

to said third computer of particular identifying information and a particular instruct-to-receive signal causing said third computer to determine that it is not prepared to receive information and to respond with a particular call-back signal. Said call-back signal instructs controller, 20, to defer further execution of the third stage until a particular deferred time--the first waiting moment after 1:00 AM the following morning--and causes controller, 20, to execute a preprogrammed time-check-and-determining sequence. Under control of said sequence, as a regular step in the sequence of the aforementioned polling fashion, controller, 20, checks the time of clock, 18, and determines whether said clock time is after said deferred time.

Having deferred further execution of the third stage, controller, 20, proceeds with other processing. The third stage is the final stage of said automatic telephone signal record transfer sequence. Accordingly, controller, 20, starts polling for instructions and commences regularly executing said redial and said time-check-and-determining sequences.

Subsequently, in the course of executing said redial instructions, controller, 20, and said second computer establish telephone communications in the fashion described in the first stage above. Controller, 20, then causes the transfer to said second computer of particular identifying information followed by a particular instruct-to-receive signal causing said second computer to respond with a particular start signal that causes controller, 20, to cause the transmitting of all recorded meter charge records to said second computer. When recorder, 20, finishes transmitting meter charge information, controller, 20, transmits a particular acknowledge receipt instruction to said second computer. Automatically said second computer responds with a particular transmission complete signal that causes controller, 20, to terminate said telephone call then to

cause recorder, 16, to erase from memory all said meter charge information. Then, in a preprogrammed fashion, controller, 20, deactivates the redial sequence instruction portion of said polling sequence.

5 So completing the second stage causes controller, 20, once again to commence polling for instructions.

Subsequently, controller, 20, determines that said clock time is after said deferred time which causes controller, 20, automatically to deactivate said time-check-  
10 and-determining sequence sequence and recommence said third stage. Automatically, controller, 20, reestablishes telephone communications with said third computer and causes said third computer to transfer to controller, 20, its particular start signal. Then controller, 20, causes the  
15 transmitting of all recorded monitor records to said third computer. When said transmitting is finished, controller, 20, transmits a particular acknowledge receipt instruction to said third computer. Automatically said third computer responds with a particular transmission complete signal that  
20 causes controller, 20, to terminate said telephone call then to cause recorder, 16, to erase from memory all said monitor record information.

Completing the final deferred instructions of said automatic telephone signal record transfer sequence causes  
25 controller, 20, to end said sequence and commence processing in the conventional fashion.

In examples #3 and #4 (and #5 if information of said 1st-new-program-message (#5) reaches buffer/comparator, 14, before any other instance of monitor information), receiving  
30 the first message of the "Wall Street Week" program causes the apparatus of the Fig. 3 subscriber station to carry out said signal record transfer sequence. Simultaneously, other stations have reached a similar level of fullness, and said command causes said other stations also to execute said  
35 transfer sequence. Accordingly, not only does transmitting

said first message cause all the functions described above in example #3 and #4 (and #5), transmitting said message also causes apparatus at one and more subscriber stations to transfer recorded information selectively to one and more remote stations at the time of execution and at deferred times, causes computers at said stations to process said information, and causes said computers to transfer information, point-to-point, to said subscriber station apparatus.

10           Examples #3, #4, and #5 do not show the second message of the "Wall Street Week" program causing information to be recorded at the recorder, 16, of the subscriber station of Fig. 3. Accordingly, said message does not cause apparatus of said station to transfer of record information to one or  
15 more remote station computers.

          Nevertheless, it is clear from the above exposition that the transmission of any SPAM command (including the pseudo command) that includes meter-monitor information can cause monitor record information to be recorded at the  
20 recorder, 16, of selected stations and can cause signal processors, 200, at selected ones of said stations (that is, at stations where recorders, 16, equal or exceed particular fullness information) to transfer meter and/or monitor record information selectively to one or more remote stations and  
25 cause computers at said stations to process the information in the fashions described herein.

          (Indeed, as the above exposition makes clear, the impact of the transmission of SPAM information can be yet more complex and meaningful. In example #4, receiving the  
30 second message does cause selected stations to record monitor record information the recorders, 16, of said stations. Said stations are those stations that are preprogrammed to collect monitor information at which the first message is not decrypted but the second message is; at which, as a  
35 consequence, program unit identification information does not

exist at SPAM-first-precondition memories and, hence, where Fig. 1C combinings fail to occur because the first precondition is not satisfied; and at which, as a consequence, receiving said second messages causes a 2nd monitor information (#4) transmission and causes processing of said 2nd monitor information (#4) at buffer/comparators, 14. At said stations, because no monitor information of the first "Wall Street Week" program message was previously processed--because none was decrypted--monitor record information of prior programming still exists at said buffer/comparators, 14, when said 2nd monitor information (#4) is received at said buffer/comparators, 14. At selected ones of said stations which ones where recorders, 16, will equal or exceed particular fullness information when the next instance of record information is recorded, receiving said second message causes the recording of said monitor record information of prior programming, causes the transferring of meter and/or monitor record information selectively to one or more remote stations, and causes computers at said stations to process the information in the fashions described herein.)

REGULATING THE RECEPTION AND USE OF PROGRAMMING ...

(INCLUDING EXAMPLE #6)

Examples #2 and #4, above, illustrate methods of controlling encryption and decryption means, well known in the art, within signal processing systems to regulate (and meter) the reception and use of control instructions that generate combined medium overlay information and cause combinings to commence and cease at selected stations. Said means and methods involve the operation of preprogrammed cipher keys (such as keys J and Z) and cipher algorithms to decrypt transmitted information.

The present invention includes other apparatus and methods for regulating the reception and use of combined medium control instructions, and the apparatus and methods of

the present invention that are used to control (and meter) combined medium communication can also regulate the reception and use of prior art electronic programming transmissions.

In the prior art, various means and methods exist for  
5 regulating the reception and use of electronically transmitted programming. Various scrambling means are well known in the art for scrambling, usually the video portion of analogue television transmissions in such a fashion that only subscriber stations with appropriate descrambling means have  
10 capacity to tune suitably to the television transmissions and display the transmitted television image information. Encryption/decryption means and methods, well known in the art, can regulate the reception and use of, for example, digital video and audio television transmissions, digital  
15 audio radio and phonograph transmissions, digital broadcast print transmission, and digital data communications. Other techniques, well known in the art, involve controlling interrupt means that may be as simple as on/off switches to interrupt or disconnect programming transmissions at stations  
20 that lack authorizing information or are determined in other fashions not to be duly authorized. Still other techniques, also well known in the art, involve controlling jamming means that spoil transmitted programming at stations that lack authorizing information or are determined not to be duly  
25 authorized, thereby degrading the usefulness of said programming. Such other techniques include, for example, inserting so-called "noise" into the transmitted programming which noise may be, for example, overlays of one or more separate transmissions.

30 The means and methods of the present invention for regulating reception and use of programming relate, in particular, to three features of the present invention. The computer system of the present invention has capacity at each subscriber station to compute station specific information  
35 based on preprogrammed information that exists at each

station and that differs from station to station. Given this capacity, any central control station of the present invention that originates a SPAM transmission can cause subscriber station apparatus to decrypt received SPAM information in different fashions with each station decrypting its received information in its own station specific fashion. A central station can cause different stations to compute different station specific decryption cipher keys and/or algorithms to use in any given step of decryption or to compute station specific key and/or algorithm identification information that differs from station to station and controls each station in identifying the key and/or algorithm to use for any given step of decrypting. A second feature of the present invention is that effective SPAM processing depends on the correspondence between the transmitted SPAM information that causes processing at the subscriber stations and the information preprogrammed at the various stations that controls the SPAM processing at each station. In order for any given SPAM execution segment to invoke any given controlled function at any given station, the received binary information of said segment (for example, "010011") must match preprogrammed controlled-function-invoking information ("010011") at each station. This feature permits each station to be preprogrammed with station specific controlled-function-invoking information that differs from station to station (which means that no single SPAM execution segment could invoke a given function at all stations without first being processed at selected stations to render its information to correspond to the station specific preprogrammed invoking information of said stations). The third feature of the present invention is an extended system of means and methods for regulating the reception and use of SPAM information--including decryption key and algorithm information--that is illustrated in Fig. 4 and discussed more fully below.

By themselves, the first and second features provide a technique whereby a message such as the second message of the "Wall Street Week" program can take affect at only selected stations (such as those stations preprogrammed with decryption key J) without being decrypted at said stations. (Hereinafter, this technique is called "covert control.")

An example #6, that focuses on the second message of the "Wall Street Week" program and is set within the context of example #4, illustrates the operation of covert control.

10 In examples #1, #2, #3, and #4, the information of the execution segment of said second message, when unencrypted, is identical from example to example. For example, if said information is "100110" in example #1, it is "100110" in example #3 and, after decryption, in examples #2 and #4. And  
15 the preprogrammed execute-conditional-overlay-at-205 information that said information of the execution segment matches when compared with controlled-function-invoking information is also "100110".

But in example #6 the information of the execution  
20 segment of said second message is different; for example, said information is "111111". And the particular binary number that is selected--"111111" in the particular example-- is selected because no subscriber station is preprogrammed, at the outset of the example, with any controlled-function-invoking information that is "111111". (In other words, were  
25 said "111111" information of the execution segment transmitted without any other action taking place first, transmitting said information would cause no controlled function to be executed at any subscriber station because  
30 said information would not match any controller-function-invoking information at any station.)

In example #6, two particular messages are transmitted each of which consists of a "01" header; execution, meter-monitor, and information segments; and an end of file signal.  
35 (Hereinafter, said messages are called the "1st supplementary

message (#6)" and the "2nd supplementary message (#6)".) In each message, the information of said segments is encrypted prior to transmission in the same fashion that the information of the first message of example #4 is encrypted, 5 except that the encryption is done with key J rather than key Z and the encrypted information of the execution segment instructs subscriber stations to decrypt with key J.

The "Wall Street Week" program originating studio embeds and transmits the 1st supplementary message (#6) 10 before transmitting said second message.

Just as is the case with the first message of example #4, at the subscriber station of Fig. 3 (and at other stations that are preprogrammed with decryption key J), receiving the 1st supplementary message (#6) causes the 15 apparatus of said station to decrypt said message (using key J) and execute any controlled functions that are invoked by the unencrypted execution segment of said message. Automatically, control processor, 39J, causes decryptor, 39K, to receive the information of said message; decryptor, 39K, 20 decrypts the encrypted information of said message and transfers said message to EOFS valve, 39H; and EOFS valve, 39H, inputs the information of said message, unencrypted, to control processor, 39J, until the end of file signal of said message is detected. Automatically, control processor, 39J, 25 compares the unencrypted information of the execution segment in said message to the aforementioned controlled-function-invoking information, and a match occurs with particular preprogrammed execute-at-39J information that causes control processor, 39J, to execute particular preprogrammed load-and-run-at-39J instructions. 30

Executing said instructions causes control processor, 39J, to record the received SPAM information of said 1st supplementary message (#6) in a fashion similar to the recording of the first message of example #4 except that the 35 information of the information segment of said 1st

5 supplementary message (#6) is recorded at particular RAM associated with control processor, 39J, rather than particular RAM of microcomputer, 205. Automatically, control processor, 39J, records all remaining command information of said 1st supplementary message (#6) together with any padding bits immediately following said command at the aforementioned SPAM-input-signal register memory then continues receiving the SPAM information of said message and loads said information (which is the information of the information segment of said message) at particular working memory of said RAM associated with control processor, 39J.

15 In due course, EOFs valve, 39H, receives complete information of the end of file signal that ends said 1st supplementary message (#6). Receiving said information causes EOFs valve, 39H, to transmit the aforementioned interrupt signal of EOFs-signal-detected information to control processor, 39J.

20 Receiving said signal while under control of said load-and-run-at-39J instructions causes control processor, 39J, to execute the information of the information segment of said 1st supplementary message (#6) that is loaded at said RAM as the so-called machine language instructions of one so-called job.

25 Executing said information causes control processor, 39J, in the predetermined fashion of the said information that is preprogrammed at said RAM at the time of execution by virtue of being so loaded prior to being so executed, to locate the location of that particular instance of controlled-function-invoking information that is "100110" (which is the execute-conditional-overlay-at-205 information that causes control processor, 39J, to execute the controlled function of said conditional-overlay-at-205 instruction) and modify the information at said location to be "111111".

30 (Simultaneously, other control processors, 39J, and at other stations that are preprogrammed with decryption key J execute  
35

information of loaded information of said information segment and modify information of the execute-conditional-overlay-at-205 information, at said control processors, 39J, to be "111111".)

5           In this fashion, the execute-conditional-overlay-at-205 information at the control processors, 39J, of those selected subscriber stations that are preprogrammed with information of decryption key J is altered from its standard "100110" and becomes "111111".

10           Accordingly, when the second message of the "Wall Street Week" program of example #6 is transmitted with its "111111" execution segment, said message is processed at those stations that are preprogrammed with said information of decryption key J precisely as the second message of  
15 example #3 is processed at said stations. (At all other stations, all information of said message is automatically discarded because the "111111" information of its execution segment fails to match any preprogrammed controlled-function-invoking information.)

20           The "Wall Street Week" program originating studio embeds and transmits the 2nd supplementary message (#6) after transmitting said second message.

          At the subscriber station of Fig. 3 (and at other stations that are preprogrammed with decryption key J),  
25 receiving said 2nd supplementary message (#6) causes precisely the same processing that is caused by receiving the 1st supplementary message (#6) with just one exception. Whereas executing the loaded information of the information segment of the 1st supplementary message (#6) causes control  
30 processor, 39J, to locate that instance of controlled-function-invoking information that is "100110" and modify the information at the location of said "100110" to be "111111", executing the loaded information of the information segment of the 2nd supplementary message (#6) causes control  
35 processor, 39J, to locate that instance of controlled-

function-invoking information that is "111111" and modify the information at the location of said "111111" to be "100110".

In this fashion, the execute-conditional-overlay-at-205 information at the control processors, 39J, of those  
5 selected subscriber stations that are preprogrammed with information of decryption key J is returned to its standard value: "100110". (Hereinafter, the normal binary value of a given instance of information that invokes a preprogrammed function--such as, for example, the "100110" that is the  
10 normal value of said execute-conditional-overlay-at-205 information--is called a "standard control-invoking value", and a value that temporary replaces a standard control-invoking value in the course a covert control application--such as "111111" in example #6--is called a "covert control-  
15 invoking value".)

Covert control provides significant benefits. One benefit is speed. For example, when covert control is employed, no time is spent decrypting messages (such as the second "Wall Street Week" message of examples #2 or #4) that  
20 convey combining synch commands. Thus the shortest possible interval of time can exist between the moment when a given combining synch command (such as the command of said second message) is embedded at the program originating studio and transmitted and the moment when it causes combining at  
25 those selected stations at which it causes combining. A second benefit arises out of the capacity to repeat. In example #6, after transmitting said 1st supplementary message (#6) and causing the covert control-invoking value, "111111", to replace the standard control-invoking value of the  
30 execute-conditional-overlay-at-205 information at those selected subscriber stations that are preprogrammed with decryption key J, the "Wall Street Week" program originating studio can invoke the aforementioned conditional-overlay-at-205 instructions at said selected stations not just once but  
35 many time by transmitting execution segments that are

"111111" before transmitting said 2nd supplementary message (#6) and causing the standard control-invoking value of said execute-conditional-overlay-at-205 information, "100110", to replace said covert control-invoking value at said selected  
5 stations.

Fig. 4 shows the Signal Processing Programming Reception and Use Regulating System that is the third feature of the present invention.

The subscriber station of Fig. 4 has capacity for  
10 receiving wireless television programming transmissions at a conventional antenna, 199, and a multi-channel cable transmission at converter boxes, 201 and 222. Said boxes, 201 and 222, are conventional cable converter boxes with capacity, well known in the art, for receiving information of  
15 a selected channel of a multiplexed multi-channel transmission and converting the selected information to a given output frequency. The selected channels whose information is received at said boxes, 201 and 222 respectively, are selected by tuners, 214 and 223  
20 respectively, which are conventional tuners, well known in the art, each with capacity for tuning to a selected channel. Antenna, 199, and boxes, 201 and 222, transmit their received information to matrix switch, 258, which is a conventional matrix switch, well known in the art, with capacity for  
25 receiving multiple inputs and outputting said inputs selectively to selected output apparatus. One apparatus that said switch has capacity for outputting to is television tuner, 215. However, the configuration Fig. 4 differs from the configuration of Figs. 1 and 3 in that television tuner, 215, outputs its audio and video outputs to said matrix  
30 switch, 258, rather than to monitor, 202M, and divider, 4, respectively. Instead, in Fig. 4, it is said switch, 258, that outputs the information that is input to said monitor, 202M, and divider, 4. Fig. 4 shows five additional devices--  
35 three decryptors, 107, 224 and 231, a signal stripper, 229,

and a signal generator, 230--associated with matrix switch, 258. Decryptors, 107, 224 and 231, are conventional decryptors, well known in the art, with capacity for receiving encrypted digital information, decrypting said  
5 information by means of a selected cipher algorithm and a selected cipher key, and outputting the decrypted information. Signal stripper, 229, is a conventional signal stripper, well known in the art, with capacity for receiving a transmission of video information, removing embedded or  
10 otherwise inserted signal information selectively, and outputting the transmission absent the removed information. Signal generator, 230, is a conventional signal inserter, well known in the art, with capacity for receiving a transmission of video information, embedding or otherwise  
15 inserting signal information selectively, and outputting the transmission with the embedded or otherwise inserted information. Matrix switch, 258, has capacity for outputting selected inputted transmissions to each said five devices, and each of said devices processes its inputted information  
20 in its specific fashion and outputs its processed information to said switch, 258.

As Fig. 4 shows, signal processor, 200, controls all the aforementioned apparatus. Signal processor, 200, controls the tuning of tuners, 214, 215, and 223; controls  
25 the switching of matrix switch, 258; supplies cipher algorithm and cipher key information to and controls the decrypting of decryptors, 107, 224 and 230; controls signal stripper, 229, in selecting transmission locations and/or information to strip and in signal stripping; and controls  
30 signal generator, 230, in selecting transmission locations at which to insert signals, in generating specific signals to insert, and in inserting.

In addition, Fig. 4 also shows divider, 4, monitor, 202M, decoder, 203, and microcomputer, 205, all of which  
35 function and are controlled as in Figs. 1 and 3.

Finally, Fig. 4 shows local input, 225, well known in the art, which has means for generating and transmitting control information to controller, 20, of signal processor, 100. The function of local input, 225, is to provide means  
5 whereby a subscriber may input information to the signal processor of his subscriber station, thereby controlling the functioning of his personal signal processor system in specific predetermined fashions that are described more fully below. In the preferred embodiment, local input, 225, is  
10 actuated by keys that are depressed manually by the subscriber in the fashion of the keys of a so-called touch-tone telephone or the keys of a typewriter (or microcomputer) keyboard. As Fig. 4 shows, microcomputer, 205, also has capacity for inputting control information to microcomputer,  
15 205, via decoder, 203, and in the preferred embodiment, microcomputer, 205, may also automatically substitute for local control, 225, in predetermined fashions in inputting control information to said controller, 20, on the basis of preprogrammed instructions and information previously  
20 inputted to said microcomputer, 205.

#### OPERATING S. P. REGULATING SYSTEMS ... EXAMPLE #7

Example #7 illustrates the operation of the the signal processing regulating system of Fig. 4 and demonstrates the  
25 interaction of the aforementioned first and third features of the present invention--the capacity to compute station specific information at each subscriber station and the system of regulating (and metering) means and methods that is illustrated in Fig. 4.

30 In example #7, the program originating studio that originates the "Wall Street Week" transmission transmits a television signal that consists of so-called "digital video" and "digital audio," well known in the art. Prior to being transmitted, the digital video information is doubly  
35 encrypted, by means of particular cipher algorithms A and B

and cipher keys Aa and Ba, in such a way that said information requires decryption at subscriber stations in the fashion described below. The digital audio is transmitted in the clear. Said studio transmits the information of said program to a plurality of intermediate transmission stations by so-called "landline" means and/or Earth orbiting satellite transponder means, well known in the art.

Each of said intermediate transmission stations receives the transmission originated by said studio and retransmits the information of said transmission to a plurality of ultimate receiver stations.

In example #7, the intermediate station that retransmits "Wall Street Week" program information to the subscriber station of Fig. 4 is a cable television system head end (such as the head end of Fig. 6). Prior to retransmission, said station encrypts the digital audio information of said transmission, in a fashion well known in the art, using particular cipher algorithm C and cipher key Ca, then transmits the information of said program on cable channel 13, commencing at a particular 8:30 PM time on a particular Friday night.

In example #7, the controller, 20, of the signal processor, 200, of Fig. 4 is preprogrammed at a particular time with particular information that indicates that the subscriber of said station wishes to view said "Wall Street Week" program when transmission of said program on cable channel 13 commences.

(So preprogramming controller, 20, can occur in several fashions. For example, prior to a particular time, a subscriber may enter particular please-fully-enable-WSW-on-CC13-at-particular-8:30 information at local input, 225, and cause said information, in a predetermined fashion, to be inputted to controller, 20, by local input, 225. Alternately, microcomputer, 205, can be preprogrammed with particular specific-WSW information and, in a predetermined

fashion that is described more fully below, caused to input said please-fully-enable-WSW-on-CC13-at-particular-8:30 information to said controller, 20.)

Receiving any given instance of please-fully-enable-WSW-on-CC13-at-particular-8:30 information causes controller, 20, in a predetermined fashion, to select particular WSW-on-CC13-at-particular-8:30 information in said received information, record said selected information at particular memory, and execute particular receive-authorizing-info-at-appointed-time instructions.

In a predetermined fashion, executing said instructions causes controller, 20, causes prepare to receive a particular enabling SPAM message at a particular time. Automatically, controller, 20, checks the time of the clock, 18, of signal processor, 200, periodically. At a particular commence-enabling time that is a predetermined interval prior to the aforementioned 8:30 PM time (when said originating studio commences transmitting the "Wall Street Week" program), controller, 20, causes all apparatus of the TV signal decoder, 30, to delete from memory all information of received SPAM information; transmits particular preprogrammed enable-next-program-on-CC13 information to the control processor, 39J, of said decoder, 30, and causes said control processor, 39J, to place one instance of said information at a particular controlled-function-invoking information location; causes the oscillator, 6, then to cause switch, 1, and mixer, 3, to select information of a particular master cable control channel (that may or may not be cable channel 13) from the multi-channel cable system transmission inputted to signal processor, 200, and to input said selected to TV signal decoder, 30; causes said control processor, 39J, to cause digital detectors, 34, 37, and 38, to cease inputting detected information to controller, 39, and commence discarding said information (which said detectors, 34, 37, and 37, have capacity to do) and to cause

particular apparatus of decoder, 30,--for example, line receiver, 33, and digital detector, 34--to commence receiving and inputting to controller, 39, SPAM information detected in the frequency inputted to decoder, 30; causes said control  
5 processor, 39J, to commence waiting to receive the header information of a SPAM message; and places one instance of said enable-next-program-on-CC13 information at a particular controlled-function-invoking-@20 information location.

In the interval between said commence-enabling time  
10 and said 8:30 PM time, said head end is caused, in a predetermined fashion, to transmit a particular enabling SPAM message that consists of a "01" header, execution segment information that matches said enable-next-program-on-CC13 information, particular meter-monitor information,  
15 information segment information of particular enable-CC13 instructions and particular enable-WSW instructions that include particular enable-WSW-programming information, and an end of file signal on the frequency of said master control channel. (Hereinafter said message is called the "local-  
20 cable-enabling-message (#7).")

In the fashions described above, so transmitting said SPAM message causes signal processor, 200, at decoder, 30, (to which said master control channel is inputted), to detect the information of said message, select the information of  
25 the execution segment in said message, and determine that said selected information matches the aforementioned instance of enable-next-program-on-CC13 information at said particular controlled-function-invoking information location. So determining a match causes the control processor, 39J, to  
30 execute particular preprogrammed transfer-this-message-to-controller-20 instructions that are associated with the instance of information at said particular location.

The matrix switch, 39I, of the controller, 39 of decoder, 30, has capacity to transfer information to  
35 controller, 20, via control transmission means and executing

said instructions causes said control processor, 39J, to cause the transfer of the information of said message to controller, 20, in the fashion in which information of first message of example #4 is transferred from control processor, 5 39J, and buffer, 39E (by way of EOFs valve, 39F), via matrix switch, 39I, to decryptor, 39K.

Receiving said message causes controller, 20, to load the enable-CC13 instructions and the enable-WSW instructions of the information segment of said message at particular RAM 10 of controller, 20, and execute said instructions as the machine language instructions of one job. Automatically, controller, 20, selects the information of the execution segment in said message, determines that said selected information matches the aforementioned instance of enable- 15 next-program-on-CC13 information at said particular controlled-function-invoking-@20 information location, executes particular preprogrammed load-and-run-@20 instructions that are associated with the instance of information at said particular location, loads the 20 information of the information segment of said message--which information is said enable-CC13 instructions--at said RAM, and executes the information so loaded. (The process of so receiving, loading, and executing the information of said message proceeds at controller, 20, in the fashion of the 25 receiving, loading, and executing the information of the aforementioned 1st supplementary message (#6) at the apparatus of the controller, 39, of decoder, 203, following the transfer of the converted information of said 1st supplementary message (#6) by the processor, 39D, of said 30 controller, 39.)

Executing said enable-CC13 instructions at controller, 20, in this fashion, causes controller, 20, to sample selected preprogrammed SPAM information of the station of Fig. 4 and determine whether unauthorized tampering has 35 occurred at said station. Automatically, in the

predetermined fashion of the said instructions, controller, 20, selects information of the unique digital code at ROM, 21, that identifies signal processor, 200, and the subscriber station of Fig. 4 uniquely; computes the quotient that  
5 results from dividing said selected information by 65,536 (which is 2 raised to the 16th power); selects the integer portion of said quotient; branches, in a branching fashion well known in the art, to a selected one of a plurality of subroutines of said enable-CC13 instructions on the basis of  
10 the value of said integer; and executes said selected one subroutine. Executing said subroutine causes controller, 20, in a predetermined fashion, to select information of a particular sixteen contiguous bit locations that contain information of said enable-CC13 instructions and compare said  
15 selected information to selected information of a particular sixteen contiguous bit locations that hold preprogrammed SPAM operating information. (Said contiguous bit locations that hold preprogrammed SPAM operating information may be bit locations at any signal processing RAM or ROM at the station  
20 of Fig. 4, such as, for example, the RAM of controller, 20; the RAM of controller, 12; the RAM associated with the control processor, 39J, of decoder, 203; the RAM associated with the processor, 39B, of the decoder, 30, of signal processor, 200; etc.) A match indicates that said sixteen  
25 contiguous bit locations that hold preprogrammed SPAM operating information are preprogrammed with properly. A match occurs at the station of Fig 4.

(Simultaneously other stations compare information of other selected information of bit locations that contain  
30 information of said enable-CC13 instructions with information of other local bit locations that hold preprogrammed SPAM operating information. At each station where a match fails to occur--which suggests that the preprogrammed SPAM operating information of said station has been tampered with  
35 in an unauthorized fashion--not resulting in a match causes

the controller, 20, of said station to cause all information of said local-cable-enabling-message (#7) to be erased from all memory of said station except for a particular portion of said enable-CC13 instructions loaded at the RAM of said  
5 controller, 20, then to execute the information of said portion as information of a so-called "machine language job". Erasing said information from memory prevents the apparatus of said station from decrypting the encrypted information of said "Wall Street Week" program, and executing said portion  
10 causes said controller, 20, to cause the auto dialer, 24, and telephone connection, 22, to establish telephone communications with a particular predetermined remote station, in the fashion described above in "Operating Signal Processor Systems ... Signal Record Transfer," and causes  
15 controller, 20, then to transmit information of the aforementioned unique digital code at ROM, 21, that identifies said station and signal processor, 200, of said station uniquely as well as particular predetermined appearance-of-tampering information. Transmitting said  
20 unique code and appearance-of-tampering information enables apparatus at said remote station to identify said remote station. If telephone communications are not established with said remote station in a predetermined fashion and/or  
25 within a predetermined time interval, executing said portion causes said controller, 20, to erase all preprogrammable RAM and EPROM of the signal processing apparatus at said station, thereby disabling said apparatus.)

Resulting in a match causes controller, 20, to execute a particular portion of said enable-CC13 instructions.

30 Executing the instructions of said portion causes controller, 20, in the predetermined fashion of the said portion, to cause selected apparatus of the station of Fig. 4 to receive the cable channel 13 transmission, to cause selected apparatus to decrypt the audio portion of said  
35 transmission, to cause selected apparatus to commence waiting

to receive further enabling information, and to create a meter record that documents the decryption of the cable audio transmission at the station of Fig. 4. Automatically, controller, 20, causes matrix switch, 258, to cease  
5 transferring video and audio information to monitor, 202M. Then, automatically, controller, 20, causes a selected tuner, 214, to tune to the frequency of cable channel 13, thereby causing its associated converter box, 201, to convert its received information of said frequency (which information is  
10 received by means of its multi-channel cable system transmission input) to a selected output frequency and transfer said information at said frequency to matrix switch, 258. (Said selected tuner, 214, said selected frequency, and all other apparatus and/or modes of operation selected by  
15 controller, 20, under control of the information of said information segment are selected in predetermined fashions.) Automatically, controller, 20, causes matrix switch, 258, to transfer the information inputted from said box, 201, to the output that outputs to television tuner, 215, and causes said  
20 tuner, 215, to tune to said selected frequency, thereby causing said tuner, 215, to receive the information of cable channel 13 and output the audio and video portions of said information to matrix switch, 258, on the separate audio and video outputs of said tuner, 215. Automatically, controller,  
25 20, causes matrix switch, 258, to transfer the information of said audio portion inputted from said tuner, 215, to the output that outputs to a selected decryptor, 107, thereby causing said decryptor, 107, to receive the information of said audio portion (said information being, as explained  
30 above, encrypted digital audio). Automatically, controller, 20, selects information of cipher key Ca from among the information of said portion; transfers said cipher key information to decryptor, 107; and causes decryptor, 107, to commence decrypting its received audio information, using  
35 said key information and selected decryption cipher algorithm

C, and outputting decrypted information of the audio portion of the "Wall Street Week" program transmission to matrix switch, 258. Automatically, controller, 20, causes matrix switch, 258, to transfer the information inputted from 5 decryptor, 107, to the output that that outputs to signal processor, 200, thereby causing signal processor, 200, to receive said information at a particular third alternate contact of switch, 1, (that is not shown in Fig. 2). Automatically, controller, 20, clears all information of any 10 prior SPAM message from decoder, 30; causes switch, 1, to connect to said third contact, thereby inputting said information to mixer, 3; and causes mixer, 3, (by control transmission means via oscillator, 6) to transfer said information without any modification; causes the control 15 processor, 39J, of decoder, 30, to cause the filter, 31, and modulator, 32, to transfer said information without any modification; causes said control processor, 39J, to cause digital detectors, 34 and 37, to cease inputting detected information to controller, 39, and commence discarding said 20 information and to cause digital detector, 38, to commence inputting detected information to controller, 39; and causes said control processor, 39J, to commence waiting to receive the header information of a SPAM message. Then automatically, said enable-CC13 instructions cause 25 controller, 20, to execute said enable-WSW instructions.

Executing said enable-WSW instructions causes controller, 20, to cause the control processor, 39J, of said decoder, 30, to place one instance of said enable-WSW-programming information (that said enable-WSW instructions 30 include) at the particular controlled-function-invoking information location occupied by said enable-next-program-on-CC13 information (thereby overwriting said information), and said instruction cause controller, 20, to places one instance of said enable-WSW-programming information at the particular 35 controlled-function-invoking-@20 information location

occupied by said enable-next-program-on-CC13 information (thereby overwriting said information at said location, too).

Finally, controller, 20, completes execution of all information of the information segment of local-cable-  
5 enabling-message (#7) loaded at controller, 20, then in the fashion of the first message of example #4, controller, 20, processes automatically the information of the meter-monitor segment as meter information, causes a meter record of prior programming to be transferred from buffer/comparator, 14, and  
10 recorded at recorder, 16, (and causes the aforementioned signal record transfer sequence if recorder, 16, equals or exceeds if predetermined level of fullness); causes information of the meter-monitor segment to be placed at particular locations of buffer/comparator, 14, thereby  
15 creating a meter record that records the decryption of the audio portion of the "Wall Street Week" program transmission; and causes monitor information to be recorded by onboard controller, 14A, if the station of Fig. 4 is preprogrammed to collect monitor information.

20 Subsequently, but still in the interval between said commence-enabling time and said 8:30 PM time, said program originating studio embeds in the audio portion and transmits a particular SPAM message that consists of a "01" header, execution segment information that matches said enable-WSW-  
25 programming information, particular meter-monitor information, particular 1st-stage-enable-WSW-program instructions as the information segment information, and an end of file signal. (Hereinafter said message is called the "1st-WSW-program-enabling-message (#7).")

30 In the fashions described above, so transmitting said SPAM message causes signal processor, 200, at the digital detector, 38, of decoder, 30, to detect the information of said message and at the control processor, 39J, to select the information of the execution segment in said message and  
35 determine that said selected information matches the

aforementioned instance of enable-WSW-programming information at said particular controlled-function-invoking information location. So determining a match causes said control processor, 39J, to execute the aforementioned transfer-this-  
5 message-to-controller-20 instructions.

Executing said instructions causes said control processor, 39J, to transfer the information of said message to controller, 20, in the fashion of the local-cable-enabling-message (#7).

10 Receiving the "1st-WSW-program-enabling-message (#7) causes controller, 20, to execute the aforementioned load-and-run-@20 instructions, to load the 1st-stage-enable-WSW-program instructions of the information segment at particular RAM of controller, 20, then to execute the information so  
15 loaded as the so-called machine language instructions of one so-called job.

Executing said 1st-stage-enable-WSW-program instructions causes controller, 20, in the predetermined fashion of said instructions, to affect a first stage of  
20 decrypting the video information of the "Wall Street Week" program transmission. Automatically, controller, 20, causes the control processor, 39J, of decoder, 30, to accept no SPAM message information from the EOFS valve, 39F. Then  
25 automatically, controller, 20, selects information of the last three significant digits of the binary information of the aforementioned unique digital code at ROM, 21; computes that particular Q quantity that is 16 less than the product of multiplying the numerical information of said digits times  
30 256 (which is 2 to the 8th power); and selects information of those particular sixteen contiguous bit locations at the RAM associated with the control processor, 39J, of decoder, 30, that commence at the first bit location that is said Q quantity of bit locations after a particular first bit location at said RAM. At the station of Fig. 4, the  
35 preprogrammed information of said sixteen contiguous bit

locations is decryption cipher key Ba. (In the present invention, the preferred method of preprogramming subscriber station signal processing apparatus is to preprogram each station with all authorized information but to vary the locations of the information from station to station in accordance with station specific information that varies from station to station--for example, in example #7, Ba cipher information can be preprogrammed at eight different RAM locations and the particular location that applies at any given station that is authorized with such information relates to the last three significant digits of the unique digital code of said station in the fashion of the above Q quantity computation.) Automatically, controller, 20, transfers said decryption cipher key Ba information to a selected decryptor, 224, and causes decryptor, 224, to commence decrypting any received information, using said key information and selected decryption cipher algorithm B, and outputting decrypted information to matrix switch, 258. Automatically, controller, 20, causes matrix switch, 258, to transfer the information of the aforementioned video output inputted from said tuner, 215, to the output that outputs to decryptor, 224, thereby causing said decryptor, 224, to receive the information of said video portion (said information being, as explained above, encrypted digital video), to decrypt said information, and to transfer decrypted information of said video portion to matrix switch, 258. Automatically, controller, 20, causes matrix switch, 258, to transfer the information inputted from decryptor, 224, to the output that that outputs to signal processor, 200, thereby causing signal processor, 200, to receive said information at the aforementioned third alternate contact of switch, 1. Automatically, controller, 20, clears all information of any prior SPAM message from decoder, 30; causes mixer, 3, and the filter, 31, and the modulator, 32, of decoder, 30, to input said information to the digital

detector, 38, without any modification (switch, 1, is already connected to said third contact); and causes the control processor, 39J, of decoder, 30, to commence accepting SPAM message information from EOFS valve, 39F, and record all  
5 received SPAM message information in a predetermined fashion at the RAM associated with said control processor, 39J, until an interrupt signal of EOFS-signal-detected information is received and then to process said EOFS-signal-detected information in a predetermined fashion.

10 In due course, but still before said 8:30 PM time, said program originating studio embeds in the video portion and transmits particular SPAM check information that is not a SPAM message and consists only of a particular check sequence of binary information followed by an end of file signal.  
15 (Hereinafter said SPAM check information is called the "1st-WSW-decryption-check (#7).") Then said program originating studio ceases transmitting a television signal of digital video and digital audio.

Receiving the binary information of said check  
20 sequence at decoder, 30, causes digital detector, 38, to detect said information and causes control processor, 39J, to record said information at the RAM associated with said control processor, 39J, in the aforementioned predetermined fashion. Then receiving said end of file signal causes EOFS  
25 valve, 39F, to transmit an interrupt signal of EOFS-signal-detected information to control processor, 39J, thereby causing said processor, 39J, to transmit a particular check-data-loaded signal to controller, 20, in the aforementioned predetermined fashion.

