5 cc. of the enzyme preparation, the actual volume depending on its activity, were mixed with 2 cc. of M/3 phosphate buffer of the same $p_{\rm H}$ as that employed in the hydrolysis experiments, and diluted to 10 cc. with water.

Willstätter and Memmen [1923] have pointed out that commercial preparations of tributyrin frequently contain an impurity, with a saponification number corresponding with that of dibutyrin, which renders them unsuitable for use, without extensive purification, in the stalagmometric estimation of lipolytic activity. As a criterion of purity they recommend the preparation of two saturated aqueous solutions of the sample, one by shaking 5 to 10 g. of the tributyrin with 200 cc. of water, and the other by shaking 3 drops with a similar volume of solvent. If the tributyrin is pure, the two solutions should give the same drop number. The experiments recorded in this communication have been made with one delivery of B.D.H. tributyrin. When this was submitted to the test described above, the two saturated aqueous solutions gave identical drop numbers. According to the above criterion the sample was therefore quite pure and was employed in our experiments without further treatment.

Influence of $p_{\rm H}$ on inhibitory action. The study of the inhibition of the hydrolysis of tributyrin by liver esterase by urethanes of the type considered in this series of communications has been carried out partly with the object of ascertaining if the inhibitory action of such urethanes is independent of the type of substrate employed and partly because, owing to the sensitivity of the stalagmometric method, only relatively small amounts of tributyrin need be employed as substrate. This renders the method eminently suitable for a study of the influence of $p_{\rm H}$ on the inhibitory process, since no difficulty is experienced in buffering the small amounts of acid which are liberated by the action of the ensyme. The inhibitory activities of the hydrochlorides and nucthiodides of each member of the three series of urethanes mentioned above have therefore been examined, using a range of concentrations of inhibitor, at two different acidities, namely, $p_{\rm H}$ 7.9 and 6.8. Table VI gives some typical

results. Similar results were obtained with the isomerides of the urethanes mentioned in Table VI; since, however, the same enzyme preparation was not employed with all the compounds, these results do not necessarily indicate correctly the relative inhibitory activities of the various compounds and are not therefore quoted. It should be mentioned in connection with these results that the same enzyme preparation was always employed in the experiments with a given urethane, although, owing to the smaller activity of the esterase at $p_{\rm H}$ 6.8 a greater volume of the enzyme preparation was used in the more acid solution. Thus in the experiments with the hydrochloride of the methylurethane of p-hydroxybenzyldimethylamine in which the enzyme showed the same activity, corresponding with a decrease of 20 in the drop number in 40 minutes, at the two acidities, 33 % more enzyme was employed at $p_{\rm H}$ 6.8 than at 7.9. In every instance quoted in Table VI the inhibitory activity of a given ure thane is smaller at $p_{\rm H}$ 6.8, i.e. on the acid side of neutrality, than at $p_{\rm H}$ 7.9, and the same effect was consistently observed with the remaining urethanes. As an example, the results with the hydrochloride of the methylurethane of p-hydroxybenxyldimethylamine, mentioned above, may be taken,

- 249 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 250 of 372

STRUCTURE & PHYSIOLOGICAL ACTION OF URETHANES 1161

since identical esterase activities, as shown by the control experiments, were employed at the two acidities. In this case, the amounts of inhibitor required to diminish the activity of the enzyme by 25 %, i.e. to diminish the decrease in drop number from 20 to 15, were 0.01 and 0.1 mg, at $p_{\rm H}$ 7.9 and 6.8 respectively. The inhibitory activity of the urethane at $p_{\rm H}$ 6.8 was thus only onetenth of that which it exhibited at $p_{\rm H}$ 7.9. Ratios of the same order of magnitude were obtained with the other urethanes. To what extent the partial inactivation of the enzyme which takes place in acid solution, and which necessitated the employment of larger volumes of the preparation at $p_{\rm H}$ 6.8, contributes to this result cannot at present be determined.

Attention should further be directed to the results obtained with the hydrochloride of the methylurethane of *m*-dimethylaminophenol. Reference to Table VI will show that 0-0001 mg. of this substance produced, at $p_{\rm H}$ 7.9, an inhibition of the activity of the liver esterase of approximately 50 %. Since, in the final reaction mixture, the inhibitor was contained in a volume of about 50 cc., the final concentration of this substance required to diminish the activity of the esterase by this amount was about 1:500,000,000. This is the greatest activity which has been observed with any of the urethanes so far examined. It agrees with other results obtained with the same urethane, which has, in fact, proved to be the most active inhibitor amongst the three series of compounds investigated.

Comparison of the inhibitory activities of isomeric urethanes. In order to obtain a direct comparison of the activities of the members of a given series of urethanes, it was necessary, for reasons stated in connection with the similar experiments carried out with methyl butyrate as substrate, to measure the inhibitory activities on the same enzyme preparation. The results are recorded in Table VII. Different esterase solutions were employed for the three series, so that the figures recorded do not necessarily give a comparison of the activities of members of different series. In the benzyl and phenyl series, an interval of some days elapsed between the experiments with the hydrochlorides and methiodides. The enzyme had meanwhile undergone slight deterioration, as shown by the figures for the second control.

The order of inhibitory activity of the various isomerides on liver esterase, using tributyrin as substrate, is, according to the results of Table VII as follows.

Miotine series. The hydrochlorides do not show large differences in activity. Nevertheless they appear to be definitely in the order m > o > p. With the methiodides, which are considerably less active, the *o*-compound exhibits the greatest activity; the *m*- and *p*-isomerides are, within the limits of experimental error, equally active.

Benzyl series. The hydrochlorides of this series show greater differences in activity, the order being quite definitely o > m > p. The methiodides again show little difference in activity; the order p > o > m is indicated by the results.

Phenyl series. In this series the *m*-hydrochloride is considerably more active than the o- and *p*-compounds, which can scarcely be distinguished from one another in activity. Of the methiodides, the *o*-compound is the most active, the *m*- and *p*-isomerides possessing the same activity. It should be noted that the order of inhibitory activity of both the hydrochlorides and methiodides of this series is identical with that of the miotime series.

DISCUSSION.

The foregoing results have established definitely that urethanes of the type which have been shown in earlier papers to possess very specific physiological properties also possess the common property of inhibiting in low concentration the activity of liver esterase. Of the nine urethanes examined, all exhibit this property to a marked degree, and not only do they do so in the form of their hydrochlorides but their methiodides are similarly, although usually somewhat less, active. It appears legitimate to conclude that a relationship exists between chemical constitution and inhibitory activity towards liver esterase group. In conformity with this conclusion, the methylurethane of choline

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 252 of 372

1162

STRUCTURE & PHYSIOLOGICAL ACTION OF URETHANES 1163

iodide, a substance containing many structural features in common with the active urethanes but lacking the essential phenyl group, is inactive. Similarly, the hydrochloride of *a*-m-hydroxyphenylethyldimethylamine, the phenol from which miotine is prepared and which contains the phenyl and basic but not the urethane group, produces no inhibition in relatively high concentration.

Whether these results hold for the enzyme, present in blood-sera from certain species and in tissue extracts, which is normally responsible for the destruction of acetylcholine, has not yet been determined. Nevertheless, the fact that urethanes of the type which possess physiological properties similar to those of physostigmine also inhibit, in minute concentration, the hydrolysis by liver esterase of a simple ester such as methyl butyrate, affords substantial support to the view that the above-mentioned serum-enzyme, the activity of which towards acetylcholine has been shown by Loewi and his co-workers and by Matthes to be inhibited by physostigmine, is a true esterase such as is present in the liver and is not one which acts specifically towards acetylcholine.

It is not proposed to discuss in detail the question, which now arises, as to whether the physiological activity of urethanes of the miotine type is an indirect result of the inhibitory action which they exert upon esterases, since this problem has already been considered from many aspects by White and Stedman [1931], who have pointed out that while much of the activity of miotine, in particular its toxicity, may probably be attributed to its inhibition of the destruction of acetylcholine, other mechanisms are possibly also involved. One fact, which supports the suggestion, originally made by Loewi and Navrstil [1926], that the action of physostigmine on the heart is due to its inhibitory action on the acetylcholine-destroying enzyme, may, however, be mentioned. It has been shown above that arecoline, in relatively high concentration, does not inhibit the activity of liver esterase. Now this alkaloid belongs, pharmacologically, to the physostigmine group of drugs and might therefore be expected to resemble physostigmine in its behaviour towards esterases. That it does not do so is in complete accord with some unpublished pharmacological experiments by Dr A. C. White, to whom we are indebted for information regarding his results, according to which arecoline, unlike physostigmine, does not potentiate the action of acetylcholine on the vagus.

It is not to be expected, even on the assumption that the whole of the physiological activity of urethanes of the miotine type is attributable to the resulting accumulation of acetylcholine in the organism, that an exact parallelism will exist between the magnitude of their physiological activities and that of their inhibitory activities towards esterases, for the drugs will be subject to many influences in the organism which are eliminated in is vitro experiments with enzymes. Thus, a property of a drug, such as adsorbability, which may render it particularly efficient in inhibiting the activity of an esterase, may actually prevent it from reaching the enzyme in the organism. Similarly, stability will be of greater influence in is vivo than in is vitro

- 252 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 253 of 372

E. STEDMAN AND E. STEDMAN

1164

more destructive agents. That no such parallelism does, in fact, exist follows from our experiments; the order of the inhibitory activity of various urethanes towards liver esterase in no way corresponds with the previously published provisional order for their miotic activities.

Perhaps the most interesting questions which call for consideration in connection with our experiments are those concerning the nature of the inhibitory action and its bearing on the mechanism of the normal action of esterases. Of a group of compounds possessing a common structural feature, every member which has been examined has been found to inhibit, in minute concentration, the activity of liver esterase. These inhibitory substances, like the normal substrate of the enzyme, are esters. Nevertheless they are either not attacked, or are only hydrolysed extremely slowly, by the esterase. The suggestion thus arises that the urethanes combine with the esterase in the same way and by means of the same mechanism as do simple esters, but that the affinity between urethane and enzyme is enormously greater than that between simple ester and enzyme. Hence the esterase-urethane compound is formed preferentially and, owing to the inability of the enzyme to decompose the urethane, the hydrolysis of the normal substrate is prevented. The latent period which occurs in the hydrolysis of ethyl mandelate by liver esterase when esters of certain keto-acids are present has been similarly explained by Willstätter, Kuhn, Lind and Memmen [1927], and further experiments in support of this explanation have been published by Bamann and Schmeller [1930]. On the above basis the relative inhibitory activities of the various urethanes will be a measure of their affinities for the esterase, and any regularity which is observed between inhibitory and other properties should give a clue as to the nature of the affinity between the urethanes and esterase, and hence of the nature of the forces normally responsible for the formation of enzyme-substrate compound. Now, the following regularities have, in fact, been noted in our experiments.

(1) In a given series of urethanes the isomerides show inhibitory activities which, although usually different, are of the same order of magnitude.

(2) Of the three series examined, the hydrochlorides of the phenyl series are outstanding with respect to their high inhibitory activities.

