Introduction: Multiple sclerosis (MS) has a profound impact on patients' quality of life (QoL), and improvement of cognitive function, depressive symptoms and levels of fatigue remains a goal of disease-modifying therapy. Such improvements would in turn potentially support adherence to therapy, consequently further enhancing treatment outcomes.

Methods: QualiCOP was a prospective, observational, non-interventional, open-label study similar to the Coptimize trial and conducted at 170 sites in Germany. Patients ($N=754$), primarily (95.6%) with relapsing-remitting MS, with or without previous treatment, were observed for 24 months following conversion to treatment with once-daily glatiramer acetate 20mg/1mL s.c. (GA), a first line disease modifying therapy with more than 2 Million patient/years on treatment. A series of 11 examinations was conducted, including assessment of relapse rate, disease progression, overall functioning, QoL, cognition, fatigue, and depression.

Results: Treatment with GA over 24 months was associated with a reduction of annual relapse rate from 0.87 to 0.49 ($P .0001$), while the proportion of relapse-free patients rose from 11.3% to 69.5%. Total remission was achieved in 56.4% of patients. MSFC scores showed slight improvement in overall functioning ($P .0001$), while PASAT and MUSIC showed robust improvement in cognition (both $P .0001$). The CES-D also showed significant improvement of depressive symptoms ($P = .0006$). Scores on the EDSS, MUSIC-Fatigue and FAMS (all NS) showed that disease severity, fatigue, and QoL were stable over the observation period.

Conclusions: These findings suggest that patients experiencing inadequate symptom control will benefit from conversion to GA therapy, with improvements going beyond the standard measures of relapse and disease severity.