30 Receiving said check-data-loaded signal causes controller, 20, under control of said 1st-stage-enable-WSW-program instructions, to cause the control processor, 39J, of decoder, 30, to transfer to controller, 20, selected information of said check sequence of binary information and  
35 compare said selected information to selected information of

said 1st-stage-enable-WSW-program instructions. A match occurs at the station of Fig 4, indicating that decryptor, 224, is decrypting its received information correctly.

(Simultaneously other stations compare selected  
5 information of said check sequence to selected information of said 1st-stage-enable-WSW-program instructions. At each station where a match fails to occur--which indicates that a decryptor, 224, is not decrypting its received information correctly and suggests that the preprogrammed SPAM operating  
10 information of said station may have been tampered with--not resulting in a match causes the controller, 20, of said station to cause all information of said 1st-WSW-program-enabling-message (#7) to be erased from all memory of said station except for a particular portion of said 1st-stage-  
15 enable-WSW-program instructions loaded at the RAM of said controller, 20, then to execute the information of said portion as instructions of a machine language job. Executing said portion causes controller, 20, to cause the auto dialer, 24, and telephone connection, 22, of said station to  
20 establish telephone communications with a particular predetermined remote station, in the fashion described above, and causes controller, 20, then to transmit the aforementioned appearance-of-tampering information together with complete information of the unique digital code that  
25 identifies said station uniquely. If telephone communications are not established with said remote station in a predetermined fashion and/or within a predetermined time interval, the instructions of said portion cause said controller, 20, to erase all preprogrammable RAM and EPROM of  
30 the signal processing apparatus at said station, thereby disabling said apparatus.)

Resulting in a match causes controller, 20, to execute a particular portion of said 1st-stage-enable-WSW-program instructions.

35 Executing the instructions of said portion causes

controller, 20, to cause the apparatus of the station of Fig. 4 to cease receiving and decrypting the television information of said cable channel 13 as digital video and audio, to commence receiving said television information as conventional analog television, and to prepare to receive particular embedded SPAM information at the decoder, 30, of signal processor, 200. Automatically, controller, 20, causes matrix switch, 258, to cease transferring the information inputted from said converter box, 201, to the output that outputs to television tuner, 215; to cease transferring the information inputted from decryptor, 224, to the output that outputs to third alternate contact of switch, 1; and to commence transferring the information inputted from said converter box, 201, to the output that outputs to said third alternate contact. Automatically, controller, 20, causes mixer, 3, to select the frequency of channel 13 and input said frequency, at a fixed frequency, to TV signal decoder, 30. Automatically, controller, 20, causes decoder, 30, to cease transferring detected digital information from digital detector, 38, to controller, 39, and to commence filtering and demodulating inputted information at filter, 31, and demodulator, 32. Automatically, controller, 20, selects information of the first three of the last four significant digits of the binary information of the aforementioned unique digital code at ROM, 21; computes that particular Q quantity that is the sum of the numerical information of said three digits plus 20; and causes decoder, 30, to commence receiving information embedded on the line Q (and only on line Q) of the inputted video at line receiver, 33, and transferring detected digital information from detector, 34, to controller, 39. (In other words, if the binary information of said three digits is "000", decoder, 30, receives information embedded on line 20; if the binary information of said three digits is "001", decoder, 30, receives information embedded on line 21; etc.) Finally,

controller, 20, completes execution of said 1st-stage-enable-WSW-program instructions then, in the fashion of the first message of example #4, processes automatically the information of the meter-monitor segment of said 1st-WSW-  
5 program-enabling-message (#7) as meter information; causes the meter record that records the decryption of the audio portion of the "Wall Street Week" program transmission to be transferred from buffer/comparator, 14, and recorded at recorder, 16, (and causes the aforementioned signal record  
10 transfer sequence if recorder, 16, equals or exceeds if predetermined level of fullness); causes information of said meter-monitor segment to be placed at particular locations of buffer/comparator, 14, thereby initiating a meter record that records the decryption of the program transmission of the  
15 "Wall Street Week" program originating studio; and causes monitor information to be recorded by onboard controller, 14A, if the station of Fig. 4 is preprogrammed to collect monitor information.

In due course, but still before said 8:30 PM time,  
20 said program originating studio commences transmitting analog television information on its transmission frequency and embeds and transmits particular SPAM message information on lines 20, 21, 22, 23, 24, 25, 26, and 27. On each line said station transmits one particular message, and the messages of  
25 said lines are addressed to apparatus at subscriber stations where the first three of the last four significant digits of the binary information of the unique digital code at the ROMs, 21, are "000", "001", "010", "011", "100", "101", "110", and "111" respectively. Each of said messages  
30 consists of a "01" header, execution segment information that matches said enable-WSW-programming information, particular meter-monitor information, particular 2nd-stage-enable-WSW-program instructions as the information segment information, and an end of file signal. Each of said messages is  
35 identical except as as regards certain differences in said

2nd-stage-enable-WSW-program instructions that are described below. Prior to being embedded and transmitted the information of each of said messages is encrypted, in the same fashion as the first message of example #4 (except that 5 key J is used), and the encrypted information of the execution segment is identical to particular controlled-function-invoking information that instructs use decryption key J to decrypt the information of said message in the fashion of the decrypting of said second message.

10 (Hereinafter, each of said SPAM messages is called a "2nd-WSW-program-enabling-message (#7).") Then said program originating studio ceases transmitting analog television information.

Transmitting said message causes the line receiver, 15 33, of decoder, 30, to receive the embedded SPAM information of that particular 2nd-WSW-program-enabling-message (#7) that is embedded on said line Q; the detector, 34, to detect the digital information of said message; and the controller, 39, to process said information. Automatically, control 20 processor, 39J, causes controller, 20, to cause the decryptor, 39K, of decoder, 30, to commence decrypting using decryption key J and causes decryptor, 39K, to receive the information of said message. Automatically, decryptor, 39K, decrypts the encrypted information of said message and 25 transfers said message to EOFS valve, 39H. Automatically, EOFS valve, 39H, inputs the information of said message, unencrypted, to control processor, 39J, until the end of file signal of said message is detected. Automatically, control 30 processor, 39J, determines that the unencrypted information of the execution segment of said message matches the aforementioned instance of enable-WSW-programming information at said particular controlled-function-invoking information location and executes the aforementioned transfer-this-message-to-controller-20 instructions.

35 Executing said instructions causes the transfer of the

information of said message to controller, 20, in the fashion of the local-cable-enabling-message (#7).

Receiving said 2nd-WSW-program-enabling-message (#7) causes controller, 20, to execute the aforementioned load-  
5 and-run-@20 instructions, to load the 2nd-stage-enable-WSW-program instructions of the information segment at particular RAM of controller, 20, then to execute the information so loaded as the machine language instructions of one job.

Executing said 2nd-stage-enable-WSW-program  
10 instructions causes controller, 20, in the predetermined fashion of said instructions, to strip particular SPAM information from said "Wall Street Week" program transmission, to generate and insert particular information into said transmission, and to affect a second and last stage  
15 of decrypting the digital video information of the "Wall Street Week" program transmission. Automatically, controller, 20, causes the control processor, 39J, of decoder, 30, to accept no SPAM message information from the EOFS valve, 39F. Automatically, controller, 20, causes  
20 matrix switch, 258, to cease transferring the information inputted from said converter box, 201, to the output that outputs to said third alternate contact; to commence transferring the information inputted from said converter box, 201, to the output that outputs to television tuner,  
25 215; to commence transferring the information inputted from decryptor, 224, to the output that outputs to signal stripper, 229; to commence transferring the information inputted from signal stripper, 229, to the output that outputs to signal generator, 230; to commence transferring  
30 the information inputted from signal generator, 230, to the output that outputs to decryptor, 231; and to commence transferring the information inputted from decryptor, 231, to the output that outputs to said third alternate contact of switch, 1. Automatically, controller, 20, causes signal  
35 stripper, 229, to strip information, in a fashion well known

in the art, from a particular strip-designated portion of the video transmission received at said stripper, 229, and transfer the received video, without said stripped information, to matrix switch, 258. (Said stripped information may be information that would cause disabling chips, well known in the art, to prevent microcomputer, 205, or monitor, 202M, from processing or displaying the information of said video transmission if said stripped information were present in said transmission when said transmission was received at microcomputer, 205, or monitor, 202M.) Automatically, controller, 20, selects complete information of the aforementioned unique digital code at ROM, 21, transmits said complete information to signal generator, 230, and causes said generator, 230, to insert said complete information, in a predetermined periodic fashion and in an inserting fashion well known in the art, into a particular insertion-designated portion of the video transmission received at said generator, 230, and to transfer the received video, with said inserted information, to matrix switch, 258. (By causing information that identifies the station at which encrypted information is decrypted to be so inserted, the present invention makes it possible to identify particular stations where their information is misused--for example, if pirated decrypted copies of information are distributed, the station at which decryption occurred can be identified by means of the inserted information--and by causing said information to be inserted and then processed at a decryptor as if said inserted information were encrypted, the present invention renders the inserted information into a form that can easily be rendered back into clear form--for example, by using the same cipher algorithm and cipher key to "encrypt" said information into its predecryption form--while rendering said inserted information into a form that others, such as pirates, can find very difficult to distinguish from other binary information, to locate or identify and, therefore, to

remove.) Automatically, controller, 20, selects information of the aforementioned first three of the last four significant digits of the binary information of the aforementioned unique digital code at ROM, 21 and computes a particular Q quantity according to a particular formula that is preprogrammed in said 2nd-stage-enable-WSW-program instructions. The information of said Q quantity is the decryption key Aa. (The formulas in each of the eight different 2nd-WSW-program-enabling-message (#7) messages differ from each other in such a way that when each station computes its own Q quantity according to its own first three of last four significant unique digital code digits, the Q quantities computed all properly preprogrammed and functioning stations are identical--for example, at stations where said three digits are "000" can compute by a formula that instructs said stations to add binary information of 9999 to the information of said three digits to compute the quantity Q while stations where said three digits are "001" can compute by a formula that instructs said stations to add binary information of 10000 to the information of said three digits to compute the quantity Q, etc.) Automatically, controller, 20, clears all information of any prior SPAM message from decoder, 30; causes mixer, 3, and the filter, 31, and the modulator, 32, of decoder, 30, to input said information to the digital detector, 38, without any modification (switch, 1, is already connected to said third contact); and causes the control processor, 39J, of decoder, 30, to commence accepting SPAM message information from EOFs valve, 39F, and record all received SPAM message information in a predetermined fashion at the RAM associated with said control processor, 39J, until an interrupt signal of EOFs-signal-detected information is received and then to process said EOFs-signal-detected information in a predetermined fashion.

35 In due course, but still before said 8:30 PM time,

said program originating studio encrypts and transmits, in its digital video transmission, particular SPAM check information that consists of a particular check sequence of binary information followed by an end of file signal (and is 5 not a SPAM message). (Hereinafter said SPAM check information is called the "2nd-WSW-decryption-check (#7).")

As with the 1st-WSW-decryption-check (#7), receiving the 2nd-WSW-decryption-check (#7) causes control processor, 39J, to record the information of the check sequence of said 10 2nd-WSW-decryption-check (#7) at the RAM associated with said control processor, 39J, then to transmit a particular check-data-loaded signal to controller, 20.

Receiving said signal causes controller, 20, under control of said 2nd-stage-enable-WSW-program instructions, to 15 cause said control processor, 39J, to transfer to controller, 20, selected information of said check sequence; to compare said selected information to selected information of said 2nd-stage-enable-WSW-program instructions; and to determine that a match results, indicating that decryptors, 224 and 20 231, are decrypting received information correctly.

Determining a match causes controller, 20, to determine, in a predetermined fashion, that signal stripper, 229, is correctly stripping information from the aforementioned strip-designated portion of the video transmission and 25 transferring received video without said stripped information and that signal generator, 230, is correctly inserting complete information of the aforementioned unique digital code into the aforementioned insertion-designated portion of the video transmission and transferring received video with 30 said inserted information.

(Simultaneously other stations compare selected information of said check sequence to selected information of said 2nd-stage-enable-WSW-program instructions and verify the correct functioning of local signal strippers, 229, and 35 generators, 230. At each station where a controller, 20,

determines that a match does not result--which indicates that a decryptor, 224 or 231, is not decrypting its received information correctly and suggests that the preprogrammed SPAM operating information of said station may have been  
5 tampered with--or determines that a stripper, 229, or a generator, 230, fails to function correctly, so determining match causes said controller, 20, to cause all information of said 2nd-WSW-program-enabling-message (#7) to be erased from all memory of said station except for a particular portion of  
10 said 2nd-stage-enable-WSW-program instructions loaded at the RAM of said controller, 20, then to execute the information of said portion as instructions of a machine language job. Executing said portion causes said controller, 20, to cause the auto dialer, 24, and telephone connection, 22, of said  
15 station to establish telephone communications with a particular predetermined remote station, in the fashion described above, and causes said controller, 20, then to transmit the aforementioned appearance-of-tampering information together with complete information of the unique  
20 digital code that identifies said station uniquely. If telephone communications are not established with said remote station in a predetermined fashion and/or within a predetermined time interval, the instructions of said portion cause said controller, 20, to erase all preprogrammable RAM  
25 and EPROM of the signal processing apparatus at said station, thereby disabling said apparatus.)

Determining that signal stripper, 229, and that signal generator, 230, are stripping and inserting correctly (after having determined that that decryptors, 224 and 231, are  
30 decrypting correctly) causes the controller, 20, of the station of Fig. 4 (and causes controllers, 20, at other stations where so determining occurs) to execute particular additional 2nd-stage-enable-WSW-program instructions, and executing said instructions causes controller, 20, to cause  
35 the apparatus of the station of Fig. 4 to commence

transferring the decrypted television information of the  
"Wall Street Week" program to microcomputer, 205, and  
monitor, 202M. Automatically, controller, 20, causes matrix  
switch, 258, to transfer the decrypted audio information  
5 inputted from decryptor, 107, to monitor, 202M, thereby  
causing monitor, 202M, to commence receiving said audio  
information and emitting sound in accordance with said audio  
information. Automatically, controller, 20, causes matrix  
switch, 258, to cease transferring the decrypted video  
10 information inputted from decryptor, 231, to the output that  
outputs to said third alternate contact of switch, 1, and to  
commence transferring said video information inputted from  
said decryptor, 231, to divider, 4, thereby causing divider,  
4, to transfer said decrypted video information to  
15 microcomputer, 205, and to decoder, 203. Automatically,  
controller, 20, causes decoder, 203, to discard any  
previously received SPAM information; to commence detecting  
SPAM information in the inputted decrypted video information  
and waiting to receive SPAM header information; and to cause  
20 microcomputer, 205, to commence transferring the decrypted  
information of the transmitted video image to monitor, 202M,  
thereby causing monitor, 202M, to commence displaying, at its  
television picture tube, the information of the transmitted  
television image. Automatically, controller, 20, causes  
25 decoder, 30, to discard all previously received SPAM  
information (including all information of said 2nd-WSW-  
program-enabling-message (#7) and said 2nd-WSW-decryption-  
check (#7)); causes oscillator, 6, and decoder, 30, to  
commence the detecting of example (#7); and in a  
30 predetermined fashion, causes oscillator, 6, to cause switch,  
1, to connect to connect its contact lever to the  
aforementioned first alternate contact of switch, 1.  
Finally, controller, 20, completes execution of said 2nd-  
stage-enable-WSW-program instructions then processes  
35 the information of the meter-monitor segment of said message

as meter information; causes selected information of said meter-monitor segment to be placed at particular locations of buffer/comparator, 14, thereby incrementing the information of the aforementioned meter record that records the  
5 decryption of the program transmission of the "Wall Street Week" program originating studio; and causes monitor information to be recorded by onboard controller, 14A, if the station of Fig. 4 is preprogrammed to collect monitor information.

10 In due course, at said 8:30 PM time, said program originating studio commences transmitting the programming information of said "Wall Street Week" program, thereby causing the apparatus of the station of Fig. 4 (and of other correctly regulated and connected stations) to commence  
15 functioning in the fashions described above in "One Combined Medium" and in examples #1, #2, #3, and #4.

It is obvious to one of ordinary skill in the art that the foregoing is presented by way of example only and that the invention is not to be unduly restricted thereby since  
20 modifications may be made in the structure of the various parts without functionally departing from the spirit of the invention. For example, the decryption cipher key information and/or algorithm instructions and/or the location or locations of said key information and/or instructions may  
25 be computed in other, more complex or less complex, fashions. And for example, the transmitted programming may be processed through fewer than three steps of decryption or more than three. And for example, the "Wall Street Week" transmission may be of conventional analog television, and the decryptors,  
30 107, 224, and 231, may be conventional descramblers, well, known in the art, that descramble analog television transmissions and are actuated by receiving digital key information. And for example, determining that a local station is not preprogrammed properly and/or that decryption,  
35 stripping, and/or signal generating apparatus are not

functioning correctly may cause apparatus of said station to perform other steps of disabling and/or communicating--eg., the local apparatus may disable local apparatus selectively and only partially by, for example, preventing a decoder, 5 203, from processing embedded SPAM combining synch commands and may interrogate remote station apparatus, by telephone, for cipher key and/or cipher algorithm instructions and information. And for example, the transmitted programming may be caused, in a predetermined fashion to be recorded at 10 an apparatus such as a properly configured video recorder rather than being played and displayed at a monitor, 202M. And for example, the transmitted programming may be only audio (for example, of a radio transmission) or print (for example, of broadcast print) rather than television. And for 15 example, the output apparatus may be speakers or one or more printers rather than a television monitor. And for example, rather than being a transmitter at a remote wireless or cable transmission station, the source of the transmission may be a local apparatus such as a video (or audio or digital 20 information) tape recorder or a laser disc player, well known in the art, that transmits a transmission of conventional rerecorded programming that has been encrypted (either fully or partially) and in which SPAM regulating instructions and information have been appropriately prerecorded which 25 transmission is inputted to matrix switch, 258, from said local apparatus and which SPAM regulating instructions cause the decryption of the encrypted programming in the fashions of the present invention. And for example, covert control means may be used to control any regulating process of the 30 present invention.

#### MONITORING RECEIVER STATION RECEPTION AND OPERATION

Fig. 5 illustrates means and methods for monitoring receiver station reception and use of programming and modes of receiver station operation and exemplifies one embodiment 35

of a subscriber station that is preconfigured and preprogrammed to collect monitor information. The means and methods facilitate the collection of statistics that identify not only what programming is received and displayed at given  
5 subscriber stations but also, for example, which local apparatus receives programming and which displays programming, how received programming is processed, what local apparatus is controlled in the course of processing and how, what locally preprogrammed data is processed by or with  
10 the received programming, which local apparatus is caused to transmit programming, etc. Efficient collection of such statistics enables suppliers of programming and of subscriber station apparatus to identify which programming subscribers demand and how subscribers use their programming and  
15 apparatus.

Fig. 5 shows a variety of input apparatus with capacity for inputting programming (including SPAM information) selectively, via matrix switch, 258, to apparatus of the subscriber station of Fig. 5, intermediate  
20 apparatus with capacity for processing and/or recording inputted programming selectively, and output apparatus for displaying or otherwise outputting programming selectively to human senses.

Input apparatus include antenna, 199, and converter  
25 boxes, 201 and 222, that input programming transmitted from remote stations. Laser disc player, 232, and record turn table, 280, which are apparatus well known in the art, input prerecorded programming. The programming input by laser disc  
30 player, 232, in particular, may include video (as, for example, from a so-called "laser videodisc player"), digital audio (as, for example, from a so-called "compact disc player"), and digital data (as, for example, from a so-called  
"CD ROM"), and systems are well known in the art with capacity for playing all three forms of programming  
35 prerecorded on one given disc. Other input, 252, which may

be, for example, a telephone, also has capacity for inputting programming to matrix switch, 258.

Intermediate apparatus include microcomputer, 205, radio tuner & amplifier, 213, TV tuner, 215, audio 5 recorder/player, 255, and video recorder/player, 217, all of which are well known in the art. The station of Fig. 5 also has capacity for including one or more other tuners and/or recorder/players, 257, well known in the art, such as, for example, computer peripheral MODEMs and/or such expanded 10 memory units as so-called "fixed disk" recorder/players.

Output apparatus that display or otherwise output programming selectively to human senses include, for example, TV monitor, 202M, multi-picture television monitor, 148, speaker system, 263, and printer, 221, all of which are well 15 known in the art. Said apparatus that output could also include one or more other output systems, 261.

(This is only a representative group of equipment; many other types of communications and computer apparatus could be included in Fig. 5.)

20 Associated with each intermediate apparatus and output apparatus is one or more appropriate decoders. At radio tuner & amplifier, 138, are radio decoder, 138, and other decoder, 281. At TV tuner, 215, is TV decoder, 282. At audio recorder/player, 255, is other decoder, 284. At video 25 recorder/player, 217, is TV decoder, 218. At microcomputer, 205, is TV decoder, 203. At other tuner and/or recorder/player, 257, is other decoder, 283. At TV monitor, 202M, is TV decoder, 145. At multi-picture TV monitor, 148, are TV decoders, 149 and 150. At speaker system, 263, is 30 other decoder, 285. At printer, 221, is other decoder, 227. At other output system, 261, is other decoder, 286. Each decoder is likely to be located physically inside the unit of its associated intermediate or output apparatus.

At any given subscriber station, any given SPAM 35 decoder may merely monitor the operation of its associated

subscriber station apparatus or may function not only to monitor the operation of its associated apparatus but also to control said apparatus in the execution of SPAM controlled functions' (in which case said decoder is preprogrammed to  
5 execute one or more controlled functions).

Fig. 5 shows each decoder as having capacity for transferring monitor information to signal processor, 200, by bus communications means. Said information is received (and processed) at signal processor, 200, by the onboard  
10 controller, 14A, which controls the communications of said bus means in a fashion well known in the art.

In Fig. 5, decoders, 138, 281, 282, 284, 218, 283, 145, 149, 150, 285, 227, and 286, merely monitor the operation of associated subscriber station apparatus. In the  
15 preferred embodiment, each one of said decoders is located at a point in the circuitry of its associated apparatus where said one receives (so as to detect all SPAM information on) the information of the selected frequency, channel or transmission to which its associated apparatus is tuned.  
20 Each one of said decoders is preprogrammed to detect and transfer to said onboard controller, 14, via said bus means, the meter-monitor information of every unencrypted SPAM message in the transmission to which its associated apparatus is tuned.

In Fig. 5, decoder, 203, which is part of the signal  
25 processor system of the station of Fig. 5, not only monitors the operation of its associated apparatus, microcomputer, 205, but also controls said apparatus, in the fashions described above, in the execution of SPAM controlled  
30 functions. Decoder, 203, has means for detecting SPAM information in any programming transmission inputted to its associated apparatus, microcomputer, 205, and not only for detecting and transferring to said onboard controller, 14, via said bus means, the meter-monitor information of every  
35 unencrypted SPAM message of said transmissions but also for

inputting selected detected information to microcomputer, 205, and for controlling microcomputer, 205, in selected fashions. (Fig. 5 also shows that decoder, 203, has capacity for inputting detected information to signal processor, 200, and for receiving from and transferring control information to signal processor, 200.)

Any given decoder may have more or less apparatus than that shown in Figs. 2A, 2B, or 2C. For example, each one of said decoders, 138, 281, 282, 284, 218, 283, 145, 149, 150, 285, 227, and 286, requires less apparatus than is shown in the appropriate corresponding figure, 2A, 2B, or 2C. Said decoders can be located in the aforementioned circuitry of their associated apparatus in such fashions that said decoders do not require filters, 31, and demodulators, 32 and 35, (in the case of TV signal decoders) or radio receiver circuitry, 41, (in the case of radio signal decoders) or other receiver circuitry, 45, (in the case of other signal decoders). On the other hand, decoder, 203, may have more apparatus than that shown in Fig. 2A. Fig. 7D, which is described more fully below, shows that a microcomputer, 205, can be controlled by SPAM information embedded in transmissions other than television transmissions. Thus, because the particular decoder that controls a particular associated apparatus will be configured and preprogrammed to detect SPAM information in every transmission that can be inputted to and control said apparatus, the decoder, 203, associated with microcomputer, 205, may be modified to constitute an "All Signal Decoder" through the addition of additional apparatus such as the radio receiver circuitry, 41, radio decoder, 42, and digital detector, 43, of the Radio Signal Decoder of Fig. 2B and the other receiver circuitry, 45, and digital detector, 46, of the Other Signal Decoder of Fig. 2C, said additional apparatus operating under the control of the controller, 39, of said decoder, 203, and inputting detected digital information to the buffer, 39A, of

said controller, 39.

If a given intermediate or output apparatus can receive transmissions from more than one source or of more than one kind--television, radio, or other--it will have  
5 sufficient apparatus to monitor every channel and kind of transmission it can receive. For example, Fig. 5 shows multi-picture TV monitor, 148, that has capacity to receive two inputted transmissions and has two TV decoders, 149 and 150. In the preferred embodiment, one decoder, 149, is  
10 located at a point in the circuitry of monitor, 148, where said decoder, 149, receives the information of one inputted transmission; the other decoder, 150, is located at a point in said circuitry said decoder, 150, receives the information of the other inputted transmission. And for example, Fig. 5  
15 shows radio tuner & amplifier, 213, that also has capacity to receive two inputted transmissions and has two decoders: radio decoder, 138, and other decoder, 281. In the preferred embodiment, one decoder, 138, is located at a point in the circuitry of tuner & amplifier, 213, where said decoder, 138,  
20 receives information of one inputted transmission (eg., the selected radio frequency that is the particular frequency, of the spectrum of wireless frequencies received at antenna, 199, and inputted via switch, 258, that is the frequency that the radio tuner of tuner & amplifier tunes to); the other  
25 decoder, 281, is located at a point in said circuitry where said decoder, 281, receives the information of the other inputted transmission (eg., the output frequency of record turn table, 280, inputted via said switch, 258).

The onboard controller, 14A, controls the operation of  
30 all the decoders that merely monitor the operation of associated subscriber station apparatus and also controls other particular apparatus of the subscriber station of Fig. 5 in particular monitor information functions. Fig. 5 shows that signal processor, 200, (at onboard controller, 14A) has  
35 bus communications means for communicating control

information to the aforementioned decoders, 138, 281, 282, 284, 218, 283, 145, 149, 150, 285, 227, and 286. By such bus means, onboard controller, 14A, can cause any on or all of said decoders to commence or cease processing and  
5 transmitting SPAM monitor information and can cause any one or all of said decoders to change the location or locations that are searched for SPAM information. Fig. 5 shows that, via said bus communications means, signal processor, 200, has capacity for for communicating control information (from  
10 onboard controller, 14A) to subscriber station player apparatus that has capacity for playing prerecorded programming (and in so doing, originating transmission at said station of said programming). Said player apparatus includes laser disc player, 232, record turn table, 280,  
15 audio recorder/player, 255, video recorder/player, 217, and other recorder/player, 257. Each of said player apparatus has capacity, under control of onboard controller, 14A, for generating, embedding in programming transmissions, and transmitting source mark information that identifies (and  
20 distinguishes from one another) each one of said player apparatus. By causing said player apparatus to transmit identifying source mark information, onboard controller, can cause local apparatus to collect monitor information that identifies which local player apparatus is the source of any  
25 given output of a locally originated, prerecorded programming transmission.

But the onboard controller, 14A, does not control the operation of those decoders that control the operation of subscriber station apparatus in the execution of SPAM  
30 controlled functions. Instead, all decoders that execute SPAM controlled functions are controlled, even in monitoring the operation of their associated apparatus, by the controller, 20, of signal processor, 200. In Fig. 5, decoder, 203, is the only such decoder with capacity to  
35 execute SPAM controlled functions. As Fig. 5 shows, decoder,

203, and signal processor, 200, (at onboard controller, 14A) have no capacity to communicate with with each other via the aforementioned bus communications means for communicating control information. Rather decoder, 203, communicates  
5 control information directly with the controller, 20, of signal processor, 200, as in Fig. 3. (In respect to a decoder and other apparatus that are controlled by a controller, 20, the onboard controller, 14A, of the signal processor, 200, of said controller, 20, is preprogrammed to  
10 input to said controller, 20, all monitor instructions addressed to said decoder or associated apparatus, and said controller, 20, is preprogrammed to receive said instructions and transfer said instructions to said decoder or associated apparatus appropriately in accordance with the priority of  
15 the operation of said decoder or associated apparatus.)

Decoders that execute SPAM controlled functions are controlled in regard to monitoring by controller, 20, rather than onboard controller, 14A, because timely execution of controlled functions (and the transmission of control  
20 information related to such execution such as, for example, decryption key information as in example #4 above) has far higher priority that the collection of monitor information.

One particular advantage of these methods for monitoring programming is that, by embedding the SPAM  
25 information in the audio and/or video and/or other parts of the programming that are conventionally recorded by, for example, conventional video cassette recorders, these methods provide techniques for gathering statistics on what is recorded, for example, on video and audio cassette recorders  
30 and on how people replay such recordings. For example, a subscriber might instruct video recorder/player, 217, automatically to record the NBC Network Nightly News as broadcast over station WNBC in New York City. Recorder, 217, might receive the programming over Manhattan Cable TV channel  
35 4 and record the programming at the time of original

broadcast transmission--from 7:00 PM to 7:30 PM on the evening of July 15, 1985. Each discrete bit of this information could be transmitted to the subscriber station of Fig. 5 in meter-monitor information (of a SPAM command with an appropriate execution segment such as information of the pseudo command) embedded in the transmitted programming. So embedding and transmitting said meter-monitor information would cause recorder, 217, to record said information. In addition, decoder, 218, would detect said information and transfer said information to signal processor, 200, together with appropriate source mark information, but no decoder apparatus associated with any of the aforementioned output apparatus would detect said information, causing said signal processor, 200, in a predetermined fashion to record a signal record of programming recorded at recorder, 217.

(Simultaneously, the information of said programming is being displayed at the monitors, 202M, of other subscriber stations that are tuned to the frequency of said News as broadcast; decoders, 145, associated with said monitors, 202M, are detecting said embedded meter-monitor information and transmitting said information to the signal processors, 200, of said stations; and said signal processors, 200, are recording signal records of programming displayed at said monitors, 202M.) Subsequently, the subscriber might play back the recorded programming and view said programming on TV monitor, 202M, from 10:45 PM to 11:15 PM the same evening. So playing back and transmitting the recorded programming to monitor, 202M, would cause TV signal decoder, 145, to detect said meter-monitor information and transfer said information, together with appropriate source mark information, to signal processor, 131, causing said signal processor, 200, to record a signal record of said information together with date and time information of said 10:45 PM to 11:15 PM the same evening selected from the clock, 18, of signal processor, 200.

Prerecorded, commercially distributed video and audio tapes, videodiscs, so-called "compact discs" of audio, and so-called "CD ROM" discs of data can also contain unique codes, embedded in the prerecorded programming, that identify  
5 the use and usage of said programming when said tapes or discs are played. For example, laser disc player, 232, can be a compact disc player upon which is loaded a compact disc. SPAM messages, embedded in the programming prerecorded on said disc, can contain pseudo command execution segment  
10 information and meter-monitor information that documents that said prerecorded programming is of Anton Bruckner's Symphony No. 4 as recorded by the Berlin Philharmoniker and the disc is distributed by EMI Records Ltd. on the Angel label with a particular catalog serial number. Through matrix switch,  
15 258, the output of player, 232, is inputted to the amplifier, 213, and the output of amplifier, 213, is inputted to speaker system, 263. When player, 232, commences playing and transmitting said prerecorded programming, transmitting said programming causes other decoder, 281, and other decoder,  
20 285, to detect said embedded messages at amplifier, 213, and speaker system, 263, respectively, and transmit said meter-monitor information to signal processor, 200, via the aforementioned bus communications means for transferring monitor information, thereby causing onboard controller, 14A,  
25 to commence retaining monitor information in a signal record that reflects the outputting of said programming and, in a predetermined fashion, to determine that the information of said record includes no information identifying a station or apparatus originating the transmission of said programming.  
30 So determining causes onboard controller, 14A, to transmit a particular transmit-source-code instruction, via the aforementioned bus communications means for transferring control information, to the local apparatus that have capacity for playing prerecorded programming, which apparatus  
35 include player, 232, and record turn table, 280. Receiving

said instruction causes player, 232, and turn table, 280, each to generate, embed in its transmitted programming in a predetermined fashion, and transmit its own preprogrammed identifier code information that identifies each distinctly  
5 differently it from all other subscriber station apparatus (all of which apparatus have the capacity so to do). Causing player, 232, to transmit its distinct code causes other decoders, 281 and 285, to detect said code and transmit information of said code to signal processor, 200, causing  
10 onboard controller, 14A, to retain information of said code in said signal record, thereby adding to said record information of the apparatus originating the transmission of said programming.

In the case of any given programming that is outputted  
15 at any given output apparatus, thereby enabling a subscriber to view or hear or read or in some other way perceive the information of said programming, the onboard controller, 14A, may and probably will receive monitor information from several different sources. For example, in the case of the  
20 "Wall Street Week" program, transmitting the first and second SPAM messages of example #3 (which are not encrypted) will cause not only decoder, 203, to process the meter-monitor information of said messages and transmit the aforementioned 1st monitor information (#3) and 2nd monitor information  
25 (#3), via the monitor information bus means of Fig. 5, to onboard controller, 14A. The programming of said "Wall Street Week" program is received at tuner, 215, and displayed at monitor, 202M. Accordingly, transmitting said messages will also cause the decoder associated with tuner, 215--  
30 decoder, 282--to detect, process, and transmit monitor information of said messages to onboard controller, 14A, that is identical to said 1st monitor information (#3) and 2nd monitor information (#3) except that the source mark information identifies decoder, 282, rather than decoder,  
35 203. Likewise, unless the Fig. 1B information overlaid at

microcomputer, 205, covers and obliterates the embedded information of said messages that is inputted from divider, 4, to microcomputer, 205, and would otherwise be transmitted to monitor, 202M, in the combined programming outputted by  
5 microcomputer, 205, (which covering and obliterating does not occur in example #3), transmitting said messages will also cause the decoder, 145, to detect, process, and transmit monitor information of said messages to onboard controller, 14A, that is also identical to said 1st and 2nd monitor  
10 information (#3) except that the source mark information identifies decoder, 145.

As described above, onboard controller, 14A, organizes its contained signal records on the basis of the different source mark information of the separate decoders of its  
15 subscriber station. Were onboard controller, 14A, preprogrammed to process monitor information just in this simple fashion, transmitting the first and second messages of example #3 would cause onboard controller, 14A, to record (and subsequently transmit to recorder, 16, then later to one  
20 or more remote stations) three separate signal records that would duplicate each other except that each would be associated with the source mark of a different decoder, 282, 203, or 145.

In the preferred embodiment, to minimize unnecessary duplication, prior to retaining monitor information in signal  
25 records, onboard controller, 14A, is preprogrammed to consolidate, in a predetermined fashion or fashions, monitor information transmissions that contain different source mark information but common "program unit identification code"  
30 information in such a way that subordinate sources are identified--which, in the "Wall Street Week" example, are tuner, 215/decoder, 282, and monitor, 202M/decoder, 145, where no combined medium functions and no SPAM controlled functions are executed--the monitor information from said  
35 sources is included, in a predetermined fashion, within the

signal record information of the principal source--which source is, in the example, decoder, 203, at microcomputer, 205--in such a way that only exception information is recorded in the recorded information of the monitor  
5 information transmitted from the subordinate sources.

#### AUTOMATING INTERMEDIATE TRANSMISSION STATIONS

The signal processing apparatus outlined in Figs. 2, 2A, 2B, 2C, and 2D, and their variants as appropriate, can be  
10 used to automate the operations of intermediate transmission stations that receive and retransmit programming. The stations so automated may transmit any form of electronically transmitted programming, including television, radio, print, data, and combined medium programming and may range in scale  
15 of operation from wireless broadcast stations that transmit a single programming transmission to cable systems that cablecast many channels simultaneously.

Fig. 6 illustrates Signal Processing Apparatus and Methods at an intermediate transmission station that is a  
20 cable television system "head end" and that cablecasts several channels of television programming. The means and methods for transmitting conventional programming are well known in the art. The station receives programming from many sources. Transmissions are received from a satellite by  
25 satellite antenna, 50, low noise amplifiers, 51 and 52, and TV receivers, 53, 54, 55, and 56. Microwave transmissions are received by microwave antenna, 57, and television video and audio receivers, 58 and 59. Conventional TV broadcast transmissions are received by antenna, 60, and TV  
30 demodulator, 61. Other electronic programming transmissions are received by other programming input means, 62. Each receiver/modulator/input apparatus, 53 through 62, transfers its received transmissions into the station by hard-wire to a  
a conventional matrix switch, 75, well known in the art, that  
35 outputs to one or more recorder/players, 76 and 78, and/or to

apparatus that outputs said transmissions over various channels to the cable system's field distribution system, 93, which apparatus includes cable channel modulators, 83, 87, and 91, and channel combining and multiplexing system, 92.  
5 Programming can also be manually delivered to said station on prerecorded videotapes and videodiscs. When played on video recorders, 76 and 78, or other similar equipment well known in the art, such prerecorded programming can be transmitted via switch 75 to field distribution system, 93.

10 In the prior art, the identification of incoming programming, however received; the operation of video player and recorder equipment, 76 and 78; and the maintenance of records of programming transmissions are all largely manual operations.