(3) The methiodides are, in general, considerably less active than the hydrochlorides of the corresponding tertiary bases.

(4) The inhibitory activity of a given urethane is considerably smaller at $p_{\rm II}$ 6.8 than in slightly alkaline medium.

We believe that these results can be best interpreted by assuming that the affinities in question are, in the first instance, of the nature of adsorptive forces. If we postulate (a) that the urethane group confers high adsorbabilities on the inhibitory substances, (b) that the adsorbability and therefore inhibitory activity is increased by any factor which tends to lower the solubility, (c) that the free bases and not the salts are the active inhibitors, our reasons for this belief will be at once clear. In accordance with postulates (b) and (c),

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 254 of 372

STRUCTURE & PHYSIOLOGICAL ACTION OF URETHANES 1165

any factor which tends to convert the readily soluble salts into the sparingly soluble bases, thus diminishing the solubility and increasing the concentration of the active constituent, would be expected to assist adsorption and hence increase inhibitory activity. Increase in alkalinity is such a factor, and as shown above this increases the inhibitory activity. Similarly diminishing the basic strength of the compounds would constitute another such factor; corresponding with this the compounds which are the weakest bases, namely, the methylurethanes of the phenyl series, show the greatest inhibitory activity. Further, solubility is increased by converting the tertiary bases into their quaternary ammonium salts, the free bases of which are readily soluble in water. This should diminish adsorbability and hence inhibitory activity, as is actually the case.

Nevertheless, adsorption is clearly not the only process involved. The possession of surface activity of a high order will not necessarily confer upon a compound the marked inhibitory activity shown by the above urethanes. Moreover, it has been shown by Willstätter, Kuhn and Bamann [1928] that esters of d- and l-mandelic acids exhibit different affinities towards esterases, while Murray and King [1930] have demonstrated that certain enantiomorphic alcohols inhibit the activity of liver esterase to different degrees. Optical isomerides would be expected to possess identical adsorbabilities; it is therefore almost certain that some factor other than adsorption is also involved. We are of opinion that, following adsorption, the inhibitor enters into especial relation with the enzyme, the exact nature of which is not at present clear, and it is probably this second stage of the combination process which is the cause of the different inhibitory activities of isomeric urethanes. One fact which has been elicited in our experiments tends to support this view. In examining the inhibitory activities of the various urethanes towards liver esterase, it has been found that the general effect of those factors which we have interpreted above as exerting their influence by producing changes in adsorbability is the same whether the substrate is methyl butyrate or tributyrin. The relative activities of isomeric urethanes vary, however, with the nature of the substrate, a result which cannot be explained on the basis of adsorption.

SUMMARY.

1. Urethanes of the type which have previously been shown to possess physiological properties of the same kind as physostigmine have been found to possess the common property of inhibiting the activity of liver esterase. A relationship thus exists between chemical constitution and inhibitory action towards liver esterase analogous to that between constitution and physiological activity in the same group.

2. This inhibitory action is exerted in high dilution. Thus, the hydrochloride of the m-dimethylaminophenyl ester of methylcarbamic acid, which Biochem, 1931 xxy 74

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 255 of 372

E STEDMAN AND E STEDMAN

1166

is the most active urethane examined, produced an inhibition of 50 % in the hydrolysis of tributyrin by liver esterase when in a final concentration of about 1:500,000,000. The same urethane inhibited the hydrolysis of methyl butyrate to about the same extent when in a final concentration of $\frac{1}{2} \times 10^{-6} M$, which corresponds with one of about 1:13,000,000.

3. Three series of isomeric urethanes, which have been termed the methylurethanes of the phenyl, benzyl and miotine series respectively, have been examined for inhibitory activity in the forms both of their hydrochlorides and methiodides. The relative activities of the isomerides, when methyl butyrate is employed as substrate, are as follows.

Hydrochlorides. Phenyl series: m > p > o; benzyl series: m > p > o; miotine series: m = p > o.

Methiodides. Phenyl series: $m \notin p > o$; benzyl series: p > o > m; miotine series: $o > p \notin m$.

Using tributyrin as substrate the following orders, which differ from those above, are obtained:

Hydrochlorides. Phenyl series: $m > p \equiv o$; benzyl series: o > m > p; miotine series: m > o > p.

Methiodides. Phenyl series: o > p = m; benzyl series: p > o > m; miotine series: o > p = m.

4. The inhibitory activity is, in every case, greater in slightly alkaline medium than at $p_{\rm H}$ 6.8.

5. In general, the methiodides exert a considerably smaller inhibitory effect than do the hydrochlorides.

6. The relative inhibitory activities of the various urethanes do not correspond with their relative miotic activities. It is pointed out that such correspondence is not to be expected even on the assumption that the whole of the physiological activity of the urethanes is due to their inhibitory action on esterases.

7. The mechanism of the inhibitory action is discussed.

Part of the expense of this investigation has been met by grants from the Earl of Moray Research Fund of this University.

DATE MAILED: 05/24/89

The amendment filed $\frac{1}{25785}$ under Rule 312 has been considered, and has been:

1. 🔲 entered.

2.
entered as directed to matters of form not affecting the scope of the invention (0.3311).

3. 🖾 disapproved. A report appears below.

4.
entered in part. A report appears below.

By Direction of the Commissioner

The information disclosure statement filed April

25, 1989 fails to comply with the provisions of MPEP 609

because it is not accompanied by:

Report: (a

- (a) A proposed amendment canceling or further restricting at least one independent claim and narrowing the scope of protection sought;
 - (b) A timely affidavit under 37 CFR 1.131 with respect to the material cited; or
 - (c) A statement by the applicant or his attorney or agent that, in the judgment of the person making the statement, the information cited (1) raises a serious question as to the patentability of the claimed subject matter, or (2) is closer than that of record, or (3) is material to the examination of the application as defined in 37 CFR 1.56(a) and is filed with an explanation of why the information disclosure statement was not earlier presented e.g., information recently cited in a corresponding foreign patent application. It has been placed in the application file, but the information referred to therein has not been considered as to the merits and will not be cited on the patent as a result of this information disclosure statement or prior art citation. Applicant is advised that the filing of the above-noted paper may not satisfy the duty of disclosure requirement of 37 CFR 1.56 insofar as any material information is referenced in the above-noted paper.

NOTICE OF ABANDONMENT

- This application is abandoned in view of:
- 1. C Applicant's failure to respond to the Office letter, mailed .
- 2.
 Applicant's letter of express abandonment which is in compliance with 37 C.F.R. 1.138.
- 3. Applicant's failure to timely file the response received ... within the period set in the Office letter.

4. Applicant's failure to pay the required issue fee within the statutory period of 3 months from the mailing date of _______ of the Notice of Allowance.

- The issue fee was received on _
- □ The issue fee has not been received in Allowed Files Branch as of _ in accordance with 35 U.S.C. 151, and under the provisions of 37 C.F.R. 1.316(b), applicant(s) may petition the Commissioner to accept the delayed payment of the issue fee if the delay in payment was unavoidable. The petition must be accompanied by the issue fee, unless it has been previously submitted, in the amount specified by 37 C.F.R. 1.17 (i), and a verified showing as to the causes of the delay.

If applicant(s) never received the Notice of Allowance, a petition for a new Notice of Allowance and withdrawal of the holding of abandonment may be appropriate in view of Delgar Inc. v. Schuyler, 172 U.S.P.Q. 513.

5. Applicant's failure to timely correct the drawings and/or submit new or substitute formal drawings by __________ as required in the last Office action.

6. The reason(s) below.

Case 118-6848

PHENYL CARBAMATES

Do Not Use No. 4 See paper No. 4

> The present invention relates to novel phenyl carbamates which are useful as pharmaceutical compositions. The invention further relates to pharmaceutical compositions having anticholinesterase activity.

Acetylcholine is a major neurotransmitter which is found in all parts of the body. Any reduction in its activity, either as a result of neuronal damage, degeneration etc. or as induced by drugs or toxins, causes marked changes in the function of the organism. Acetylcholine itself has an extremely short half life, since it is rapidly hydrolysed at its site of action and in plasma by specific cholinesterase enzymes. Drugs that inhibit acetylcholine, thereby enhancing cholinergic transmission. Three such agents are used clinically, i.e., physostigmine, a naturally occurring alkaloid, and two synthetic analogues, neostigmine and pyridostigmine. The latter two agents are strongly ionised at physiological pH and therefore are only poorly absorbed from the gastro-intestinal tract, and do not penetrate the central nervous system to any significant extent. Physostigmine is absorbed after

- 267 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 268 of 372 oral administration and readily enters the brain. As a therapeutic agent it has several disadvantages. It is chemically unstable and must be prepared in solution with an antioxidant, and protected from light. It has a relatively short half-life (20-40 mins) thereby necessitating frequent administration. The latter is of particular importance when the drug is to be administered chronically. It has a low therapeutic ratio, a value of 3-5 being reported in the majority of studies in laboratory animals, and a small therapeutic window, i.e. small range of dose in which it can be given without the accompaniment of side effects. Although physostigmine is absorbed from the gastro-intestinal tract, this is reported to be irregular and unpredictable, and therefore it is usually preferred to administer the drug parenterally. This is a serious drawback if it is to be used chronically on an outpatient basis.

2

118-6848

••

There are a number of clinical and pathological conditions which are associated with cholinergic under-activity which can be improved by the administration of an anticholinesterase agent. These include reduction in cholinergic transmission induced by a variety of exogenous substances acting in the peripheral, or central nervous system. Peripherally acting agents are gallamine, d-tubocurarine and pancuronium, which are used as muscle relaxants. Their action can readily be overcome by an anticholinesterase drug. Drugs which interfere with central cholinergic transmission are numerous, anticholinergic, atropine-like drugs including antiparkinson drugs, tricyclic antidepressants, neuroleptics, opiate analgesics; benzodiazepines and some types of general anaesthetics. So far the only agent that has proved to be of any value in reversing the effects of the latter group of drugs is physostigmine. In all reported cases of drug overdose or lack of recovery when the agent was used peri-operatively, physo-

- 268 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 269 of 372 118-6848

stigmine is usually administered parenterally, and administration is repeated every 20-30 minutes as required.

- 3

Chronic treatment with neuroleptics often results in tardive dyskinesias. The widespread use of agents having anticholinesterase activity for the treatment of schizophrenia makes this side effect an ever increasing possibility. Physostigmine injected intravenously produces a significant but short lived improvement in a proportion of patients.

A number of pathological and degenerative diseases has also been shown to be associated with a reduction or loss of cholinergic transmission. This includes myasthenia gravis and Eaton Lambert syndrome in which there is an interference with neuromuscular transmission.

A selective loss of choline acetyltransferase (the enzyme that synthesises acetylcholine) has been found in specific brain regions of patients with pre-senile dementia-of the Alzheimer type. These include the frontal and temporal cortex, hippocampus, amygdala, caudate nucleus, substantia innominata. Degeneration of cholinergic neurons in some of these areas appears to be associated with the aphasia, apraxia, agnosia and loss of short term memory that occurs in Alzheimer's disease. A similar type of dementia is also found in patients with Down's syndrome that survive to the age of 40 years and show similar cholinergic deficits. There is also a loss of cholinergic transmission in the caudate nucleus and putamen of patients with Huntingdon's chorea. Physostigmine injections have also been of some benefit in this condition. Treatment with a centrally acting anticholinesterase should also prove to be beneficial in Friedrich's ataxia.