15 Fig. 6 shows the introduction of signal processing apparatus and methods to automate these and other operations.

In line between each of the aforementioned receiver/demodulator/input apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, and matrix switch, 75, is a dedicated distribution  
20 amplifier, 63, 64, 65, 66, 67, 68, 69, or 70, that splits each incoming feed into two paths. One path is the conventional path whereby programming flows from each given receiver/demodulator/input apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, to matrix switch, 75. The other path  
25 inputs the transmission of said given receiver/demodulator/input apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, individually to signal processor system, 71. (In other words, distribution amplifier, 63, continuously inputs the programming transmission of receiver, 53, to matrix switch,  
30 75, and separately to signal processor system, 71; distribution amplifier, 64, inputs the programming transmission of receiver, 54, to matrix switch, 75, and separately to signal processor system, 71; etc.)

35 At signal processor system, 71, which is a system as shown in Fig. 2D, the outputted transmission of each

distribution amplifier, 63, 64, 65, 66, 67, 68, 69, or 70, is inputted into a dedicated decoder (such as decoders, 27, 28, and 29 in Fig. 2D) that processes continuously the inputted transmission of said distribution amplifier, 63, 64, 65, 66, 5 67, 68, 69, or 70; selects SPAM messages in said transmission that are addresses to ITS apparatus of said intermediate transmission station; automatically adds, in a predetermined fashion, source mark information that identifies said associated distribution amplifier, 63, 64, 65, 66, 67, 68, 10 69, or 70; and transfers said selected messages, with said source mark information, to code reader, 72. Signal processor system, 71, also has signal processor means to control signal processor system, 71, to record meter-monitor information of said message information, and to transfer 15 recorded information to external communications network, 97.

Code reader, 72, buffers and passes the received SPAM message information, with source mark information, to cable program controller and computer, 73.

Cable program controller and computer, 73, is the 20 central automatic control unit for the transmission station. Computer, 73, has an installed clock and is preprogrammed with information on the operating speeds and capacities of all station apparatus and the connections of said apparatus with matrix switch, 75.

25 Computer, 73, has capacity for maintaining records on the station's programming schedule and records on the status of operating apparatus. Computer, 73, has means for receiving input information from local input, 74, and from remote stations via telephone or other data transfer network, 30 98. Such input information can include the complete programming schedule of the station of Fig. 6, with each discrete unit of programming identified by its own "program unit identification code" information. Such input information can indicate when and how the station should 35 expect to receive each program unit, when and on which

channel or channels and how the station should transmit the unit, what kind of programming the unit is--eg., conventional television, television/computer combined medium programming, etc.--and how the station should process the programming.

5 Computer, 73, is preprogrammed to receive and record said schedule information and may record it in RAM or on an appropriate recording medium such as a magnetic disk at a disk drive. Likewise, computer, 73, is preprogrammed to maintain records of the control instructions that computer, 10 73, transmits to all controlled apparatus which records indicate, at any given time, the operating status of each controlled apparatus.

Computer, 73, monitors the operation of the head end station by means of TV signal decoders, 77, 79, 80, 84, and 15 88, each of which are shown in detail in Fig. 2A. Computer, 73, has means to communicate control information with each decoder, 77, 79, 80, 84, and 88, to instruct each how to operate and how and where to search for SPAM information. (The control system of the station of Fig. 6 may be 20 reconfigured to have the signal processor of system, 71, control said decoders, 77, 79, 80, 84, and 88, if decryption of encrypted SPAM message information is required at said decoders.)

Computer, 73, monitors outgoing programming by means 25 of decoders, 80, 84, and 88. By decoders, 80, 84, and 88, to select and transfer SPAM meter-monitor information and by comparing said information to information of its contained schedule records, computer, 73, can determine whether scheduled programming is being transmitted properly to field 30 distribution system, 93, on each cable channel of the station of Fig. 6. Whenever computer, 73, detects errors, computer, 73, can execute predetermined error correction procedures which may include sounding an alarm to alert station personnel.

35 Computer, 73, monitors incoming programming by means

of the aforementioned dedicated decoders of signal processor system, 71. By means of the SPAM message information, with source mark information, received from code reader, 72, computer, 73, determines what specific program unit has been  
5 received by each receiver, 53 through 62, and is passing in line, via each distribution amplifier, 63 through 70, to matrix switch, 75.

By comparing selected meter-monitor information of said message information with information of the programming  
10 schedule received earlier from input, 74, and/or network, 98, computer, 73, can determine, in a predetermined fashion, when and on what channel or channels the station of Fig. 6 should transmit the programming of each received program unit.

Computer, 73, has means for communicating control  
15 information with matrix switch, 75, and video recorders, 76 and 78, and can cause selected programming to be transmitted to field distribution system, 93, or recorded.

Determining that particular incoming programming is scheduled for immediate retransmission can cause computer,  
20 73, to cause matrix switch, 75, to configure its switches so as to transfer said incoming programming to a scheduled output channel. For example, computer, 73, receives a given SPAM message that contains given "program unit identification code" information and the added source mark information of  
25 said message identifies distribution amplifier, 63.

Receiving said message causes computer, 73, to determine, in a predetermined fashion, that said "code" information matches particular preprogrammed schedule information of programming that is scheduled to be retransmitted immediately upon  
30 receipt to field distribution system, 93, via cable channel modulator, 87. In its preprogrammed fashion, so determining causes computer, 73, to cause matrix switch, 75, to configure its switches so as to transfer the programming transmission inputted (via distribution amplifier, 63) to matrix switch,  
35 75, from TV receiver, 53, to that output of matrix switch,

75, that outputs to modulator, 87.

Determining that particular incoming programming is scheduled for time deferred transmission can cause computer, 73, to cause the recording of said programming. For example, 5 computer, 73, receives a given SPAM message that contains given "program unit identification code" information and the added source mark information of said message identifies distribution amplifier, 67. Receiving said message causes computer, 73, to determine, in a predetermined fashion, that 10 said "code" information matches particular preprogrammed schedule information of programming that is scheduled to be recorded upon receipt and transmitted to the field system, 93, at a later time. So determining causes computer, 73, in its preprogrammed fashion, to select a video recorder/player, 15 76 or 78; to cause said selected recorder, 76 or 78, to turn on and record programming; and to cause matrix switch, 75, to configure its switches so as to transfer the programming transmission inputted (via distribution amplifier, 67) from television receiver, 58, to the output that leads to said 20 selected recorder, 76 or 78. In so doing, computer, 73, causes said selected recorder, 76 or 78, to record said programming.

Determining that particular incoming programming is not scheduled for transmission can cause computer, 73, to 25 cause station apparatus to discard the transmission of said programming. For example, computer, 73, receives a given SPAM message that contains given "program unit identification code" information and the added source mark information of said message identifies distribution amplifier, 69. 30 Receiving said message causes computer, 73, to determine, in a predetermined fashion, that said "code" information matches no particular preprogrammed schedule information. In its preprogrammed fashion, so determining causes computer, 73, either to cause matrix switch, 75, to configure its switches 35 so as to transfer the programming transmission inputted (via

distribution amplifier, 69) to matrix switch, 75, from TV demodulator, 61, to no output of matrix switch, 75; or to cause a selected recorder, 76 or 78, to cease recording; or both.

5           Computer, 73, has capacity for determining what programming is prerecorded on the magnetic tapes (or other recording media) loaded on the recorders, 76 and 78, and capacity for positioning the start points (or other selected points) of program units at the play heads of said recorders.  
10 Whenever programming is played on recorder, 76 or 78, decoder, 77 or 79 respectively, detects SPAM information embedded in the prerecorded programming played at the play heads of recorder, 76 or 78, and transmits said SPAM information to computer, 73. Said SPAM information can  
15 include not only "program unit identification code" information but also information regarding of the distance from the point on the tape at which a given SPAM message is embedded to the point on the tape where the program unit begins and ends (or to any other selected point). To  
20 position the start point (or another selected point) of a given program unit at the play heads of a given recorder, 76, computer, 73, instructs switch, 75, to configure its switches so as to transfer the transmission input from said recorder, 76, to no output. Then by instructing recorder, 76, to play  
25 and decoder, 77, to detect SPAM information in a particular location or locations, computer, 73, causes decoder, 77, to detect and transfer to computer, 73, said program unit and distance information. Receiving said information causes computer, 73, to cause recorder, 76, to stop playing; to  
30 analyze said distance information in a predetermined fashion; and to compute the precise time required to rewind to reach the start of the program unit or to move fast forward to reach the end. Then automatically, computer, 73, causes said recorder, 76, first, to start rewinding or moving fast  
35 forward then to stop after the precise time elapses.

(Such distance information can be embedded as SPAM message information segment information anywhere in the programming that SPAM information can be embedded and need not repeat continuously--one embedded signal word is  
5 sufficient for this method to work. But a method wherein only one instance of distance information is embedded in any given program unit of programming has the disadvantage of causing too much apparatus at too many stations to spend too much time searching for said instance. In the preferred  
10 embodiment, distance information is embedded in the relevant normal transmission location of its programming and occurs periodically throughout a program unit with increasing frequency as the closeness of the start or end of the programming approaches and with one instance, in television  
15 programming, occurring on the first and fourth frames and the last two frames of the programming.)

Computer, 73, has capacity for automatically organizing the locations of units of prerecorded programming on recording media such as magnetic video tapes loaded on a  
20 plurality of recorder/players to play according to a given schedule. For example, four spot commercials--program units Q, Y, W, and D--are loaded on 76 and 78. D and Q are recorded on the video tape loaded on recorder, 76, with D first. W and Y are recorded on the tape on recorder, 78,  
25 with W first. According to the schedule recorded at computer, 73, Q should play first on the cable channel modulated by cable channel modulator, 83; then subsequently Y and W should start to play simultaneously on the channels  
30 modulated by modulators, 83 and 87 respectively; then D should play on the channel modulated by modulator, 83, immediately after Y ends. Caused to organize the locations of said units to play according to said schedule, computer, 73, determines automatically, in a predetermined fashion, that units Q, Y and D should be recorded on the tape loaded  
35 on recorder, 76, with Q recorded first and D recorded

immediately after Y. In a predetermined fashion, computer, 73, determines that insufficient available space exists on the tape on recorder, 76, to record Y immediately before D or on recorder, 78, to record D immediately after Y. So  
5 determining causes computer, 73, automatically to locate a place on the tape loaded on recorder, 78, that contains sufficient space for recording D. (Computer, 73, can contain records that identify how space on particular tapes is allocated or it can locate this space by playing the tapes,  
10 retaining information of "program unit identification code" and distance information prerecorded on said tapes [or the absence of such information], and analyzing said information in a predetermined fashion.) Automatically, computer, 73, verifies that the space is truly available by causing  
15 recorder, 78, to move forward or rewind to the start of the located space then to play for the duration of the space; by causing decoder, 79, simultaneously to search for embedded SPAM message information, detect said information, and transfer said information to computer, 73; and by checking  
20 the detected SPAM information in a predetermined fashion to ensure that detected meter-monitor information does not identify a program unit that is scheduled to be transmitted at a future time. Determining said located space to be available causes computer, 73, to cause recorder, 76, to move  
25 forward or rewind to the start of program unit D; to cause recorder, 78, to rewind to the start of said located space; and to cause switch, 75, to configure its switches so as to transfer the output of recorder, 76, to the input of recorder, 78. Automatically, computer, 73, then causes  
30 recorder, 76, to play and recorder, 78, to record for the duration of program unit D. Then automatically, in a predetermined fashion, computer, 73, alters the records it contains to reflect the location of unit D on recorder, 78, and that the space on the tape on recorder, 76, that program  
35 unit D had occupied is now available and may be recorded

over. (Computer, 73, may automatically make available the the space on the tape on recorder, 76, that program unit D has occupied by causing recorder, 76, to rewind to the start of said space and to erase or record for the duration of D--  
5 since the output of recorder, 78, is the input to recorder, 76, and since recorder, 78, is not playing, a recording so recorded by recorder, 76, would contain no programming or SPAM information.) Program unit D is now recorded on the tape on recorder, 78, and program unit Q is the only unit on  
10 recorder, 76. Then automatically, in the locating fashion described above, computer, 73, locates an available space on the tape on recorder, 76, that is large enough for recording program units Y and D together. Computer, 73, verifies the availability of the space in the verifying fashion above.  
15 Computer, 73, causes recorder, 78, to move forward or rewind to the start of program unit Y; causes recorder, 76, to rewind to the start of the available space; and causes switch, 75, to configure its switches so as to transfer the output of recorder, 78, to the input of recorder, 76.  
20 Computer, 73, causes recorder, 78, to play and recorder, 76, to record for the duration of program unit Y. Computer, 73, causes recorder, 78, to move forward or rewind to the start of program unit D and causes recorder, 78, to play and recorder, 76, to record for the duration of program unit D.  
25 Finally, in the record keeping fashion above, computer, 73, alters its contained records to document the locations of Y and D on the tape on recorder, 76, and the availability of the spaces that Y and D have occupied on the tape on recorder, 78, for recording other programming. (The station  
30 of Fig. 6 may have, at recorders, 76 and 78, stripping and embedding apparatus such as signal strippers, 81 and 85, and signal generators, 82 and 86, and computer, 73, may cause said generator apparatus to record at particular places on the tapes loaded at recorders, 76 and 78, information of the contained records of computer, 73, that identify how space on  
35

said tapes is allocated.) In this fashion, computer, 73, causes units Y and W to be located on different recorders because said units are scheduled to be transmitted simultaneously and units Y then D to be located in sequence  
5 on the same recorder because unit D is scheduled to play on the same channel immediately after Y.

Computer, 73, has capacity for automatically playing organized scheduled program units according to its recorded station schedule. Computer, 73, may be caused to commence  
10 playing any given unit of programming previously loaded at a recorder, 76 or 78, in any of a number of different fashions. For example, a remote program originating studio can embed and transmit a SPAM message that contains particular cueing information, and receiving said message can cause controller,  
15 73, to cause a selected recorder, 76 or 78, to commence playing a tape that has been positioned at the tape head of said recorder, 76 or 78, according to the schedule of computer, 73. Or for example, the aforementioned clock of computer, 83, may be caused, in a predetermined fashion, to  
20 transmit time information periodically, and receiving particular time information can cause controller, 73, to cause a selected recorder, 76 or 78, to commence playing said tape.

In the preferred embodiment, in the case of so-called  
25 "cut ins" to network transmissions, any given intermediate station computer, 73, is cued (that is, caused) to cut in any given local transmission of prerecorded programming (or top a given local transmission) by a SPAM message (that contains an execution segment and a meter-monitor segment that contains  
30 "program unit identification code" information of the program unit in which it is embedded) that is a cueing message and that is embedded in a given network transmission and transmitted by the program originating studio that originates the transmission of said network. In the case of sequential  
35 transmissions of more than one program unit of so-called

"local origination" programming, each intermediate station computer, 73, is cued to start transmission of the first unit by a time transmission of the aforementioned clock of said computer, 73, (or in the case of a cut in to a network  
5 transmission, by a network transmitted SPAM cueing message), and the transmission of each subsequent unit is cued by such a SPAM cueing message that is embedded in the last one-half second of the programming of its predecessor program unit.

For example, in the case of the aforementioned  
10 schedule of computer, 73, units Q, Y, and D are scheduled to be cut into a particular first network transmission that is received at receiver, 53, and is transferred to field distribution system, 93, via modulator, 83. Unit W is scheduled to be cut into a particular second network  
15 transmission that is received at receiver, 58, and is transferred to field distribution system, 93, via modulator, 87.

Completing the organization of any given group of pre-scheduled tapes causes computer, 73, automatically to  
20 position the first organized unit or units to play according to schedule. Accordingly, completing the above described organization of any units Q, Y, W, and D causes computer, 73, automatically to cause recorder, 76, to move forward or rewind to the start of unit Q and to cause recorder, 78, to  
25 move forward or rewind to the start of unit W.

In due course, a particular first instance of the aforementioned SPAM cueing message is embedded in said first network transmission and transmitted at the program  
originating studio that originates said transmission  
30 (hereinafter, said first instance is called the "first-network-cue-to-transmit-locally message (#8)") then, after an interval of time equal to the duration of the playing of unit Q passes, a particular second instance of said message is embedded at said studio and transmitted in said transmission  
35 (hereinafter, said second instance is called the "first-

network-cue-to-transmit-network message (#8)").

Said first and second instances are each detected at that decoder of signal processor system, 71, that continuously processes the transmission outputted by distribution amplifier, 63, and are inputted to computer, 73, with appropriate source mark information.

Receiving said first instance causes computer, 73, under control of instructions of said schedule, to cause recorder, 76, to commence playing and to cause matrix switch, 75, to configure its switches to cease transferring the transmission received at receiver, 53, to modulator, 83, and to commence transferring the output of recorder, 76, to modulator, 83. In so doing, computer, 73, causes the cable head end station of Fig. 6 to cease transmitting said first network transmission to field distribution system, 93, and to commence transmitting the locally originated transmission of unit Q. Then receiving said second instance causes computer, 73, under control of instructions of said schedule, to cause matrix switch, 75, to configure its switches to cease transferring the output of recorder, 76, to modulator, 83, and to commence transferring the transmission received at receiver, 53, to modulator, 83, and to cause recorder, 76, to cease playing and to move forward or rewind to the start of unit Y. In so doing, computer, 73, causes the head end station of Fig. 6 to cease transmitting to field distribution system, 93, the locally originated transmission of unit Q; to recommence transmitting said first network transmission; and to prepare to play the locally originated transmission of unit Y. In this locating and playing fashion, computer, 73, can then play program units Y, W, and D according to its recorded schedule. (Because unit D is scheduled to play immediately after Y on the same channel, no SPAM cueing message causes computer, 73, to cause recorder, 76, to stop playing or matrix switch, 75, to switch another transmission to modulator, 83, until Y and D have both played.)

Fig. 6 shows particular signal processor system monitoring apparatus associated with the intermediate station of Fig. 6. In field distribution system, 93, amplifier, 94, inputs programming transmissions to signal processor system, 5 71, (where said transmissions are inputted to one alternate contact of the switch, 1, of the signal processor of said system, 71), and amplifier, 95, inputs programming transmissions to signal processor, 96, which permits both signal processor apparatus to monitor all programming 10 transmitted by the cable television system head end station to field distribution system, 93, in the fashion of the signal processor, 200, of Fig. 3 in example #5. By recording all different received "program unit identification code" information in the fashion described above, said signal 15 processor apparatus can automatically record, for each transmission channel of the station of Fig. 6, information, for example, that the U. S. Federal Communications Commission requires broadcast station operators to maintain as station logs. And said signal processor apparatus can transmit such 20 records of programming to remote sites via telephone or other data transfer networks, 97 and 99 respectively. In this fashion, said signal processor apparatus can automatically provide their contained records to one or more remote independent auditor stations.

25 In the preferred embodiment, at least two signal processors (such as the signal processor of said system, 71, and signal processor, 96) monitor the transmissions of any given transmission station. One (eg., the signal processor of said system, 71) is at said station which permits station 30 personnel to inspect said one and ensure that said one is operating continuously and correctly. At least one other (eg., signal processor, 96) is located at a site within the distribution system of said station (eg., field system, 93) that is remote from the transmission station of said site, 35 and said is inspected and serviced by independent auditor

personnel. The records of said processors are regularly caused to be transmitted to one or more remote auditing stations (eg., by networks, 98 and 99), in the fashions described above, and computers at said stations are caused to  
5 receive said records, compare said records with each other, and record any differences between the two sets of records are recorded.

The cases of the transmission of units Q, Y, W, and D provide examples of the operation of signal processor  
10 apparatus, 71 and 96. As the aforementioned program originating studio of the aforementioned first and second network transmissions transmit programming, at said signal processor apparatus, 71 and 96, switches, 1; mixers, 3; and TV signal decoders, 30, detect SPAM message information in  
15 successive channel transmissions of the station of Fig. 6, under control of controllers, 20, and oscillators, 6, and transmit detected SPAM information to onboard controllers, 14A, causing signal records of program units transmitted at said station to be retained, recorded, and retransmitted to  
20 remote auditing stations in the fashion of example #5, above. Any SPAM message that contains meter-monitor information can cause said apparatus, 71 and 96, to detect, transmit, retain, record, and retransmit in the fashion described above. For example, a SPAM cueing message such as the aforementioned  
25 first-network-cue-to-transmit-locally message (#8) can cause not only the cut in and transmission of locally originated programming (eg. the programming of unit Q) but also the processing of meter-monitor information. in the fashion described in example #5, at said apparatus, 71 and 96. Said  
30 message could cause said apparatus, 71 and 96, to add time information to retained signal records, thereby documenting a last instance of receiving the "program unit identification code" information contained in the meter-monitor information of said message. And embedding SPAM messages in the  
35 prerecorded programming of, for example, program unit Q that

contain "program unit identification code" information that identifies unit Q can cause the station of Fig. 6 to transmit said messages in its transmission of Q, thereby causing said apparatus, 71 and 96, to detect, retain, and retransmit  
5 signal records of said "code" information which signal records serve as so-called "proof of performance" that the programming of said program unit Q was transmitted according to schedule by the station of Fig. 6.

So far this disclosure has described an intermediate  
10 transmission station that transmits conventional television programming; however, the intermediate station automating concepts of the present invention apply to all forms of electronically transmitted programming. The station of Fig. 6 can process and transmit radio programming in the fashions  
15 of the above television programming by adding radio transmission and audio recorder/player means, each with associated radio decoder means as shown in Fig. 2B, wherever television means are shown in Fig. 6, all with similar control means to that shown in Fig. 6 and by processing radio  
20 programming with appropriately embedded signals according to the same processing and transmitting methods described above. Likewise, said station can transmit broadcast print and data communications programming by adding appropriate transmission and recorder/player means and decoder/detector means with  
25 control means and using the same processing and transmitting methods. This example has described methods at a multi-channel intermediate transmission station; the methods are also applicable in a station that transmits only a single channel of television, radio, broadcast print or data. In  
30 addition, the programming and SPAM information transmitted to intermediate transmission station can be encrypted and decrypted and monitored in the fashions described above. Intermediate transmission station apparatus can include signal processing regulating system apparatus such as the  
35 apparatus of Fig. 4 by means of which encrypted transmissions

that are transmitted to intermediate stations are caused to be decrypted and metered. Intermediate transmission station apparatus can include encryptor apparatus that encrypt programming transmissions selectively. And intermediate transmission station apparatus can include signal processing monitoring system apparatus in the spirit of the apparatus of Fig. 5 whereby the availability, use, and usage of programming at selected intermediate station apparatus is recorded and records are transmitted to remote stations that process such records.

AUTOMATING INTERMEDIATE TRANSMISSION STATIONS ... EXAMPLE #8

Using the capacity described above for identifying, selecting, and recording received programming; for organizing recorded programming to play according to schedule; for playing selected organized programming on schedule; and for retaining, recording, and retransmitting monitor records that document the transmission of program units, a remote distribution station can transmit to a plurality of intermediate transmission stations programming that is scheduled for delayed transmission, cause each station of said plurality automatically to select and retransmit programming according to its own specific schedule, and cause signal processing apparatus automatically to transmit to a remote auditing station or stations signal records that document the transmission of specific program units at the specific stations of said plurality.

One such remote distribution station might be, for example, a so-called "satellite uplink" that transmits programming, in a fashion well known in the art, to a plurality of receiver stations via a satellite transponder (said intermediate transmission stations being among said receiver stations). Said programming might be, for example, so-called "television spot commercials." Providing means where by one station can transmit programming to a plurality

of intermediate transmission stations and cause each intermediate station to transmit its own specific selected units of said programming according to its own specific schedule enables one such distribution station such as a so-called "spot rep." agency that sells the so-called "spot time" of many, widely separated local broadcast stations and cable systems to transmit many different spot commercial program units to said stations and systems automatically and cause each station or system automatically to retransmit its specific selected commercial program units according to its specific schedule. And providing means that document the specific program units transmitted at each specific station enables said distribution station to provide so-called "proof of performance" to parties who pay for the transmission of said spot commercials.

Example #8 illustrates a remote distribution station transmitting programming and causing apparatus at a plurality of intermediate transmission stations to operate in this fashion.

In example #8, a given remote distribution station that is located in Carteret, New Jersey, USA transmits television programming to a plurality of intermediate transmission stations by means of a satellite that is located approximately 20,000 miles above the Earth in so-called "geosynchronous orbit" and transmits programming to the North American continent. Among said intermediate stations are cable system head ends located in California and Florida, broadcast stations located in Texas and Washington, D.C., and the station of Fig. 6 which is, for example, in Vermont.

At each intermediate transmission station is a computer, 73, that is preprogrammed to receive, process, and record, in a predetermined fashion, program schedule information that is transmitted from said remote distribution station. And the signal processor system, 71, and the computer, 73, of each station are preprogrammed to process

particular SPAM message instructions are transmitted from said remote distribution station.

At a particular time on a particular day--for example, at 5 P.M. eastern standard time, on January 27, 1988--said  
5 remote distribution station commences contacting,  
individually and in turn in a fashion well known in the art, the computers, 73, of each of said intermediate station, via telephone or other data transfer network, 98 (which has capacity to communicate information individually between said  
10 remote station and each of said computers, 73). Said remote station inputs schedule information to each computer, 73. Said information identifies the particular time and date when all of said intermediate transmission stations should commence receiving a particular satellite transmission--for  
15 example, at 4 A.M. eastern standard time, on January 28, 1988--and which particular satellite transponder transmission said stations should prepare to receive the programming on--for example, transponder 23 on the Galaxy 1 satellite. Said schedule information also identifies to each specific  
20 computer, 73, which specific program units, transmitted via said transponder, said computer, 73, should cause the apparatus of its station to select and record, and when and on which channel of said station said computer, 73, should cause the apparatus of said station to transmit each of said  
25 program units to the field distribution system, 93, of said station. For example, in the case of the computer, 73, of the station of Fig. 6, said remote distribution station informs said computer, 73, to select and record program units Q, D, Y, and W; to transmit program unit Q at 2:30:30 PM  
30 eastern standard time, on January 29, 1988 on the cable channel transmitting the Cable News Network; to transmit program unit Y at 2:45:00 PM eastern standard time, on January 29, 1988 on the cable channel transmitting the Cable News Network; to transmit program unit W at 2:45:00 PM  
35 eastern standard time, on January 29, 1988 on the cable

channel transmitting the USA Cable Network; to transmit program unit D at 9:15:30 PM eastern standard time, on January 30, 1988 on the cable channel transmitting the Cable News Network.

5 In inputting schedule information to each computer, 73, said remote distribution station instructs different computers, 73, to operate differently. For example, said remote station instructs a particular Florida computer, 73, at a cable system head end station in Florida (which  
10 computer, 73, is not the computer, 73, of the station of Fig. 6) to select and record program units Q, J, and L; to transmit program unit J at 2:30:30 PM eastern standard time, on January 29, 1988 on the cable channel of said station in Florida that transmits the Cable News Network; and to  
15 transmit units Q and L subsequently at particular times on the cable channel of said station that transmits the Spanish International Network.

Subsequently, at a particular time--more precisely, at 3:50 A.M. eastern standard time, on January 28, 1988--said  
20 schedule information and particular preprogrammed receive-scheduled-programming instructions at each computer, 73, cause the computers, 73, at said intermediate transmission stations each, in a predetermined fashion, to commence preparing its particular station to receive and record  
25 information of the transmission of transponder 23 of the Galaxy 1 satellite. Automatically, at the station of Fig. 6, the computer, 73, instructs a selected earth station, 50, to move its antenna so as to receive transmissions from a  
30 satellite and instructs amplifier, 51, and receiver, 53, to amplify and tune as required to receive the transmission of the frequency of the transponder 23 of said satellite. (Said celestial coordinates and the transmission frequency of said transponder are preprogrammed at the computer, 73, of each of  
35 said intermediate stations, and while Fig. 6 does not show

means whereby computer, 73, can control earth station, 50, amplifier, 51, and receiver, 53, said means are well known in the art and exist at each of said intermediate stations, including the station of Fig. 6.) Automatically, at the station of Fig. 6, the computer, 73, causes matrix switch, 75, to configure its switches so as to transfer transmissions from receiver, 53, to a selected primary recorder, 76; causes said recorder, 76, to turn on; and causes said recorder, 76, to move forward or rewind to a particular place on the tape loaded at its record head such as the start of the tape. Automatically, said computer, 73, also causes a selected secondary recorder, 78, to turn on and causes said recorder, 78, to move forward or rewind to a particular place on the tape loaded at its record head such as the start of the tape. (The station could include apparatus well known in the art for automatically loading tape on said recorders, 76 and 78, and control means whereby computer, 73, could instruct said apparatus to load a particular tapes selectively on recorder, 76 and 78.) Simultaneously, the computer, 73, of every other one of said intermediate stations similarly to prepare to receive and record information of the transmission of transponder 23 of the Galaxy 1 satellite.

At 4 A.M. eastern standard time, on January 28, 1988 said remote distribution station commences transmitting programming by satellite up-link means, well known in the art. Said programming consists of a sequence of the program units of 26 spot commercials, each of thirty seconds duration. In succession, said station transmits units A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, U, V, W, X, Y, and Z. Embedded in each of said program units are SPAM messages containing appropriate "program unit identification code" information and distance information. Separating the transmission of the end of each program unit and the commencement of the succeeding unit is a brief interval of time. Before transmitting the first program unit

and, subsequently, in each one of said intervals, said distribution station transmits a SPAM message that contains execution and meter-monitor segments. Each message contains the same execution segment information that is addressed to  
5 ITS computers, 73, and instructs each computer, 73, to identify the information in the meter-monitor segment of said message, to compare said "code" information to the preprogrammed schedule information of said computer, 73, and if a match results, to select and record the programming of  
10 the program unit that follows said message, or if no match results, to not select and not record said programming. Each message contains meter-monitor "program unit identification code" information of the program unit that immediately follows. (Hereinafter, said messages are called individually  
15 the "select-A-message (#8)," the "select-B-message (#8)," the "select-C-message (#8)," and so forth up to the "select-Z-message (#8)," each message referring to the corresponding program unit: A, B, C, and so forth up to Z, respectively, and said messages are called collectively the "cue-to-select  
20 messages (#8).") In the preferred embodiment, the length of each of said intervals is greater than the minimum amount of time necessary for each and every one of said intermediate stations to cause a recorder to commence recording a properly recorded recording of said programming, and said distribution  
25 station transmits each of said SPAM messages early enough before commencing to transmit its succeeding program unit to enable all intermediate stations that record said unit to record said unit completely.

Transmitting said programming and said cue-to-select  
30 messages (#8) causes signal processing system apparatus at each of said stations to detect said cue-to-select messages (#8) and input said messages to the computers, 73, of said intermediate stations. At the station of Fig. 6, said cue-to-select messages (#8) are detected and transferred to  
35 computer, 73, by that dedicated decoder of signal processing

system, 71, that receives a transmission from distribution amplifier, 63.

The computers, 73, of said intermediate stations are preprogrammed to process the information of said cue-to-  
5 select messages (#8), and receiving any given one of said messages causes each computer, 73, of one of said intermediate transmission stations to determine whether the "program unit identification code" information of said one  
10 matches schedule information previously inputted to said computer, 73, by said distribution station. Determining a match causes said computer, 73, to cause apparatus of its station to record the programming of the program unit transmitted immediately after said one. Not determining a match causes said computer, 73, to cause apparatus of its  
15 station not to record said program unit.

At the computer, 73, of the station of Fig. 6, receiving the select-A-message (#8), the select-B-message (#8), and the select-C-message (#8), cause said computer, 73, not to cause recording of the programming of program units A, B, and C. Then receiving the select-D-message (#8) causes  
20 said computer, 73, to determine that the "program unit identification code" information of unit D matches preprogrammed schedule information which causes said computer, 73, to cause recorder, 76, to commence recording, thereby causing said recorder, 76, to record the programming  
25 of program unit D which follows said select-D-message (#8). Then receiving the select-E-message (#8) causes said computer, 73, to determine that the "program unit identification code" information of unit E does not match any preprogrammed schedule information which causes said  
30 computer, 73, to cause recorder, 76, to cease recording, thereby causing said recorder, 76, not to record the programming of program unit E which follows said select-E-message (#8). Subsequently, receiving the select-Q-message (#8) causes said computer, 73, to determine that the "program  
35

unit identification code" information of unit Q matches preprogrammed schedule information which causes said computer, 73, to cause recorder, 76, to commence recording, thereby causing said recorder, 76, to record the programming of program unit Q which follows said select-Q-message (#8). Then receiving the select-R-message (#8) causes said computer, 73, to determine that the "program unit identification code" information of unit R does not match any preprogrammed schedule information which causes said computer, 73, to cause recorder, 76, to cease recording, thereby causing said recorder, 76, not to record the programming of program unit R which follows said select-R-message (#8).

Each computer, 73, of said intermediate stations is preprogrammed to account for and keep track of the quantity of time available for additional recording on the individual tapes loaded on the recorders (eg., 76 and 78) of its station, and receiving any given message of said cue-to-select messages (#8) can cause any given computer, 73, to cause the apparatus of its station to switch from a primary to a secondary recorder of said station. For example, at the station of Fig. 6, each time computer, 73, receives a SPAM message that identifies the end of a program unit that its primary recorder, 76, has been recording, said computer, 73, determines, in a predetermined fashion, whether sufficient tape recording capacity exists on said recorder, 76, to continue recording. Determining that sufficient capacity does not exist causes computer, 73, to switch the input of the received transmission of said remote distribution station to the aforementioned alternate recorder, recorder, 78. At the station of Fig. 6, receiving said select-R-message (#8) causes said computer, 73, (after causing recorder, 76, to cease recording) to cause matrix switch, 75, to configure its switches to commence transferring the transmission from receiver, 53, to recorder, 78, and to cease transferring said

transmission to recorder, 76.

In due course, receiving the select-W-message (#8) causes said computer, 73, to determine that the "program unit identification code" information of unit W matches  
5 preprogrammed schedule information which causes said computer, 73, to cause recorder, 78, to commence recording, thereby causing said recorder, 78, to record the programming of program unit W which follows said select-W-message (#8). Then receiving the select-X-message (#8) causes said  
10 computer, 73, to cause recorder, 78, to cease recording, thereby causing said recorder, 78, not to record the programming of program unit X. Then, receiving the select-Y-message (#8) causes said computer, 73, to cause recorder, 78, to commence recording, thereby causing said recorder, 78, to  
15 record the programming of program unit Y. Then receiving the select-Z-message (#8) causes said computer, 73, to cease recording.

Whenever any given computer, 73, of said intermediate stations causes a recorder (eg., 76 or 78) of its station to  
20 cease recording, said computer, 73, then checks its contained records in a predetermined fashion to determine whether all scheduled program units have been received (and, hence, that no further units will be received). And when said remote distribution station finishes transmitting the final program  
25 unit (unit Z), said station transmits a particular final SPAM message that, in a predetermined fashion, causes any given computer, 73, whose records show that one or more program units remain unreceived to determine that no units will be received.

Whenever any given computer, 73, of said stations  
30 determines that no further units will be received, said computer, 73, causes apparatus of its station to cease receiving the transmission of said remote distribution station, alters its operating records to show that the  
35 receiver apparatus receiving said transmission is available

for other use; and commences automatically organizing, in the fashions described above, the order of the program units so selected and recorded and playing said units according to its contained schedule.

5           At the station of Fig. 6, receiving said select-Z-message (#8) causes computer, 73, to determine that program units Q, Y, W, and D have been received and that no further units will be received. Determining that no further units will be received causes computer, 73, to cause matrix switch,  
10 75, to configure its switches so as to transfer transmissions inputted from receiver, 53, to no output; to alter its operating records to show that the receiver apparatus receiving the transmission of said remote distribution station is no longer in use and is available; and to  
15 organize the locations of the recorded program units, D, Q, W, and Y, to play according to the schedule inputted by said distribution station in the fashion described above (in the paragraph of the section, "AUTOMATING INTERMEDIATE TRANSMISSION STATIONS," that begins, "Computer, 73, has  
20 capacity for automatically organizing the locations of units of prerecorded programming ... to play according to a given schedule").

(In so transmitting said programming and said cue-to-select messages (#8), said remote distribution station causes  
25 different intermediate transmission stations to select and record different programming and to organize recorded program units differently. For example, transmitting the select-J-message (#8), the select-K-message (#8) the select-L-message (#8), the select-M-message (#8), the select-Q-message (#8),  
30 and the select-R-message (#8) causes signal processing apparatus at the aforementioned cable system head end station in Florida to input the aforementioned Florida computer, 73, that said distribution has instructed to select, record, and play program units Q, J, and L according to schedule.  
35 Receiving said select-J-message (#8), the select-L-message

(#8), and the select-Q-message (#8) cause said Florida computer, 73, to determine that "program unit identification code" information matches preprogrammed schedule information which causes said Florida computer, 73, to cause a selected  
5 recorder of said station to commence recording, thereby causing said recorder to record the programming of program units J, L, and Q. Receiving the select-K-message (#8) and the select-M-message (#8) causes said Florida computer, 73, to determine that "program unit identification code"  
10 information does not match preprogrammed schedule information which causes said computer, 73, to cause said recorder, 76, to cease recording. And receiving the select-R-message (#8) and the select-M-message (#8) causes said Florida computer, 73, to determine that no further units will be received and  
15 to organize the locations of the recorded program units, J, L, and Q, to play according to its own schedule, previously inputted by said distribution station.)

In due course, as described above, completing the organization of units Q, Y, W, and D causes the computer, 73,  
20 of the station of Fig. 6 automatically to cause recorder, 76, to move forward or rewind to the start of unit Q and to cause recorder, 78, to move forward or rewind to the start of unit W. (Completing the organization of units J, L, and Q causes said Florida computer, 73, automatically to cause the  
25 aforementioned recorder of its station to move forward or rewind to the start of unit J.)

At a particular time prior to 2:30 PM eastern standard time, on January 29, 1988 particular preprogrammed schedule-network information and receive-scheduled-programming  
30 instructions cause the computer, 73, of the station of Fig. 6 to cause apparatus at said station to receive the transmission of the Cable Channel Network; to transmit said transmission to field distribution system, 93, via the cable channel of modulator, 83; and to commence processing monitor  
35 information embedded in said transmission. Automatically,

said computer, 73, causes earth station, 50, to move its antenna so as to receive transmissions from a satellite at particular preprogrammed celestial coordinates; causes amplifier, 51, and receiver, 53, to amplify and tune as  
5 required to receive the transmission of the particular preprogrammed frequency of a particular CNN transponder of said satellite; and causes matrix switch, 75, to configure its switches so as to transfer transmissions from receiver, 53, to modulator, 83. Automatically, signal processor, 96,  
10 and the signal processor of signal processor system, 71, each commence detecting SPAM messages in said transmission and retaining and recording signal records of Cable News Network program units.

At 2:30:29 PM eastern standard time, on January 29,  
15 1988 the Atlanta, Georgia program originating studio that originates said transmission of the Cable Channel Network embeds the aforementioned first-network-cue-to-transmit-locally message (#8) in said transmission and transmits said transmission to said CNN transponder. Automatically, said  
20 transponder retransmits said transmission, said transmission is received at the station of Fig. 6, and said message is inputted to computer, 73, with source mark information of distribution amplifier, 63. (Automatically, said message is also inputted to the computers, 73, of others of said  
25 intermediate transmission stations including said Florida computer, 73.)

Receiving said first-network-cue-to-transmit-locally message (#8) causes the computer, 73, of the station of Fig. 6, as described above, to cause the apparatus of said station  
30 to cease transmitting the Cable News Network transmission to field distribution system, 93, and to commence transmitting the locally originated transmission of unit Q. (Receiving said first-network-cue-to-transmit-locally message (#8) causes said Florida computer, 73, to cause the apparatus of  
35 its station to cease transmitting the Cable News Network

transmission to its field distribution system and to commence transmitting the locally originated transmission of unit J.)

Because said first-network-cue-to-transmit-locally message (#8) is transmitted, via matrix switch, 73, to field distribution system, 93, at the station of Fig. 6 (and so transmitted also at the station of said Florida computer, 73) before receiving said message can cause said switch, 73, to cease transmitting said Cable News Network transmission to said field, 93, receiving said first-network-cue-to-transmit-locally message (#8) causes the signal processor of the signal processor system, 71, and the signal processor, 96, of station of Fig. 6 to retain signal record information of the meter-monitor information of said first-network-cue-to-transmit-locally message (#8) as described above.

(Receiving said message causes corresponding signal processor apparatus at the station of said Florida computer, 73, similarly to retain signal record information.)

Causing the apparatus of the station of Fig. 6 to commence transmitting the locally originated transmission of unit Q to field distribution system, 93, causes the signal processor of the signal processor system, 71, and the signal processor, 96, of station of Fig. 6 to retain signal record information of the meter-monitor information of SPAM messages embedded in the prerecorded programming of said unit Q, as described above; causes said processors (in the fashion described in example #3 above) each to record previously retained signal record information of the prior programming--i.e., programming of said Cable News Network--and may cause one or both of said processors to transmit signal record information or one or more remote auditing stations.

At 2:30:59 PM eastern standard time, on January 29, 1988 said program originating studio that originates said transmission of the Cable Channel Network embeds the aforementioned first-network-cue-to-transmit-network message (#8) in said transmission and transmits said transmission to

said CNN transponder. And automatically, said message is inputted, with source mark information, to the computer, 73, of the station of Fig. 6 (and to said Florida computer, 73).

Receiving said first-network-cue-to-transmit-network message (#8) causes the computer, 73, of the station of Fig. 6, to cause the apparatus of said station, as described above, to cease transmitting to field distribution system, 93, the locally originated transmission of unit Q; to recommence transmitting said Cable News Network transmission; and to prepare to play the locally originated transmission of unit Y. (At the station of said Florida computer, 73, receiving said first-network-cue-to-transmit-network message (#8) causes said Florida computer, 73, to cause the apparatus of said station to cease transmitting the locally originated transmission of unit J; to recommence transmitting said Cable News Network transmission; and to prepare to play the locally originated transmission of unit Q or unit L.)

Subsequently, other SPAM cueing messages cause the computer, 73, of the station of Fig. 6; said Florida computer, 73; and the computers, 73, of others of said intermediate transmission stations to locate, position to play, and transmit automatically other local origination program units. And the transmission of other SPAM messages with meter-monitor information cause the signal processors at said intermediate transmission station to retain, record, and transmit to remote auditing stations signal records that document the specific program units transmitted at each specific one of said stations.

In this fashion, a remote distribution station can deliver prerecorded programming to a plurality of intermediate transmission stations, control the automatic time-delayed insertion of specific program units of programming into other programming transmissions at specific intermediate transmission stations according to the specific schedule of each station, and cause records to be recorded

and transmitted to a remote auditing station or stations that document which specific program units were transmitted at which specific station at what specific times.

5 AUTOMATING INTERMEDIATE STATION COMBINED MEDIUM OPERATIONS

... (INCLUDING EXAMPLE #9)

The station of Fig. 6 has capacity to automatically process and transmit television-based combined medium programming such as that of the "Wall Street Week" example above. In the case of programming that is transmitted to said station with all required program instruction sets and combining synch commands already properly embedded, said station records and transmits said programming just as said station records and transmits conventional television programming.

But said station also has means for automatically generating and embedding combined medium programming control instructions in certain fashions. Fig. 6 shows signal strippers, 81, 85, and 89, of which models exist well known in the art, that computer, 73, can cause to remove SPAM information from programming as required, and signal generators, 82, 86, and 90, also well known in the art, that computer, 73, can cause to embed SPAM information as required. Said generators, 82, 86, and 90, have capacity for receiving control information and programming in a transmission from computer, 73, and distinguishing, in a predetermined fashion, said control information from said programming. Said strippers, 81, 85, and 89, and generators, 82, 86, and 90, have capacity for stripping or embedding SPAM information at as little as one portion of one line of one frame of a television transmission or as much as as every line of every frame and capacity to strip or insert SPAM information on a given frame at multiple, noncontiguous locations.

For sake of example, program units, Q and D, above are

combined medium programming of the same sort as "Wall Street Week" except that computer, 73, must insert one or more particular locally generated program instruction sets into a local transmission of the programming of each of said program units. For example, program unit Q is a spot commercial of a supermarket chain that describes discounts and so-called "cents-off coupon specials" at local supermarkets. The particular formulas that apply to discounts and the particular items on special vary from specific supermarket to specific supermarket and from time to time, and the information in the embedded program instruction sets of any given transmission of unit Q must reflect the particular formulas and items that apply at specific local supermarkets at the time of said transmission.

Program units Q and D are delivered, organized to play, and played according to schedule in the automatic fashions described above but with certain variations.

Computer, 73, is preprogrammed to process combined medium programming. When the aforementioned remote distribution station inputs information to computer, 73, via network, 98, regarding unit Q, said distribution station inputs information that Q is particular combined medium programming and instructs computer, 73, to commence particular program instruction set generation in a particular fashion at a particular time interval prior to the scheduled playing of Q. (Hereinafter, a particular instance of such a time period is called "interval," as in "interval Q" of unit Q.) Inputting said information and instructions causes Computer, 73, to record said information and instructions in its record keeping fashion together with the scheduled generation time which computer, 73, calculates as the scheduled play time minus interval Q. Prior to the scheduled generation time, particular local-formula-and-item information is inputted to computer, 73, regarding the formulas and items that apply in the case of this particular

transmission of Q. (In other words, said local-formula-and-item information reflects specific information such as the particular discounts and cents-off coupon specials that apply at the scheduled time of the transmission of unit Q at the particular supermarket or markets that are local to the station of Fig. 6.) Said information may be inputted from local input, 74, or over network, 98, and computer, 73, records said information in a predetermined fashion.

Computer program instructions, of the sort well known in the art, are also inputted to computer, 73, and computer, 73, is caused to execute said instructions. Executing said instructions causes computer, 73, to generate information of a program instruction set. (Hereinafter, an instance of computer program instructions that cause a computer, at an intermediate transmission station, to generate information of a program instruction set is called an "intermediate generation set.")

For example, when executed, one particular intermediate generation set that is inputted to computer, 73, causes computer, 73, in a fashion that is described more fully below, to generate particular program instruction set information of the combined medium programming of program unit Q.

Computer, 73, can receive and be caused to execute intermediate generation set information in any fashion that a computer receives and is caused to execute computer program instructions.

In the case of prerecorded programming, in the preferred embodiment, the information of any given intermediate generation set is prerecorded in a program unit with the conventional programming--for example, the conventional television or radio programming--into whose transmission is embedded the program instruction set whose generation said given intermediate set causes. And said intermediate set is prerecorded in said program unit before.

the start of said conventional programming. For example, in the case of television programming such as the programming of unit Q, the particular intermediate set that is inputted to computer, 73, is located on the recording medium of unit Q  
5 within the defined space of program unit Q immediately following the point at which unit Q starts and before the point at which the conventional television information of Q commences. Said intermediate generation set information is embedded in the so-called "full frame" video on each  
10 successive frame until complete information of said set information is embedded; that is, embedding of said set information commences at the first line of the normal transmission location and continues on each successive detectable line of a first frame and, continuing in this  
15 fashion, on each successive frame until all intermediate generation set information is embedded. The conventional television video and audio information of program unit Q are prerecorded in the conventional fashion, commencing at the frame immediately following the last frame in which  
20 intermediate generation set information is embedded.

Any given intermediate generation set contains generally applicable information of the particular program instruction set whose generation it causes. Generally applicable information is specific. For example, the  
25 generally applicable information of the intermediate generation set of the programming of Q includes binary sound image information of a particular announcer's voice saying, "forty-three", "forty-five", "forty-six", "low-salt Vindaloo", "Mild version Quick", and "Hot version Quick".  
30 And any given datum of generally applicable information may be specific information only of selected subscriber stations. Yet such information is generally applicable at any given transmission station because any given datum may be applicable at any or all of the subscriber stations of said  
35 transmission station.

Said generally applicable information lacks specific information that is required to complete the generation of a given instance of a generated program instruction set. (For example, in the case of unit Q, the intermediate generation  
5 set lacks information of the particular discount formulas and items offered as cents-off coupon specials that apply at the scheduled time of the transmission of unit Q at the particular supermarket or markets that are local to the station of Fig. 6.)

10 When executed at a computer, 73, that is preprogrammed with particular local-formula-and-item information (that is, particular data), the instructions of a given intermediate generation set (that is, of a given computer program) cause said computer, 73, to generate particular formula-and-item-  
15 of-this-transmission information and incorporate said information into said generally applicable information of said particular program instruction set, thereby generating the particular program instruction set instance applicable to a particular transmission at a particular intermediate  
20 transmission station. The set information so generated may consist of computer program instructions and/or data.

An example #9, that focuses on generating, embedding, and transmitting combined medium program instruction set programming of unit Q at the station of Fig. 6 illustrates  
25 automating intermediate station combined medium operations.

At the aforementioned interval Q time prior to the scheduled playing of Q, particular preprogrammed preplay-and-generate instructions cause computer, 73, to commence said program instruction set generation. Said instructions cause  
30 computer, 73, to cause matrix switch, 75, to switch the input from recorder, 76, to no output; to cause recorder, 76, to position the start of unit Q at its play head; to cause decoder, 77, to commence detecting signals on all video lines from the beginning of the normal transmission pattern to the  
35 end of the last detectable line of the full video frame; then

to cause recorder, 76, to commence playing which causes recorder, 76, to transmit and decoder, 77, to detect a particular SPAM message. (Hereinafter, said message is called the "generate-set-information message (#9)".) Said  
5 message is addressed to ITS computers, 73, and contains a particular execution segment, appropriate meter-monitor information, padding bits as required, an information segment whose information is the intermediate generation set of Q, and an end of file signal. (Hereinafter, the intermediate  
10 generation set that causes any given intermediate transmission station to generate a program instruction set of an instance of the transmission of the programming of program unit Q is called the "intermediate generation set of Q".)

Detecting said message causes decoder, 77, to transmit  
15 said message to computer, 73, and receiving said message at computer, 73, causes particular SPAM decoder apparatus of computer, 73, (which apparatus is analogous to SPAM-controller, 205C, at microcomputer, 205, above and is not distinguished from computer, 73, hereinafter) to execute  
20 particular controlled functions. In the fashion of the first message of the "Wall Street Week" example at microcomputer, 205, computer, 73, is caused to load information of said intermediate generation set at particular RAM. Then  
25 receiving the end of file signal that ends said message causes computer, 73, to execute particular additional instructions of said controlled functions. Executing said instructions, causes computer, 73, to cause recorder, 76, to cease playing and position the start of the unit Q  
30 conventional television programming at the play head of recorder, 76; to cause decoder, 77, to commence detecting information in the normal transmission location alone; to cause stripper, 81, and generator, 82, to prepare to commence stripping and embedding information, respectively, in the normal transmission location; and to execute the information  
35 of said intermediate generation set as a compiled, machine

language job.

Executing the information of said set causes computer, 73, to compute said formula-and-item-of-this-transmission information in the predetermined fashion of said intermediate generation set according to the prerecorded data of said local-formula-and-item information; to compile formula-and-item-of-this-transmission information into a machine language program module; and to link said module to other program modules of said program instruction set (which modules may include modules of the aforementioned generally applicable information of said program instruction set and may also include modules preprogrammed at computer, 73). (Formula-and-item-of-this-transmission information can be incorporated into more than one module by any given intermediate generation set.)

Said formula-and-item-of-this-transmission information can consist of both computer program instructions and data. For example, one of the aforementioned discounts and cents-off coupon specials is of a 15 cents off coupon special on an offered product that varies from week to week and market to market. The information of the particular product that is offered at the particular time of the scheduled transmission at the station of Fig. 6 and at the particular supermarkets in the locality of said station is data that exist in the aforementioned local-formula-and-item information--eg., "Nabisco Zweiback Teething Toast". Other data in said local-formula-and-item information includes, for example, the street address of every one of said supermarket chain's markets in the locality said station.

Other formula-and-item-of-this-transmission information can be computer program instructions. For example, another of the aforementioned discounts and cents-off coupon specials is of a particular product--eg. untrimmed pork bellies--that is advertised in the conventional television programming of unit Q. In the

conventional programming, an announcer makes an offer, "Super Discount Supermarkets will deliver to you, at cost, all the pork you need ... ." In the example, the costs of delivery involve transportation from the central warehouse of the supermarket chain to each local market and transportation from each market to the station of any given subscriber who orders a pork belly package. In the example, the cost of delivery for any given subscriber is calculated under control of formulae that are computer program instructions.

10 The particulars of the untrimmed pork belly and "Nabisco Zweiback Teething Toast" specials of example #9 illustrate generating formula-and-item-of-this-transmission information.

15 The cost of a unit of pork belly product for any given subscriber is computed according to a particular formula:

$$Y = a + b + c(X) \quad (1)$$

20 where: Y is the delivered cost to said subscriber per unit of pork belly product,  
a is the supermarket chain's cost per unit of pork belly onboard an outbound vehicle at said warehouse,  
25 b is the cost of transportation to the market of said subscriber,  
c is the cost per mile of transportation that applies to deliveries from said market, and  
30 X is the distance in miles between said market the station of said subscriber.

Pork belly prices vary from day to day as so-called "spot" prices change on commodity markets. And transportation costs vary from time to time and place to place according to

variations in, for example, costs of gasoline and wages of vehicle drivers. Accordingly, each time the programming of unit Q is transmitted to subscribers, the values of variables a, b, and c in equation (1) that are applicable to the particular time and place of transmission must be computed and processed. For any given transmission of the television commercial of program unit Q, the price of an advertised unit of pork bellies (which price is a) is a datum that is pre-entered into computer, 73, and recorded in said local-formula-and-item information. And said values of b and c are computed according to the following equations (2) and (3) respectively:

15 
$$b = (p + q + d)Z \quad (2)$$

where: b is the b of equation (1),  
p is the cost of gasoline per pork belly unit mile between said warehouse and said market,  
20 q is the wage of the driver per unit mile between said warehouse and said market,  
d is the depreciation of the vehicle per unit mile between said warehouse and said market, and  
Z is the distance in miles between said warehouse and said market.  
25

$$c = r + s + dd \quad (3)$$

30 where: c is the c of equation (1),  
r is the cost of gasoline per unit mile between said market and the station of said subscriber,  
s is the wage of the local driver per unit mile between said market and said station, and  
35 dd is the depreciation of the local vehicle per

unit mile between said market and said station.

For any given transmission of the television commercial of  
5 program unit Q, the following variables are also data that  
are pre-entered into computer, 73, and recorded in said  
local-formula-and-item information: p, q, d, Z, r, s, and  
dd.

At the aforementioned interval Q time prior to the  
10 scheduled playing of Q, when computer, 73, commences  
generating said program instruction set, the local-formula-  
and-item information of computer, 73, includes information  
that:

15  
a is 1000.00  
p is .00625  
q is .12  
d is .1  
20 Z is 275  
r is .007  
s is 2.00  
dd is .11

25 The intermediate generation set information of said  
generate-set-information message (#9) includes program  
instructions that cause each addressed ITS computer, 73, to  
compute values of variables b and c according to formulas (2)  
and (3), given the local-formula-and-item information of p,  
30 q, d, Z, r, s, and dd, and to incorporate said computed  
values of b and c into generally applicable program  
instruction set information of equation (1).

Executing the information of said intermediate  
35 generation set causes computer, 73, to generate said program

instruction set in the following fashion. Automatically, computer, 73, selects information of each of the aforementioned variables, a, p, q, d, Z, r, s, and dd; computes the value of variable b, under control of  
5 intermediate generation set instructions of equation (2), to be 62.21875; computes the value of variable c, under control of intermediate generation set instructions of equation (3), to be 2.117; and replaces particular variable values, a, b, and c, in a particular so-called "higher language line of  
10 program code" that is among the aforementioned generally applicable information of said program instruction set and is:

$$Y = a + b + (c * X)$$

15 [which is equation (1) in the language of the IBM BASIC of the IBM Personal Computer Hardware Reference Library] with said selected information of a and the so computed information of b and c to become formula-and-item-of-this-  
20 transmission information of:

$$Y = 1000.00 + 62.21875 + (2.117 * X)$$

[which is formula-and-item-of-this-transmission information in said BASIC]. Automatically, computer, 73, selects and  
25 computes information of other variables and replaces other variable values of said generally applicable program instruction set information until a complete instance of higher language code of said program instruction set with all  
30 required formula-and-item-of-this-transmission information has been generated and exists at particular memory. Automatically, computer, 73, compiles the information of said instance and places the resulting so-called "object module" at particular memory (which compiling could be done, in the  
35 case of a program written in IBM BASIC, with the IBM BASIC

Compiler of the IBM Personal Computer Computer Language Series). Automatically, computer, 73, links the information of said object module with information of other compiled object modules that exist in memory at computer, 73, (and may  
5 have been transmitted to computer, 73, in the generally applicable program instruction set information if said intermediate generation set); generates a particular PROGRAM.EXE output file that is said program instruction set; and places said file at particular program-set-to-transmit  
10 memory of computer, 73, (which linking could be done, in the case of a program compiled by the IBM BASIC Compiler with the linker program of the IBM Disk Operating System of the IBM Personal Computer Computer Language Series). One of said other compiled object modules is a module that, when accessed  
15 in a fashion well known in the art, computes the shortest vehicle driving distance between any two locations in the local vicinity of the station of Fig. 6 when passed two street addresses of said vicinity. (Hereinafter, the program instruction set generated in example #9, under control of  
20 said intermediate generation set of Q, is called the "program instruction set of Q".)

Executing the information of said intermediate generation set causes computer, 73, also to generate a particular associated data module. (Hereinafter, a data  
25 module that is transmitted to subscriber stations and processed by computers of said stations under control of instructions of a program instruction set is called a "data module set," and any given intermediate generation set may cause generation of information of a data module set or sets  
30 in addition to or rather than generating information of a program instruction set or sets.) In a fashion well known in the art, computer, 73, selects, from among the data in said local-formula-and-item information, information of the aforementioned "Nabisco Zweiback Teething Toast"; information  
35 of the street address of every one of said supermarket

chain's markets in the local vicinity of the station of Fig. 6; particular cost-of-a-trimmed-pork-belly-unit information of 1987.25 that is the cost of all the trimmed cuts of meat of a pork belly unit; binary video image information of several telephone numbers, including a particular southwest delivery route telephone number, "456-1414", and a particular northwest delivery route telephone number, "224-3121"; and information of the particular local-automatic-order-taking telephone number of the supermarket chain applicable in the vicinity of the intermediate transmission station of Fig. 6 which is 1-(800) 247-8700. Automatically, computer, 73, places said selected information (and any other information so selected) in a particular file called DATA\_OF.ITS until the information of said file constitutes a complete instance of a particular data module set of Q. (Hereinafter, the data module set generated in example #9, under control of said intermediate generation set of Q, is called the "data module set of Q".)

Subsequently, at the scheduled time of the playing of Q, the station of Fig. 6 is transmitting via modulator, 83, a television network transmission that is inputted to matrix switch, 75, from distribution amplifier, 63. At said time, at the particular program originating studio that originates said network transmission, a particular SPAM message that contains execution and meter-monitor segments and that is addressed to ITS computers, 73, is embedded in said network transmission and transmitted. (Hereinafter, said message is called the "first cueing message (#9).")

Transmitting said message causes that decoder of signal processing system, 71, that receives the transmission of said distribution amplifier, 63, to detect said message and input said message, with appropriate source mark information, via code reader, 72, to computer, 73.

Receiving said message and said mark information causes computer, 73, to so-called "cue" recorder, 76, and

generator, 82, and to operate in its automatic playing fashion. Receiving said message and mark causes computer, 73, to cause recorder, 76, to commence playing and to cause matrix switch, 75, to configure its switches so as to cease  
5 transferring programming inputted from distribution amplifier, 63, to modulator, 83, then to commence transferring the output of recorder, 76, to modulator, 83, which causes the transmission of unit Q to field distribution system, 93. In addition, because the playing schedule of the  
10 station of Fig. 6 includes preprogrammed information that program unit Q is combined medium programming, receiving said message causes generator, 82, to cease embedding other signal information in the normal transmission location (such as, for example, teletext information well known in the art [and in  
15 so causing said generator, 82, to cease embedding said other information--for, example, said teletext--detecting said message at said intermediate station causes subscriber stations that are receiving said other information--for, example, said teletext--to cease receiving said other  
20 information]) and to transmit information of a SPAM end of file signal (and in so doing, to cause subscriber station decoder apparatus--for example, apparatus at teletext processor units--to commence detecting and discarding SPAM messages of the combined medium programming of Q).

25 Causing recorder, 76, to play causes recorder, 76, to transmit programming of Q, via matrix switch, 75, and modulator, 83, to field distribution system, 93, and also causes recorder, 76, to input the programming of Q to decoder, 77.

30 Immediately after commencing to transmit said programming of Q, recorder, 76, plays and transmits three SPAM messages that are embedded in the prerecorded programming of Q.

35 The first message is addressed to URS signal processors, 200, and causes subscriber stations that are

tuned to the channel of transmission of said modulator, 83, to combine their microcomputers, 205, to the computer system of said transmission, which transmission is originated by said recorder, 76. (Said message and the functioning that  
5 said message causes are described more fully below, and hereinafter, said message is called the "align-URS-microcomputers-205 message (#9)".)

The second message is embedded in the prerecorded programming of Q at a distance after said first message that  
10 is sufficient to allow time for apparatus at each of said subscriber stations so to combine. The execution segment of said second message is of the aforementioned pseudo command, and transmitting said message causes decoder apparatus at said subscriber stations each to detect an end of file signal  
15 and to commence identifying and processing the individual SPAM messages of the SPAM information subsequently embedded in the transmission of the programming of Q. (Said message and the functioning that said message causes are described more fully below, and hereinafter, said message is called the  
20 "synch-SPAM-reception message (#9)".) Thereafter, embedding and transmitting any given SPAM message in said transmission invokes a controlled function or functions at particular ones of said decoder apparatus.

The third message invokes broadcast control of the  
25 microcomputers, 205, of said stations in the invoking broadcast control fashion described above in "One Combined Medium." Said third message is embedded in said prerecorded programming of Q immediately after said second message and is addressed to URS decoders, 203. (Said message is described  
30 more fully below, and hereinafter, said message is called, the "control-invoking message (#9)".) Said message causes each decoder, 203, to input control invoking instructions (that are preprogrammed at said decoder, 203) to its associated microcomputer, 205. In so doing, transmitting  
35 said control-invoking message (#9) causes the microcomputers,

205, of said subscriber stations to come under control of the computer system of said recorder, 77.

Causing recorder, 76, to play unit Q causes the decoder, 77, of the station of Fig. 6 then to detect a series  
5 of SPAM messages that are embedded in the programming of Q and are addressed to ITS computers, 73. Detecting said messages causes decoder, 77, to transfer said messages to computer, 73. (Decoder, 80, can detect and transfer said messages to computer, 73, but in respect to any given  
10 embedded signal in a programming transmission, computer, 73, is preprogrammed to operate under the control of just one decoder; decoder, 77 or 79, is the default decoder for transmissions from recorder, 76 or 78 respectively, and signal processor, 71, contains the default decoder of any  
15 given transmission received at a receiver; and computer, 73, is preprogrammed to operate under the control of signals from decoder, 80, only for verifying the transmission of signals unless its methods of processing signals from decoder, 80, are changed in a predetermined fashion.)

20 The first message of said series contains execution and meter-monitor segments. (Said first message is called, hereinafter, the "transmit-data-module-set message (#9)".)

Receiving said transmit-data-module-set message (#9) causes computer, 73, to generate a particular first outbound  
25 SPAM message that includes information of the aforementioned data file, DATA\_OF.ITS, whose information constitutes a complete instance of a data module set of Q and to cause said message to be embedded in the transmission of the programming of Q and transmitted to field distribution system, 93, in the  
30 following fashion. (Hereinafter, said first outbound SPAM message is called the "data-module-set message (#9)".) Automatically, computer, 73, causes stripper, 81, to commence stripping all signals from the normal transmission location; causes generator, 82, to commence embedding information  
35 received from computer, 73; selects the information of said

meter-monitor segment, adds particular information that identifies the station of Fig. 6 and the time of transmission, modifies the meter-monitor format field information to reflect said added information, and retains  
5 the received, added, and modified meter-monitor information; and selects and transmits to generator, 82, complete information of said data-module-set message (#9). In selecting and transmitting said complete information, computer, 73, automatically selects and transmits information  
10 of a "01" header; information of a particular SPAM execution segment that is addressed to URS microcomputers, 205; said retained meter-monitor information; any required padding bits (the requirement for and number which computer, 73, determines in a predetermined fashion); complete information  
15 of said data file, DATA\_OF.ITS; and information of a SPAM end of file signal.

(The apparatus of the station of Fig. 6 may be preprogrammed in such a fashion that computer, 73, causes generator, 82, to cease embedding in the normal transmission  
20 location other signal information such as teletext information then to transmit an end of file signal each time computer, 73, causes generator, 82, to embed a SPAM message of the programming of Q then to recommence transmitting other signal information such as teletext automatically upon  
25 embedding said last named message by transmitting an "01" header; execution segment information addressed to appropriate URS receiver apparatus such as URS teletext receiver apparatus; appropriate meter-monitor information; padding bits as required; and information segment information  
30 of said other signal information such as teletext. [No end of file signal is transmitted until generator, 82, is caused to cease the transmission of said other signal information.]

Receiving the information of said data-module-set message (#9) causes generator, 82, to embed said information  
35 in the normal transmission location of the programming of Q

transmission being transmitted via generator, 82, to field distribution system, 93, thereby transmitting said data-module-set message (#9) to said system, 93.

In due course, decoder, 77, detects the second SPAM  
5 message in the aforementioned series of SPAM messages that are addressed to ITS computers, 73, and transfers said message to computer, 73.

Said second message contains execution and meter-monitor segments (and is called, hereinafter, the "transmit-  
10 and-execute-program-instruction-set message (#9).")

Receiving said transmit-and-execute-program-instruction-set message (#9) causes computer, 73, to generate a second outbound SPAM message that includes information of said program instruction set of Q and to cause said message  
15 to be embedded in the transmission of the programming of Q and transmitted to field distribution system, 93, in the following fashion. (Hereinafter, said second outbound SPAM message is called the "program-instruction-set message (#9).") Automatically, computer, 73, selects the information  
20 of said meter-monitor segment, adds particular information that identifies the station of Fig. 6 and the time of transmission, modifies the meter-monitor format field information to reflect said added information, and retains the received, added, and modified meter-monitor information.  
25 Then, automatically, computer, 73, selects and transmits to generator, 82, information of a "01" header; information of a particular SPAM execution segment that is addressed to URS microcomputers, 205; said retained meter-monitor information; any required padding bits; complete information of the  
30 aforementioned file that is at the aforementioned program-set-to-transmit memory of computer, 73, and that is said program instruction set of Q; and information of a SPAM end of file signal. Said selected and transmitted information is complete information of said program-instruction-set message  
35 (#9).

Receiving said information causes generator, 82, to embed said information in the normal transmission location of the programming of Q transmission being transmitted via generator, 82, to field distribution system, 93, thereby  
5 transmitting said program-instruction-set message (#9) to said system, 93.

Then decoder, 77, detects the third SPAM message in the aforementioned series of SPAM messages that are addressed to ITS computers, 73, and transfers said message to computer,  
10 73.

Said third message contains an execution segment and is addressed to ITS computers, 73. (Said third message is called, hereinafter, the "cease-stripping-and-embedding message (#9)".)

15 Receiving said message causes computer, 73, to cause stripper, 81, to cease stripping signal information from the normal transmission location and to cause generator, 82, to cease embedding signal information in the normal transmission location.

20 Subsequently, as recorder, 76, plays and transmits the programming of Q, via modulator, 83, to field distribution system, 93, recorder, 76, transmits eight SPAM messages that are embedded in the prerecorded programming of Q.

(Hereinafter, said messages are called [in the order in which  
25 said messages are transmitted], the "1st commence-outputting message (#9)", the "2nd commence-outputting message (#9)", the "3rd commence-outputting message (#9)", the "1st cease-outputting message (#9)", the "4th commence-outputting message (#9)", the "5th commence-outputting message (#9)",  
30 the "6th commence-outputting message (#9)", and the "2nd cease-outputting message (#9)".) Each of said eight SPAM messages contains execution segment information addressed to URS microcomputers, 205, (which causes decoder, 77, to discard the information of said messages). Said messages are  
35 discussed more fully below.

At the scheduled end time of the playing of program unit Q, another particular SPAM message that contains an execution segment and that is addressed to ITS computers, 73, is embedded at said program originating studio and  
5 transmitted in said network transmission. (Hereinafter, said message is called the "second cueing message (#9).")

Transmitting said message causes said decoder of signal processing system, 71, to detect said message and input said message, with appropriate source mark information,  
10 to computer, 73.

Receiving said message and said mark information causes computer, 73, to so-called "cue" said network transmission and continue in its automatic playing fashion. Automatically, computer, 73, causes matrix switch, 75, to  
15 configure its switches to cease transferring the output of recorder, 76, to modulator, 83, and commence transferring the transmission inputted from distribution amplifier, 63, to modulator, 83, which causes the transmission said network transmission to field distribution system, 93.

20 Automatically, computer, 73, may cause generator, 82, to embed a particular message (that is described more fully below and called, hereinafter, the "disband-URS-microcomputers-205 message (#9)") that causes subscriber stations whose microcomputers, 205, are combined to the computer system of the transmission of recorder, 76, to  
25 separate said microcomputers, 205, from said transmission.

Automatically, according to the play schedule of the station of Fig. 6, computer, 73, may cause generator, 82, to commence embedding other signal information in the normal transmission location (such as, for example, teletext information [and in  
30 so causing said generator, 82, to commence embedding said other information--for, example, said teletext--detecting said message at said intermediate station causes subscriber stations that are receiving said other information--for, example, said teletext--to commence receiving said other  
35

information]), by transmitting an "01" header then execution  
segment information addressed to receiver apparatus of said  
other information then appropriate meter-monitor information  
then said other information. And automatically, computer,  
5 73, causes recorder, 76, to cease playing and to commence  
preparing to play its next scheduled local origination  
program unit.

(Example #9 ends, insofar as intermediate station  
operations are concerned, with computer, 73, commencing to  
10 prepare to play said next program unit; however, the effects  
of so transmitting unit Q and said data-module-set message  
(#9), said program-instruction-set message (#9), said 1st  
commence-outputting message (#9), said 1st cease-outputting  
message (#9), said 2nd commence-outputting message (#9), said  
15 3rd commence-outputting message (#9), and said 2nd cease-  
outputting message (#9) are described more fully below.)

#### NETWORK CONTROL OF INTERMEDIATE GENERATING AND EMBEDDING ...

##### EXAMPLE #10

20 In the present invention, a remote network origination  
and control station, such as the aforementioned program  
originating studio that originates the transmission of the  
"Wall Street Week" program, can control a plurality of  
intermediate transmission stations in generating and  
25 embedding combined medium control instructions--that is,  
program instruction sets, data module sets, and combining  
synch commands--that control generating and transmitting at  
pluralities of ultimate receiver stations.

30 An example #10, focuses on combined medium network  
control of intermediate transmission stations, controlling  
ultimate receiver stations.

In example #10, a particular program originating  
studio transmits the commercial of program unit Q in a  
network transmission and controls a plurality of intermediate  
35 transmission stations each of which controls, in turn, a

plurality of subscriber stations that are ultimate receiver stations.

The station of Fig. 6 is one intermediate transmission station controlled by said studio. The station of Fig. 6  
5 receives said network transmission at receiver, 53, and retransmits said transmission immediately via modulator, 83.

The program unit Q of example #10 is identical to the program unit Q of example #9, and each intermediate transmission station must generate transmit its own, station  
10 specific program instruction set and data module set information that contains its own, station specific formula-and-item-of-this-transmission information.

Prior to a particular early time, complete local-formula-and-item information is inputted to and caused to be  
15 recorded at the computer, 73, of each controlled intermediate transmission station in such a way that each computer, 73, contains complete information relevant to the particular discounts and specials in effect at the particular markets in the vicinity of said station and at the particular time of  
20 the network transmission of Q. Thus each computer, 73, contains the specific values of a, p, q, d, Z, r, s, and dd of its specific station; the specific street address of every one of said supermarket chain's markets in the locality of said station; and other specific data of said station such  
25 as, for example, "Nabisco Zweiback Teething Toast".

Local-formula-and-item information can be inputted to said computers, 73, in any fashion that said computers, 73, can receive information. However, in the preferred  
embodiment, information that applies at all network stations  
30 at the time of any given transmission of a given program unit--for example, the undelivered per unit cost of pork bellies: a--is transmitted to all stations simultaneously in a SPAM message that causes each station to select and record properly said information. And information that applies only  
35 at a selected one of said stations--for example, the street

address of every one of said supermarket chain's markets in the locality of a given station--is inputted individually to the computers, 73, of said stations by means of, for example, a local input, 74, or a network, 98.

5           At the computer, 73, of the station of Fig. 6, the local-formula-and-item information in example #10 is identical to the local-formula-and-item information in example #9. For example, said local-formula-and-item information in example #10 includes:

10

a is 1000.00  
p is .00625  
q is .12  
15           d is .1  
            Z is 275  
            r is .007  
            s is 2.00  
            dd is .11

20

(At a particular second intermediate transmission station, the local-formula-and-item information of the computer, 73, include the specific values: a is 1000.00, p is .00625, q is .13, d is .11, Z is 537, r is .0082, s is 1.98, and dd is .10. Said local-formula-and-item information also includes the specific street address of one of said supermarket chain's markets in the locality of said station, particular cost-of-a-trimmed-pork-belly-unit information of 2021.42 that is the cost of the trimmed meat of one pork belly unit; binary video image information of several telephone numbers, including a particular southeast delivery route telephone number, "623-3000"; information of the particular local-automatic-order-taking telephone number of the supermarket chain applicable in the vicinity of said

35

second intermediate station which is 1-(800) 371-2100; and specific data of "Cheerios Toasted Oat Cereal" instead of "Nabisco Zweiback Teething Toast."

At said early time (which time is, in the preferred embodiment, a time of reduced operational requirement such as, for example, the middle of the night that precedes said network transmission of Q), the computers, 73, of said controlled intermediate transmission stations are caused to receive information of a particular transmission. For example, at 3:00 AM on said night, automatic schedule information and instructions (previously inputted by a computer at said network originating and control station, via network, 98, individually to each of said computers, 73) causes said computers, 73, to cause their associated earth station receivers, 50, amplifiers, 51, and TV receivers, 53, to tune to a particular satellite transmission (while causing the switches, 75, to output information of said transmission to no modulator, 83, 87, or 91). Causing said station apparatus to tune to said transmission causes those particular dedicated decoders of the signal processor systems, 71, of said stations that process continuously the inputted transmission of the distribution amplifiers, 63, to detect SPAM information embedded in the normal transmission location of said transmission and input said SPAM information to the computers, 73, of said stations.

Then the program originating studio at said network originating and control station, embeds in said normal transmission location and transmits a SPAM message that is addressed to ITS computers, 73, and consists of a "01" header, a particular execution segment, appropriate meter-monitor information, padding bits as required, information segment information of the aforementioned intermediate generation set of Q, and an end of file signal.