- 269 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 270 of 372 There are two major classes of potent inhibitors of the enzyme cholinesterase. The first group was modelled primarily on the natural alkaloids physostigmine (a carbamate) and an inhibitor of cholinesterase, and d-tubocurarine, an antagonist of acetylcholine. The second group consists of various organophosphorus compounds, such as diisopropylfluorophosphonate, paraxon etc. The vast majority of the compounds of both these series were designed primarily as insecticides. In the first group of carbamate derivatives, almost all of the potent insecticides are monomethyl carbamates lacking a charged nitrogen function. This enables the molecule to penetrate rapidly the insect cuticle and fatty nerve sheath. The dimethyl derivatives are slightly less potent but are particularly toxic to houseflies and aphids. The monomethyl derivatives tend to be unstable in solution and hydrolyse readily at physiological pH. This greatly limits their biological action in mammals and makes them less suitable as pharmaceutical or therapeutic agents.

118-6848

The organo-phosphorus group of compounds causes irreversible inhibition of cholinesterase and other serine containing enzymes, which, together with their high relative toxicity, virtually precludes their use in pharmaceutical preparations. The only exception is echothiopate, a quaternary ammonium organophosphorus compound, employed in eye drops for the treatment of glaucoma.

The synthetic anticholinesterase agents currently employed as pharmaceuticals all contain a charged nitrogen function and can be broadly classified into 3 groups.

 Reversible inhibitors which contain a charged nitrogen function attached to an aromatic ring, e.g. edrophonium.

118-6848

 Dimethyl carbamates with an aromatic or heterocyclic ring containing a charged nitrogen, neostigmine, pyridostigmine.

5

 Bisquaternary structures, e.g. Demacarium, Ambenonium. These agents tend to be more selective inhibitors of acetylcholinesterase than butyrylcholinesterase, compared with the monoquaternary molecules.

The pharmaceutical application of the quaternary anticholinesterase agents is limited because of their poor penetration through cell membranes. They are therefore used for actions outside the central nervous system, and are usually given parenterally, since they are not reliably absorbed from the gastrointestinal tract. Edrophonium, neostigmine and pyridostigmine and the bisquaternary analogues are used in anaesthetic practice for the reversal of the action of muscle relaxants. They are also used for the treatment of myasthenia gravis, and paralytic ileus.

Physostigmine is the only potent anti-cholinesterase agent which has been used clinically to treat conditions in which an elevation of brain acetylcholine activity is desired. These include, Alzheimer's disease, tardive dyskinesia, Down's syndrome and Huntingdon's chorea. Physostigmine is also used to reverse the effects of overdose of anticholinergic agents, anti-Parkinson drugs, benzodiazepines and opiate analgesics.

Physostigmine is a natural alkaloid extracted from calabar beans and the seeds of the vine Physostigma venenosum and has the formula

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 272 of 372

сн3

There is a need to provide new carbamate derivatives which show greater chemical stability than physostigmine.

CH

Furthermore there is a need to provide new compounds which inhibit acetylcholinesterase in the brain for periods exceeding 3 nours but not more than 12 hours after a single administration.

There is also a need to provide new compounds which will be completely and reliably absorbed after oral administration.

There is also a need to provide new compounds which will be relatively less toxic than physostigmine. This means that the therapeutic ratio, defined as

> dose to produce therapeutic effect dose to produce mortality in 50 % of animals

should be significantly higher than those of physostigmine and that the incidence and severity of side effects should be less than those of physostigmine at therapeutic doses.

There is also a need to provide new compounds which can be given orally or parenterally to treat chronic conditions in which it is

118-6848

desired to raise cholinergic activity in the central nervous system. These include, Alzheimer's disease, Down's syndrome, Huntingdon's chorea, Friedrich's ataxia.

7

There is also a need to provide compounds that can be given parenterally at the end of operations, and anaesthetic procedures, to restore wakefulness, respiration and cardiovascular parameters to normal, after the use of anticholinergic, opiates, benzodiazepines, neuroleptics and general anaesthetics, thereby shortening the stay of patients in the recovery room.

There is also a need to provide compounds that can be given together with narcotic analgesics to patients suffering from severe pain, e.g. traumatic, post-operative, or due to carcinomatosis etc. in order to reduce the side effects (respiratory depression, somnolence, constipation and urinary retention) commonly encountered with narcotics, without impairing their analgesic potency.

There is also a need to provide compounds that can be given to patients receiving antipsychotic drugs, which have developed tardive dyskinesias, in order to diminish or abolish the latter syndrome, without exascerbating the psychosis.

According to the present invention it has now been surprisingly found that certain novel and known phenyl carbamates also inhibit acetylcholinesterase in the mammalian brain after administration to provide systemic activity, e.g. oral or parenteral administration.

Thus according to the present invention there is now provided a pharmaceutical composition adapted to produce anticholinesterase

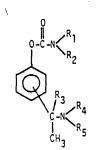

÷.,

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 274 of 372

Ţ

activity in the central nervous system of mammals comprising a compound of the general formula I

wherein

R1 is hydrogen, lower alkyl, cyclohexyl, allyl or benzyl,

R₂ is hydrogen, methyl, ethyl or propyl, or

 R_1 and R_2 together with the nitrogen to which they are attached form a morpholino or piperidino radical,

R3 is hydrogen or lower alkyl,

 R_4 and $R_5\,$ are the same or different and each is a lower alkyl, and the dialkylaminoalkyl group is in the meta, ortho or para position,

or a pharmacologically acceptable salt thereof and a physiologically acceptable carrier therefor. Hereinafter these compounds are called compounds of the invention.

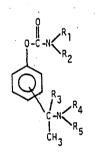

Especially preferred are pharmaceutical compositions having anticholinesterase activity in the central nervous system of mammals, wherein the dialkylaminoalkyl group is in the meta position, and R_4 and R_5 are both methyl.

- 274 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 275 of 372 - 118-6848

Certain compounds falling within the above formula have previously been described i.e. the m disubstituted compound in which R_1 and $R_3 = H$ and R_2 , R_4 and $R_5 =$ methyl which is known as Miotine(R) was claimed to be an insecticide and a myopic agent for use in eye drops. The m disubstituted compound in which R_1 and R_2 are methyl, R_3 is H and R_4 and R_5 are methyl has been described as an insecticide. The p and o disubstituted derivatives in which R_1 and $R_3 = H$ and R_2 , R_4 and $R_5 = CH_3$ have been shown to inhibit a preparation of liver cholinesterase. The m disubstituted derivative in which $R_1 = H$ and R_2 , R_3 , R_4 and $R_5 =$ CH_3 has also been shown to inhibit liver cholinesterase.

The remaining compounds are believed to be novel and thus the present invention also provides novel phenyl carbamate derivatives of the general formula I'

wherein

- R1 is hydrogen, lower alkyl, cyclohexyl, allyl or benzyl,
- R₂ is hydrogen, methyl, ethyl or propyl, or
- R_1 and R_2 together with the nitrogen to which they are attached form a morpholino or piperidino radical,
- R3 is hydrogen or lower alkyl,

- 275 -

1'

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 276 of 372 - 10 - 118-6848

۰.

R4 and R5 are the same or different and each is a lower alkyl, and the dialkylaminoalkyl group is in the meta, ortho or para position,

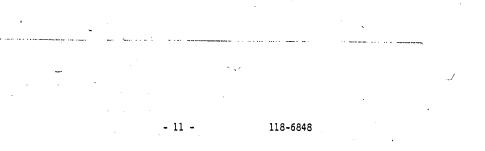

and pharmacologically acceptable salts thereof, provided that for compounds wherein R_4 and R_5 are both methyl and having the dialkylamino group in the meta position, when R_2 is methyl and R_3 is hydrogen, R_1 is neither hydrogen nor methyl, and when R_2 and R_3 are methyl, R_1 is not hydrogen, and for compounds wherein R_4 and R_5 are both methyl and having the dialkylamino group in the ortho or para position when R_1 and R_3 are both hydrogen R_2 is not methyl.

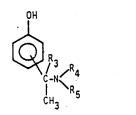

Preferred compounds of the above formula are N-ethyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-propyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N-allyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-ethyl, N-methyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N,N-diethyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N-butyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-methyl, N-propyl-3[1-(dimethylamino)ethyl]phenyl carbamate and N-ethyl, N-methyl-3[1-(dimethylamino)isopropyl]phenyl carbamate.

As indicated, the invention also includes the pharmacologically acceptable salts of these compounds such as the acetate, salicylate, fumarate, phosphate, sulphate, maleate, succinate, citrate, tartrate, propionate and butyrate salts thereof.

The compounds of formula I can be prepared by amidating a compound of formula II Σ

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 277 of 372

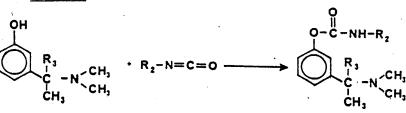

. .

ÍI

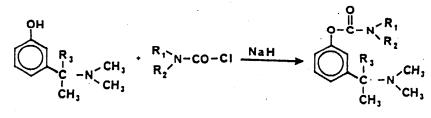

wherein R_3 , R_4 and R_5 are as defined above.

The process can be effected in conventional manner, e.g. by reacting the compound of formula II with an appropriate isocyanate if a compound wherein R_1 is hydrogen is desired, or with an appropriate carbamoyl halogenide, e.g. as described below in processes A and B.

PROCESS A:

PROCESS B:

- 277 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 278 of 372

118-6848

PROCESS A:

A stirred suspension of α -m-Hydroxyphenylethyldimethylamine or α -m-hydroxyphenylisopropyldimethylamine in benzene (0.2 - 0.3 g/ml) is treated with 2.5 - 3 fold molar excess of the isocyanate. After stirring for 15 - 24 hours at ambient temperature the reaction mixture is connected to a rotovaporator (20 mm Hg). The residue obtained is dissolved in dry ether (25 ml) and the solution, which is ice cooled, is saturated with dry HCl (g). The formed precipitate (the anticipated carbamate) is filtered off, washed with dry ether (25 ml) and dried to constant weight in a dessicator over KOH pellets under high vacuum (0.1 mm Hg).