(Hereinafter, said message is called the "generate-set-information message (#10)".) Except for its meter-monitor

information, said generate-set-information message (#10) is identical to the aforementioned generate-set-information message (#9).

5 Transmittting said generate-set-information message (#10) causes said dedicated decoders to detect and input said message to the computers, 73, of said stations.

Receiving said message at said computers, 73, causes each of said computers, 73, to load information of said intermediate generation set at particular RAM. Then  
10 receiving the end of file signal that ends said message causes each of said computers, 73, to execute the information so loaded as a machine language job; to compute the specific formula-and-item-of-this-transmission-information of said computer, 73, in the predetermined fashion of said  
15 intermediate generation set according to the prerecorded data of the local-formula-and-item information of said computer, 73; to compile said specific formula-and-item-of-this-transmission information into one or more specific machine language program modules; and to link said specific module or  
20 modules to other program modules to become complete program instruction set information of this instance of the network transmission of Q; and to record said information at particular memory. (Hereinafter, the program instruction set generated at the station of Fig. 6 in example #10 is called  
25 the "program instruction set of Q.1", signifying that said set is one version of complete program instruction set information of said instance of the network transmission of Q.) Executing the information of said intermediate generation set also causes each said computers, 73, to generate and  
30 record complete information of a data module set.

(Hereinafter, the data module set generated at the station of Fig. 6 in example #10 is called the "data module set of Q.1", signifying that said set is one version of complete data module set information of said instance of the network  
35 transmission of Q.) In the preferred embodiment, executing

said intermediate generation set at said early time causes said computers, 73, to record said program instruction set of Q and said data module set of Q information at non-volatile, disk memory.

5           At the station of Fig. 6, for example, executing the information of said intermediate generation set causes the computer, 73, in precisely the fashion that applied in example #9, to compute the value of a particular variable b to be 62.21875; to computes the value of a particular  
10 variable c to be 2.117; and to replaces particular variable values, a, b, and c, in a particular so-called "higher language line of program code" to become formula-and-item-of-this-transmission information of:

15                            $Y = 1000.00 + 62.21875 + (2.117 * X)$

to select, compute, and replace other variable information until complete program instruction set information exists in higher language code at particular memory; to compile said  
20 higher language information; to link the information so complied with other compiled information; and to record the information so computed, compiled, and linked (which is complete information the program instruction set of Q of the station of Fig. 6) in a file named "PROGRAM.EXE", in a  
25 fashion well known in the art, on a computer memory disk of computer, 73. In so doing, said computer, 73, generates the specific program instruction set version--that is, the program instruction set of Q.1--that applies to the particular discounts and specials in effect at the particular  
30 markets in the vicinity of said station and at the particular time of the network transmission of Q. In precisely the fashion that applied in example #9, executing the information of said intermediate generation set causes said computer, 73, to select data, from among the local-formula-and-item  
35 information of said station, including the aforementioned

"Nabisco Zweiback Teething Toast" and the street address of every one of said supermarket chain's markets in the local vicinity of the station of Fig. 6, and to record said selected data on said memory disk in a data file named  
5 DATA\_OF.ITS. In so doing, said computer, 73, generates said data module set of Q.1.

(At said second intermediate transmission station, executing the information of said intermediate generation set causes the computer, 73, of said station to compute the  
10 values of variables b and c as 132.2362 and 2.0882 respectively; to replace variable values, a, b, and c, with formula-and-item-of-this-transmission information of:

$$Y = 1000.00 + 132.2362 + (2.0882 * X)$$

15 to process other variable information; and to compile, link, and record information at a particular peripheral memory unit of said computer, 73, in a file named "PROGRAM.EXE" that is the specific program instruction set of said second  
20 intermediate station. [Hereinafter, the program instruction set generated at said second station is called the "program instruction set of Q.2", signifying that said set is a second version of complete program instruction set information of said instance of the network transmission of Q.] Executing  
25 the information of said intermediate generation set causes said computer, 73, also to select particular data, including said "Cheerios Toasted Oat Cereal" and the street address of every one of said supermarket chain's markets in the locality of said second intermediate station and to record said  
30 selected data at said memory unit in a data file named DATA\_OF.ITS that corresponds in content to the file of the same name generated at the intermediate station of Fig. 6. [Hereinafter, the data module set generated at said second station is called the "data module set of Q.2", signifying that said set is a second version of complete data module set  
35

information of said instance of the network transmission of Q.]

(One difference between example #9 and example #10, which is based on the preprogrammed schedule information of each intermediate transmission station, is that executing the information of the generate-set-information message (#10) causes the generated program instruction set and data module set information to be recorded at non-volatile, disk memory whereas in example #10 the generated information may be recorded merely at RAM.)

Shortly before commencing to transmit the television programming of unit Q, at a time when all controlled intermediate transmission stations are receiving and retransmitting said network transmission (which the station of Fig. 6 and said second station each receives at a receiver, 53, and transmits via a modulator, 83), said program originating studio embeds in the normal transmission location of said transmission and transmits a second SPAM message. Said second message is addressed to ITS computers, 73, and consists of a "01" header, a particular execution segment, appropriate meter-monitor information, padding bits as required, particular information segment instruction information, and an end of file signal. (Hereinafter, said message is called the "load-set-information message (#10)".)

Transmitting said message causes the decoders of the signal processing systems, 71, of said stations that receive programming transmissions from the distribution amplifiers, 63, to detect and input said message to the computers, 73, of said stations.

Receiving said message causes each of said computers, 73, to load said information segment instruction information at particular RAM. Then receiving said end of file signal causes each of said computers, 73, to execute the instruction information of so loaded as an compiled, machine language job.

Executing said instruction information causes said computers, 73, each to load the information of said files, PROGRAM.EXE and DATA\_OF.ITS, at particular program-set-to-transmit and data-set-to-transmit RAM memories of computer, 5 73, and each to cause a generator, 82, to cease embedding any other signal information in the normal transmission location and to transmit information of a SPAM end of file signal. (Said other signal information may include, for example, teletext information, and in so causing said generators, 82, 10 to cease embedding said other information--for example, said teletext--transmitting said message causes pluralities of ultimate receiver stations that are subscriber stations of said intermediate transmission stations to cease receiving said other information--for example, said teletext.)

15 Then said program originating studio starts to transmit the conventional television programming of unit Q.

Immediately after commencing to transmit said programming of Q, said studio embeds in the normal transmission location of the transmission of said programming 20 and transmits a particular SPAM message is addressed to URS signal processors, 200, and that causes ultimate receiver stations to combine their microcomputers, 205, to the computer system of the transmission of said program originating studio. (Said message and the functioning that 25 said message causes are described more fully below, and hereinafter, said message is called the "align-URS-microcomputers-205 message (#10)".)

After an interval that is sufficient to allow apparatus at each ultimate receiver station so to combine, 30 said studio embeds in said transmission and transmits a particular SPAM message whose execution segment is of the aforementioned pseudo command. Transmitting said message causes particular decoder apparatus at said ultimate receiver stations to detect an end of file signal and to 35 commence identifying and processing the individual SPAM

messages of the SPAM information subsequently embedded in the transmission of the programming of Q. (Said message and the functioning that said message causes are described more fully below, and hereinafter, said message is called the "synch-  
5 SPAM-reception message (#10)".) Thereafter, embedding and transmitting any given SPAM message in said transmission invokes a controlled function or functions at particular ones of said decoder apparatus.

Then said studio invokes broadcast control of the  
10 microcomputers, 205, of said stations. Said studio embeds in said transmission and transmits a particular SPAM message that is addressed to URS decoders, 203. (Said message is described more fully below, and hereinafter, said message is called, the "control-invoking message (#10)".) Said message  
15 causes each decoder, 203, to input the aforementioned control invoking instructions (that are preprogrammed at said decoder, 203) to its associated microcomputer, 205. In so doing, transmitting said control-invoking message (#10) causes said microcomputers, 205, to come under control of the  
20 computer system of the transmission of said studio.

Then said studio embeds in said transmission and transmits a SPAM message is addressed to ITS computers, 73, and that contains execution and meter-monitor segments. (Said message is called, hereinafter, the "transmit-data-  
25 module-set message (#10)".) Receiving said transmit-data-module-set message (#10) causes each of said computers, 73, to cause stripping and embedding to commence; to generate a particular first outbound SPAM message that includes information of the data file, DATA\_OF.ITS, at its data-set-  
30 to-transmit RAM memory; and to cause said message to be transmitted to its field distribution system, 93.

(Hereinafter, the first outbound SPAM message of any given one of said computers, 73, is called a "data-module-set message (#10)" and all of said first messages are the "data-  
35 module-set messages (#10)".) At the station of Fig. 6, the

computer, 73, automatically causes stripper, 81, station to commence stripping all signals from the normal transmission location; causes generator, 82, to commence embedding information received from said computers, 73; selects the  
5 information of the meter-monitor segment of said transmit-data-module-set message (#10); adds particular information that identifies the station of Fig. 6 and the time of transmission; modifies the meter-monitor format field information to reflect said added information; and retains  
10 the received, added, and modified meter-monitor information. Then said computer, 73, selects and transmits to generator, 82, complete information of its data-module-set message (#10) in the following fashion. Automatically, said computer, 73, selects and transmits information of a "01" header;  
15 information of a particular SPAM execution segment that is addressed to URS microcomputers, 205; said retained meter-monitor information; any required padding bits (the requirement for and number which said computer, 73, determines in a predetermined fashion); complete information  
20 of the data file at the data-set-to-transmit RAM memory of said computer, 73, which is said file, DATA\_OF.ITS and which is complete information of said data module set of Q.1; and information of a SPAM end of file signal. (Receiving said message at said second intermediate station causes the  
25 apparatus of said station, in the same fashion, to generate and transmit the data-module-set message (#10) of said station which includes meter-monitor information that identifies said second station and said data module set of Q.2.)

30 Receiving the information of the particular data-module-set message (#10) of the computer, 73, of its station causes each generator, 82, to embed said information in the normal transmission location of the programming of Q transmission being transmitted via said generator, 82, to the  
35 field distribution system, 93, of said station, thereby

transmitting the particular data-module-set message (#10) of said station to said system, 93.

Then said program originating studio embeds in the normal transmission location of said transmission and  
5 transmits a SPAM message that is addressed to ITS computers, 73, and that contains execution and meter-monitor segments. (Said message is called, hereinafter, the "transmit-and-execute-program-instruction-set message (#10)".)

Receiving said message causes each of said computers,  
10 73, to generate a second outbound SPAM message that includes information of the program instruction set at its program-set-to-transmit RAM memory and to cause said message to be transmitted to its field distribution system, 93.

(Hereinafter, the second outbound SPAM message of any given  
15 one of said SPAM computers, 73, is called a "program-instruction-set message (#10)", and all of said second messages are the "program-instruction-set messages (#10).") Automatically, each of said computers, 73, selects the information of said meter-monitor segment, adds particular  
20 information that identifies its station and the time of transmission, modifies the meter-monitor format field information to reflect said added information, and retains the received, added, and modified meter-monitor information. Then, automatically, each of said computers, 73, selects and  
25 transmits to the generator, 82, of its station, information of a "01" header; information of a particular SPAM execution segment that is addressed to URS microcomputers, 205; its retained meter-monitor information; any required padding bits; complete information of the program instruction set  
30 that is at its program-set-to transmit RAM memory; and information of a SPAM end of file signal. Said selected and transmitted information that each of said computers, 73, transmits is complete information of the particular program-instruction-set message (#10) of said computer, 73.  
35 (Receiving said message causes the apparatus of the

intermediate station of Fig. 6 to transmit the program instruction set of Q.1 in the program-instruction-set message (#10) of said station and causes the apparatus of said second intermediate station to transmit the program instruction set of Q.2 in the program-instruction-set message (#10) of said second station.)

Receiving the information of the particular program-instruction-set message (#10) of the computer, 73, of its station causes a generator, 82, to embed said information in the normal transmission location of the programming of Q transmission being transmitted via said generator, 82, to the field distribution system, 93, of said station, thereby transmitting the particular program-instruction-set message (#10) of said station to said system, 93.

(After transmitting the aforementioned transmit-data-module-set message (#10) and before transmitting a particular commence-outputting message (#10) that is discussed more fully below, said program originating studio embeds and transmits other SPAM messages that are addressed to URS microcomputers, 205. Said other messages correspond in function to the data-module-set messages (#10) and program-instruction-set messages (#10) of the intermediate transmission stations of example #10 but said other messages are transmitted to and control microcomputers, 205, at particular direct-receiving ultimate receiver stations that receive the transmission of said studio directly rather than via a retransmission of one of said intermediate transmission stations. Information of said other messages is received at the aforementioned decoders of the signal processing systems, 71, of said stations that process the transmission of said studio, but said decoders discard said SPAM messages because said decoders are preprogrammed only to transmit or execute controlled functions of SPAM messages that are addressed to intermediate transmission station apparatus. And said other SPAM messages do not reach the ultimate receiver stations to

which said intermediate transmission stations transmit said data-module-set messages (#10) and program-instruction-set messages (#10) because said other SPAM messages are stripped from the transmissions of said stations by the strippers, 81, 5 of said stations.)

Then said program originating studio embeds in the normal transmission location of said network transmission and transmits a SPAM message that is addressed to ITS computers, 73, and that contains an execution segment. (Said message is 10 called, hereinafter, the "cease-stripping-and-embedding message (#10)".)

Receiving said message causes each of said computers, 73, to cause the stripper, 81, of its station to cease stripping signal information from the normal transmission 15 location and causes each of said computers, 73, to cause the generator, 82, to cease embedding signal information generated under control of said intermediate generation set in the normal transmission location.

Subsequently, said program originating studio embeds 20 in the normal transmission location of said network transmission and transmits a further series of messages that are addressed to URS microcomputers, 205, and that are described more fully below. (Hereinafter, said messages are called [in the order in which said messages are transmitted 25 at said studio]: the "1st commence-outputting message (#10)", the "2nd commence-outputting message (#10)", the "3rd commence-outputting message (#10)", the "1st cease-outputting message (#10)", the "4th commence-outputting message (#10)", the "5th commence-outputting message (#10)", the "6th 30 commence-outputting message (#10)", and the "2nd cease-outputting message (#10)".)

After transmitting the last conventional programming of Q, said studio embeds and transmits a particular message (that is described more fully below and called, hereinafter, 35 the "disband-URS-microcomputers-205 message (#10)") that

causes subscriber stations whose microcomputers, 205, are combined to the computer system of the transmission of said studio to separate said microcomputers, 205, from said transmission.

5 Then said studio embeds and transmits a particular SPAM message that contains an execution segment and that is addressed to ITS computers, 73. (Hereinafter, said message is called the "local-output-cueing message (#10).")

Receiving said message and said mark information  
10 causes intermediate transmission stations to continue transmitting locally originated programming in their scheduled fashions. At the station of Fig. 6, the dedicated decoder of signal processor system, 71, that processes the inputted transmission of distribution amplifier, 63,  
15 detects said message and inputs said message, with appropriate source mark information, to computer, 73. Automatically, receiving said message may cause computer, 73, to cause generator, 82, to commence embedding other signal information in the normal transmission location, such as, for  
20 example, teletext information. Automatically, generator, 82, embeds a "01" header; execution segment information addressed to appropriate URS receiver apparatus such as URS teletext receiver apparatus; appropriate meter-monitor information; padding bits as required; and information segment information  
25 of said other signal information--for example, teletext. (No end of file signal is transmitted until generator, 82, is caused to cease the transmission of said other signal information.) In so doing, transmitting said local-output-cueing message (#10) causes one or more ultimate receiver  
30 stations that are subscriber stations of said intermediate transmission station of Fig. 6 to commence receiving said other information--for example, said teletext. Simultaneously, other intermediate stations such as said second station commence embedding their specific other signal  
35 information--for example, their own specific teletext

information which has different information content from the information of the station of Fig. 6--causing subscriber stations of said other intermediate stations that are tuned to receive said other information to commence receiving said  
5 other information.

(Example #10 ends, insofar as intermediate station operations are concerned, with said computers, 73, causing their associated generators, 82, to commence embedding said other signal information; however, the effects of so  
10 transmitting the conventional programming of program unit Q and the SPAM messages that are associated with the network transmission of said programming and that are addressed to URS apparatus are discussed more fully below.)

So far this disclosure has described an intermediate transmission station transmitting conventional television  
15 programming. The station could process and transmit radio programming in the same fashions by adding radio transmission and audio recorder/player means, each with associated radio decoder means as shown in Fig. 2B, wherever television means  
20 are shown in Fig. 6, all with similar control means to that shown in Fig. 6 and by processing radio programming with appropriately embedded signals according to the same processing and transmitting methods described above.

Likewise, the station could transmit broadcast print and data  
25 communications programming by adding appropriate transmission and recorder/player means and decoder/detector means with control means and using the same processing and transmitting methods. This example has described methods at a multi-channel intermediate transmission station; the methods are  
30 also applicable in a station that transmits only a single channel of television, radio, broadcast print or data. In addition, intermediate transmission station can be encrypted and decrypted and monitored in the fashions described above. Intermediate transmission station apparatus can include  
35 signal processing regulating system apparatus such as the

apparatus of Fig. 4 by means of which encrypted transmissions that are transmitted to intermediate stations are caused to be decrypted and metered. Intermediate transmission station apparatus can include encryptor apparatus that encrypt programming transmissions selectively. And intermediate transmission station apparatus can include signal processing monitoring system apparatus in the spirit of the apparatus of Fig. 5 whereby the availability, use, and usage of programming at selected intermediate station apparatus is recorded and records are transmitted to remote stations that process such records.

#### AUTOMATING ULTIMATE RECEIVER STATIONS

Ultimate receiver stations are stations where programming is displayed (or otherwise outputted) to one or more subscribers, thereby enabling said subscriber or subscribers to view (or otherwise perceive) the information content of the programming. The programming so displayed (or outputted) may be any form of electronically transmitted programming, including television, radio, print, data, and combined medium programming and may be received via any electronic transmission means including wireless and cable means. The programming so displayed (or outputted) may also include computer and/or combined medium programming that is locally generated under control of SPAM message information.

The signal processing apparatus outlined in Figs. 2, 2A, 2B, 2C, and 2D, and their variants as appropriate, can be used to automate the operations of ultimate receiver stations in varieties of ways.

Fig. 7 exemplifies one embodiment of an ultimate receiver station; is a subscriber station in the field distribution system, 93, of the intermediate transmission station of Fig. 6; and may be a home, an office, a theater, a hotel, or any other station where programming such as television or radio is displayed to persons.

(NOTE: "Automating Ultimate Receiver Stations" focuses on controlling subscriber station apparatus in functions that do not necessarily involve generating or combining programming. Accordingly, whereas SPAM message transmission means have been depicted in Figs. 1 through 6 by solid lines that depict programming transmission [said lines are often marked "SIGNALS ONLY" meaning SPAM information only], in Fig. 7 et seq. the means for transmitting SPAM messages that have been detected in and separated from programming transmissions are depicted by dashed lines that depict control information transmissions.)

Fig. 7 shows a variety of input apparatus with capacity for inputting programming (including SPAM information) selectively, via matrix switch, 258, to other apparatus of the subscriber station of Fig. 7; intermediate apparatus with capacity for processing and/or recording inputted programming selectively; output apparatus for displaying or otherwise outputting programming selectively to human senses; other controlled apparatus; and other meter apparatus.

Input apparatus include satellite earth station, 250, satellite receiver circuitry, 251, converter boxes, 201 and 222 (by means of which the station of Fig. 6 receives the multiplexed multi-channel cable transmission of the cable head end station of Fig. 6), antennas, 298 and 299, and other input apparatus, 252 (which may be, for example, a laser disc player or a record player); and the subscriber station of Fig. 4 has capacity for receiving wireless programming transmissions (for example, at a satellite earth station, 250, and satellite receiver circuitry, 251), a multi-channel cable transmission (for example, at converter boxes, 201 and 222), and locally transmitted input (for example, at other input apparatus, 252). Said input apparatus input their received information to matrix switch, 258, which is a conventional matrix switch, well known in the art.

Intermediate apparatus include microcomputer, 205, television recorder/player, 217, audio recorder/player, 255, computer memory unit, 256 (which may be, for example, a so-called "fixed disk"), decryptor, 224, decryptor, 231, signal  
5 stripper, 229, signal generator, 230, and other intermediate apparatus, 257, which could be, for example, other receiver/amplifier apparatus. In addition, the TV tuner apparatus of TV set, 202--that is, TV tuner, 215--(which is not distinguished from the TV monitor, 202M, apparatus of  
10 said set, 202, in Fig. 7), and the tuner/amplifier apparatus of radio, 209--that is, radio tuner & amplifier, 213--(which is not distinguished from radio, 209, in Fig. 7), are also intermediate apparatus. All said intermediate apparatus receive their programming inputs from and transmit their  
15 programming outputs to matrix switch, 258.

Output apparatus that display or otherwise output programming selectively to human senses include, for example, TV monitor apparatus of TV set, 202, printer, 221, speaker system, 263, and one or more other output systems, 261 (which  
20 could be, for example, electronically actuated apparatus that emit odors). All said output apparatus receive their programming inputs from matrix switch, 258. (The monitor apparatus of TV set, 202, and the amplifier and speaker apparatus of radio, 209, have capacity for receiving a  
25 programming input that is separate from the inputs to the intermediate apparatus of said TV set, 202, and radio, 209, respectively.)

Other controlled apparatus include electronically actuated window opening and closing means, 208, furnace, 206, air conditioning system, 207, and other controlled apparatus,  
30 260, which could be, for example, an electronically actuated automatic lawn watering system, all of which are well known in the art. Said other apparatus do not output programming and receive no input of programming.

35 Other meter apparatus include an electronically

actuated utilities meter, 262, of which many models exist in the prior art for metering flows of electricity, gas, water, etc. Said meter, 262, does not output programming and receive no input of programming.

5 One or more appropriate SPAM decoders exist at each apparatus that receives and is controlled by SPAM message information. Appropriate SPAM decoders exist at microcomputer, 205, (which can be controlled in the fashions described above) at recorder/players, 217 and 255, (which  
10 recorder/players can be caused to operate in fashions similar to the recorder/players of the intermediate transmission station of Fig. 6) at radio, 209, and TV set, 202, (which radio and TV set can be actuated, tuned, and controlled in other functions) and at computer memory unit, 256, other  
15 intermediate apparatus, 257, printer, 221, speaker system, 263, and other output means, 261, (which unit, apparatus, printer, system, and means can be actuated individually and controlled in other functions. (For simplicity, Fig. 7 does not distinguish said decoders at or separately from their associated apparatus.)

20 Two matrix switches, 258 and 259, communicate the programming and SPAM message/control information transmissions among station apparatus. Matrix switch, 258, is a conventional matrix switch, well known in the art, with  
25 capacity for switching programming transmissions of television, radio, and other forms of electronically transmitted programming. Matrix switch, 259, is a digital matrix switch, well known in the art, with capacity for switching binary information transmissions. By means of  
30 matrix switch, 259, all apparatus communicate control information and the information of SPAM messages that have been detected in programming transmissions.

The station of Fig. 7 is preprogrammed to collect monitor information, and said decoders have bus means of the sort illustrated in Fig. 5 for communicating monitor  
35

information to an onboard controller, 14A, at signal processor, 200. (For simplicity, Fig. 7 does not show said monitor information bus means.)

For communicating particular switching request control information to the controller, 20, of signal processor, 200, said decoders also have separate control information bus means (which, for simplicity, is also not shown in Fig. 7). A particular control processor, 20A, that is located, with appropriate RAM and ROM, at controller, 20; that is separate from the CPU of controller, 20; and that is controlled by said CPU in particular functions controls the communications of said control information bus means. Said communications are conducted in a contention fashion, well known in the art.

Signal processor, 200, is the basic SPAM control apparatus of the station of Fig. 7 and has means for communicating control information (from its controller, 20) and SPAM messages (from its controller, 12) with each of said decoders and their associated apparatus. Signal processor, 200, communicates control information directly with decryptors, 224 and 231, signal stripper, 229, signal generator, 230, microcomputer, 205, and matrix switch, 259. Via matrix switch, 259, signal processor, 200, has means for communicating control information individually to all other controlled apparatus including satellite earth station, 250; satellite receiver circuitry, 251; converter boxes, 201 and 222; other input apparatus, 252; radio tuner & amplifier, 213; TV tuner, 215; television recorder/player, 217; audio recorder/player, 255; computer memory unit, 256; other intermediate apparatus, 257; the TV monitor apparatus, 202M, of TV set, 202; the speaker apparatus of radio, 209; printer, 221; speaker system, 263; and other output system, 261. In addition, the aforementioned SPAM decoders at those of said other controlled apparatus where there are SPAM decoders have capacity for communicating with each of said other controlled apparatus by means of said matrix switch, 259, in a fashion

described more fully below. Signal processor, 200, controls matrix switches, 258 and 259, and has means for communicating switch control instructions to said switches, 258 and 259.

(Fig. 7 also shows capacity whereby microcomputer, 205, can communicate switch control instructions to said switches, 258 and 259; said capacity is intended to suggest that microcomputer, 205, may control said switches, 258 and 259, at stations that lack a signal processor, 200--for example, stations that are not configured and preprogrammed to generate and/or display/output combined medium programming.)

Microcomputer, 205, controls apparatus of the station of Fig. 7 in accordance with the preprogrammed instructions of the subscriber of said station. Microcomputer, 205, has means for controlling window opening and closing means, 208, furnace, 206, air conditioning system, 207, and other controlled apparatus, 260. Microcomputer, 205, has capacity to communicate control information (under control of signal processor, 200) with other selected apparatus of the station of Fig. 7 by means of matrix switch, 259.

In the spirit of the present invention, signal processor, 200, enables local apparatus of the station of Fig. 6 to process and/or display/output received programming and SPAM information in accordance with the intentions of the owners and suppliers of said programming and information (who may, for example, wish to be paid for use of their programming). Simultaneously, the apparatus of said station are configured and microcomputer, 205, is preprogrammed to process and/or display/output said supplied programming and information in accordance with the demands of said subscriber. Local input, 225, has capacity to input control instructions to signal processor, 200, and enables the subscriber of the station of Fig. 7 to manually input control instructions at any relevant time. Microcomputer, 205, also has capacity to input control information (under control of signal processor, 200) to signal processor, 200, which

enables microcomputer, 205, at any relevant time, to automatically input control information that reflects particular instructions of said subscriber that are preprogrammed at microcomputer, 205.

5 (This is only a representative group of equipment; many other types of input, intermediate, output, controlled, and meter apparatus could be included in Fig. 7.)

Features, benefits, and modes of operation of the station of Fig. 7 are demonstrated in the following individual examples.  
10

MORE REGARDING THE PREFERRED CONTROLLER  
OF A SPAM DECODER

The controller, 39, 44, or 47, of any given SPAM decoder (such as, for example, the decoder, 203, associated  
15 with microcomputer, 205) has capacity for communicating information from the matrix switch, 39I, of said decoder to matrix switch, 259, and for receiving information from matrix switch, 259, at the decryptor, 39K, buffer, 39G, and control  
20 processor, 39J. Said control processor, 39J, also has capacity to communicate particular switch request information to the controller, 20, of signal processor, 200, directly via the aforementioned control information bus means. In  
addition, said control processor, 39J, has particular SPAM-  
25 control-information-matrix-switch-connection register memory at which said control processor, 39J, retains information that identifies the particular station apparatus to which  
matrix switch, 259, connects said matrix switch, 39I.

AUTOMATING U.R. STATIONS ... REGULATING STATION ENVIRONMENT  
30

Fig. 7A illustrates methods for regulating automatically the environment of subscriber stations such as homes and offices. Particular SPAM regulating messages are embedded in one or more television program channels that are  
35 inputted to signal processor, 200, and cable converter box,

201. Said messages include weather bulletin messages that convey local weather information and instructions, including, for example, current outside temperature information, barometric readings, and forecast data. Said messages also  
5 include meter reading messages that cause meter records of subscriber station utilities meters to be transmitted to remote metering stations.

Each subscriber station microcomputer, 205, is preprogrammed with particular weather condition instructions that control selected subscriber station apparatus under  
10 alternate weather conditions such as, for example, forecast rain instructions, forecast no rain instructions, forecast warming instructions, and forecast cooling instructions. And each subscriber station signal processor, 200, is  
15 preprogrammed at its controller, 20, with particular meter reading instructions.

Each subscriber station signal processor, 200, operates continuously; scans all incoming channels sequentially at its switch, 1, and mixer, 3, as described in  
20 example #5 above; is preprogrammed at its controller, 20, to cause its apparatus to tune to a particular master channel at a particular master-control time; and is preprogrammed at the controller, 39, of its decoder, 30, and at its controller,  
12, to transfer to the decoder, 203, of the microcomputer,  
25 205, of its station any detected SPAM message with an instance of particular URS-205 execution segment information (which information is different from the execution segment information of the combining synch commands of the "Wall Street Week" example). Said controller, 39, is also  
30 preprogrammed to transfer to said controller, 20, via control transmission means, any detected SPAM message with an instance of particular URS-200 execution segment information (which information is different from the execution segment information of any encrypted combining synch commands of the  
35 "Wall Street Week" example).

The master-control time preprogrammed at the controller, 20, of the station of Figs. 7 and 7A is daily at 2:32 AM, 10:32 AM, and 6:32 PM.

At 6:32 PM on February 27, 1988, receiving particular  
5 time information from the clock, 18, of said signal processor, 200, causes said controller, 20, to cause the switch, 1, and mixer, 3, of said signal processor, 200, to input the transmission of said master channel to the decoder, 30, of said signal processor, 200, and to cause said decoder,  
10 30, to clear all information of any SPAM message from memory and commence processing to detect a SPAM end of file signal.

In due course, the computer, 73, of the station of Fig. 6 causes an end of file signal to be embedded in the normal transmission location of said master channel, causing  
15 the control processor, 39J, of said decoder, 30, to commence waiting to detect a SPAM header.

Then said computer, 73, causes the embedding in said location and the transmission of a particular Weather-Bulletin-125 SPAM message that consists of a "01" header, an execution segment of said URS-205 execution segment  
20 information, a meter-monitor segment that contains Weather-Bulletin-125 identification information that distinguishes said Weather-Bulletin-125 from all other weather bulletins, appropriate padding bits, an information segment that  
25 contains particular current temperature thirty-two degrees centigrade, forecast rain, and forecast cooling to twenty-one degrees centigrade information, and an end of file signal.

Said message is detected at said decoder, 30, and inputted to said controller, 39, in the above described  
30 fashion.

Receiving said message causes said controller, 39, to execute particular preprogrammed controlled function instructions that cause said controller, 39, to locate said Weather-Bulletin-125 identification information and determine  
35 that said information does not match particular information

at particular last-weather-bulletin-identification RAM at  
said controller, 39; to input said message to the  
buffer/comparator, 8, of said signal processor, 200; to  
retain information of said Weather-Bulletin-125  
5 identification information at said last-weather-bulletin-  
identification RAM; and to input particular step-completed  
information to said controller, 20.

(Receiving said step-completed information causes  
controller, 20, to cause said switch, 1, mixer, 3, and  
10 decoder, 30, to commence functioning to identify program unit  
identification signal information in the fashion described in  
example #5.)

Receiving said Weather-Bulletin-125 message causes  
buffer/comparator, 8, to input said message to controller,  
15 12.

Receiving said message causes said controller, 12, to  
execute particular preprogrammed controlled function  
instructions that cause said controller, 12, to transfer said  
message to decoder, 203. Automatically, controller, 12,  
20 determines that said message is addressed to URS  
microcomputers, 205; compares particular preprogrammed to-203  
information to the information at its particular SPAM-  
control-information-matrix-switch-connection-@12 register  
memory (which memory serves the same function as the  
25 aforementioned SPAM-control-information-matrix-switch-  
connection register memory at each SPAM decoder of the  
station of Fig. 7). A match results which signifies that the  
switches of matrix switch, 259, are configured in such a way  
that the input to switch, 259, that receives the output of  
30 controller, 12, is switched to transfer information to the  
output of switch, 259, that inputs to the buffer, 39G, of  
decoder, 203. Resulting in a match causes controller, 12, to  
transfer said Weather-Bulletin-125 SPAM message to matrix  
switch, 259, which causes matrix switch, 259, to input said  
35 message to said buffer, 39G, and causes said buffer, 39G, to

input said message, in a fashion well known in the art, to control processor, 39J.

Receiving said Weather-Bulletin-125 SPAM message causes decoder, 203, to execute the information of the information segment of said message as a machine language job. Automatically, control processor, 39J, executes particular preprogrammed Weather-Bulletin controlled function instructions that cause said control processor, 39J, to locate the Weather-Bulletin-125 identification information of said message; to determine that said information does not match particular information at particular last-weather-bulletin-identification RAM associated with said control processor, 39J; to input the information of the information segment of said message to the CPU of microcomputer, 205; to retain information of said Weather-Bulletin-125 identification information at said last-weather-bulletin-identification RAM; and to cause said CPU to execute the information so inputted as a machine language job.

So executing said information causes microcomputer, 205, to reducing the power usage of said air conditioning system, 207, causes any open windows at said station to be closed. Automatically, microcomputer, 205, interrogates air conditioning system, 207, in a predetermined fashion well known in the art; determines that the thermostat setting at said system, 207, is a particular maintain-22-degrees-centigrade setting and that the thermostat is programmed to cause said system, 207, to cease operating when the thermometer of said thermostat reads twenty-one degrees centigrade; computes particular a particular cease-operating-at-22-degrees-centigrade temperature that reflects the forecast drop in temperature; transmits said instructions of said temperature to said system, 207, thereby reducing the power usage of said system, 207, by causing said thermostat, thenceforth, to cause said system, 207, to cease operating when the thermometer of said thermostat reads twenty-two

degrees centigrade; so-called "chains to", in a fashion well known in the art, the aforementioned forecast rain instructions; and executes said instructions. Executing said forecast rain instructions causes microcomputer, 205, to cause window opening and closing means, 208, to close any open windows (and could cause the aforementioned other controlled apparatus, 260, which could be an automatic lawn watering system to cease watering).

Simultaneously, by transmitting said Weather-Bulletin-125 SPAM message to other subscriber stations of its field distribution system, 93, the station of Fig. 6 causes other subscriber stations to function in the fashion of the station of Fig. 7.

In this fashion, SPAM messages can control and regulate the operation of individual subscriber station controlled apparatus (the thermostat control of furnace, 206, for example, could be similarly controlled) and control and regulate controlled apparatus at pluralities of stations.

(TV signal decoder, 203, has capacity, itself, to detect said Weather-Bulletin-125 SPAM message but only when TV set, 202, is on and operating and when the frequency of said master channel is the one TV channel transferred by box, 201, to TV set, 202. Accordingly, decoder, 203, may receive said message more than once. For this reason, decoder, 203, is preprogrammed to load and execute the information segment only once. Receiving said message a second time causes the control processor, 39J, of decoder, 203, to execute the aforementioned Weather-Bulletin controlled function instructions, and said instructions cause said control processor, 39J, to locate the aforementioned Weather-Bulletin-125 identification information in said message and determine that said information matches the aforementioned information of said Weather-Bulletin-125 identification information retained at particular last-weather-bulletin-identification RAM associated with said control processor,

39J. So matching causes said control processor, 39J, under control of said controlled function instructions to discard the information of said message by transferring the information segment to the null output of the matrix switch, 39I, of said decoder, 203, and deleting all information of said message at the SPAM-input-signal memory of said control processor, 39J.)

(No other SPAM decoder at the station of Fig. 7 is preprogrammed with SPAM-controlled-function-invoking information that matches said URS-205 execution segment information. SPAM decoders of said station such as, for example, the decoder, 218, of video recorder/player, 218, may detect said Weather-Bulletin-125 SPAM message, but doing so will cause said decoders to discard said message because the execution segment information of said message will fail to match any SPAM-controlled-function-invoking information.)

A second example illustrates the capacity of signal processor, 200, for interrogating receiver station utilities meters (as shown in Fig. 7A), recording so-called "readings," and transmitting said readings to remote stations.

The next day, February 28, 1988 at 2:32 AM, receiving particular time information from said clock, 18, causes said controller, 20, again to cause said switch, 1, and said mixer, 3, to input the transmission of said master channel to said decoder, 30, and to cause said decoder, 30, to commence processing to detect a SPAM end of file signal.

In due course, the computer, 73, of the station of Fig. 6 causes an end of file signal to be transmitted, causing the control processor, 39J, of said decoder, 30, to commence waiting to detect a SPAM header.

Then said computer, 73, causes the embedding and transmission of a particular Read-Meters-of-Selected-Stations SPAM message that consists of a "01" header, an execution segment of said URS-200 execution segment information, a meter-monitor segment that contains Meter-Reading-of-2/28/88

identification information that distinguishes said Read-Meters-of-Selected-Stations SPAM message from all other meter reading messages, appropriate padding bits, an information segment that contains particular determine-if-station-I.D.-  
5 is-in-particular-range instructions and particular if-so-read-meter-262 instructions, and an end of file signal.

Said message is detected at said decoder, 30, and inputted to the controller, 39, of said decoder, 30.

Receiving said message causes said controller, 39, to  
10 transmit said Read-Meters-of-Selected-Stations SPAM message to the controller, 20, of the signal processor, 200, of said station. Automatically, controller, 39, executes particular preprogrammed controlled function instructions that cause said controller, 39, to locate said Meter-Reading-of-2/28/88  
15 identification information and to transmit a particular read-meter instruction and information of said Meter-Reading-of-2/28/88 identification information to said controller, 20. Receiving said instruction and information causes controller, 20, to determine that said Meter-Reading-of-2/28/88  
20 information does not match particular information at particular last-meter-reading-identification RAM at said controller, 20, and to transmit a particular transmit-to-20 instruction to said controller, 39. Receiving said instruction causes said controller, 39, to transmit said  
25 message to said controller, 20, via control information transmission means and to commence waiting for the header of a subsequent SPAM message.

Receiving said Read-Meters-of-Selected-Stations message causes said controller, 20, to execute the  
30 information of the information segment of said message as a job. Automatically, said controller, 20, executes particular preprogrammed load-and-execute controlled function instructions that cause said controller, 20, to input the information of the information segment of said message to the  
35 CPU of controller, 20, to retain information of said Meter-

Reading-of-2/28/88 identification information at said last-meter-reading-identification RAM, and to cause said CPU to execute the information so inputted as a machine language job.

5           So executing said information causes controller, 20, under control of said determine-if-station-I.D.-is-in-particular-range instructions, to locate at ROM, 21, the unique digital code information that identifies the station of Fig. 7 uniquely and to determine that the numeric value of  
10 said information is greater than a particular lower range limit of said instructions and less than a particular upper range limit. So determining causes controller, 20, to execute said if-so-read-meter-262 instructions.

15           (At any station where a controller, 20, determines that the numeric value of the unique digital code information that identifies said station is less than said lower limit or greater than said upper limit, so determining causes said controller, 20, to discard all information of said message, except information at the last-meter-reading-identification  
20 RAM of said station, and to commence processing in the conventional fashion.)

          Executing said instructions causes controller, 20, first, to determine whether a communications link exists between controller, 20, and utilities meter, 262. Automatically, controller, 20, compares particular  
25 preprogrammed to-262 information to the information at its particular SPAM-control-information-matrix-switch-connection-@20 register memory (which memory serves the said function at controller, 20, that a SPAM-control-information-matrix-  
30 switch-connection register memory serves at each SPAM decoder of the station of Fig. 7). No match results which signifies that the switches of matrix switch, 259, are configured to transfer the input from controller, 20, to switch, 259, to apparatus different from utilities meter, 262. Not resulting  
35 in a match causes controller, 20, to input a particular

preprogrammed switch-to-262 instruction to the aforementioned control processor, 20A.

Receiving said instruction causes control processor, 20A, to establish a transmission link between controller, 20, and meter, 262. Automatically, control processor, 20A, executes particular instructions, preprogrammed at the aforementioned appropriate RAM and ROM located with said processor, 20A, and under control of said instructions, causes matrix switch, 259, to configure its switches in such a way that the input to switch, 259, from controller, 20, is switched to transfer information to the output of switch, 259, that inputs to meter, 262--thereby establishing said link between controller, 20, and meter, 262--and to transfer a particular to-262 instruction to said controller, 20.

Receiving said to-262 instruction causes controller, 20, in a predetermined fashion, to place particular to-262 information at said particular SPAM-control-information-matrix-switch-connection-@20 register memory then to execute particular ones of said if-so-read-meter-262 instructions.

Executing said ones causes controller, 20, to transmit the current reading information of utilities meter, 262, to a remote metering station computer and cause said computer to process said information. Automatically, controller, 20, transmits particular instructions, via said transmission link, to meter, 262, thereby causing meter, 262, to transmit its particular THIS-READING information (which is the current reading information of said meter), via said said transmission link, to controller, 20; activates telephone connection, 22; inputs a particular telephone number (which number is preprogrammed among said ones) to auto dialer, 24, causing said dialer, 24, to dial said number; establishes a telephone communication link with a particular remote metering station computer in the fashion described above; and transmits said THIS-READING information and information of the aforementioned unique digital code that identifies the

station of Fig. 7 uniquely to said computer, in a fashion well known in the art, causing said computer to process said information as particular meter reading information of said station and to respond by transmitting to said controller, 5 20, via said link, particular reading-received information.

Receiving said reading-received information causes controller, 20, to deactivate telephone connection, 22, to discard all information of said Read-Meters-of-Selected-Stations SPAM message, except information at the last-meter-reading-identification RAM of said station, and to commence 10 processing in the conventional fashion.

(In an alternate meter reading fashion, said if-so-read-meter-262 instructions are permanently preprogrammed at ROM, 21, and receiving particular day-of-month and time 15 information from clock, 18, causes said controller, 20, at a particular time each month, to execute said instructions, causing the transmission of meter reading information of said meter, 262, said remote metering station, in the above fashion, and the processing of said information at said 20 station. Each station of the field distribution system, 93, of an intermediate station such as Fig. 6 is preprogrammed to function in this fashion at a different time over the course of a month, and all stations transmit meter reading information during said month.)

(No SPAM decoder at the station of Fig. 7 other than 25 said decoder, 30, is preprogrammed with SPAM-controlled-function-invoking information that matches said URS-200 execution segment information. Thus, while a SPAM decoder such as, for example, decoder, 203 or 218, may detect said 30 Read-Meters-of-Selected-Stations SPAM message, doing so will cause said decoder to discard said message.)

#### AUTOMATING U. R. STATIONS ... COORDINATING A STEREO SIMULCAST

Fig. 7B illustrates automatic control of one kind of 35 combined medium presentation--a stereo simulcast.

(In the present invention, turning on or changing a channel at a receiver, 215, of a television set, 202, causes apparatus at said receiver automatically to transmit an interrupt signal of new-channel-input information and input  
5 said interrupt signal directly to the control processor, 39J, of the controller, 39, of the decoder, 203, associated with said receiver, 215, [which signal said apparatus has means to input directly].)

At the station of Fig. 7 and 7B, a subscriber decides  
10 to watch a particular television program the audio of which is stereo simulcast on a local radio station, in a fashion well known in the art. Said subscriber switches power on to TV set, 202, and manually selects the proper channel, which is, for example, channel 13, at the television tuner, 215, of  
15 said set, 202, thereby display of the video and audio information of the transmission of said channel.

Switching power on to said set, 202, and tuning said tuner, 215, in this fashion causes said tuner, 215, to input an interrupt signal of new-channel-input information to the  
20 control processor, 39J, of the controller, 39, of TV signal decoder, 203, and to commence inputting the demodulated transmission of said channel to said decoder, 203.

Receiving said interrupt signal causes said control processor, 39J, to cause all apparatus of decoder, 203, to  
25 cease receiving television transmission information and to delete all previously received SPAM information (and, in so doing, to set the information at the EOFS WORD Counter of the EOFS valve, 39F, of said controller, 39 to "00000000", thereby discarding any previously received end of file signal  
30 information); to cause the matrix switch, 39I, to commence transferring information from EOFS valve, 39F, to its null output; to cause EOFS valve, 39F, to commence processing detected SPAM information for an end of file signal; and to cause all apparatus of decoder, 203, to commence receiving  
35 television transmission information.

Then so inputting said demodulated transmission to said decoder, 203, causes said decoder, 203, to commence detecting and processing SPAM message information embedded in said transmission.

5 In due course, the program originating studio that originates the transmission of said channel embeds an end of file signal in said transmission, causing the EOFS valve, 39F, of said controller, 39, to detect said signal and transfer an interrupt signal of EOFS-signal-detected  
10 information to the control processor, 39J, of said controller, 39.

Receiving said interrupt signal at said control processor, 39J, causes said control processor, 39J, to process the next received SPAM information as information of the header of a SPAM message, thereby causing said  
15 controller, 39, to commence identifying and processing the individual SPAM messages of said detected SPAM information.

Periodically thereafter, said program originating studio embeds in said transmission and transmits a particular  
20 Tune-Radio-to-FM-104.1 SPAM message that consists of a "01" header, an execution segment of particular activate-simulcast information that is addressed to URS radio decoders, 210, a meter-monitor segment that contains the "program unit identification code" information of said particular  
25 television program, appropriate padding bits, an information segment that contains particular 104.1-MHz information, and an end of file signal.

Said message is detected at said decoder, 203, and inputted to said controller, 39, in the above described  
30 fashion.

Receiving said message causes said controller, 39, to execute particular preprogrammed controlled function instructions that cause said controller, 39, to transfer said message to the radio decoder, 210, of radio, 209. First, said controller, 39, determines whether a transmission link  
35

exists between said controller, 39, and said controller, 44. Automatically, said controller, 39, compares particular preprogrammed to-210 information to the information at its particular SPAM-control-information-matrix-switch-connection register memory. No match results which signifies that the switches of matrix switch, 259, are configured to transfer the input to switch, 259, from said controller, 39, to apparatus other than radio decoder, 210. Not resulting in a match causes said controller, 39, to input a particular preprogrammed switch-203-to-210 instruction to the aforementioned control processor, 20A, via the aforementioned control information bus means for communicating particular switching request control information.

Receiving said instruction causes control processor, 20A, to establish a transmission link between the controller, 39, of decoder, 203, and the controller, 44, of decoder, 210. Automatically, under control of particular preprogrammed instructions, control processor, 20A, causes matrix switch, 259, to configure its switches in such a way that the input to switch, 259, from the controller, 39, of decoder, 203, is switched to transfer information to the output of switch, 259, that inputs to the buffer, 44G, of the controller, 44, of said decoder, 210, (said controller, 44, being identical to the controller, 39, of Fig. 3A, but the alphanumeric designation of the components of said controller, 44, being designated with a "44" rather than a "39" number)--thereby establishing said transmission link--and to transfer a particular to-210 instruction to said controller, 39.

Receiving said to-210 instruction causes said controller, 39, in a predetermined fashion, to place particular to-210 information at said SPAM-control-information-matrix-switch-connection register memory then to execute particular ones of said controlled function instructions.

Executing said ones causes said controller, 39, to

transfer said message to the radio decoder, 210, of radio, 209. Automatically, the control processor, 39J, of said decoder, 203, causes the matrix switch, 39I, to commence transferring information to matrix switch, 259, and causes  
5 the apparatus of controller, 39, in the fashion for transferring a "01" header message described above, to transfer said Tune-Radio-to-FM-104.1 SPAM message, via said communications link, to the controller, 44, of said decoder, 210.

10 Receiving said SPAM message causes said controller, 44, switch power on to and tune radio, 209, to the frequency, 104.1 MHz. (Controller, 44, has means for transmitting control information from its matrix switch, 44I, to a particular switch, 212, and a particular digital tuner, 213,  
15 that are digitally actuated apparatus, well known in the art, that have capacity, respectively, for switching power on to radio, 209, and for tuning radio, 209.) Automatically, the control processor, 44J, of said controller, 44, executes particular preprogrammed activate-simulcast controlled  
20 function instructions, loads said 104.1-MHz information of the information segment of said message at particular tune-to working register memory, and determines that the information at said working memory does not match information at particular SPAM-is-tuned-to register memory (which signifies  
25 that radio, 209, is not tuned to the radio frequency, 104.1 MHz). Not resulting in a match causes said controller, 44, to determine, in a predetermined fashion, that radio, 209, is not on and operating. So determining causes said controller, 44, under control of said instructions, to transmit  
30 particular preprogrammed instructions, via said matrix switch, 44I, to switch, 212, thereby causing said switch, 212, to switch on and actuate radio, 209; to transmit particular preprogrammed instructions, via said matrix switch, 44I, to tuner, 213, thereby causing said tuner, 213,  
35 to tune radio, 209, to said frequency, 104.1 MHz; and to

place information of said 104.1-MHz information at said SPAM-  
is-tuned-to register memory. Automatically, the speaker  
apparatus of said radio, 209, commences receiving information  
of the radio transmission of said frequency and emitting the  
5 audio sound of said simulcast.

Thus switching power on to TV set, 202, and selecting  
channel 13 at television tuner, 215, are the only manual  
steps necessary to actuate the radio simulcast of said  
channel at radio, 209.

10 In addition, because the station of Fig. 7 (and Fig.  
7B) is preprogrammed to collect monitor information,  
receiving said Tune-Radio-to-FM-104.1 SPAM message also  
causes the transmission of monitor information to the onboard  
controller, 14A, of said signal processor, 200, in the  
15 fashion of example #3 above. At decoder, 203, completing the  
controlled functions invoked by receiving said message causes  
the transfer, via the aforementioned bus means for  
communicating monitor information, to said onboard  
controller, 14A, of a first information transmission of the  
20 execution and meter-monitor information of said message with  
particular first source mark information that identifies TV  
set, 202. At decoder, 210, completing the controlled  
functions invoked by receiving said message causes the  
transfer, via said bus means, to said onboard controller,  
25 14A, of a second information transmission of the execution  
and meter-monitor information of said message with  
appropriate source mark information identifying radio, 209.

In the fashion of example #3 above, receiving said  
first transmission of monitor information causes said onboard  
controller, 14A, to cause a signal record of prior  
30 programming of TV set, 202, to be recorded at the recorder,  
16, of signal processor, 200, (and may cause records to be  
transferred to a remote location) and causes said onboard  
controller, 14A, to initiate a first signal record,  
associated with source mark information that identifies TV  
35

set, 202, that is based on the "program unit identification code" information of said particular television program in the meter-monitor information of said Tune-Radio-to-FM-104.1 SPAM message.

5           In the same fashion, receiving said second transmission of monitor information causes said onboard controller, 14A, to cause a signal record of prior programming of radio, 209, to be recorded at the recorder, 16, of signal processor, 200, (and may cause records to be  
10 transferred to a remote location) and causes said onboard controller, 14A, to initiate a second signal record, associated with source mark information that identifies radio, 209, that is based on said "program unit identification code" of said Tune-Radio-to-FM-104.1 SPAM  
15 message. However, to minimize unnecessary duplication, in a predetermined fashion, onboard controller, 14A, determines that TV set, 202/decoder, 203, is the principal source of information associated with said "program unit identification code"; retains information of said "program unit  
20 identification code" in said second signal record together with information that identifies said second record as a secondary record of said first signal record; and retains information at said first signal record that identifies  
25 radio, 209/decoder, 210, as a secondary source of monitor information associated with said "program unit identification code." In so doing, onboard controller, 14A, consolidates signal record information of two different monitor  
information transmissions that contain different source mark information but common "program unit identification code" information.

30           (If receiving said Tune-Radio-to-FM-104.1 SPAM message causes decryption at decoder, 203, as receiving the first message of example #4 caused decryption, receiving said Tune-Radio-to-FM-104.1 SPAM decoder, 203, causes, in the fashion  
35 of example #4, the decrypting of said message at decoder,

203, and thereafter, the processing of the unencrypted information of said message. Said processing includes processing at signal processor, 200, as in example #4, of meter and monitor information transferred from decoder, 203. 5 Said processing includes the transmitting of unencrypted information of said message from decoder, 203, to decoder, 210; the execution of the controlled functions invoked at decoder, 210, by receiving said message; the transmission of monitor information of said message, in the fashion of 10 example #3, from decoder, 210, to signal processor, 200. and the processing of said monitor information at signal processor, 200, in the fashion of example #3.)

(In the present invention, switching power on to a radio, 209, or changing a frequency at a radio, 209, causes 15 apparatus at said radio, 209, automatically to transmit an interrupt signal of new-frequency-input information and input said interrupt signal directly to the control processor, 44J, of the controller, 44, of the decoder, 210, associated with said radio, 209 [which signal said apparatus has means to 20 input directly].)

Switching power on to said radio, 209, and tuning radio, 209, to said frequency, 104.1 MHz, causes decoder, 210, to commence processing SPAM message information in the transmission of said frequency. In the fashion of TV set, 202, and decoder, 203, above, switching on and tuning radio, 25 209, causes said radio, 209, to input an interrupt signal of new-frequency-input information to the control processor, 44J, of the controller, 44, of radio decoder, 210, and to commence inputting the received transmission of said 30 frequency to said decoder, 210, (which decoder, 210, does not include the radio receiver circuitry, 41, of Fig. 2B because the transmission input decode, 210, is the transmission already received by the receiver circuitry of radio, 209, and which input is input directly to the radio decoder, 42, apparatus of said decoder, 210). 35

In the same fashion, receiving said interrupt signal of new-frequency-input information causes said controller, 44, to delete all previously received SPAM information, to commence processing detected SPAM information for an end of file signal, and to discard all detected SPAM information until and end of file signal is detected.

In due course, the program originating studio that originates the transmission of said frequency embeds an end of file signal in said transmission, causing said controller, 44, to detect said signal and commence identifying and processing the individual SPAM messages of said detected SPAM information.

Periodically thereafter, said program originating studio embeds in said transmission and transmits a particular Activate-Stereo-Output SPAM message that consists of a "01" header, an execution segment of particular activate-speakers information that is addressed to URS signal processors, 200, a meter-monitor segment that contains secondary "program unit identification code" information of the audio program unit of said radio transmission and primary "program unit identification code" information of said particular television program, and appropriate padding bits, an information segment that contains information of television channel 13 and radio frequency 104.1 MHz, and an end of file signal.

Said message is detected at said decoder, 210, and inputted to said controller, 44.

Receiving said message causes said controller, 44, to execute particular preprogrammed controlled function instructions that cause said controller, 44, to transfer said message to the controller, 20, of signal processor, 200. Automatically, said controller, 44, compares particular preprogrammed to-20 information to the information at its particular SPAM-control-information-matrix-switch-connection register memory. No match results which signifies that the

switches of matrix switch, 259, are configured to transfer the input to switch, 259, from said controller, 44, to apparatus different from said controller, 20. Not resulting in a match causes said controller, 44, to input a particular  
5 preprogrammed switch-210-to-20 instruction to the aforementioned control processor, 20A, via the aforementioned control information bus means for communicating switching request information.

Receiving said instruction causes control processor, 20A, to establish a control information transmission link  
10 between said controller, 44, and said controller, 20. Automatically, under control of particular preprogrammed instructions, control processor, 20A, causes matrix switch, 259, to configure its switches to transfer the input from said controller, 44, to the output of switch, 259, that  
15 inputs to said controller, 20--thereby establishing said transmission link--and transfers a particular to-20 instruction to said controller, 44.

Receiving said to-20 instruction causes said controller, 44, to transfer said Activate-Stereo-Output  
20 message to said controller, 20. Automatically, in a predetermined fashion, controller, 44, places particular to-20 information at said SPAM-control-information-matrix-switch-connection register memory then executes particular ones of said controlled function instructions.  
25 Automatically, under control of said ones, said controller, 44, causes its matrix switch, 44I, to commence transferring information to matrix switch, 259, and causes, in the fashion for transferring a "01" header message described above, transfers said Activate-Stereo-Output SPAM message, via said  
30 link, to said controller, 20.

Receiving said SPAM message causes said controller, 20, to determine that certain preconditions are satisfied--more precisely, that TV set, 202, and radio, 209, are tuned, respectively, to the proper television channel and the radio  
35

frequency of the stereo simulcast. Automatically, controller, 20, executes particular preprogrammed conditional-speaker-activation controlled function instructions; loads the information of television channel 13 and radio frequency 104.1 MHz of the information segment of said message at particular first and second register memory respectively; causes control processor, 20A, to cause matrix switch, 259, to establish a communications link between controller, 20, and the control processor, 39J, of decoder, 203; determines, in a predetermined fashion, that information of the channel to which TV set, 202, is tuned matches the television channel 13 information at said first register memory; causes control processor, 20A, to cause matrix switch, 259, to establish a communications link between controller, 20, and the control processor, 44J, of decoder, 210; and determines, in a predetermined fashion, that information of the frequency to which radio, 209, is tuned matches the radio frequency 104.1 MHz information at said second register memory. Determining a match with said television channel 13 information and a match with said radio frequency 104.1 MHz information satisfies said certain preconditions and causes controller, 20, to execute particular station-specific-stereo-simulcast instructions.

Station-specific-stereo-simulcast instructions reflect the particular fashion in which the subscriber of any given station wishes to have audio of stereo simulcasts outputted at his station, and preprogrammed station-specific-stereo-simulcast instructions vary from subscriber station to subscriber station.

Executing the particular station-specific-stereo-simulcast instructions of the station of Figs. 7 and 7C causes the controller, 20, of said station to cause stereo speaker system, 263 to emit the audio sound of said transmission in a particular fashion and causes apparatus of TV set, 202, and of radio, 209, to cease emitting sound.

Automatically, controller, 20, transmits switch control information to matrix switch, 258, that causes said switch, 258, to configure its switches in such a way that the programming input to switch, 258, from radio, 209, (which  
5 inputs the audio information received at radio, 209) is switched to transfer information to the output of switch, 258, that inputs to speaker system, 263; causes control processor, 20A, to cause matrix switch, 259, to establish a communications link between controller, 20, and speaker  
10 system, 263; and causes speaker system, 263, to switch power on and commence operating, in a fashion well known in the art, at a particular so-called "balance" and a particular sound emitting volume. In so doing, controller, 20, causes speaker system, 263, to commence receiving and emitting sound  
15 of the audio information of the stereo simulcast radio transmission received at radio, 209, in a particular fashion. Then automatically, under control of said station-specific-stereo-simulcast instructions, controller, 20, causes control processor, 20A, to cause matrix switch, 259, to establish a  
20 communications link between controller, 20, and the control processor, 39J, of decoder, 203; causes TV set, 202, in a predetermined fashion, to cease emitting sound of received audio; causes control processor, 20A, to cause matrix switch, 259, to establish a communications link between controller,  
25 20, and the control processor, 44J, of decoder, 210; and causes radio, 209, in a predetermined fashion, to cease emitting sound of received audio. In so doing, controller, 20, causes speaker system, 263, to be the only apparatus of the station of Fig. 7 emitting sound of said stereo  
30 simulcast.

(At other stations where said Activate-Stereo-Output SPAM message is received, said certain preconditions may not be satisfied--at one given station, for example, the radio, 209, of may be tuned to radio frequency 104.1 MHz but the TV set, 202, may be tuned to a channel other than television  
35

channel 13 which would signify that the subscriber of said station was not viewing a simulcast. Said stations would not execute station-specific-stereo-simulcast instructions. Instead, other instructions would be executed, and said  
5 instructions might, for example, merely discard all information of said Activate-Stereo-Output SPAM message. And at stations where station-specific-stereo-simulcast instructions are executed, the executed instructions, which are station specific and vary from station to station, will  
10 cause different functioning at different stations. For example, balance and sound emitting volume can vary from station to station, and at some stations, radios, 209, and/or TV sets, 202, may continue emitting sound of received audio.)

Thus, by switching power on to TV set, 202, and  
15 selecting channel 13 at television tuner, 215, said subscriber not only actuates automatically the radio simulcast of said channel at radio, 209, but also causes the apparatus of his station automatically to emit the sound of the received audio in his own predetermined fashion.

And automatically, monitor information is collected at  
20 signal processor, 200, that reflects the operation of speaker system, 263.

Because the information of said Activate-Stereo-Output SPAM message is transmitted periodically in said radio programming transmission, a subsequent instance of said  
25 information is received at speaker system, 263, embedded in the audio information received (via switch, 258) from radio, 209. Receiving said subsequent instance causes the SPAM decoder apparatus associated (in the fashion of the decoder, 285, if Fig. 5) with said speaker system, 263, to detect the  
30 Activate-Stereo-Output SPAM message information of said instance and to transfer to the onboard controller, 14A, of signal processor, 200, via the aforementioned bus means for communicating monitor information, a particular third  
35 transmission of monitor information containing the execution

and meter-monitor information of said instance, with appropriate source mark information identifying speaker system, 263.

In the fashion described above, receiving said third  
5 transmission of monitor information causes said onboard controller, 14A, to cause a signal record of prior programming of speaker system, 263, to be recorded at the recorder, 16, of signal processor, 200, (and may cause records to be transferred to a remote location) and causes  
10 said onboard controller, 14A, to initiate a third signal record, associated with source mark information that identifies speaker system, 263, that is based on the aforementioned secondary "program unit identification code" information of the audio program unit of said radio  
15 transmission. However, to minimize unnecessary duplication, in a predetermined fashion, onboard controller, 14A, determines that radio, 209/decoder, 210, is the principal source of information associated with said secondary "program unit identification code"; retains information of said  
20 secondary "code" in said third signal record together with information that identifies said third record as a subordinate record of the aforementioned second signal record; and retains information at the aforementioned first signal record that identifies speaker system, 263, as a  
25 tertiary source of monitor information associated with the "program unit identification code" information of said particular television program. In so doing, onboard controller, 14A, consolidates signal record information of three different monitor information transmissions that  
30 contain different source mark information but common "program unit identification code" information.

AUTOMATING U. R. STATIONS ... RECEIVING SELECTED PROGRAMMING

Fig. 7C illustrates methods for monitoring multiple  
35 programming channels, selecting programming and information

of interest, and receiving said selected programming and information.

The microprocessor, 205, of the station of Fig. 7 and 7C, is preprogrammed to hold records of a portfolio of stocks 5 and to receive and process automatically news items about said stocks and about the industries of said stocks. The signal processor, 200, of said station is preprogrammed at the RAM associated with the control processor, 39J, of the controller, 39, of its decoder, 30, with particular news- 10 items-of-interest information that includes identification information of the particular stocks in said portfolio and at its controller, 20, with particular cause-selection instructions that control said controller, 20, in selecting transmissions of news items of interest.

One company whose stock is preprogrammed at said 15 microprocessor, 205, is the American Telephone and Telegraph Company whose stock is identified by particular binary information of "T". And among the news-items-of-interest information at said RAM is an instance of said binary 20 information of "T".

Two remote stations--remote news-service-A station and remote news-service-B station--transmit, from geographically separate locations, two different broadcast print transmissions.

The intermediate transmission station of Fig. 6 25 receives and retransmits information the transmissions of said remote stations on digital data channels A and B, respectively, that are inputted to converter boxes, 222 and 201, and to signal processor, 200. (Other intermediate 30 stations receive and retransmit information of said transmission on other channels.)

Each remote station transmits each particular news item within the particular format of a Transmit-News-Item SPAM message, and receiving any given message in a Transmit- 35 News-Item SPAM message format causes the computer, 73, of any

given intermediate transmission station to transmit a particular Select-News-Item message a particular preprogrammed number of times in a particular Select-Digital-News-Item message format then to transmit the information of  
5 said news items within a message that is transmitted particular Specific-Digital-News-Item message format.

In due course, said remote news-service-A station transmits a particular AT&T news item in a particular Transmit-AT&T-News-Item message that is in said Transmit-News-Item SPAM message format and that consists of an "01" header, an execution segment of particular transmit-news-message information that is addressed to ITS computers, 73, a meter-monitor segment that contains the "program unit identification code" information of said AT&T news item and  
10 subject matter information of said binary information of "T", appropriate padding bits, an information segment that contains said AT&T news item, and an end of file signal.  
15

Receiving said Transmit-AT&T-News-Item message causes the computer, 73, of the station of Fig. 6 to transmit a particular preprogrammed number of times on digital data  
20 channel A a particular Select-AT&T-News-Item message then to transmit a particular Specific-AT&T-News-Item message. (Receiving said Transmit-AT&T-News-Item message causes a computer, 73, at each one of said other intermediate  
25 transmission stations to cause the transmission of similar messages on a selected channel a each of said stations.) Said Select-AT&T-News-Item message is in said Select-Digital-News-Item message format and consists of an "01" header; an execution segment of particular select-news-item information that is addressed to URS signal processor, 200; a meter-  
30 monitor segment that consists of the meter-monitor information of said Transmit-News-Item SPAM message plus information that identifies said intermediate station (the format information of said meter-monitor information being  
35 modified to reflect the addition of said information that

identifies said station); appropriate padding bits; an information segment that contains the binary information of "T" information of said subject matter information; and an end of file signal. The particular number of times that any  
5 given intermediate station transmits said message is the number of times necessary to permit apparatus of a signal processor, 200, at each subscriber station of said intermediate station, functioning in the fashion of example #5, to detect and process at least one instance of said  
10 Select-AT&T-News-Item message and to permit apparatus each station then to tune to the transmission of a selected digital data channel and receive, in the fashion described below, said Specific-AT&T-News-Item message. And said Specific-AT&T-News-Item message is in said Specific-  
15 Digital-News-Item message format consists of an "01" header; an execution segment of particular process-news-item information that is addressed to URS microcomputers, 73; a meter-monitor segment that is identical to the meter-monitor segment of said Select-AT&T-News-Item message; appropriate  
20 padding bits; an information segment that contains the information of said AT&T news item; and an end of file signal.

At the station of Fig. 7 and 7C, signal processor, 200, scans sequentially all channels at its switch, 1, mixer, 3, and decoder, 30, in the fashion of example #5.  
25

In due course, one instance of said Select-AT&T-News-Item message is detected at said decoder, 30, and inputted to the controller, 39, of said decoder, 30.

Receiving said Select-AT&T-News-Item message causes said controller, 39, to transmit said message to the  
30 controller, 20, of said signal processor, 200. Automatically, controller, 39, executes particular preprogrammed controlled function instructions that cause said controller, 39, to load the binary information of "T" information of the information segment of said message at  
35

particular working register memory and determine that the information at said memory matches the aforementioned binary information of "T" that is among the news-items-of-interest information at the RAM associated with control processor,  
5 39J. Determining a match causes said controller, 39, to transmit said message, with channel mark information that identifies the particular channel in which said message was embedded, to said controller, 20, via control information transmission means and to continue functioning in the fashion  
10 of example #5.

Receiving said message causes said controller, 20, to cause a selected cable converter box, 222, to receive the transmission identified by said channel mark; to cause All signal decoder, 290, (which is identical to the TV signal decoder of Fig. 2A with the added capacity of the radio  
15 signal decoder of Fig. 2B to receive, detect, and input SPAM information embedded in radio frequency transmissions to a controller, 39, plus the added capacity of the other signal decoder of Fig. 2C to receive, detect, and input SPAM  
20 information embedded in other frequency transmissions to said controller, 39) at microcomputer, 205, to receive the transmission of a particular television frequency transmission and to commence processing detected SPAM information for an end of file signal; and to establish a  
25 programming transmission link between said selected box, 222, and All signal decoder, 290, at microcomputer, 205.

Automatically, controller, 20, executes the instructions of a particular preprogrammed controlled function (that is different from the function invoked by said message at said controller, 39). Automatically, controller, 20, establishes  
30 a control information transmission link between controller, 20, and the tuner, 223, of said selected box, 222, by inputting a particular instruction to control processor, 20A, that causes control processor, 20A, to cause matrix switch, 259, to configure its switches in such a way that its input  
35

from controller, 20, is switched to its output that inputs to said tuner, 223. Then receiving a particular to-223 instruction from said control processor, 20A, causes controller, 20, to transmits particular instructions, via  
5 said control information transmission link, to said tuner, 223, thereby causing said tuner, 223, to tune its associated cable converter box, 222, the to the particular channel transmission of said multi-channel cable transmission that is identified by said channel mark. Automatically, controller,  
10 20, establishes a control information transmission link between controller, 20, and said decoder, 290, by inputting a particular instruction to control processor, 20A, that causes control processor, 20A, to cause matrix switch, 259, to configure its switches to transfer information from its input  
15 from controller, 20, to its output that inputs to said decoder, 290. Then receiving a particular to-290 instruction from said control processor, 20A, causes controller, 20, to input an interrupt signal of new-channel-input information, in a predetermined fashion, to the control processor, 39J, of  
20 the controller, 39, of said decoder, 290. Receiving said interrupt signal causes said control processor, 39J, to delete all previously received SPAM information; to cause its associated matrix switch, 39I, to commence transferring information from the EOFS valve, 39F, to its null output; and  
25 to cause said EOFS valve, 39F, to commence processing detected SPAM information for an end of file signal. Then automatically, controller, 20, inputs switch control instructions to matrix switch, 258, thereby causing matrix switch, 258, to configure its switches in such a way that the  
30 input to switch, 258, from cable converter box, 222, is switched to transfer information to the output of switch, 258, that inputs to said decoder, 290. In so doing, controller, 20, causes said decoder, 290, to commence receiving the programming transmission of digital data  
35 channel A and causes said decoder, 290, to commence detecting

and processing SPAM message information embedded in said transmission.

In due course, a subsequent instance of said Select-AT&T-News-Item message is transmitted on said channel A, causing the EOF5 valve, 39F, of said decoder, 290, to detect the end of file signal of said message and causing the controller, 39, of said decoder, 290, to commence identifying and processing the individual SPAM messages detected in the transmission of said channel A. (Said decoder, 290, is not preprogrammed with any controlled-function-invoking information that matches the execution segment information of a said Select-AT&T-News-Item message, so receiving any given instance of said message causes decoder, 290, merely to discard said message.)

In due course, said Specific-AT&T-News-Item message is transmitted on said channel A.

Transmitting said message causes decoder, 290, to detect and input said message to the controller, 39, of said decoder, 290.

Receiving said message causes said controller, 39, to cause microcomputer, 205, to process information of said message. Automatically, controller, 39, executes the instructions of a particular preprogrammed controlled function and inputs to an input buffer of microcomputer, 205, a particular input-from-290 computer job that consists of process-this-data-input-from-290 instructions and particular data. Said data includes the meter-monitor information of said message and the information of the information segment of said message--that is, said AT&T news item.

In due course and in a predetermined fashion, microcomputer, 205, processes said job; determines that the preprogrammed instructions entered by the subscriber of the station of Fig. 7 and 7C are to print at printer, 221, data of any job of process-this-data-input-from-290 instructions; and causes said AT&T news item to be printed at said printer,

221. Automatically, microcomputer, 205, executes particular preprogrammed instructions and inputs a particular switch-205-to-221 instruction to the controller, 20, of signal processor, 200. Receiving said instruction causes said controller, 20, to input particular switch control instructions to matrix switch, 258, thereby causing matrix switch, 258, to configure its switches in such a way that the input to switch, 258, from microcomputer, 205, is switched to transfer information to the output of switch, 258, that inputs to said printer, 221. Then automatically, microcomputer, 205, transfers said data to said printer, 221. In so doing, microcomputer, 205, causes printer, 221, in a predetermined fashion, to print said AT&T news item. (Said preprogrammed instructions entered by the subscriber might cause said microcomputer, for example, then to establish a programming communication link with computer memory unit, 256, and to cause said unit, 256, to record said AT&T news item.)

Receiving the aforementioned instance of said Select-AT&T-News-Item message and said Specific-AT&T-News-Item message at the station of Fig. 7 also causes processing of monitor information at said signal processor, 200, in the fashions described above. After transferring the information of said Select-AT&T-News-Item message to said controller, 20, said controller, 39, automatically transfers monitor information of said message to buffer/comparator, 14, thereby causing the onboard controller, 14A, to process information of the availability at said station of said AT&T news item. After executing the controlled functions invoked by said Specific-AT&T-News-Item message, said controller, 20, automatically transfers monitor information of said message to buffer/comparator, 14, thereby causing the onboard controller, 14A, to process information of the use of said AT&T news item at microcomputer, 205. And receiving said data at printer, 221, causes other decoder, 227 (see Fig. 5),

in a predetermined fashion, to detect in said data the meter-  
monitor information of said Specific-AT&T-News-Item message  
and to transmit said meter-monitor information to signal  
processor, 200, thereby causing said onboard controller, 14A,  
5 to retain monitor information and initiate a secondary signal  
record in the fashion described above.

AUTOMATING U. R. STATIONS ... MORE ON EXAMPLE #7 ...  
RECEIVING SELECTED PROGRAMMING AND COMBINING  
10 SELECTED URS MICROCOMPUTERS, 205, AUTOMATICALLY  
TO THE COMPUTER SYSTEM OF A SELECTED  
PROGRAMMING TRANSMISSION

In the present invention, the computer information of  
any given combined medium combining is processed by a  
15 computer system that consists of a plurality of computers  
each of which is at a subscriber station and all of which  
process, in parallel, and output their specific information  
under control of one transmission of embedded computer  
programming inputted to said system at a program originating  
20 studio. The Fig. 1C combining of the "Wall Street Week"  
example provides one example of such a combining. The  
computer system of said example consists of a plurality of  
microcomputers, 205, each of which is at a different  
subscriber station, and the program originating studio that  
25 originates transmission of the "Wall Street Week" programming  
embeds and transmits a series of SPAM messages that control  
all of said microcomputers, 205. Under control of the first  
message, each one of said plurality of microcomputers, 205,  
generates its own specific Fig. 1A information. Then, under  
30 control of the second message, each of said microcomputers,  
205, combines its specific Fig. 1A information with  
transmitted Fig. 1B information, and all of said  
microcomputers, 205, display their specific Fig. 1C images  
(which differ from station to station).

35 The present invention includes capacity whereby SPAM

message information transmitted by any given program originating studio can cause a plurality of selected computers to select programming in the fashion described above, and in so doing, to combine to an come under control  
5 of the computer system of said studio.

For example, all URS microcomputers, 205, of a large plurality of subscriber stations (of which the station of Figs. 7 and 7C is one station) are preprogrammed with particular program-unit-of-interest information and with  
10 particular station-specific-television-program-selection-and-display instructions. Said program-unit-of-interest information includes information of particular television programs that the subscribers of the stations of said microcomputers, 205, wish to view when said programs are  
15 transmitted. Some among said television programs are combined medium television programs. Said station-specific-television-program-selection-and-display instructions reflect the specific fashion in which any selected one of said programs is to be selected and displayed when said program is  
20 transmitted.

The program-unit-of-interest information preprogrammed at the microcomputer, 205, of the station of Figs. 7 and 7C includes particular specific-WSW information that reflects the wish of the subscriber of said station to view (or  
25 record) said "Wall Street Week" program when said program is transmitted. In a predetermined fashion, said subscriber has caused to be included in said program-unit-of-interest information. (Microcomputers, 205, of selected other stations of said large plurality of stations are also so  
30 preprogrammed.) The station-specific-television-program-selection-and-display instructions at the microcomputer, 205, of the station of Figs. 7 and 7C includes particular information that said subscriber will pay up to a certain limit--for example, twenty-five cents--to be permitted to  
35 receive said program and that, if the TV set, 202, of said

station is switched off when information of the transmission of said program is detected, power should be switched on to said TV set, 202, and said program should be displayed at the monitor, 202M, of said set and, in addition, power should be  
5 switched on to the video recorder/player, 217, of said station, and said program should be recorded at said recorder/player, 217.