- 12 --

PROCESS B:

A solution of α -m-hydroxyphenylethyldimethylamine or α -m-hydroxyphenylisopropyldimethylamine in dry acetonitrile (0.1 - 0.5 M) is reacted with 50 - 70 % molar excess of the corresponding carbamoyl chloride in the presence of 200 % molar excess of NaH dispersion (50 - 80 % in mineral oil). The reaction mixture is left to stir at ambient temperature for 15 - 24 hours. Removal of the acetonitrile under reduced pressure (20 mm Hg) is followed by the addition of water (10 - 25 ml). The pH of the aqueous solution is adjusted to pH = 11 by the addition of the appropriate amount of NaOH 0.1 N followed by extraction with ether (3 x 25 ml). The combined organic phases are washed with brine (25 ml) dried over MgSO4 anhydride which is then filtered off. The ice cooled etheral filtrate is saturated with a stream of HCl (g) resulting in the formation of a heavy precipitate (the anticipated carbamate) which is collected by filtration, washed with dry ether (20 ml) and dried to constant weight in a desiccator under high vacuum (0.1 mm Hg) over KOH pellets.

- 278 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 279 of 372

118-6848

The compounds of the invention e.g. in free form or salt form can be utilized by formulating one or more of them in compositions such as tablets, capsules or elixirs for oral administration or in sterile solutions or suspensions for parenteral administration. A compound or mixture of compounds of formula (I) or physiologically acceptable salt(s) thereof is compounded with a physiologically acceptable vehicle, carrier, excipient, binder, preservative, stabilizer, flavor, etc., in a unit dosage form as called for by accepted pharmaceutical practice. The amount of active substance in these compositions or preparations is such that a suitable dosage is obtained.

- 13 -

Illustrative of the adjuvants which may be incorporated in tablets, capsules and the like are the following: a binder such as gum tragacanth, acacia, corn starch or gelatin; an excipient such as dicalcium phosphate; a disintegrating agent such as corn starch, potato starch, alginic acid and the like; a lubricant such as mangnesium stearate; a sweetening agent such as sucrose, lactose or saccarin; a flavoring agent such as peppermint, oil of wintergreen or cherry. When the dosage unit form is a capsule, it may contain in addition to materials of the above type a liquid carrier such as a fatty oil. Various other mterials may be present as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets may be coated with shellac, sugar or both. A syrup or elixir may contain the active compound, sucrose as a sweetening agent, methyl and propyl parabens as preservatives, a dye and a flavoring such as cherry or orange flavour.

Sterile compositions for injection can be formulated according to conventional pnarmaceutical practice by dissolving or suspending the active substance in a vehicle such as water for injection.

- 279 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 280 of 372

- 14 - 118-6848

Buffers, preservatives, antioxidants and the like can be incorporated as required.

Preferred antioxidants for use with the compounds of the present invention include sodium metabisulphite and ascorbic acid.

While the invention will now be described in connection with certain preferred embodiments in the following examples, it will be understood that it is not intended to limit the invention to these particular embodiments. On the contrary, it is intended to cover all alternatives, modifications and equivalents as may be included within the scope of the invention as defined by the appended claims. Thus, the following examples which include preferred embodiments will serve to illustrate the practice of this invention, it being understood that the particulars described are by way of example and for purposes of illustrative discussion of preferred embodiments of the present invention only and are presented in the cause of providing what is believed to be the most useful and readily understood description of procedures as well as of the principles and conceptual aspects of the invention.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 281 of 372 - 15 -

118-6848

EXAMPLE 1

0.5 g (3.03 mmole) of α -m-hydroxyphenylethyldimethylamine are dissolved in 15 ml of dry acetonitrile and 0.70 g (5.2 mmole) of diethylcarbamylchloride are added to the mixture with stirring. This is followed by NaH 150 mg (50 %) of dispersion. The reaction mixture is stirred overnight at 25 - 30 ° C. Removal of acetonitrile under reduced pressure is followed by addition of water (10 ml) and adjustment of the pH to 11. The product is extracted in ether, which is washed by brine, dried over MgSO4 and filtered. Upon addition of HCl (g) precipitation occurs immediately, the product is filtered off, washed by dry ether and dried in a desiccator under high vacuum over KOH pellets.

The carbamate is obtained as a white powder 640 mg (80 %) mp. 137 - 138 * and identified as N,N-diethyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, having the formula

 $-\ddot{\mathbf{C}}-\mathbf{N}(\mathbf{Et})_{2}$ -N(Me) ĊH,

EXAMPLE 2

0.75 g (4.55 mmol) of α -m-hydroxyphenylethyldimethylamine are suspended in benzene (3 ml) and 0.898 g of ethylisocyanate are added to the mixture with stirring. After stirring 12 hours at room temperature the solvent is removed under reduced pressure.

- 281 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 282 of 372 - 16 - 118-6848

The residue obtained was dissolved in dry ether. Introduction of dry HCl gas into the reaction mixture causes a heavy precipitation. The product is filtered off, washed with ether and dried in a desiccator over KOH pellets. The carbamate is obtained as a white powder 800 mg (75 %) mp. 177 - 179 $^{\circ}$ C and identified as N-ethyl-3[1-(dimethylamino)ethyl]phenyl carbamate having the formula

O-CO-NH-Et -N(Me)

The compounds of the present invention are useful as pharmaceuticals. In particular they show the following activities in vitro and in vivo in the tests specified below.

The values are correct when taken in comparison with the standard drug physostigmine.

IN VITRO EXPERIMENTS:

Tests for anticholinesterase activity

A solubilized preparation of acetylcholinesterase was prepared from mouse whole brain (minus cerebellum). The brain was homogenized with (100 mg/ml) phosphate buffer; pH 8.0, centrifuged, the supernatant discarded, and the pellet mixed with a similar volume as above of buffer pH 8.0 plus 1 % Triton; mixed, centrifuged and the supernatant which contained most of the solubilized enzyme, was used for the subsequent determinations of anticholinesterase activity.

- 282 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 283 of 372

- 17 -

118-6848

The activity of the enzyme (rate of hydrolysis of substrate, acetylthiocholine) was measured using at least 4 different concentrations of substrate, and at least 3 different concentrations of each inhibitor. The enzyme was incubated with inhibitor for 5 periods ranging for 2 - 180 mins. at 37 ° C, substrate was then added, and its rate of hydrolysis measured by the spectrophotometric method of Ellman et al. (1961).

The molar concentration of each agent that inhibited the activity of the enzyme by 50 % (IC₅₀) at the peak time of activity (15 -10 60 min) was calculated from this data and recorded in Table 1 hereinafter. The compounds in general produce a significant inhibition from about 10⁻⁵ to about 10⁻⁸ molar. IN VIVO EXPERIMENTS:

a) Assessment of acetylcholinesterase inhibition

15

20

25

The effect of each compound on brain acetylcholinesterase in vivo was measured, after subcutaneous or oral administration to mice. Animals were sacrificed, at different times ranging from 0.25 - 8 hours after drug administration. The brain was rapidly removed, and the enzyme acetylcholinesterase extracted and solubilized with 0.1 % Triton, and its ability to hydrolyse acetylthiocholine assessed as described above (in vitro experiments), in comparison with the enzyme removed from mice injected with normal saline. The compounds have in general a potency of from about 2% to about 90% that of physostigmine. Assessment of acute toxicity

Mice were given one of at least three different doses of each compound, orally or subcutaneously, a minimum of 10 mice allotted to each dose. The number of animals which died at

- 283 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 284 of 372

- 18 - 118-6848

each dose within 3 hours was determined. From these data, the LD50 (dose in mg/kg which was lethal to 50 % of the mice) was computed.

This experiment was repeated after the animals had been pretreated with atropine sulphate, which blocks both peripheral and central muscarinic receptors. The data from these experiments enabled the assessment of the relative degrees of toxicity of the carbamates which result from excessive activation of muscarinic receptors, and from respiratory muscle paralysis, which is insensitive to this blocking agent.

The incidence and degree of side effects was noted for each dose of drug, starting with the lowest that caused any significant (> 20 %) inhibition of whole brain acetylcholinesterase.

15 c) Antagonism of the sommolent and respiratory depressant effects of opiates

5

10

20

25

30

Different doses of the carbamate compounds were injected intravenously with morphine in rabbits. Respiration rate, arterial blood gas tensions and pH were monitored continuously before and after drug administration for 4 -5 hours. In another series of experiments the effect of the anticholinesterase drugs was assessed on the analgesic effect of opiates in rabbits after application of a nociceptive stimulus, i.e. electrical stimulation of the sciatic nerve.

All specific examples of formula I' mentioned hereinbefore, e.g. on specification page 10, and after especially Tables 1 to 3, are prepared in analagous manner to Example 1 when R_1 and R_2 are each other than hydrogen and Example 2 when one of R_1 and R_2 are hydrogen. They are thus obtained as hydrochloride salts (except where otherwise specified). The specific compounds have metal substitutions.

118-6848

The data in Tables 1 and 2 demonstrate that somewhat larger quantities are required of all the drugs of the RA series than of physostigmine to inhibit the enzyme acetylcholinesterase. However, a comparison of the data in Table 1 with that in Table 2, shows that compounds RA5, RA6, RA15, RA14, RA10, RA7 and RAg are all relatively more active <u>in vivo</u> compared to physostigmine than one would expect from the <u>in vitro</u> data. This greater <u>in vivo</u> potency is particularly marked when the drugs are administered orally. This relatively greater <u>in vivo</u> activity may be due to:

- a) greater chemical stability
- b) a slower metabolic degradation or/and excretion
- c) a higher lipid solubility, enabling a greater proportion of the drug to gain access to the enzyme in the central nervous system
- d) more efficient absorption from gastro-intestinal tract.

For the purposes of their therapeutic application it is of little importance if one needs to give the drug (to human subjects) at a dose of 1 - 2 mg (physostigmine) or 2 - 50 mg that may be required of the compounds of the RA series. What is important is the safety of the drugs and the presence and severity of side effects that may occur at therapeutic doses. A commonly-used measure of drug safety is the therapeutic index - or LD50/ED50

Dose to kill 50 % of animals

Dose to cause the desired therapeutic effect,

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 290 of 372 - 24 -

118-6848

The duration of significant brain enzyme inhibition (> 30 %) induced by physostigmine (ED₅₀ dose) is less than 2 hours. Compounds RA4, 5, 6, 7, 8, 12, 14, 15 all act for more than 3 hours at their respective ED₅₀ doses and RA6 and RA7 still causes significant inhibition (36 %) after 7 hours. Since none of these drugs caused noticeable side effects at the ED₅₀ doses, an even longer duration of action may be achieved by giving between 50 and 100 % larger doses. The longer duration of action is a distinct advantage, particularly if the drugs are to be administered chronically to subjects suffering from neurological and behavioural conditions associated with a deficit in cholinergic transmission in the central nervous system, e.g. Alzheimer's disease, tardive dyskinesias, Huntingdon's chorea, Down's syndrome and Friedrich's ataxia.

The better the absorption of the drug after oral administration the more closely the LD₅₀ given by this route resembles that after subcutaneous injection. Table 3 shows that RA6, 13, 7 and 4 are more efficiently absorbed from the gastro-intestinal tract than is physostigmine. The ED₅₀ of RAg after oral administration is the same as that after S.C. injection, indicating a much better oral bioavailability than that of physostigmine. The higher oral bioavailability of these compounds may be a considerable advantage for their clinical use.

RA10, RA6, RA14 and RA15 produce significant antagonism of the respiratory depressant effects of morphine in rabbits for periods lasting between 3 - 5 hours depending on the drug and the dose administered. The analgesic activity of morphine is not reduced by the RA compounds. Muscle fasciculations are not evident at the doses of drugs administered. Physostigmine (0.1 - 0.2 mg/kg) antagonizes the respiratory depressant effect of morphine for

- 290 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 291 of 372 - 25 -

118-6848

30 - 60 mins only and fasciculations are marked at the higher dose.

These findings show that the RA compounds may be given together with morphine to obtain adequate analgesia without significant degrees of respiratory depression.

The most preferred compounds of the RA series are RA4, RA5, RA6, RA15, RA14, RA7 and RAg, all of which produce inhibition of brain acetylcholinesterase after parenteral administration of significantly longer duration than that induced by physostigmine or miotine. These compounds also have a greater safety margin (therapeutic ratio) than physostigmine. RA4, 6, 7 and 8 also show better bioavailability after oral administration than physostigmine. In addition, the acute toxicity (lethality) induced by RA7 can be decreased more than 10-fold and that of RA14 more than 8-fold by the antidote atropine, compared to only a 3-fold decrease for physostigmine and miotine.

The compounds of the invention are therefore useful for the treatment of senile dementia, Alzheimer's disease, Huntingdon's chorea, tardive dyskinesias, hyperkinesia, mania, acute confusion disorders, Down's syndrome and Friedrich's ataxia.

For these indications, the exact dosage will of course vary depending upon the compound employed, mode of administration and treatment desired. The compounds may be administered by any conventional route, non-oral or preferably orally.

In general, satisfactory results are obtained when administered at a daily dosage of from about 0.05 to 10 mg/kg animal body weight. For the larger mammals, an indicated total daily dosage

- 291 -

- 26 -

118-6848

is in the range from about 0.5 to about 25 mg of the compound, conveniently administered in divided doses 2 to 4 times a day in unit dosage form containing for example from about 0.1 to about 12 mg of the compound or in sustained release form.

The compounds may be administered in similar manner to known standards for use in these utilities. The suitable daily dosage for a particular compound will depend on a number of factors such as its relative potency of activity.

The compounds according to the invention may be administered in free base form or as a pharmaceutically acceptable acid addition salt. Such salts may be prepared in conventional manner and exhibit the same order of activity as the free forms.

It will be evident to those skilled in the art that the invention is not limited to the details of the foregoing illustrative embodiments and examples and that the present invention may be embodied in other specific forms without departing from the essential attributes thereof, and it is, therefore, desired that the present embodiments and examples be considered in all respects as illustrative and not restrictive, reference being made to the appended claims, rather than to the foregoing description, and all changes which come with the meaning and range of equivalency of the claims are, therefore, intended to be embraced therein.

is hydrogen, R_1 is neither hydrogen nor methyl, and when R_2 and R_3 are methyl, R_1 is not hydrogen, and for compounds wherein R_4 and R_5 are both methyl and having the dialkyl amino group in the ortho or para position when R_1 and R_3 are both hydrogen and R_2 is not methyl.

REMARKS

The claims in the application are claims 14 to 25. Claims 23 and 24 were indicated as allowable in the parent application.

Volume 29 of Advances in Behavioural Biology brought to the attention of the Examiner was published approximately the middle of 1986. The Weinstock et al. article, p. 539 to 549, was reported at the 30th OHOLO Biol. Conference in Eilat, Israel on March 24 to 27, 1985. This conference had previously been mis-identified as the 3rd. and the date of November instead of March.

The article in "Advances in Behavioral Biology" is not prior art. The evidence of this article has not been presented earlier because it is basicly the same data as is included in the patent application specification. The article is cited now in order to show that the data was presented in a recognized scientific publication.

The compounds of Aeschlimann have not been compared because it is believed that they are not as close to miotine and to the Meltzer compound than the RA compounds of Table 1 which all have the dialkylaminoalkyl group in the meta position, whereas the only compound specifically mentioned in Aeschlimann with a dialkyl group

- 303 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 304 of 372 Page Six

u

•

has the ortho configeration. The therapeutic ratio of RA10 is comparable to the claimed compounds as can be seen by reference to Table 3 but RA10 has a short duration of action compared to all the other RAs tested as can be seen by reference to Table 2.

For the reasons given hereinabove it is believed that all of the present claims are allowable.

Respectfully submitted, Richard T. Laughlin Attorney for Applicant

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

In re application (A) Howin Serial No. 320,704 Filed: 03/08 (3, 104) For: Phenyl Cardinates

Office of Assistant Commissioner For Patents

Commissioner of Patents and Trademarks

Washington, D. C. 20231

PETITION FOR ASSIGNING A FILING DATE

By a letter dated May 9, 1989 Applicants were informed that a filing date of the subject patent application would not be granted because:

The filing included a new specification or copies of a specification from the prior application. Under 37 CFR 1.62, all changes are required to be made in the form of an amendment to the prior application as it exists at the time of filing the application under 37 CFR 1.62. Therefore, it is unclear whether filing under 37 CFR 1.60 or 1.62 was intended.

This Petition request that the filing date be granted.

As applicants understand the basis for refusal it is grounded on the belief that applicants did not indicate whether it was the intention of applicants to abandoned the parent application and therefore the new application be an application under 37 CFR 1.62 or to keep the parent application pending under 37 CFR 1.60. It is applicants position that the application meet each of the requirements of 37 CFR 1.62 and that it was clearly indicated in

040 05/26/89 320700

1 124 120.00 CK

- 307 -

the papers filed that this was the intention of applicants. It is not seen how the application could be refused the filing date.

At the time of filing, applicants, through their attorney, filed a certified copy of the parent application (See the attached Exhibit A) along with an amendment amending the claims of the parent application. Further the document filed at that time entitled "REQUEST FORM FOR FILE WRAPPER CONTINUING APPLICATION UNDER 37 CFR 1.62" would seem to clearly indicate that it was the intention to file under 37 CFR 1.62 and not 1.60. Further in the paragraph which appears in the middle of page 2 of that document applicants request the abandonment of the parent application. In view of these filings the application had to be under 37 CFR 1.62 and not under 37 CFR 1.60. Still further in the amendment accompanied the application it was also clear that the provisions of 37 CFR 1.62 were being followed. Additionally in paragraph numbered 6 in the conveying form it was requested to amend the specification to state that the application is a "continuation" of the parent application. In view of these filings it is not seen what else applicants could have done to meet the requirements of 37 CFR 1.62 and it is believed that they did comply with all of the requirements.

2

- 308 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 309 of 372 It is respectively requested that in view of the aforesaid comments that this petition be granted and that the application be given the filing date of March 8, 1989. In view of the fact that all of the requirements were meet, it is requested that the Petition fee be refunded.

Respectively submitted, Richard T. Laugelin

ASSISTANT COMMISSIONER'S OFFICE

In re Application of Marta W. Rosin et al Serial No. 07/320,700 Filed March 8, 1989 For: PHENYL CARBAMATES

DECISION ON PETITION

This is a decision on the petition filed May 24, 1989 requesting that the above-identified application be treated as a proper continuation application under 37 CFR 1.62.

1

:

When the application was filed, it included a form requesting a continuation under 37 CFR 1.62 but the proper procedures were not followed for filing a FWC application.

Accordingly, in response to a Notice of Improper FWC Filing Under 37 CFR 1.62 mailed May 9, 1989, the present petition was filed requesting the PTO to accept the application as one filed under 37 CFR 1.62.

When petitioners originally filed a request for a continuation application under 37 CFR 1.62, they submitted a certified copy of the prior application along with the request. Such a copy is usually filed with a request for an application under 37 CFR 1.60 (see 37 CFR 1.60(b)). 37 CFR 1.62(a) states that

"An application filed under this section will utilize the file wrapper and contents of the prior application to constitute the new continuation..."

Therefore, petitioners' intentions were unclear and resulted in the need for special handling of the application. Thus, the present petition and petition fee were necessary to correct applicants' filing error.

Since the petition clearly states that it was applicants' intention to file the application under 37 CFR 1.62, the copy of the prior application filed on March 8, 1989 is considered withdrawn and will <u>not</u> be entered or used in the prosecution of the present case.

The petition is granted.

7/2/8 50 IN THE UNITED STATES PATENT AND TRADEMARK OFFICE In re application of: Rosin Serial No. 320,700 Group Art Unit: 12 Filed: 03/08/89 M. Shippen Examiner For: Phenyl Carbamates AMENDMENT Commissioner of Patents and Trademarks Washington, D. C. 20231 Dear Sir: Please amend the above identified application as follows: IN THE CLAIMS Cancel all of the claims and substitute the following claims: ZA. N-cyclohexyl-3[1-(dimethylamino)ethyl]phenyl carbamate and pharmacologically acceptable salts thereof. 232 N-allyl-3[1-(dimethylamino)ethyl]phenyl carbamate and pharmacologically acceptable salts thereof. 10°, 16. N-methyl-3[1-(dimethylamino)ethyl]phenyl N-ethyl, carbamate and pharmacologically acceptable salts thereof. A method of treating a subject suffering from senile dementia, Alzheimer's disease, Huntingdon's chorea, tardive dyskinesias, hyperkinesia, mania, acute confusion disorders, syndrome, Friedrich's ataxia and Down's which comprises administering to such a subject a therapeutically effective amount of a compound selected from the group consisting of N-cyclohexyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N-allyl-3[1+

- 317 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 318 of 372 (dimethylamino)ethyljphenyl carbamate, N-ethyl, (dimethylamino)ethyljphenyl carbamate, and pr (dimethylamino)ethyljph

Claims 14, 15 and 16 were allowed in the parent application. Claim 17 is a method claim directed to the use of the compounds of the other claims and should be allowable for the same reasons that the product claims were allowed.

REMARKS

It is respectfully requested that the claims remaining in the application be allowed.

Respectfully submitted,

0 a Richard T. Laughlin ()

Attorney for Applicants 129 Headquarters Plaza Morristown, New Jersey 07960 201-539-0080

Serial No. 320,700

Art Unit 126

20

-2-

The claims presented in the papers filed March 8, 1989 and July 31, 1989 have been renumbered in accordance with 37 CFR 1.126.

The following is a quotation of the appropriate paragraphs of 35 U.S.C. § 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless --(a) the invention was known or used by others in this country, or patented or described in a printed publication in this or a foreign country, before the invention thereof by the applicant for a patent.

(b) the invention was patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of application for patent in the United States.

Claims 38-41 are rejected under 35 U.S.C. § 102(a or b) as being anticipated by Weinstock, or the 30th OHOLO Biol Conference wherein the Weinstock paper was presented, or any published abstract of the paper presented at that conference. Applicants state in the paper filed March 8, 1989 that the Weinstock article was published "approximately in the middle of 1986." The instant application is entitled to the benefit of a parent application filed on March 3, 1986. From applicants' statement the actual publication date of the Weinstock reference is unclear. It may in fact be earlier than the effective filing date in the United States making it prior art under 35 USC 102 (a). The conference was clearly held before the effective filing date of the instant application make it prior art under 35 USC 102 (a), note <u>Massachusetts Institute of Technology v. AB Fortia</u>, 227 USPQ 428.