The signal processor, 200, of said station scans sequentially all received television transmission channels in  
10 the fashion described above and is preprogrammed at the RAM associated with the control processor, 39J, of its decoder, 30, to respond in a particular controlled function fashion whenever a SPAM message with an execution segment of  
15 particular available-television-program information is detected. Said signal processor, 200, has capacity for actuating and tuning TV set, 202, and video recorder, 217, and for controlling microcomputer, 205.

(The microcomputers, 205, of selected other stations of said large plurality of stations are also preprogrammed  
20 with select-WSW information and with station-specific-television-program-selection-and-display instructions [which instructions differ from station to station], and the signal processors, 200, of said stations are preprogrammed function in the same fashion as the signal processor, 200, of the  
25 station of Figs. 7 and 7C.)

The program originating studio that originates the "Wall Street Week" program originates, embeds, and transmits the programming in the encrypted fashion of example #7 above, and the intermediate transmission station of Fig. 6 receives and retransmits said programming, in the fashion of example  
30 #7, on cable channel 13 which is inputted, at the station of Figs. 7 and 7C, to converter boxes, 222 and 201, and to signal processor, 200. (Other intermediate stations receive and retransmit information of said transmission on other  
35 channels, and the aforementioned specific-WSW information

[that is included in program-unit-of-interest information] is specified above, in example #7, at page 289, line 35.)

Before transmitting any given program unit of television programming, any given program originating studio transmits a particular intermediate-station-control message  
5 in the particular format of a Prepare-To-Retransmit-Television-Program-Unit SPAM message, and receiving any given SPAM message in said format causes the computer, 73, of any given intermediate transmission station to generate a particular series of messages and retain complete information  
10 of said messages at particular memory locations, to prepare particular apparatus of said station to retransmit the programming of said program unit, and to transmit said retained messages in a particular fashions at particular times.

15 The cable program controller & computer, 73, of each intermediate station is preprogrammed with schedule information that reflects the particular time at which and the channel on which said station will retransmit said "Wall Street Week" program. The particular channel information of  
20 the computer, 73, of the station Fig. 6 is CC13 and the particular time information is particular-8:30, reflecting that said station is schedule to retransmit said program on cable channel 13 at a particular 8:30 PM time (which is the time at which the program originating studio that originates  
25 the "Wall Street Week" program transmits the so-called "live" programming of said program. (A particular other computer, 73, is preprogrammed with particular channel information of CC11 and particular time information of particular-9:30, reflecting that the station of said other computer, 73, is  
30 schedule to retransmit said program, so-called "time delayed," on cable channel 11 at a particular 9:30 PM time.)

In due course, the program originating studio that originates the transmission of said "Wall Street Week" program transmits a particular Prepare-To-Retransmit-WSW

35

message (which is the particular intermediate-station-control message of said "Wall Street Week" program) in said Prepare-To-Retransmit-Television-Program-Unit format, and said message consists of an "01" header; an execution segment of particular load-and-execute information that is addressed to ITS computers, 73; a meter-monitor segment that contains the "program unit identification code" information of said "Wall Street Week" program; appropriate padding bits; an information segment of particular incorporate-and-retain-Select-WSW-Program-Unit-SPAM-message instructions that include particular generally applicable please-fully-enable-WSW-on-XXXX-at-YYYYYYYYYYYYYYYY information and specific-WSW information, particular incorporate-and-retain-Specific-WSW-Enabling-message instructions that include the aforementioned particular enable-WSW instructions, particular timing instructions that include particular-8:30-PM information, and particular interconnect-and-encrypt-the-audio-of-WSW instructions; and an end of file signal.

Receiving said Prepare-To-Retransmit-WSW message causes apparatus of the station of Fig. 6 to input the information of the information segment of said message to the computer, 73, of said station and to execute the information so inputted as a machine language job. (Receiving said message causes apparatus at other stations to function similarly.)

Executing said incorporate-and-retain-Select-WSW-Program-Unit-SPAM-message instructions causes said computer, 73, to generate particular please-fully-enable-WSW-on-CC13-at-particular-8:30 information and a particular Select-WSW-Program-Unit SPAM message and to retain said message at particular Select-Program-Unit-Message-to-Transmit memory. Automatically, said computer, 73, generates said please-fully-enable-WSW-on-CC13-at-particular-8:30 information by replacing the information of particular variables, XXXX and YYYYYYYYYYYYYYYY, in said generally applicable please-fully-

enable-WSW-on-XXXX-at-YYYYYYYYYYYYYYY information with said  
CC13 and said particular-8:30 information that are  
preprogrammed at said computer, 73, and that reflect that the  
schedule of the intermediate station of said computer, 73.  
5 Said Select-WSW-Program-Unit message consists of an "01"  
header; an execution segment of information that is identical  
to the aforementioned available-television-program  
information; a meter-monitor segment that consists of the  
meter-monitor information of said Prepare-To-Retransmit-WSW  
10 message plus information that identifies said intermediate  
station (the format information of said meter-monitor  
information being modified to reflect the addition of said  
information that identifies said station); appropriate  
padding bits; an information segment of generally applicable  
15 determine-whether-to-select instructions of said Transmit-  
Select-WSW message that contain said particular specific-WSW  
information and said please-fully-enable-WSW-on-CC13-at-  
particular-8:30 information; and an end of file signal.

(The modified meter-monitor format information in said  
20 message is preprogrammed in said incorporate-and-retain-  
Select-WSW-Program-Unit-SPAM-message instructions and is  
caused, by said instructions, to replace the meter-monitor  
format information of said Prepare-To-Retransmit-WSW message  
message to reflect the addition of the aforementioned  
25 information that identifies the station of Fig. 6. In other  
words, a station specific identification datum is added at  
each station to the meter-monitor information of said  
Prepare-To-Retransmit-WSW message. The station specific  
identification data vary from station to station. However,  
30 all station specific identification data are in the same  
format and are added to said meter-monitor information in the  
same fashion. Hence, all instances of Select-WSW-Program-  
Unit message meter-monitor information are in the same  
format.)

35 (Executing said incorporate-and-retain-Select-WSW-

Program-Unit-SPAM-message instructions causes said other computer, 73, that is preprogrammed with particular CC11 and particular-9:30 information to generate particular please-fully-enable-WSW-on-CC11-at-particular-9:30 information that  
5 reflects the schedule of the station of said other computer, 73, and to incorporate said information into the information segment of the station specific Select-WSW-Program-Unit SPAM message of said station.)

Executing said incorporate-and-retain-Specific-WSW-Enabling-message instructions causes the computer, 73, of the  
10 station of Fig. 6 to generate a Specific-WSW-Enabling-message, which is the aforementioned local-cable-enabling-message (#7) (see the paragraph that begins above at page 291, line 9), and to retain said message at particular  
15 Specific-WSW-Enabling-Message-to-Transmit memory. (see the paragraph that begins above at page 291, line 9.) All information of said message is preprogrammed at said computer, 73, prior to the executing of said instructions (including the aforementioned enable-WSW instructions and  
20 enable-WSW-programming information that are preprogrammed in said incorporate-and-retain-Specific-WSW-Enabling-message instructions), and said incorporate-and-retain-Specific-WSW-Enabling-message instructions cause said computer, 73, to select the specific preprogrammed information of said message  
25 from among all the preprogrammed information of said computer, 73, and to assemble said selected information at said memory. When assembled, said message consists of an "01" header; an execution segment of particular preprogrammed enable-next-program-on-CC13 information that is addressed to  
30 URS signal processors, 200; a meter-monitor segment whose information is identical to the meter-monitor information of said Select-WSW-Program-Unit SPAM message; appropriate padding bits; an information segment that contains particular enable-CC13 instructions and said enable-WSW instructions  
35 which include said enable-WSW-programming information; and an

end of file signal.

Executing said timing instructions, causes each intermediate station to commence transmitting its station specific Select-WSW-Program-Unit SPAM message at a station  
5 specific time; to transmit said message over and over for a station specific interval of time; to execute said interconnect-and-encrypt-the-audio-of-WSW instructions at a particular time; and to transmit its station specific Specific-WSW-Enabling-message after a particular enabling  
10 time. The particular time at which any given station commences transmitting its station specific Select-WSW-Program-Unit SPAM message is before the minimum time prior to the commence enabling time of said station necessary for each subscriber station of said intermediate station, functioning  
15 in the fashion of example #5, to detect and process at least one instance of said Select-WSW-Program-Unit message and then to tune to the transmission of a selected master cable control channel and receive, in the fashion described below, the station specific Specific-WSW-Enabling-message of its  
20 intermediate transmission station. The particular number of times that any given intermediate station transmits its station specific Select-WSW-Program-Unit SPAM message is the number of times necessary to permit apparatus of a signal processor, 200, at each subscriber station of said  
25 intermediate station to detect and process at least one instance of said Select-WSW-Program-Unit message.

In due course, executing said timing instructions causes the computer, 73, of the station of Fig. 6 to commence transmitting the SPAM message at its particular  
30 Select-Program-Unit-Message-to-Transmit memory, which is its station specific Select-WSW-Program-Unit SPAM message, embedded in the normal transmission location of cable channel 13.

Subsequently, executing said timing instructions causes said computer, 73, to execute said interconnect-and-  
35

encrypt-the-audio-of-WSW instructions.

Executing said last named instructions causes said computer, 73, to cause apparatus of said station to receive the transmission of the program originating studio of the "Wall Street Week" program; to input said transmission, via the matrix switch, 75, of said station, to particular apparatus, well known in the art, that encrypt the audio portion of said transmission and output the video and encrypted audio portions of said transmission in proper synchronization; to cause said apparatus to encrypt the information of said audio portion using a particular preprogrammed cipher algorithm C and cipher key Ca; and to transfer the output of said apparatus, via matrix switch, 75, to field distribution system, 93, via the particular modulator, 82, 86, or 90, of cable channel 13.

In due course, while scanning sequentially all channels in the fashion of example #5, the apparatus of the signal processor, 200, of the station of Fig. 7 and 7C detects one instance of the Select-WSW-Program-Unit SPAM message of the station of Fig. 6 and inputs said message to the controller, 39, of the decoder, 30, of said signal processor, 200.

Receiving said Select-WSW-Program-Unit message causes the apparatus of said signal processor, 200, to input said message to the microcomputer, 205, of said station. Automatically, said controller, 39, determines that the execution segment of said message matches its preprogrammed available-television-program controlled-function-invoking information; executes the associated controlled function instructions; inputs said message to the buffer/comparator, 8, of said signal processor, 200; and to inputs particular step-completed information to said controller, 20.

(Receiving said information causes controller, 20, to cause the relevant apparatus of said signal processor, 200, to commence functioning to identify program unit identification

signal information in the fashion described in example #5.) Receiving said message causes buffer/comparator, 8, to input said message to controller, 12. Receiving said message causes controller, 12, to execute particular preprogrammed  
5 controlled function instructions; to establish a control information communications link , via matrix switch, 259, to the buffer, 39G, of the controller, 39, of said decoder, 203; to transfer said message, via said link, to said buffer, 39G.

Receiving said Select-WSW-Program-Unit message causes  
10 decoder, 203, to execute the information of the information segment of said message as a machine language job. Automatically, control processor, 39J, executes particular preprogrammed available-television-program controlled function instructions that cause said control processor, 39J,  
15 to input the information of the information segment of said message to the CPU of microcomputer, 205, and to cause said CPU to execute the information so inputted as a machine language job. The information so inputted is the aforementioned determine-whether-to-select instructions that  
20 contain said particular specific-WSW information and said please-fully-enable-WSW-on-CC13-at-particular-8:30 information.

Executing said determine-whether-to-select instructions causes microcomputer, 205, to input said please-  
25 fully-enable-WSW-on-CC13-at-particular-8:30 information to the controller, 20, of signal processor, 200. Said instructions contain one instance, and the the aforementioned program-unit-of-interest information that is preprogrammed at said microcomputer, 205, contains a second instance of  
30 specific-WSW information, which second instance reflects the wish of the subscriber of said station to view (or record) said "Wall Street Week" program when said program is transmitted. Automatically, microcomputer, 205, compares said one instance to said program-unit-of-interest  
35 information and determines a match with said second instance.

Determining a match causes microcomputer, 205, automatically to input said please-fully-enable-WSW-on-CC13-at-particular-8:30 information to the controller, 20.

5 Receiving said please-fully-enable-WSW-on-CC13-at-particular-8:30 information causes controller, 20, in a predetermined fashion, to prepare particular apparatus of signal processor, 200, to receive said local-cable-enabling-message (#7) (which is the station specific Specific-WSW-Enabling-message of the station of Fig. 6). Controller, 20,  
10 is preprogrammed with particular receive-authorizing-info-at-appointed-time instructions, information of a particular standard-local-station-interval quantity of time, particular enable-next-program-on-CC13 information, and information of a particular master cable control channel. Receiving said  
15 please-fully-enable-WSW-on-CC13-at-particular-8:30 information causes controller, 20, to execute said receive-authorizing-info-at-appointed-time instructions. Automatically, controller, 20, selects said CC13 and said particular-8:30 information from the information of said  
20 please-fully-enable-WSW-on-CC13-at-particular-8:30 information and computes the aforementioned commence-enabling time (see example #7) by subtracting said standard-local-station-interval quantity of time from the schedule time information of said particular-8:30 information. At said  
25 commence-enabling time, receiving time information from clock, 18, causes controller, 20, automatically to cause all apparatus of decoder, 30, to delete from memory all information of received SPAM information; to cause the controller, 39J, of said decoder, 30, to place one instance  
30 of said enable-next-program-on-CC13 information at a particular controlled-function-invoking information location; to cause apparatus of signal processor, 200, to input the transmission of said cable control channel to decoder, 30; and to cause the EOFs valve, 39F, of said decoder, 30, to  
35 commence processing detected SPAM information to detect an

end of file signal. In so doing, controller, 20, causes decoder, 30, to commence receiving the transmission of said master cable control channel and processing SPAM information in said transmission. In addition, controller, 20,  
5 automatically places one instance of said enable-next-program-on-CC13 information at a particular controlled-function-invoking-@20 information location at controller, 20.

In due course, executing said timing instructions causes the computer, 73, of the station of Fig. 6 to transmit  
10 a particular message that ends with an end of file signal.

Receiving said message causes said EOFS valve, 39F, to detect the end of file signal in said message, thereby causing the apparatus of decoder, 30, to commence identifying and processing the individual SPAM messages embedded in said  
15 transmission.

Then executing said timing instructions causes said computer, 73, to transmit said local-cable-enabling-message (#7).

(At each other intermediate transmission station that  
20 receives and executes the information of said Prepare-To-Retransmit-WSW message, executing said information causes said station to transmit its own station specific Specific-WSW-Enabling-message on its own station specific master cable control channel, thereby enabling its subscriber stations  
25 that receive and execute the information of said message to receive the "Wall Street Week" retransmission of said intermediate transmission station in a fashion that differs from intermediate station to intermediate station. For example, whereas the intermediate station of Fig. 6 encrypts  
30 the audio of said transmission using cipher key Ca, another intermediate transmission station can use a different cipher key--for example, Ta--and cause its selected subscriber stations to decrypt said audio properly by means of the information of its own station specific Specific-WSW-Enabling-message.)  
35

Receiving said local-cable-enabling-message (#7) at the station of Fig. 7 causes the apparatus of said station to function in precisely the fashion of example #7. Receiving said message causes the decoder, 30, of signal processor, 200, to detect and transfer said message to the controller, 20. Receiving said message causes said controller, 20, to execute said enable-CC13 instructions; to sample selected SPAM information of the station of Fig. 7 and determine that unauthorized tampering has not occurred; to cause selected apparatus of said station--cable converter box, 201, matrix switch, 258, and a decryptor, 107 (that exists at said station, that receives its input from and transfers its output to matrix switch, 258, and is controlled by controller, 20, but that is not shown in Fig 7)--to receive the transmission of cable channel 13; to cause said selected decryptor, 107, to decrypt the audio portion of said transmission using selected cipher algorithm and key information; to cause selected apparatus of signal processor, 200, to commence waiting to receive further enabling information; to execute said enable-WSW instructions; and to place instances of said enable-WSW-programming information at particular controlled-function-invoking information memory locations at the controller, 39, of decoder, 30, and at controller, 20. And completing said enable-WSW instructions causes controller, 20, to initiate a meter record at buffer/comparator, 14, that documents the decryption of the cable audio transmission at said station.

(Simultaneously, other subscriber stations [i.e., ultimate receiver stations] of the field distribution system, 93, of the intermediate transmission station of Fig. 6 sample selected SPAM information in their subscriber station specific fashions and determine whether unauthorized tampering has occurred and decrypt the audio portion of said transmission or respond in the fashions described above in example #7 if they determine that unauthorized tampering has

occurred. Meanwhile, at the field distribution systems, 93, of other intermediate transmission stations, other subscriber stations each receive the station specific Select-WSW-Program-Unit SPAM messages of their specific intermediate station, tune to an intermediate station specific transmission channel [eg. cable channel 11 rather than 13] in an intermediate station specific fashion [eg. by decrypting with cipher key Ta rather than Ca] and even at an intermediate station specific time [eg. at 9:30 PM rather than 8:30 PM] to receive said "Wall Street Week" program, sample selected subscriber station specific SPAM information in their subscriber station specific fashions, determine whether unauthorized tampering has occurred, and respond station specifically in the fashions described above.)

Subsequently, but still in the interval between said commence-enabling time and said 8:30 PM time, said program originating studio that originates the "Wall Street Week" transmission embeds and transmits the 1st-WSW-program-enabling-message (#7) SPAM message.

Transmitting said message causes said message to be detected at the signal processor, 200, of the station of Fig. 7 and inputted to the controller, 20, and causes controller, 20, to load and execute the 1st-stage-enable-WSW-program instructions in said message.

Executing said 1st-stage-enable-WSW-program instructions causes controller, 20, in the predetermined fashion of said instructions (which fashion that is not described in example #7 above), to cause microcomputer, 205, to authorize reception of said "Wall Street Week" program so-called "pay-per-view" basis. Automatically, under control of said instructions, controller, 20, inputs to microcomputer, 205, a particular check-station-specific-selection-and-display instruction and particular reception-of-WSW-costs-20-cents information (which instruction and information is preprogrammed in said 1st-stage-enable-WSW-program

instructions). Receiving said instruction and said information causes microcomputer, 205, to execute particular preprogrammed instructions and, in a predetermined fashion, to determine that the aforementioned station-specific-  
5 television-program-selection-and-display instructions at said microcomputer, 205, include particular information that the subscriber of said station is willing pay up to a certain limit--twenty-five cents--to receive said program. So determining, under control of said instructions, causes  
10 microcomputer, 205, to input a particular preprogrammed pay-per-view-authorizing instruction to said controller, 20.

Receiving said instruction causes controller, 20, under control of said 1st-stage-enable-WSW-program instructions, to perform a first stage of decrypting the  
15 video information of the "Wall Street Week" program transmission in precisely the fashion described in example #7.

(Executing the information of said 1st-WSW-program-enabling-message (#7) message causes the microcomputers, 205,  
20 of selected other stations that receive said message also to authorize so-called "pay-per-view" reception of said "Wall Street Week" program. At said stations that authorize reception, apparatus receive and process subsequent information of the "Wall Street Week" transmission just as at  
25 the station of Fig. 7. However, at certain other stations that receive and process said message the preprogrammed station-specific-television-program-selection-and-display instructions at the microcomputers, 205, do not include information that the subscribers of said last named stations  
30 are willing pay to receive said program. Executing the information of said message at said last named stations causes the microcomputers, 205, of said stations to identify and execute particular station-specific-alternate-handling ones of said station-specific-television-program-selection-and-display instructions. Executing said ones causes each  
35

station in its preprogrammed fashion to handle subsequent information of said transmission. Under control of their particular station-specific-alternate-handling instructions, selected ones of said certain other stations discard all  
5 subsequent information of said transmission by causing their station apparatus to cease receiving and decrypting the information of said transmission. Under control of their particular station-specific-alternate-handling instructions, selected others of said certain other stations cause  
10 apparatus of their specific stations to record the information of said transmission--albeit, the encrypted information--thereby enabling a subscriber at each of said specific stations individually and manually to so-called "play back" the recorded encrypted information of said  
15 transmission and input a pay-per-view-authorizing instruction to a controller, 20, at his specific station, thereby causing said controller, 20, and other apparatus of the station of said subscriber [under control of said controller, 20] at a delayed time to decrypt, process, and display the information  
20 of said transmission in the fashion of the apparatus of the station of Fig. 7 [because in the preferred embodiment, the information of said 1st-WSW-program-enabling-message (#7) SPAM message embedded and transmitted more than once in said transmission in a fashion that enables a video  
25 recorder/player, 217, to record at least one full instance of an end of file signal followed by said information at every one of said certain other stations]. Executing said station-specific-alternate-handling instructions at said certain other stations causes a controller, 20, at each of said  
30 stations to switch power on to a video recorder/player, 217, at each of said stations; to cause a matrix switch, 258, at each of said station to commence transferring the output of the decryptor, 107, of said station to said recorder/player, 217; and to cause said recorder/player, 217, to commence  
35 recording the inputted transmission.)

Subsequently, but still before said 8:30 PM time, the program originating studio that originates the "Wall Street Week" transmission embeds and transmits the 1st-WSW-decryption-check (#7), the eight SPAM messages each of which  
5 is called a "2nd-WSW-program-enabling-message (#7)", and the 2nd-WSW-decryption-check (#7) just as in example #7.

Up to a particular point, receiving each of said messages causes the apparatus of the station of Fig. 7 (and all other subscriber stations that receive said messages--  
10 whether so-called "live" or so-called "time delayed") to function just as receiving said messages causes the apparatus of the station of Fig. 4 in example #7 to function. Said point occurs after controller, 20, executes the  
15 aforementioned additional 2nd-stage-enable-WSW-program instructions which, at the station of Fig. 4, cause the apparatus of said station to commence transferring the decrypted television information of the "Wall Street Week" program to microcomputer, 205, and monitor, 202M.

Executing said additional 2nd-stage-enable-WSW-program instructions at the station of Fig. 7 causes controller, 20,  
20 first to cause the apparatus of said station to commence transferring the decrypted television information of the "Wall Street Week" program transmission to decoder, 203, and microcomputer, 205. Automatically, controller, 20, causes  
25 matrix switch, 258, to cease inputting the decrypted video information of said transmission to signal processor, 200, (at switch, 1), and to commence transferring said video information (which is inputted to matrix switch, 258, from  
30 said decryptor, 231) to divider, 4, thereby causing divider, 4, to transfer said decrypted video information to microcomputer, 205, and to decoder, 203. Automatically, controller, 20, causes decoder, 203, to discard any  
35 previously received SPAM information and to commence detecting and processing SPAM information in the inputted decrypted video information in the fashion described above.

In so doing, controller, 20, causes decoder, 203, to detect and process any embedded SPAM information of the transmission of the program originating station that originates said "Wall Street Week" program and combines the microcomputer, 205, of the station of Fig. 7 to the computer system of the program originating station that originates said "Wall Street Week" program.

(Simultaneously, the SPAM message information embedded and transmitted at said originating station cause microcomputers, 205, at other stations to be combined to said computer system in the same fashion.)

Thereafter, said additional 2nd-stage-enable-WSW-program instructions affect the apparatus of the station of Fig. 7 differently from the station of Fig. 4. At the station of Fig. 4 where the television programming output transmission of the PC MicroKey System of microcomputer, 205, is inputted directly to TV monitor, 202M. By contrast, at the station of Fig. 7, the television programming output transmission of microcomputer, 205, is inputted to matrix switch, 258. Furthermore, the station of Fig. 7 is preprogrammed with the aforementioned station-specific-television-program-selection-and-display instructions.

At the station of Fig. 7, executing said additional 2nd-stage-enable-WSW-program instructions causes controller, 20, thereafter to cause the apparatus of said station to determine that monitor, 202M, is not on and operating. Automatically, controller, 20, causes control processor, 20A, in the fashion described above, to establish a control information communications link, via matrix switch, with a SPAM TV signal decoder, 145, at monitor, 202M, that controls monitor, 202M. Automatically, controller, 20, transmits particular information to said decoder, 145, that causes said decoder, 145, to determine, in a predetermined fashion, that power is not on to monitor, 202M, and to respond by transmitting particular 202M-is-not-on information to

controller, 20, via said link.

The fact that monitor, 202M, is not on signifies that the subscriber of the station of Fig. 7 is not viewing television information at monitor, 202M, and suggests that  
5 said subscriber may not even be present at said station.

Receiving said 202M-is-not-on information causes controller, 20, under control of said additional 2nd-stage-enable-WSW-program instructions, to cause microcomputer, 205, to input particular preprogrammed instructions to said  
10 controller, 20, which instructions reflect the the specific fashion in which said subscribe wants any given selected program to be selected and displayed. Automatically, controller, 20, inputs a particular choose-mode-of-selection-and-display instruction and said 202M-is-not-on information  
15 to microcomputer, 205, and receiving said instruction and said information causes microcomputer, 205, in a predetermined fashion, to process the aforementioned station-specific-television-program-selection-and-display instructions. Automatically, under control of said  
20 instructions, microcomputer, 205, inputs to controller, 20, particular preprogrammed display-at-202M-and-record-at-217 instructions.

Receiving said display-at-202M-and-record-at-217 instructions causes controller, 20, to switch power on to  
25 monitor, 202M, and commence transferring the television output transmission of microcomputer, 205, to said monitor, 202M; to switch power on to video recorder/player, 217, (which has capacity to receive and record the information of an audio and a composite video transmission); to commence  
30 transferring the television output transmission of microcomputer, 205, to said recorder/player, 217; and to cause said recorder/player, 217, to record said transmission. Automatically, controller, 20, inputs a particular instruction to decoder, 145, via said communications link,  
35 that causes decoder, 145, to switch power on to monitor,

202M, and to tune monitor, 202M, in a predetermined fashion. Automatically, controller, 20, causes matrix switch, 258, to transfer the decrypted audio information inputted from decryptor, 107, to monitor, 202M, and also to  
5 recorder/player, 217. Automatically, controller, 20, causes matrix switch, 258, to transfer the video information inputted from microcomputer, 205, to monitor, 202M, and also to recorder/player, 217. Automatically, controller, 20, causes control processor, 20A, to establish a control  
10 information communications link, via matrix switch, 259, with a SPAM TV signal decoder, 218, at recorder/player, 217, that controls recorder/player, 217, and transmits particular information to said decoder, 218, that causes said decoder, 218, to switch power on to recorder/player, 217, and to cause  
15 recorder/player, 217, to record the inputted audio and video information (including any SPAM message information embedded in said audio and video information). In so doing, controller, 20, causes monitor, 202M, to receive the decrypted video and audio information of the "Wall Street  
20 Week" program, to display the video image of said information, and to emit sound in accordance with said audio information and causes recorder/player, 217, to record said information of the "Wall Street Week" program.

(Simultaneously, the SPAM message information embedded  
25 and transmitted at said program originating station and the station-specific-television-program-selection-and-display instructions of other stations cause the apparatus of said stations to handle the programming transmitted by said originating station in station specific fashions. Some  
30 stations, where monitors, 202M, are determined to be off, may respond by causing receiver apparatus to cease receiving the transmission of said programming, thereby discarding all information of said "Wall Street Week" program. At other stations that lack microcomputers, 205, the controllers, 20,  
35 operating under control of said said additional 2nd-stage-

enable-WSW-program instructions, cause the apparatus of said stations to transfer the decrypted video information outputted by decryptors, 231, directly to monitors, 202M, thereby causing said monitors, 202M, to display the  
5 conventional television information of said program [eg. Fig. 1B] without any combined, locally generated information [eg. Fig. 1A].)

In due course, at said 8:30 PM time, said program originating studio commences transmitting the programming  
10 information of said "Wall Street Week" program, thereby causing the apparatus of the station of Fig. 7 (and of other correctly regulated and connected stations) to commence functioning in the fashions described above in "One Combined Medium" and in examples #1, #2, #3, and #4.

And in the fashions described above, receiving each  
15 SPAM message that causes decrypting causes the station of Fig. 7 (and causes other stations) to retain and process meter information. And receiving at any SPAM decoder of said station any SPAM message that contains meter-monitor  
20 information causes the apparatus of said station (and causes apparatus at other stations that are preprogrammed to collect monitor information) to retain and process monitor information.

#### 25 CONTROLLING COMPUTER-BASED COMBINED MEDIA OPERATIONS

So far in this specification has treated the process of controlling combined medium operations as if the process of generating the computer information of any given computer based combining--for example, the Fig. 1A information of the  
30 Fig. 1C combining--begins with the embedding, at a program originating studio, and transmitting of instructions that cause subscriber station microcomputers, 205, to generate said computer information. (In the case of said Fig. 1A information, this specification has, so far, treated the  
35 process of generating the particular information of said Fig.

1A as if said process begins with the embedding and transmitting of the first message of the "Wall Street Week" example.)

In actuality, the process of controlling computer-based combined media operations is continuous and involves systematic inputting and maintaining of up-to-date user specific data at each subscriber station. (For example, only at subscriber stations where user specific stock data is maintained systematically and up-to-date can the program instruction set of the first message of the "Wall Street Week" example generate Fig. 1A images that actually show the performance of the portfolios of the subscribers of said stations.)

Of course, individual subscribers can, themselves, maintain their data systematically and up-to-date. And at stations where subscribers so do, control computer-based of combined medium operations can, indeed, begin with the embedding, at a program originating studio, and transmitting of instructions that cause subscriber station microcomputers, 205, to generate the computer information of a given computer based combining.

However, the present invention provides means and methods for systematically inputting and maintaining user specific data at subscriber stations.

Microcomputer, 205, has an installed modem; receives information that is transmitted by means of telephone or data communications network, 262; is preprogrammed to answer telephone calls automatically, in a fashion well known in the art; and is preprogrammed to process data received via said network, 262. Each time the stockbroker who represents the subscriber of the station of microcomputer, 205, executes a transaction (that is, buys or sells stocks) for said subscriber's account, a computer at said broker's office station telephones microcomputer, 205; inputs data of the transaction (which data includes, for example, the identity

of the company whose shares were traded, the number of shares bought or sold, and whether the transaction was a buy or a sale); and causes microcomputer, 205, to update its stock portfolio records in a predetermined fashion (for example, by adding to said records data of shares bought and removing data of shares sold). In so doing, said office station computer causes an up-to-date record of the identity of the stocks and number of shares in the subscriber portfolio automatically to exist at microcomputer, 205.

10 (While a time lag may exist between the actual purchase or sale and the updating at microcomputer, 205, said updating always occurs before 4:30 PM on the day of sale or purchase.)

Each weekday after 4:30 PM, a remote stock-price-data-transmission station transmits all closing stock price data applicable that day and causes apparatus at each subscriber station, in a predetermined fashion, to select and record at the microcomputer, 205, of said station the particular closing price datum or data that apply to the particular stock or stocks of the preprogrammed portfolio of said computer. (Said remote station transmits said closing stock price data and causes specific subscriber stations to select and process their specific information of interest in the fashion in which remote news-service-A station transmitted the AT&T news item and caused selected stations to select and process, in their specific fashions, the information of said item.) Alternatively, microcomputer, 205, is caused in a predetermined fashion (for example, by a SPAM message a given transmission monitored by signal processor, 200, in any of the above described fashions) automatically to telephone a remote data service computer, by means of network, 262, in a fashion well known in the art, and to cause said remote computer to select and transmit the particular closing price datum or data of the stock or stocks of the portfolio of said microcomputer, 205, thereby causing said microcomputer, 205, to record said datum or data in a predetermined fashion.

In this fashion, by a particular time (for example, 8:00 PM) on a particular Friday evening, the microcomputer, 205, of the station of Fig. 7 (and microcomputers, 205, similarly at each of a large plurality of other subscriber 5 stations) has been updated and contains all relevant stock information.

Subsequently, but before the aforementioned 8:30 PM time (which is 8:30 PM, Eastern Standard Time on said Friday evening and is the time when so-called "live" transmission of the "Wall Street Week" program commences), the program 10 originating studio that originates transmission of the "Wall Street Week" program transmits the aforementioned Prepare-To-Retransmit-WSW message, 1st-WSW-program-enabling-message (#7), 1st-WSW-decryption-check (#7), eight SPAM messages each of which is called a "2nd-WSW-program-enabling-message (#7)", 15 and 2nd-WSW-decryption-check (#7). In so doing, said studio causes a plurality of intermediate transmission stations that are preprogrammed and function in the fashion of the station of Fig. 6 and a plurality of subscriber stations that are 20 preprogrammed and function in the fashion of the station of Fig. 7 (and 7C) to cause apparatus at each of said subscriber stations to interconnect, receive information of said transmission, decrypt said information, and prepare to display (or otherwise output) information of said "Wall 25 Street Week" program in the fashions of example #7 and of the above description called "MORE ON EXAMPLE #7".

(To accomplish all this has required only that the subscriber of microcomputer, 205, [and other subscribers at other stations] cause the installation and connection of the 30 apparatus shown in the figures of this submission, especially Fig. 7 (and 7C); caused his microcomputer, 205, to be preprogrammed as described above; and preinformed microcomputer, 205, of his wish to view said "Wall Street Week" program by causing the aforementioned select-WSW information to be recorded at said microcomputer, 205.) 35

Then the combined medium combining process described above in "One Combined Medium" and in examples #1, #2, #3, #4, etc. commences. And the Fig. 1C combining is displayed.

But the combining of Fig. 1C is just part of a larger  
5 process.

When the "Wall Street Week" transmission begins at 8:30 PM on a Friday evening, the program instruction set in the first message of the "Wall Street Week" example instructs microcomputer, 205, to generate not one but a  
10 plurality overlays. The combining of Fig. 1C is merely the first.

Computer operations take time and some computers are slower than others. Partly this is a question of hardware; a so-called eight bit microprocessor is generally slower  
15 performing a given operation than a sixteen bit processor for reasons that are well known in the art. But even with precisely the same hardware and systems software, two computers can take different times to complete a given operation if only because they contain different data. For  
20 example, it takes longer to calculate the value of a portfolio containing one thousand stocks than a portfolio of one. Furthermore, it is undesirable to separate computer operations merely because they result in the generation of separate overlays because such separation may result in  
25 unnecessary duplication of calculations. For example, the Fig. 1C display of user specific overall stock portfolio performance could be followed by second and third displays that analyze portions of the subscriber's portfolio--eg., the portion invested in New York Stock Exchange listed stocks in  
30 comparison to the so-called "NYSE" index and the portion invested in so-called "over-the-counter" stocks in comparison to the so-called "NASDAQ" index. In order to calculate the value of the overall portfolio, it is necessary to calculate the value of these portions. To require that the values of  
35 the portions be recalculated for subsequent overlays would be

inefficient.

In computer-based combined medium communications, the amount of information that a given system can convey is dependent on the efficiency of the employment of program 5 instruction sets and combining synch commands.

In the preferred embodiment, unlike conventional television where information is presented strictly in the sequence of its transmission, the transmission and execution of program instruction set information for second (or 10 subsequent) overlays can precede the transmission of the combining synch command of first overlays and the time of first overlay ceasings. To minimize waiting time, the controllers, 39, of decoders, 203, (or analogous controllers, 44 or 47, of analogous radio decoders of Fig. 2C of other 15 decoders of Fig. 2D that execute SPAM message information at a microcomputer, 205) combining synch commands that cause combining or the ceasing of combining (as, for example, the commands of the second and third messages of the "Wall Street Week" example) are processed as interrupts to the CPUs of 20 microcomputers, 205; program instruction sets, once executed, instruct microcomputers, 205, to wait only when further processing, under the control of the instructions of said sets, would entail overwriting RAM information whose overlay time or processing time has not yet ended. And to prevent 25 microcomputers, 205, that fall behind from displaying incomplete overlays, any given SPAM message that causes a combining specifies the identity of the particular overlay information whose combining it causes and causes a combining only at subscriber station where information exists of the completion of the identified overlay. For example, receiving 30 the second message of the "Wall Street Week" program causes the combining of Fig. 1A information and Fig. 1B information only at stations where information at the aforementioned SPAM-first-precondition and SPAM-second-precondition register memories matches selected information of the meter-monitor 35

segment of said message.

Finally, in order to cause microcomputers, 205, that fall behind to catch up, a particular fashion exists in the preferred embodiment for restoring efficient operations.