- 320 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 321 of 372 Serial No. 320,700 Art Unit 126 -3-

Any abstract of the article presented at the meeting would also constitute prior art under 35 USC 102 (a) and if published more than one year before the United States effective filing date would it would be prior art under 35 USC 102 (b). In their response applicants should indicate the earliest actual publication date of the Weinstock article known to them. They should also identify any such abstracts cited above and the actual publication dates thereof (a copy should also be supplied).

Applicants' priority date is noted; however, the right of priority has not been perfected under 35 USC 119 and as such the claims are not entitled to the priority date, also note MPEP 201.15.

The following is a quotation of 35 U.S.C. § 103 which forms the basis for all obviousness rejections set forth in this Office action:

A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

Subject matter developed by another person, which qualifies as prior art only under subsection (f) or (g) of section 102 of this title, shall not preclude patentability under this section where the subject matter and the claimed invention were, at the time the invention was made, owned by the same person or subject to an obligation of assignment to the same person.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 322 of 372 Serial No. 320,700 Art Unit 126

Claims 38-41 are rejected under 35 U.S.C. § 103 as being unpatentable over Weinstock, or the 30th OHOLO Biol Conference wherein the Weinstock paper was presented, or any published abstract of the paper presented at the conference. The references are applied as above. If they do not anticipate the claims they at least render the claims obvious.

The remaining references are cited as of interest. It is noted that the rejections of the claims over such prior art was overcome in the parent application USSN 185,451.

BU IN THE UNITED STATES PATENT AND TRADEMARK OFFICE In re application of: Rosin : Serial No. 320,700 Group Art Unit: 126 M. Shippen Filed: 03/08/89 Examiner Phenyl Carbamates For: 60 60 08.204/ AMENDMENT Commissioner of Patents and Trademarks Washington, D. C. 20231 ్ర 2

22

This is in response to the Official Action of September 26, 1989.

The article appearing in Advances in Behavioral Biology, 29 p 539-49 (1986) was a report of an oral lecture delivered by Professor Weinstock-Rosin at a Congress which took place in Eilat during the period of March 24th through March 27, 1985 which was three weeks after the convention date. There is no publication date of the article and the only information is the copyright date of 1986 appearing in the volume. Professor Weinstock-Rosin has examined Volume 29 and can give no better date. No written material or abstracts were distributed at or before the conference and the first written material was the aforementioned article.

In view of this information it is submitted that the references relied on are subsequent to the convention date of the Israel patent application of March 5, 1985, and therefore can RECEVED in 100

AMENDMENT

This is in further response to the Official Action of September 26, 1989.

Attached hereto are the priority documents which is a certified copy of the priority application which was filed in Israel.

It is believed that the filing of this document overcomes the date of the references and accordingly it is respectively requested that the application be passed to issue.

For the reasons given hereinabove reconsideration of the rejection of the application is earnestly solicited.

- 330 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 331 of 372

The present invention relates to novel phenyl carbamates which are useful as pharmaceutical compositions. The invention further relates to pharmaceutical compositions having anticholinesterase activity.

Acetylcholine is a major neurotransmitter which is found in all parts of the body. Any reduction in its activity, either as a result of neuronal damage, degeneration etc. or as induced by drugs or toxins, causes marked changes in the function of the organism. Acetylcholine itself has an extremely short half life, since it is rapidly hydrolysed at its site of action and in plasma by specific cholinesterase enzymes. Drugs that inhibit acetylcholinesterase, markedly increase and prolong the action of acetylcholine, thereby enhancing cholinergic transmission. Three such agents are used clinically, i.e., physostigmine, a naturally occurring alkaloid, and two synthetic analogues, neostigmine and pyridostigmine. The latter two agents are stongly ionised at physiological pH and therefore are only poorly absorbed from the gastro-intestinal tract, and do not penetrate the central nervous system to any significant extent. Physostigmine is absorbed after oral administration and readily enters the brain. As a therapeutic agent it has several disadvantages. It is chemically unstable and must be prepared in solution with an antioxidant, and protected from light. It has a relatively short half-life (20-40 mins) thereby necessitating frequent administration. The latter is of particular importance when the drug is to be administered chronically. It has a low therapeutic ratio, a value of 4-5 being reported in the majority of studies in laboratory animals, and a small therapeutic window, i.e. small range of dose in which it can be given without the accompaniment of side effects. Although physostigmine is absorbed from the gastrointestinal tract, this is reported to be irregular and unpredictable, and therefore it is usually preferred to administer the drug parenterally. This is a serious drawback if it is to be used chronically on an outpatient basis.

-2-

- 331 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 332 of 372

There are a number of clinical and pathological conditions which. are associated with cholinergic under-activity which can be improved by the administration of an anticholinesterase agent. These include reduction in cholinergic transmission induced by a variety of exogenous susbtances acting in the peripheral, or central nervous system. Peripherally acting agents are gallamine, d-tubocurarine and pancuronium, which are used as muscle relaxants. Their action can readily be overcome by an anticholinesterase drug. Drugs which interfere with central cholinergic transmission are numerous, anticholinergic, atropinelike drugs including antiparkinson drugs, tricyclic antidepressants, neuroleptics, opiate analgesics, benzodiazepines and some types of general anaesthetics. So far the only agent that has proved to be of any value in reversing the effects of the latter group of drugs is physostigmine. In all reported cases of drug overdose or lack of recovery when the agent was used peri-operatively, physostigmine is usually administered parenterally, and administration is repeated every 20-30 minutes as required.

Chronic treatment with neuroleptics often results in tardive dyskinesias. The widespread use of agents having anticholinesterase activity for the treatment of schizophrenia makes this side effect an ever increasing possibility. Physostigmine injected intravenously produces a significant but short lived improvement in a proportion of patients.

A number of pathological and degenerative diseases has also been shown to be associated with a reduction or loss of cholinergic transmission. This includes myasthenia gravis and Eaton Lambert syndrome in which there is an interference with neuromuscular transmission.

-3-

- 332 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 333 of 372 A selective loss of choline acetyltransferase (the enzyme that synthesises acetylcholine) has been found in specific brain regions of patients with pre-senile dementia of the Alzheimer type. These include the frontal and temporal cortex, hippocampus, amygdala, caudate nucleus substantia innominata. Degeneration of cholinergic neurons in some of these areas appears to be associated with the aphasia, apraxia, agnosia and loss of short term memory that occurs in Alzheimer's disease. A similar type of dementia is also found in patients with Down's syndrome that survive to the age of 40 years and show similar cholinergic deficits. There is also a loss of cholinergic transmission in the caudate nucleus and putamen of patients with Huntington's chorea. Physostigmine injections have also been of some benefit in this condition. Treatment with a centrally acting anticholinesterase should also prove to be beneficial in Friedrich's ataxia.

There are two major classes of potent inhibitors of the enzyme cholinesterase. The first group was modelled primarily on the natural alkaloids physostigmine (a carbamate) and an inhibitor of cholinesterase, and d-tubocurarine, an antagonist of acetylcholine. The second group consists of various organophosphorus compounds, such as diisopropylfluorophosphonate, paraxon etc. The vast majority of the compounds of both these series were designed primarily as insecticides. In the first group of carbamate derivatives, almost all of the potent insecticides are monomethyl carbamates lacking a charged nitrogen function. This enables the molecule to penetrate rapidly the insect cuticle and fatty nerve sheath. The dimethyl derivatives are slightly less potent but are

-4-

- 333 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 334 of 372 particularly toxic to houseflies and aphids. The monomethyl derivatives tend to be unstable in solution and hydrolyse readily at physiological pH. This greatly limits their biological action in mammals and makes them less suitable as pharmaceutical or therapeutic agents.

۰. د

The organo-phosphorus group of compounds causes irreversible inhibition of cholinesterase and other serine containing enzymes, which, together with their high relative toxicity, virtually precludes their use in pharmaceutical preparations. The only exception is echothiopate, a quaternary ammonium organo-phosphorus compound, employed in eye drops for the treatment of glaucoma.

The synthetic anticholinesterase agents currently employed as pharmaceuticals all contain a charged nitrogen function and can be broadly classified into 3 groups.

 Reversible inhibitors which contain a charged nitrogen function attached to an aromatic ring, e.g. edrophonium.

 Dimethyl carbamates with an aromatic or heterocyclic ring containing a charged nitrogen, neostigmine, pyridostigmine.

3) Bisquaternary structures, e.g. Demacarium, Ambenonium. These agents tend to be more selective inhibitors of acetylcholinesterase than butyrylcholinesterase, compared with the monoquaternary molecules.

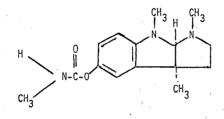

The pharmaceutical application of the quaternary anticholinesterase agents is limited because of their poor penetration through cell membranes. They are therefore used for actions outside the central nervous system, and are usually given parenterally, since they are not reliably absorbed from the gastrointestinal tract. Edrophonium, neostigmine and pyridostigmine and the bisquaternary analogues are used in anaesthetic practice for the reversal of the action of muscle relaxants. They are also used for the treatment of myasthenia gravis, and paralytic ileus.

-5

- 334 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 335 of 372 Physostigmine is the only potent anti-cholinesterase agent which has been used clinically to treat conditions in which an elevation of brain acetylcholine activity is desired. These include, Alzheimer's disease, tardive dyskinesias, Down's syndrome and Huntingdon's chorea. Physostigmine is also used to reverse the effects of overdose of anticholinergic agents, anti-Parkinson drugs, benzodiazepines and opiate analgesics.

Physostigmine is a natural alkaloid extracted from calabar beans and the seeds of the vine Physostigma venenosum and has the formula

An object of the present invention is to provide new carbamate derivatives which show greater chemical stability than physostigmine. Another object of the present invention is to provide new compounds

which inhibit acetylcholinesterase in the brain for periods exceeding 3 hours but not more than 12 hours after a single administration.

Another object of the present invention is to provide new compounds which will be completely and reliably absorbed after oral administration.

Another object of the present invention is to provide new compounds which will be relatively less toxic than physostigmine. This means that the therapeutic ratio, defined as

> dose to produce therapeutic effect dose to produce mortality in 50% of animals

> > -6-

- 335 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 336 of 372 should be significantly higher than those of physostigmine and that the incidence and severity of side effects should be less than those of physostigmine at therapeutic doses.

Another object of the present invention is to provide new compounds which can be given orally or parenterally to treat chronic conditions in which it is desired to raise cholinergic activity in the central nervous system. These include, Alzheimer's disease, Down's syndrome, Huntingdon's chorea, Friedrich's Ataxia.

It is also an object of this invention to provide compounds that can be given parenterally at the end of operations, and anaesthetic procedures, to restore wakefulness, respiration and cardiovascular parameters to normal, after the use of anticholinergic, opiates, benzodiazepines, neuroleptics and general anaesthetics, thereby shortening the stay of patients in the recovery room.

It is also an object of this invention to provide compounds that can be given together with narcotic analgesics to patients suffering from severe pain, e.g. traumatic, post-operative, or due to carcinomatosis etc. in order to reduce the side effects (respiratory depression, somnolence, constipation and urinary retention) commonly encountered with narcotics, without impairing their analgesic potency.

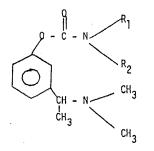

It is also an object of this invention to provide compounds that can be given to patients receiving antipsychotic drugs, which have developed tardive dyskinesias, in order to diminish or abolish the latter syndrome, without exascerbating the psychosis.

According to the present invention it has now been surprisingly found that certain novel and known phenyl carbamates also inhibit acetylcholinesterase in the mammalian brain after oral or parenteral administration.

-7-

- 336 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 337 of 372 Thus according to the present invention there is now provided a pharmaceutical composition having antichlorinesterase activity comprising a compound of the general formula I

wherein

R1 is hydrogen, lower alkyl, cyclohexyl, allyl or benzyl,

 R_p is hydrogen methyl, ethyl or propyl, or

 $\rm R_1$ and $\rm R_2$ together with the nitrogen to which they are attached form a morpholino or piperidino radical

or a pharmacologically acceptable salt thereof and a physiologically acceptable carrier therefor.

Two compounds of the above formula, i.e., the N-methyl and dimethyl derivatives have previously been described in the literature. The former which is known as $Miotine^{(R)}$ was claimed to be an insecticide and a myopic agent for use in eye drops, and the latter has only been described as an insecticide.

The remaining compounds are believed to be novel and thus the present invention also provides novel phenyl carbamate derivatives of the general formula I

-8-

- 337 -

I

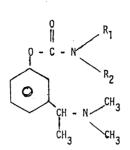

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 338 of 372 Said article is however an academic work which comes to no conclusions and does not teach or suggest structural changes in the carbamates discussed therein.

In an article by Meltzer, CA-71-111828M there are disclosed two compounds with the code numbers KD 1207 and 1261 which fall under the proviso of the present invention and provides results as to their insecticidal activity. There is also a general statement mentioning that the anticholinesterase activity of alkylphenyl N-methylcarbamates can be improved by introducing a p-dimethylaminomethyl group. There is however no alkyl group in addition to the dialkylaminoalkyl group in the compounds of formula I. Thus said article does not teach the specific compounds of the present invention.

The present invention also provides novel phenyl carbamate derivatives of the general formula I

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 339 of 372

- 8a -

wherein

 R_1 is hydrogen, lower alkyl, cyclohexyl, allyl or benzyl R_2 is hydrogen, methyl, ethyl or propyl, or R_1 and R_2 together with the nitrogen to which they are attached form a morpholino or piperidino radical and pharmacologically acceptable salts thereof, provided that when R_2 is methyl, R_1 is neither hydrogen nor methyl.

Preferred compounds of the above formula are N-ethyl-3-[1-(dimethylamino) ethyl]phenyl carbamate, N-propyl-3[1-(Dimethylamino)ethyl]phenyl carbamate, N-allyl-3-[1-(dimethylamino)ethyl]phenyl carbamate, N-ethyl,N-methyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N,N-diethyl-3[1-(dimethylamino)ethyl] phenyl carbamate, N-cyclohexyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N,N-dimethyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N,N-dimethyl-3[1-(dimethylamino)ethyl]phenyl carbamate, N,N-dimethyl-3[1-(dimethylamino)ethyl]phenyl carbamate, ethyl] morpholino carbamoyl phenolate.

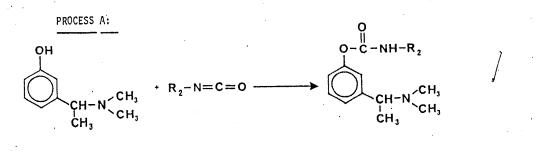

As indicated, the invention also includes the pharmacologically acceptable salts of these compounds such as the acetate, salicylate fumarate, phosphate, sulphate, maleate, succinate, citrate, tartrate, propionate and butyrate salts thereof.

The compounds of the present invention can be prepared by the following processes which processes can be summarized and represented by the following reactions:

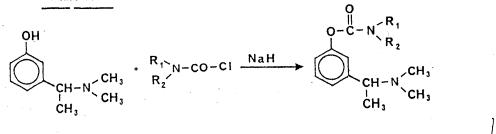

-9-

- 339 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 340 of 372 e

PROCESS B:

- 340 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 341 of 372

NOVARTIS EXHIBIT 2058

PROCESS A:

A stirred suspension of α -m-Hydroxyphenylethyldimethyl amine in benzene (0.2 -0.3 g/ml) is treated with 2.5-3 fold molar excess of the isocyanate. After stirring for 15-24 hr at ambient temperature the reaction mixture is connected to rotovaporator (20 mm Mg). The residue obtained is dissolved in dry ether (25 ml) and the solution, which is ice cooled, is saturated with dry HCl (g). The formed precipitate (the anticipated carbamate) is filtered off washed with dry ether (25 ml) and dried to constant weight in a desiccator over KOH pellets under high vacuum (0.1 mm Hg).

PROCESS B:

A solution of α -m-hydroxyphenylethyldimethyl amine in dry acetonitrile (0.1-0.5 M) is reacted with 50-70% molar excess of the corresponding carbamoyl chloride in the presence of 200% molar excess of NaH dispersion (50-80% in mineral oil). Reaction mixture is left to stir at ambient temperature for 15-24 hr. Removal of the acetonitrile under reduced pressure (20 mm Hg) is followed by the addition of water (10-25 ml). The pH of the aqueous solution is adjusted to pH = 11 by the addition of the appropriate amount of NaOh 0.1N followed by extraction with ether (3 x 25 ml). The combined organic phases are washed with brine (25 ml) dried over MgSO₄ anhydride which is then filtered off. The ice cooled etheral filtrate is saturated with a stream of HCl(g) resulting in the formation of a heavy precipitate (the anticipated carbamate) which is collected by filtration washed with dry ether (20 ml) and dried to constant weight in a desiccator under high yacuum (0.1 mm Hg) over KOH pellets.

-11-

- 341 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 342 of 372 The compounds of the invention can be utilized by formulating one or more of them in compositions such as tablets, capsules or elixirs for oral administration or in sterile solutions or suspensions for parenteral administration. A compound or mixture of compounds of formula (I) or physiologically acceptable salt(s) thereof is compounded with a physiologically acceptable vehicle, carrier, excipient, binder, preservative, stabilizer, flavor, etc., in a unit dosage form as called for by accepted pharmaceutical practice. The amount of active substance in these compositions or preparations is such that a suitable dosage is obtained.

Illustrative of the adjuvants which may be incorporated in tablets, capsules and the like are the following: a binder such as gum tragacanth, acacia, corn starch or gelatin; an excipient such as dicalcium phosphate; a disintegrating agent such as corn starch, potato starch, alginic acid and the like; a lubricant such as magnesium stearate; a sweetening agent such as sucrose, lactose or saccharin; a flavoring agent such as peppermint, oil of wintergreen or cherry. When the dosage unit form is a capsule, it may contain in addition to materials of the above type a liquid carrier such as a fatty oil. Various other materials may be present as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets may be coated with shellac, sugar or both. A syrup or elixir may contain the active compound, sucrose as a sweetening agent, methyl and propyl parabens as preservatives, a dye and a flavoring such as cherry or orange flavor.

-12-

- 342 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 343 of 372 Sterile compositions for injection can be formulated according to conventional pharmaceutical practice by dissolving or suspending the active substance in a vehicle such as water for injection. Buffers, preservatives, antioxidants and the like can be incorporated as required.

Preferred antioxidants for use with the compounds of the present invention include sodium metabisulphite and ascorbic acid.

While the invention will now be described in connection with certain preferred embodiments in the following examples, it will be understood that it is not intended to limit the invention to these particular embodiments. On the contrary, it is intended to cover all alternatives, modifications and equivalents as may be included within the scope of the invention as defined by the appended claims. Thus, the following examples which include preferred embodiments will serve to illustrate the practice of this invention, it being understood that the particulars described are by way of example and for purposes of illustrative discussion of preferred embodiments of the present invention only and are presented in the cause of providing what is believed to be the most useful and readily understood description of procedures as well as of the principles and conceptual aspects of the invention.

EXAMPLE 1

0.5g (3.03 mmole) of α -m-hydroxyphenylethyldimethylamine are dissolved in 15 ml of dry acetonitrile and 0.70g (5.2 mmole) of diethylcarbamylchloride are added to the mixture with stirring. This is followed by NaH 150 mg (50%) of dispersion. The reaction mixture is stirred overnight at 25-30°C. Removal of acetonitrile under reduced pressure is followed by addition of water (10 ml) and adjustment of the pH to 11. The product is extracted in ether,which is washed by brine, dried over MgSO₄ and filtered. Upon addition of HCl(g) precipitation occurs immediately, the product is filtered off, washed by dry ether and dried in a desiccator under high vacuum over KOH pellets.

The carbamate is obtained as a white powder 640 mg (80%) mp. 137-138° and identified as N,N-diethy1-3-[1-(dimethylamino)ethyl]phenyl carbamate, having the formula

EXAMPLE 3

Tests for anticholinesterase activity in vitro

A solubilized preparation of acetylcholinesterase was prepared from mouse whole brain (minus cerebellum). The brain was homogenized (100 mg/ml) phosphate buffer, pH 8.0), centrifuged, the supernatant discarded, and the pellet mixed with a similar volume as above of buffer pH 8.0 plus 1% Triton; mixed, centrifuged and the supernatant which contained most of the solubilized enzyme, was used for the subsequent determinations of anticholinesterase activity.

The activity of the enzyme (rate of hydrolysis of substrate, acetylthiocholine) was measured using at least 4 different concentrations of substrate, and at least 3 different concentrations of each inhibitor. The enzyme was incubated with inhibitor for periods ranging for 2-180 mins. at 37°C, substrate was then added, and its rate of hydrolysis measured by the spectrophotometric method of Ellman et al. (1961).

The molar concentration of each agent that inhibited the activity of the enzyme by 50% (IC_{50}) at the peak time of activity (15-60 min) was calculated from this data and recorded in Table I hereinafter.

- 346

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 347 of 372

IN VIVO EXPERIMENTS:

a) Assessment of acetylcholinesterase inhibition

The effect of each compound on brain acetylcholinesterase <u>in vivo</u> was measured, after subcutaneous or oral administration to mice. Animals were sacrificed, at different times ranging from 0.25-8 hours after drug administration. The brain was rapidly removed, and the enzyme acetylcholinesterase extracted and solubilized with 0.1% Triton, and its ability to hydrolyse acetylchiocholine assessed as described above (in vitro experiments), in comparison with the enzyme removed from mice injected with normal saline.

b) Assessment of acute toxicity

Mice were given one of at least three different doses of each compound, orally or subcutaneously, a minimum of 10 mice allotted to each dose. The number of animals which died at each dose within 3 hours was determined. From these data, the LD_{50} (dose in mg/kg which was lethal to 50% of the mice) was computed.

This experiment was repeated after the animals had been pretreated with with atropine sulphate, which blocks both peripheral and central muscarinic receptors. The data from these experiments enabled the assessment of the relative degrees of toxicity of the carbamates which result from excessive activation of muscarinic receptors, and from respiratory muscle paralysis, which is insensitive to this blocking agent.

-17-

- 347 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 348 of 372 The incidence and degree of side effects was noted for each dose of drug, starting with the lowest that caused any significant (>20%) inhibition of whole brain acetylcholinesterase.

.. ·

c) Antagonism of the somnolent and respiratory depressant effects of opiates

Different doses of the carbamate compounds were injected intravenously with morphine in rabbits. Respiration rate, arterial blood gas tensions and pH were monitored continuously before and after drug administration for 4-5 hours. In another series of experiments the effect of the anticholinesterase drugs was assessed on the analgesic effect of opiates in rabbits after application of a nociceptive stimulus, i.e. electrical stimulation of the sciatic nerve.

<u>Table 4</u> Acute toxicity of carbamates in mice

*Atropine sulphate, 5mg/kg was injected subcutaneously 15 mins before the drugs. ^aToxicity of this drug was not tested in the presence of atropine because the LD_{50} had not been reached in the absence of atropine.

The data in Tables 1-3 demonstrate that somewhat larger quantities are required of all the drugs of the RA series than of physostigmine to inhibit the

-22-

- 352 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 353 of 372 enzyme acetylcholinesterase. However, a comparison of the data in columns B and C with that in column A in Table 3, shows that compounds RA_6 , RA_{15} , RA_{14} , RA_{10} , RA_7 and RA_8 are all 2-75 times relatively more active <u>in vivo</u> compared to physostigmine than one would expect from the <u>in vitro</u> data. This greater <u>in vivo</u> potency is particularly marked when the drugs are administered orally. This relatively greater <u>in vivo</u> activity may be due to:

a) greater chemical stability

b) a slower metabolic degradation or/and excretion

c) a higher lipid solubility, enabling a greater propotion of the drug to gain access to the enzyme in the central nervous system

d) more efficient absorption from gastro-intestinal tract.

For the purposes of their therapeutic application it is of little importance if one needs to give the drug (to human subjects) at a dose of 1-2mg (physostigmine) or 2-50mg that may be required of the compounds of the RA series. What is important is the safety of the drugs and the presence and severity of side effects that may occur at therapeutic doses. A commonly-used measure of drug safety is the therapeutic index - or LD_{50}/ED_{50}

Dose to kill 50% of animals

Dose to cause the desired therapeutic effect

It is assumed that the therapeutic effect of these anticholinesterase agents results from an elevation of brain cholinergic activity. This in turn, should be related to the degree of inhibition of acetylcholinesterase. For the

-23-

- 353 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 354 of 372 purpose of the computation of the denominator of the therapeutic ratio, there is used the dose of drug that inhibits the activity of acetylcholinesterase by 50%. This is based on the observation by Thal et al. (Ann. Neurology 13: 491, 1983) that the maximum improvement in short term memory obtained in a series of patients with Alzheimer's disease was achieved with a dose of physostigmine which blocked the acetylcholinesterase in the cerebro-spinal fluid by 50%. The numerator is the dose found to kill 50% of the animals within 4 hours of a subcutaneous injection.

The therapeutic ratios of compounds RA6,15,14,10 and 8 are all significantly higher than that of physostigmine (see Table 4). This indicates that all these compounds have a wider margin of safety than that of physostigmine. Moreover, these RA compounds do not produce any significant undesirable side effects such as defaecation, lachrymation, fasciculations or tremor at the doses which inhibit the brain enzyme by 50%, while the former 3 side effects are clearly evident when physostigmine is given at the appropriate dose (ED₅₀).

The data in Table 4 show that atropine can afford considerably greater protection against the lethality of the derivatives RA_{10} , RA_{15} , RA_{13} and RA_7 . This is particularly important in the treatment of drug overuse since the respiratory muscle paralysis which is not affected by atropine and which is the cause of death induced by excess drug administration in the presence of atropine cannot be satisfactorily reversed by specific antidotes.

-24-

- 354 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 355 of 372 The duration of significant brain enzyme inhibition (>30%) induced by physostigmine (ED_{50} dose) is less than 2 hours. Compounds RA_6 , RA_{15} , RA_{14} , RA_{12} , RA_7 and RA_8 all act for more than 3 hours at their respective ED_{50} doses and RA_6 still causes significant inhibition (36%) after 7 hours. Since none of these drugs caused noticeable side effects at the ED_{50} doses, an even longer duration of action may be achieved by giving between 50 and 100% larger doses. The longer duration of action is a distinct advantage, particularly if the drugs are to be administered chronically to subjects suffering from neurological and behavioural conditions associated with a deficit in cholinergic transmission in the central nervous system, e.g. Alzheimer's disease, tardive dyskinesias, Huntingdon's chorea, Down's syndrome an Friedrich's ataxia.

The better the absorption of the drug after oral administration the more closely the ED_{50} given by this route resembles that after subcutaneous injection. Table 2 shows that all the drugs of the RA series except RA_{10} are more efficiently absorbed from the gastro-intestinal tract than is physostigmine. The higher oral bioavailability of these compounds is a considerable advantage for their clinical use.

 $-RA_{10}$, RA_6 , RA_{14} and RA_{15} produce significant antagonism of the respiratory depressant effects of morphine in rabbits for periods lasting between 3-5 hours depending on the drug and the dose administered. The analgesic activity of morphine is not reduced by the RA compounds. Muscle fasciculations are not evident at the doses of drugs administered. Physostigmine (0.1-0.2mg/kg) antagonizes the

-25-

- 355 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 356 of 372 respiratory depressant effect of morphine for 30-60 mins only and fasciculations are marked at the higher dose.

. 1

These findings show that the RA compounds may be given together with morphine to obtain adequate analgesia without significant degrees of respiratory depression.

The most preferred compounds of the RA series are RA_6 , RA_{15} , RA_{14} , RA_7 and RA_8 , all of which produce inhibition of brain acetylcholinesterase after parenteral administration of significantly longer duration than that induced by physostigmine or miotine. These compounds also have a greater safety margin (therapeutic ratio) and show a better bioavailability after oral administration than physostigmine. In addition, the acute toxicity (lethality) induced by RA_7 can be decreased more than 10-fold by the antidote atropine, compared to only a 3-fold increase for physostigmine and miotine.

The next preferred compounds are RA_{12} and RA_{10} . RA_{12} has a longer duration of action and higher oral bioavailability than physostigmine, while RA_{10} , has a much higher margin of safety with and without atropine than either physostigmine or miotine.

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 357 of 372 It will be evident to those skilled in the art that the invention is not limited to the details of the foregoing illustrative embodiments and examples and that the present invention may be embodied in other specific forms without departing from the essential attributes thereof, and it is, therefore, desired that the present embodiments and examples be considered in all respects as illustrative and not restrictive, reference being made to the appended claims, rather than to the foregoing description, and all changes which come with the meaning and range of equivalency of the claims are, therefore, intended to be embraced therein.

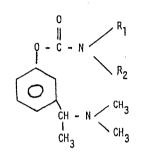

- 357 -

- 27-

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 358 of 372

WHAT IS CLAIMED IS:

1. A pharmaceutical composition having anticholinesterase activity comprising a compound of the general formula ${\bf I}$

wherein

R1 is hydrogen, lower alkyl, cyclohexyl, allyl or benzyl,

 ${\rm R}_{\rm 2}$ is hydrogen, methyl, ethyl or propyl, or

 $\rm R_1$ and $\rm R_2$ together with the nitrogen to which they are attached form

' a morpholino or piperidino radical

acceptable carrier therefor.

2. A pharmaceutical composition having anticholinesterase activity $% \label{eq:composition}$

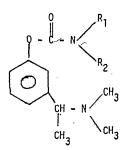

according to claim 1 wherein R_2 is hydrogen or methyl.

-28-

I

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 359 of 372

3. A phenylcarbamate of the general formula I

wherein

 R_1 is hydrogen, lower alkyl, cyclohexyl, allyl or benzyl R_2 is hydrogen, methyl, ethyl or propyl, or R_1 and R_2 together with the nitrogen to which they are attached form a morpholino or piperidino radical and pharmacologically acceptable salts thereof, provided that when R_2 is methyl, R_1 is neither hydrogen nor methyl.

4. N-ethyl-3-[l-(dimethylamino)ethyl]phenyl carbamate.

5. N-propyl-3[1-(dimethylamino)ethyl]phenyl carbamate.

6. N-ethyl, N-methyl-3[l-(dimethylamino)ethyl]phenyl carbamate.

7. N,N-diethy1-3[1-(dimethy1amino)ethy1]pheny1 carbamate.

8. N-cyclohexyl-3[l-(dimethylamino)ethyl]phenyl carbamate.

29

- 359 -

NOVARTIS EXHIBIT 2058 Noven & Mylan v. Novartis & LTS Lohmann IPR2014-00549 Page 360 of 372 9. N-ally1-3[1-(dimethylamino)ethyl]phenyl carbamate.

.

10. N-isopropy1-3[1-(dimethylamino)ethyl]phenyl carbamate.

11. N,N-dimethy1-3[1-(dimethy1amino)ethy1]pheny1 carbamate.

12. 3-[1-(dimethylamino)ethyl] morpholino carbamoyl phenolate.

13. A phenyl carbamate substantially as hereinbefore described and with reference to the examples.

THE APPLICATION IDENTIFIED ABOVE HAS BEEN EXAMINED AND IS ALLOWED FOR ISSUANCE AS A PATENT. PROSECUTION ON THE MERITS IS CLOSED._

THE ISSUE FEE MUST BE PAID WITHIN <u>THREE MONTHS</u> FROM THE MAILING DATE OF THIS NOTICE OR THIS APPLICATION SHALL BE REGARDED AS ABANDONED. THIS STATUTORY PERIOD CANNOT BE EXTENDED.

HOW TO RESPOND TO THIS NOTICE:

I. Review the SMALL ENTITY Status shown above. If the SMALL ENTITY is shown as YES, verify your

wn as YES, verify your is: If the SMALL ENTITY is shown as NO: A. Pay FEE DUE shown above, or B. File verified statement of Small Entity Status before, or with,

current SMALL ENTITY status: A. If the Status is changed, pay twice the amount of the FEE DUE shown above and notify the Patent and Trademark Office of the change in status, or

B. If the Status is the same, pay the FEE DUE shown above.

II. Part B of this notice should be completed and returned to the Patent and Trademark Office (PTO) with your ISSUE FEE. Even if the ISSUE FEE has already been paid by a charge to deposit account, Part B should be completed and returned. If you are charging the ISSUE FEE to your deposit account, Part C of this notice should also be completed and returned.

III. All communications regarding this application must give series code (or filing date), serial number and batch number.

Please direct all communications prior to issuance to Box ISSUE FEE unless advised to the contrary.

IMPORTANT REMINDER: Patents issuing on applications filed on or after Dec. 12, 1980 may require payment of maintenance fees.