5 Microcomputers, 205, that fall behind are caused to jump over and avoid executing instructions that control the generating of overlay information (such as Fig. 1A) whose overlay time (that is, combining time) has passed. In a fashion well known in the art, selected so-called "lines of code" of

10 program instruction sets are preprogrammed with label information that identifies each one of said line, and the instructions of said set periodically compare preprogrammed information of said set to information at particular overlay-target RAM memory in order to control efficient operation in

15 a fashion described more fully below. When a combining fails to occur at any given station because information of the completion of an identified overlay does not exist at said station, the controller, 203, of said station automatically causes the microcomputer, 205, to so-called "jump", in a jump

20 fashion well known in the art, to that selected one of said lines of code where the instructions of said program instruction set commence causing the generation of the information of that particular overlay that is next to be combined. For example, at the start of the "Wall Street

25 Week" example, information of "00000000" exists at the SPAM-second-precondition register memories of the decoders, 203, of every subscriber station. The overlay of Fig. 1A is the first overlay of the "Wall Street Week" program, and the information of the meter-monitor field of the second message

30 of said example identifies said overlay with binary information of "00000001". The next overlay of said program, which is the second overlay, is identified with information of "00000010". Receiving said second message causes the decoders, 203, at each subscriber station to compare

35 information at said SPAM-second-precondition register

memories to the "00000001" information of the overlay number field of said message. At those stations that have completed generating at RAM the information of said first overlay (eg., Fig. 1A), the instructions of the program instruction set of

5 said example have caused information of "00000001" to be placed at said SPAM-second-precondition memories. At said stations, matches result and cause the combining of locally generated overlay information (eg., Fig. 1A) with the transmitted Fig. 1B information and cause the display of

10 combined medium information (eg., Fig. 1C). At other stations that have not completed generating at RAM the information of said first overlay (eg., Fig. 1A), matches do not result, causing the controllers, 39, of the decoders, 203, of said stations to execute the aforementioned

15 particular second-condition-test-failed instructions of the aforementioned conditional-overlay-at-205 instructions. Executing said second-condition-test-failed instructions causes each of said controllers, 39, to compute a particular overlay-target number; to interrupt the operation of the CPU

20 of the microcomputer, 205, of its station; to cause said CPU to place information of said overlay-target number at particular overlay-target RAM memory; to cause said CPU to execute a so-called "machine language jump" to the particular so-called "offset address" of the information at RAM of said

25 program instruction set that is associated, in the predetermined fashion of the instructions of said set, with said overlay-target number; and to cause said microcomputer, 205, to continue executing the instructions of said set from the instruction at said address. In so doing, said

30 microcomputer, 205, can skip over and avoid executing instructions whose overlay time has passed.

The particular overlay-target number that any given controller, 39, calculates, under control of said second-condition-test-failed instructions, is a function of the overlay number information of the SPAM message that invokes

35

said conditional-overlay-at-205 instructions and is also a function of the history of the efficiency of the operation of the microcomputer, 205, of the subscriber station of said controller, 39, at the time when said instructions are  
5 invoked. In the case the second message of the "Wall Street Week" example, the overlay that said message causes to be combined is the first overlay generated under control of the program instruction set that generates said overlay.  
Accordingly, the information recorded, in a predetermined  
10 fashion, at particular history-of-efficiency memory at each controller, 39, of a decoder, 203, of said other stations (that have not completed generating the information of said first overlay at the time of receiving said second message) is "00000000" and indicates that said microcomputer, 205, has  
15 not failed to generate any overlay, generated under control of said set, on time. Thus when receiving said second message at said other stations causes the execution of said second-condition-test-failed instructions, said instructions cause said controllers, 39, to increment by one the overlay  
20 number information of said message, thereby generating overlay-target information of "00000010"; to cause the microcomputers, 205, of said stations to place information of said "00000010" at said overlay-target RAM memory; to cause said microcomputers, 205, to jump to and continue executing  
25 the instructions of said program instruction set at the instruction at the particular preprogrammed "offset address" of the particular line of code of said set that is identified by the particular label associated, in a predetermined fashion, with said "00000010"; and to increment by one the  
30 information at said history-of-efficiency memory, thereby generating history-of-efficiency information of "00000001" which indicates that said microcomputer, 205, has failed to generate one overlay, generated under control of said set, on time. Thereafter, whenever receiving a SPAM message of said  
35 "Wall Street Week" program causes a controller, 39, of said

other stations to execute said second-condition-test-failed instructions, said instructions cause said controller, 39, to compute its overlay-target number by incrementing the overlay number information of said message by more than one and to  
5 cause the microcomputer, 205, of its station to restore efficiency by skipping over instructions that cause the generation of more than one overlay (including one or more overlays whose overlay time has not yet come). As said microcomputer, 205, generates the information of the overlay  
10 that is identified by said overlay-target number, the instructions of said set cause said microcomputer, 205, in a predetermined fashion that involves comparing preprogrammed particular overlay-being-generated information of said set to information at said overlay-target RAM memory, to identify  
15 particular instructions of said set that control just the generation of said one or more overlays whose overlay time has not yet come and to jump over and avoid executing said instructions, thereby executing only those instructions that control generation of information of said identified overlay  
20 (or of overlays whose overlay time follows the overlay time of said identified overlay). In so doing, said microcomputer, 205, can skip over and avoid executing selected instructions whose overlay time has not passed in order to catch up and recommence combining at an overlay time  
25 that is after the overlay time of the overlay or overlays whose generation is controlled by said selected instructions.

Thus transmitting to a plurality of subscriber stations any given SPAM message that invokes said conditional-overlay-at-205 instructions causes apparatus at  
30 selected ones of said stations to combine locally generated overlay information (eg., Fig. 1A) with transmitted information (eg., Fig. 1B) and to cause the display of combined medium information (eg., Fig. 1C) and causes apparatus at selected other stations to generate information  
35 of overlays whose combining is not caused by receiving said

message (because the overlay times of said overlays is subsequent to the overlay time of said locally generated overlay information [eg., Fig. 1A] whose combining is caused by said message). Furthermore, transmitting said messages  
5 causes the apparatus at said selected other stations to generate information of overlays in such a way that each station generates information of an overlay that has a specific overlay time and the specific overlay time of the overlays generated at specific station varies from station to  
10 station and is different at different stations.

#### TRANSMITTING AND RECEIVING PROGRAM INSTRUCTION SETS

In television, the normal transmission location is in the vertical interval of the television transmission. SPAM  
15 signals are not normally transmitted in the visible portion of the television picture because the information of said signals can be seen by viewers (often as so-called "snow"). However, the transmission capacity of the vertical interval is limited.

In computer-based combined medium communications, the  
20 amount of locally generated information that any given system can display (or otherwise output) to subscribers is dependent on maximizing the volume of program instruction set instructions that said system can transmit and maximizing the  
25 time interval between the transmission (more precisely, the execution) of the instructions of any given program instruction set and the overlay times of the individual locally generated overlays whose generation said instructions  
30 cause. The greater the volume of program instruction set information that is transmitted in any given combined medium program, the greater is the amount of overlay information can be generated at subscriber stations. And the earlier said  
35 information is transmitted in said program, the greater is the efficiency with which generating is controlled at subscriber stations (because the longest possible time

intervals can separate the commencement of the generating of the information of individual overlays and the individual overlay times of said overlays).

In the preferred embodiment, the program instruction set information of any given combined medium program is transmitted as soon as possible after commencement of said program, and the present invention includes means and methods to maximize the transmission of program instruction set information at the start of combined medium programs. (As related above, in the preferred embodiment, all SPAM commands are transmitted in the normal transmission location of any given transmission.)

In the video/computer combined medium, capacity is found by transmitting said sets in portions of the television picture that are covered by locally generated overlays (which in digital television transmissions can include frames of transmitted video that are "frozen" after reception in fashions well known in the art). One controlled function that is preprogrammed at the controllers, 39, of the decoders, 203, of subscriber stations and that is caused to be executed by receiving a SPAM message containing expand-to-full-field-search execution segment information is a function whose instructions cause said controller, 39, to cause the line receivers, 33, of said decoders, 203, to commence detecting digital information in every frame of its received video information from the first detectable portion of line 20 of said frame to the last detectable portion of the last line of said frame. A second controlled function that is preprogrammed at said controllers, 39, and that is caused to be executed by receiving a SPAM message containing resume-normal-location-search execution segment information is a function whose instructions cause said controller, 39, to cause said line receivers, 33, to commence detecting digital information in the normal transmission location of every frame of its received video information.

An example illustrates transmitting program instruction set information in a portion of the television picture that is normally visible but that is temporarily covered by an overlay. In the example, the program  
5 originating studio that originates a given program causes each subscriber station to generate information of the so-called "titles" of said program (that is, the textual information listing the title said program, the names of the cast and crew members, etc.), causes said locally generated  
10 information to overlay and obscure completely the transmitted video information of said program, and transmits program instruction set information in the full field video of the transmission so obscured (that is, in every frame of the transmitted video information from the first detectable  
15 portion of line 20 of said frame to the last detectable portion of the last line of said frame).

The decoder, 203, of the station of Fig. 7 and 7C (and the decoder, 203, of every other subscriber station tuned to said program) is preprogrammed to respond to SPAM messages  
20 containing expand-to-full-field-search execution segment information and resume-normal-location-search information and responsively to alter automatically the portions of its received video information that are searched for embedded digital information.

At the start of the conventional television  
25 information of said program, said program originating studio embeds a SPAM message that contains the execution segment information that is identical to the execution segment information of the first message of the "Wall Street Week"  
30 example and information segment information of a particular set-to-color program instruction set. Receiving said message causes apparatus at each station, in the fashions described above, to execute the information of said set; to clear the video RAM of the microcomputer, 205, of said station; and to  
35 set all of said RAM, in a fashion well known in the art, to

an opaque background color such as light blue.

Next said program originating studio embeds a SPAM message that contains the execution segment information that is identical to the execution segment information of the  
5 second message of the "Wall Street Week" example. Receiving said message causes said apparatus to combine the overlay information of said video RAM and the transmitted video and to continue executing the instructions of said first set. In so doing, said apparatus causes said transmitted video to be  
10 covered and obscured completely by said opaque background color.

Then said studio embeds a SPAM message that contains one instance of said expand-to-full-field-search execution segment information. Receiving said message causes apparatus  
15 at each station to cause the line receiver, 33, of the decoder, 203, of said station to commence detecting digital information in every frame of its received video information from the first detectable portion of line 20 of said frame to the last detectable portion of the last line of said frame.

Then said studio embeds in the full field video and transmits a SPAM message that contains said execute-at-205  
20 execution segment information and information segment information of a particular titles-of-this-program program instruction set. Receiving said message causes apparatus at each station to execute the information of said set at the  
25 microcomputer, 205, of said station. So executing said information causes said microcomputer, 205, to commence generating at said RAM, in a fashion well known in the art, the image information of a so-called "crawl" of said titles.  
30 In so doing, said studio causes said microcomputer, 205, to display the information of said titles at the monitor, 202M, of said station. (Simultaneously, a microcomputer, 205, at every other subscriber station executes the same information and displays the same titles, and said studio transmits audio  
35 information of appropriate so-called "program theme music,"

causing apparatus at each station to emit the sound of said music.)

Then said studio embeds in the full field video and transmits a particular program-instruction-set-of-this-  
5 program SPAM message that contains particular record-at-256 execution segment information and information segment information of a particular generate-overlays-of-this-program program instruction set.

Receiving said message causes apparatus at each  
10 station to transfer the information of said message to the computer memory unit, 256, of said station (which is shown in Fig. 7 and is, for the purposes of this example, a floppy disk drive of microcomputer, 205, that is labelled drive "C:" by said microcomputer, 205, and that is capable of receiving  
15 and recording information independently of said microcomputer, 205), and receiving said message causes said unit, 256, to record said program instruction set.

Automatically, the controller, 39, of said decoder, 203, causes the control processor, 20A, of said station to  
20 establish a control information communication link, via matrix switch, 259, with the controller, 20, of the signal processor, 200; transmits particular instructions to said controller, 20, that cause said controller, 20, to establish a programming information communication link, via matrix  
25 switch, 258, with said computer memory unit, 256; and transmits said message, via said matrix switch, 258, to a SPAM decoder, 256A, at said unit, 256. Automatically, said decoder, 256A, receives said message; invokes particular  
30 preprogrammed controlled function instructions; causes said unit, 256, to record inputted information in a particular file, "OVERLAYS.EXE"; and inputs the information of said program instruction set to said unit, 256, in the fashion that decoder, 203, inputs the information of the information  
35 example to microcomputer, 205, thereby causing said unit,

256, to record the information of said set in said file.  
(Simultaneously, other computer memory units, 256, that are  
labelled drive "C:" of the microcomputers, 205, of other  
stations record the information of said set as  
5 "OVERLAYS.EXE".)

Then said studio embeds a SPAM message that contains  
one instance of said resume-normal-location-search execution  
segment information. Receiving said message causes apparatus  
at each station to cause the line receiver, 33, of the  
10 decoder, 203, of said station to commence detecting digital  
information in just the normal transmission location of every  
frame of its received video information.

Then said studio commences transmitting conventional  
television video image information and embeds and transmits a  
15 SPAM message that that is identical to the third message of  
the "Wall Street Week" example. Receiving said message  
causes apparatus of said station (and similar apparatus at  
every other station) to cease combining the overlay  
information of said video RAM and the transmitted video and  
20 to cause the display of only the transmitted video  
information at said monitor, 202M. In so doing, said studio  
causes each station to cease displaying the locally generated  
information of said "titles" and to commence displaying the  
information of said conventional television video image.

Then said studio embeds a SPAM message that contains  
25 execution segment information that is identical to the  
execution segment information of the first message of the  
"Wall Street Week" example and information segment  
information of a particular "C:OVERLAYS". Receiving said  
message causes apparatus at each station to input the  
30 information of said "C:OVERLAYS" to the microcomputer, 205,  
of said station and execute said information. Executing said  
information causes said microcomputer, 205, to load from its  
C: drive (which is said unit, 256) the information of said  
OVERLAYS.EXE file and execute the information so loaded as a  
35

machine language job.

In this fashion, a program originating studio can transmit information of a program instruction set to a multiplicity of subscriber stations in the full field video of its video transmission and execute the information so transmitted at the microcomputer, 205, of each of said stations as a machine language job without having a viewer of any station view any information of said set at a monitor, 202M.

(To minimize the risk that program instruction sets may become separated from their associated television programming, said sets are normally embedded in their associated television transmissions. But it is not an absolute requirement of the preferred embodiment that all program instruction sets be so embedded. If the volume of program instruction set information that a given programming transmission must transmit exceeds the transmission capacity of said transmission [eg., if the audience includes viewers who do not have overlay capacity and would see "snow" were set information transmitted in portions of the transmission obscured by overlays], at the proper time transmission stations can transmit said set information outside the conventional transmission [a program originating studio may transmit said set information, for example, in a satellite side lobe of the transponder transmission transmitting the conventional transmission, and a cable head end intermediate transmission station transmits it in a separate television channel or in a transmission in a multiplexed FM frequency spectrum transmission].)

### 30 AUDIO OVERLAYS AND OTHER OVERLAYS

In the present invention, many combinings are caused and controlled besides combinings of video overlay information (such as Fig. 1A) and transmitted television image information (such as Fig. 1B). SPAM messages cause

user specific audio to be combined with transmitted radio or television audio information and emitted as sound at subscriber stations. SPAM messages insert user specific print into broadcast print. And SPAM messages insert user  
5 specific data into data communications.

Fig. 7D illustrates a radio/computer combined medium. Radio tuner, 209T, receives a conventional radio broadcast transmission. Divider, 209D, splits the received transmission into two paths and transmits one to  
10 microcomputer, 205, and the other to radio decoder, 211, (where the received transmission is inputted to the radio decoder, 42, component). Decoder, 211, detects embedded digital SPAM information; corrects and converts said information; processes said information at the control  
15 processor, 44J, of its controller, 44; and inputs selected SPAM information to microcomputer, 205. Microcomputer, 205, has installed capacity to receive an inputted audio transmission; capacity to receive control information and SPAM program instruction set information from said  
20 controller, 44; to generate and enter information into audio RAM; to combine audio overlay programming, by means of audio synthesizing techniques and overlay techniques well known in the art, into the received audio transmission; and to  
25 transmit the combined audio to speaker system, 263, which has capacity, well known in the art, to convert the received audio into sound.

An example illustrates the operation of the subscriber station of Figs. 7 and 7D.

A radio station transmits radio programming at 9:00 PM, immediately following the time at which said "Wall Street  
30 Week" program ends. At each subscriber station, the stock portfolio and closing price data are recorded precisely as at the start of said "Wall Street Week" program. In the normal transmission location of the radio transmission of said  
35 programming, said station embeds and transmits particular

SPAM information.

At the station of Figs. 7 and 7D, the transmission of said station is received at tuner, 209T, and inputted to divider, 209D, which inputs the received radio transmission 5 separately to decoder, 211, and to microcomputer, 205. Receiving said transmission causes decoder, 211, to detect the SPAM information embedded in said transmission and to input information of said SPAM information to microcomputer, 205, which is preprogrammed to process said inputted 10 information. And receiving said transmission causes microcomputer, 205, to input said transmission to speaker system, 263, which is caused thereby to emit sound.

In due course, said radio station embeds a SPAM message that is analogous to the first message of the "Wall 15 Street Week" example. Receiving information of said message causes microcomputer, 205, to record at RAM the digital audio images of three statements made and prerecorded by an announcer--"And the value of your portfolio went up more than the market", "And your portfolio went up but no faster than 20 the market", and "But the value of your portfolio went down"--to compute a first value of the subscriber's portfolio as of the close of business of the day before said transmission; to compute a second value of the subscriber's portfolio as of the close of business of the day of said transmission; 25 to determine that said first value is greater than said second value; to clear audio RAM in a clearing fashion well known in the art; to select information of the audio image, "But the value of your portfolio went down", in a predetermined fashion; and to transfer said selected 30 information to audio RAM. (Receiving said message causes apparatus of other station to function in their own user specific fashions.)

Simultaneously, the audible audio portion of said radio transmission has conveys information of the announcer's 35 voice describing the activity of the stock market and saying,

"Stock prices rose today in heavy trading."

Then said radio station transmits an interval of silent audio and embeds, at the beginning of said interval, a SPAM command that causes microcomputer, 205, to generate the  
5 synthesized audio of one instance of the image at said audio RAM, to overlay said audio into the transmitted audio, and to transmit the combined audio to speaker system, 263. In so doing, said station causes system, 263, to emit the sound of the announcer's voice saying, "But the value of your stock  
10 portfolio went down." (Simultaneously, receiving said message causes apparatus every other station receiving said radio transmission its one selected one of said three statements.)

After an interval of transmitting silent audio that is  
15 longer than the longest time required to cause any given subscriber station speaker system, 263, to emit the sound of one of said selected audio images completely, said radio station transmits the audio of said announcer's voice saying, "Now let us turn to the bond markets."

(A broadcast print and computer combined medium  
20 subscriber station operates in a similar fashion and is configured similarly to the apparatus of Fig. 7D [except that said station has no divider apparatus analogous to divider, 209D]. Said station has receiver apparatus analogous to  
25 radio, 209T; appropriate decoder apparatus that may consist of the digital detector, 46, and controller, 47, of the other decoder of Fig. 2C; a microcomputer, 205; and a printer, 221, instead of speaker system, 263. Said receiver apparatus receives the broadcast print transmission of a broadcast  
30 print transmission station and inputs said transmission to said decoder apparatus. Said decoder detects digital information in the inputted transmission; processes SPAM information in the detected digital information; and inputs selected digital information to the CPU of said  
35 microcomputer, 205, or transfers other selected digital

information to a buffer at microcomputer, 205, that is an  
input buffer to said printer, 221. In operation, the  
apparatus of said station receives, transfers to printer,  
221, and prints the digital information of a SPAM message  
5 information segment [which information conveys stock  
market information and ends with information that is printed  
as, "Stock prices rose today in heavy trading,"]. Then the  
decoder of said station detects a SPAM end of file signal and  
a subsequent SPAM message. Receiving said subsequent message  
10 causes said decoder to input information of said message to  
said CPU. Receiving said information at said CPU causes  
microcomputer, 205, to receive digital information of three  
alternate print messages; to compute a first value of the  
portfolio of the subscriber of said station as of the close  
15 of business of the day before said transmission; to compute a  
second value of the subscriber's portfolio as of the close of  
business of the day of said transmission; to determine that  
said first value is greater than said second value; and to  
transfer to said printer, 221, selected digital information  
20 of the print message, "but the value of your portfolio went  
down." In so doing, said microcomputer, 205, causes said  
printer, 221, to print the information of said selected print  
message. Then the decoder of said station detects a SPAM end  
of file signal and a subsequent SPAM message. Receiving said  
25 subsequent message causes said decoder to input information  
of said message to printer, 221, and causes printer, 221, to  
initiate a new print paragraph and commence printing  
information of the information segment of said last named  
message, beginning with, "Now let us turn to the bond  
30 markets." [Simultaneously, the transmission received at said  
station is also received at other similar stations and causes  
apparatus at said other stations to print general message  
information with user specific information. For example:

35 Stock prices rose today in heavy trading, and the

value of your portfolio went up more than the market.  
Now let us turn to the bond markets.

is printed at a particular other station where the  
5 computations of a microcomputer, 205, determine that the  
value of the portfolio of said last named station's  
subscriber increased at a faster rate than the rate of  
increase of a particular market average.])

Fig. 7E shows how the audio system of Fig. 7D is added  
10 to the video system of Fig. 1 to achieve the full combined  
medium of television and computers. To the apparatus of Fig.  
1, a divider, 202D, is added in the audio transmission path  
which splits the transmission into two paths and transmits  
one to the appropriate audio processing apparatus of TV  
15 decoder, 203, and the other to microcomputer, 205, at  
particular apparatus, well known in the art, that has  
capacity for combining computer synthesized audio into the  
transmitted audio and that inputs its received audio  
20 RAM and audio synthesizing and combining capacities. Using  
precisely the same methods whereby the apparatus of Fig. 7D  
is caused to input audio information (including user specific  
audio information) to speaker system, 263, (causing said  
system, 263, to emit the sound of the voice of the radio  
25 announcer as described above), the apparatus of the station  
of Fig. 7E can be caused to input audio information  
(including user specific audio information) to the speaker of  
monitor, 202M, (causing said speaker to emit the sound of the  
voice of an announcer making the above audio statements).  
30 The only difference between the systems of Figs. 7D and 7E is  
that SPAM information of the audio of Fig. 7E is transmitted,  
in the preferred embodiment, in the normal transmission  
location of television (which means that said information is  
embedded in the video rather than the audio).

35

AUTOMATING U. R. STATIONS ... EXAMPLES #9 AND #10 CONTINUED  
COORDINATING COMPUTERS, TELEVISION, AND PRINT

Fig. 7F illustrates a method for generating and communicating information to selected subscribers through the coordination of computers, television, and broadcast print. Fig. 7F also illustrates use of a local input, 225.

The microcomputer, 205, of the station of Fig. 7 and 7F, is preprogrammed to receive and process automatically meal recipe instructions and holds records of the size of the family of the subscriber of said station together with the tastes and dietary habits of the members of said family. For example, particular information is recorded in a file named DATA\_OF.URS that is on a so-called "floppy disk" that is loaded at the A: disk drive at said microcomputer, 205. Said information specifies that said family prefers particular very hot and spicy foods, prefers to minimize salt consumption, and consists of four adults.

(Simultaneously, a particular second microcomputer, 205, that is at the different station of a second subscriber and is also preprogrammed to receive and process automatically meal recipe instructions, holds information in a file named DATA\_OF.URS on a floppy disk that is loaded at its A: disk drive which information specifies that the family of said second subscriber prefers particular mild foods, is indifferent regarding salt consumption, and consists of two adults. And a particular third microcomputer, 205, that is at another different station of a third subscriber and that is also preprogrammed to receive and process automatically meal recipe instructions, holds information in a file named DATA\_OF.URS on a floppy disk that is loaded at its A: disk drive which information specifies that the family of said third subscriber prefers particular moderately hot and spicy foods, is indifferent regarding salt consumption, and consists of two adults and three children.)

The program originating studio of a particular network

transmits the programming transmission of a particular conventional television program on cooking techniques that is called "Exotic Meals of India." Said transmission is received at the intermediate transmission station of Fig. 6 and retransmitted immediately on the cable channel of modulator, 83. (Said transmission is also received at the aforementioned second intermediate transmission station of example #10 and retransmitted immediately.)

At the station of Fig. 7 and 7F (which station is a subscriber station of the intermediate station of Fig. 6), in the fashions described above, apparatus is caused to receive the particular transmission of said program that is retransmitted by the intermediate station of Fig. 6; to interconnect in such a way that the audio information received at a tuner, 215, and the video information received at said tuner, 215, are inputted separately, via matrix switch, 258, to monitor, 202M; to retain and process meter and monitor information of the use and usage of the information of said transmission, and to display the television information of said transmission (that is, information of said audio and video) at monitor, 202M. (In other words, because said "Exotic Meals of India" programming is conventional television programming rather than combined medium programming, no information of said programming is inputted to microcomputer, 205, and no programming outputted by microcomputer, 205, is inputted to monitor, 202M.)

(Simultaneously and in the same fashion, apparatus of the station of said second subscriber [which station is a subscriber station of the intermediate station of Fig. 6] receives, interconnects, meters and monitors, and displays at a monitor, 202M, the information of said transmission. And apparatus of the station of said third subscriber [which station is a subscriber station of said second intermediate station] also receives, interconnects, meters and monitors, and displays at a monitor, 202M, the information of the

transmission of said program that is transmitted by said second intermediate station.)

The program is devoted to the subject of cooking a particular fish curry that can be mild or moderately hot and 5 spicy or, as a vindaloo, very hot and spicy.

Halfway through the program the host says, "If you are interested in cooking what we are preparing here and want a your own printed copy of the recipe tailored to your own tastes and your own shopping list for a charge of only 10 cents, enter on your Widget Signal Generator and Local Input 10 the information that you see on your screen." The information that appears on the screen of each subscriber is "TV567#".

Each subscriber--in particular, the subscriber of the station of Figs. 7 and 7F, said second subscriber, and said 15 third subscriber--enters TV567#, in a fashion well known in the art, at the keyboard of the specific local input, 225, of his own station which causes said input, 225, to transmit a particular preprogrammed process-local-input instruction and said TV567# information to the controller, 20, of the signal 20 processor, 200, of said station.

Receiving said instruction and information causes the controller, 20, at each station where TV567# is entered, in a predetermined fashion, to retain said TV567# information at 25 particular last-local-input-# memory.

Five minutes later, said program originating studio embeds in the transmission of the "Exotic Meals of India" programming and transmits a particular first SPAM message that consists of an "01" header, particular execution segment information that is addressed to URS signal processors, 200, 30 appropriate meter-monitor information, padding bits as required, an information segment of particular check-for-entered-information-and-process instructions, and an end of file signal.

At the station of Figs. 7 and 7F, said message is 35

detected at TV signal decoder, 145, and said execution  
segment information invokes particular controlled function  
instructions that cause said message to be transferred to the  
controller, 20, of signal processor, 200. Automatically,  
5 the controller, 39, of decoder, 145, transmits particular  
switching request information to the control processor, 20A,  
of signal processor, 200, via the aforementioned control  
information bus means. Receiving said information causes  
control processor, 20A, to cause matrix switch, 259, to  
10 establish a communications link between said controller, 39,  
and said controller, 20. Automatically, said controller, 39,  
transfers said message to said controller, 20.

Receiving said message causes controller, 20, to load  
and execute said check-for-entered-information-and-process  
15 instructions, and executing said instructions causes  
controller, 20, to determine that TV567# information exists  
at said last-local-input-# memory and to cause an instance of  
particular covert control information (which is preprogrammed  
in said instructions) to be placed at particular control-  
20 function-invoking information memory of the controller, 39,  
of decoder, 145, and also at particular control-function-  
invoking information memory of the controller, 39, of  
decoder, 203. Executing said instructions also causes  
controller, 20, to initiate a particular signal record of  
25 meter information at the buffer, 14, of signal processor,  
200, which record contains particular program unit  
information and TV567# information. (At stations where  
TV567# information does not exist at last-local-input-#  
memory of the controllers, 20, said instructions cause said  
30 controllers, 20, to cease executing and delete all  
information of said instructions without placing any  
information at the decoders, 145 and 203, or initiating any  
meter information.)

(Receiving said first message at the stations of said  
second and said third subscribers causes apparatus of said  
35

station to function in the fashion of the station of Figs. 7 and 7F.)

One minute later, said program originating studio embeds in the transmission of said "Exotic Meals of India" programming and transmits a particular second SPAM message that consists of an "01" header, particular execution segment information that is identical to said covert control information, appropriate meter-monitor information including unit code identification information that identifies the programming of the information segment of said message, padding bits as required, information segment of particular generate-recipe-and-shopping-list instructions, and an end of file signal.

At the station of Figs. 7 and 7F, said message is detected at TV signal decoder, 145, and said execution segment information invokes particular controlled function instructions that cause said message to be transferred to the controller, 39, of decoder, 203. Automatically, the controller, 39, of decoder, 145, transmits particular switching request information to the control processor, 20A, of signal processor, 200, via the aforementioned control information bus means. Receiving said information causes control processor, 20A, to cause matrix switch, 259, to establish a communications link between the controller, 39, of decoder, 145, and the controller, 39, of decoder, 203. Automatically, said controller, 39, of decoder, 145, transfers said message to the controller, 39, of decoder, 203.

Receiving said message causes the controller, 39, of decoder, 203, to load and execute said generate-recipe-and-shopping-list instructions at microcomputer, 205, and to transfer particular meter-monitor information to the buffer/comparator, 14, of signal processor, 200, causing said buffer/comparator, 14, to increment the information of said signal record of meter information in the fashion described

above.

Executing said generate-recipe-and-shopping-list instructions causes microcomputer, 205, to generate information of the specific fish curry recipe and fish curry shopping list of the family of the subscriber of the station of Figs. 7 and 7F; to cause said recipe and shopping list to be printed at printer, 221; and to retain information of said shopping list at particular memory. Automatically, microcomputer, 205, accesses its A:DATA\_OF.URS file, in a fashion well known in the art, and selects the aforementioned information that specifies the size of the family of the subscriber of said station together with the tastes and dietary habits of the members of said family; determines that one ingredient of the recipe of said family is "Patak's low-salt Vindaloo Curry Paste" (because said family prefers particular very hot and spicy foods and prefers to minimize salt consumption); computes that, at one-half pound of halibut fish and one teaspoonful of said Vindaloo Paste per adult, the recipe of said family (which is of four adults) calls for two pounds of halibut and four teaspoonfuls of said Paste and that the shopping list of said family lists two pounds of halibut and one jar of "Patak's low-salt Vindaloo Curry Paste"; incorporates information of said two pounds and four teaspoonfuls of "Patak's low-salt Vindaloo Curry Paste" into generally applicable information of the recipe of said "Exotic Meals of India" programming and information of said two pounds and one jar of "Patak's low-salt Vindaloo Curry Paste" into generally applicable information of the shopping list of said programming, thereby generating (through the processes of so determining, computing, and incorporating) output information of the specific recipe and shopping list of said family; records one instance of the output of said shopping list at particular shopping-list memory; and outputs output information of said specific recipe and list to printer, 221.

Receiving said output information causes printer, 221, to print the information of said specific recipe and list.

(Receiving said second message at the stations of said second and said third subscribers causes apparatus of said station to function in the fashion of the station of Figs. 7 and 7F except that the specific recipe and list information processed, recorded, outputted, and printed at said stations are the specific recipes and lists of the families of said subscribers. The microcomputer, 205, of the station of said second subscriber determines that one ingredient of the recipe of said family is "Patak's Quick Curry Paste (Mild)" (because said family prefers particular mild foods and is indifferent regarding salt consumption); computes that the recipe of said family (which is of two adults) calls for one pound of halibut and two teaspoonfuls of said Paste and that the shopping list of said family lists one pound of halibut and one jar of "Patak's Quick Curry Paste (Mild)"; completes generating; records selectively at particular shopping-list memory; outputs; and causes to be printed output information of the specific recipe and shopping list of said family that reflects the one pound, two teaspoonfuls, and one jar of "Patak's Quick Curry Paste (Mild)" information so determined and computed. The microcomputer, 205, of the station of said third subscriber determines that one ingredient of the recipe of said family is "Patak's Quick Curry Paste (Hot)" (because said family prefers particular moderately hot and spicy foods and is indifferent regarding salt consumption); computes that, at one-half pound of halibut fish and one teaspoonful of said Paste per adult and at one-quarter pound of halibut fish and one-half teaspoonful of said Paste per child, the recipe of said family (which is of two adults and three children) calls for one and three-quarters pounds of halibut and three and one-half teaspoonfuls of said Paste and that the shopping list of said family lists one and three-quarters pounds of halibut and one jar of "Patak's Quick Curry Paste

(Hot)"; completes generating; records selectively at particular shopping-list memory; outputs; and causes to be printed output information of the specific recipe and shopping list of said family that reflects the one and three-  
5 quarters pounds, three and one-half teaspoonfuls, and one jar of "Patak's Quick Curry Paste (Hot)" information so determined and computed.)

(At stations where TV567# information was not entered at a local input, 225, the decoders, 145, discard all  
10 information of said second message because the executions segment information of said message fails to match any controlled-function-invoking information, and receiving said message causes no further processing.)

One benefit of this method of transmitting the  
15 information of said generate-recipe-and-shopping-list instructions is that by causing said instructions to be embedded in the transmission of said "Exotic Meals of India" programming this method enables any subscriber who records the transmission of said programming at a recorder/player,  
20 217, to access the embedded information of said instructions automatically in this fashion whenever the recorded transmission of said programming is played back--and in so doing, to cause the signal processor, 200, of his station to process meter-monitor information of said embedded first and  
25 second messages anew whenever TV567# is entered at a local input, 225, in the course of the play back of said transmission. However, this method has the drawback of making the information of said instructions relatively vulnerable to programming pirates (who may be able to  
30 manipulate and extract said information relatively easily without causing meter information to be transmitted to remote metering stations) because the embedded location of said instructions is relatively easy to find.

(An alternate method for inputting said second message  
35 to the microcomputers, 205, at stations where TV567# is

entered at a local input, 225, is to embed said message in a particular second transmission that is different from the transmission of said "Exotic Meals of India" programming and to cause a selected All signal decoder, 290, at each one of 5 said stations to receive said second transmission, thereby causing said decoder, 290, to detect and transfer the information of said second message to the microcomputer, 205, of said station. In this alternate method, executing said check-for-entered-information-and-process instructions of 10 said first SPAM message causes controller, 20, of signal processor, 200, of each one of said stations to cause the tuner, 223, of a selected converter box, 222, to tune said box, 222, to receive said second transmission; to cause the matrix switch, 258, to establish a programming communication 15 link between said selected converter box, 222, and said decoder, 290; to cause the appropriate receiver apparatus of said decoder, 290, to receive said transmission and the appropriate detector and EOFS valve, 39F, to commence detecting an end of file signal; and to cause an instance of 20 particular covert control information that is in said instruction to be placed at particular control-function-invoking information memory of the controller, 39, of said decoder, 290. In due course, said programming originating studio causes the intermediate transmission station to embed 25 an end of file signal then said second message in said second transmission. Transmitting said end of file signal then said second message causes the apparatus of said decoder, 290, to detect and process properly the information of said second message. This method has the advantage of making the 30 information of said instructions relatively invulnerable to programming pirates because the location of said instructions [more precisely, the particular transmission in which said instructions are embedded] is harder to identify without causing meter information [if only of said first message] to 35 be transmitted to remote metering stations.)

(Whichever transmission method is employed the information of said second message can be encrypted and caused to be decrypted in any of the methods described above--for example, in the method of the first message of 5 example #4.)

Toward the end of the transmission of said "Exotic Meals of India" programming and after each microcomputer, 205, that processes the information of said second message records one instance of specific shopping list output 10 information at particular shopping-list memory, said programming origination studio commences the example #10 transmission of the programming of the supermarket chain commercial of Q. While still transmitting said "Exotic Meals of India" programming, said studio embeds and transmits said 15 load-set-information message (#10) in the transmission of said programming.

As described above, receiving said message causes intermediate transmission stations, including the station of Fig. 6 and said second intermediate transmission station, 20 each to load the information of particular files, PROGRAM.EXE and DATA\_OF.ITS, at particular program-set-to-transmit and data-set-to-transmit RAM memories of a computer, 73.

Then said studio ceases transmitting "Exotic Meals of India" programming for a so-called "commercial break" and 25 commences transmitting the conventional television video and audio information of program unit Q.

Immediately after commencing to transmit said video and audio of Q, said studio transmits said align-URS- 30 microcomputers-205 message (#10), embedded in the programming transmission of Q. Said message consists of a "10" header, and information of a particular SPAM align-subscriber-station-microcomputers-to-receive-combined-medium-computer-programming execution segment that is addressed to URS signal processors, 200, and any required padding bits.

35 Receiving said message at the station of Figs. 7 and

7F causes TV signal decoder, 282, to detect said message and execute particular preprogrammed controlled function instructions that cause said decoder, 282, to cause a communications link to be established that links said  
5 decoder, 282, via matrix switch, 259, with the controller, 20, of signal processor, 200; to transfer said message to controller, 20; and to transfer particular preprogrammed source mark information that identifies said decoder, 282, as the local source inputting said message to controller, 20.  
10 (Decoder, 145, is not preprogrammed with controlled-function-invoking information that matches the execution segment information of said message, and decoder, 145, discards all information of said message.)

Receiving said message causes controller, 20, to  
15 combine microcomputer, 205, to the computer system of said program originating studio and to cause the video and audio output transmissions of microcomputer, 205, to be inputted to monitor, 202M. Automatically, controller, 20, determines, in a predetermined fashion, that the television information  
20 received at tuner, 215, is displayed at monitor, 202M; that the audio emitted at monitor, 202M, is inputted to said monitor, 202M, via matrix switch, 258, from said tuner, 215; and that the video displayed at monitor, 202M, is also inputted to said monitor, 202M, via matrix switch, 258, from  
25 said tuner, 215. Automatically, controller, 20, causes matrix switch, 258, to configure its switches so as to transfer the video information that is inputted to monitor, 202M, also to divider, 4, and to configure its switches so as to transfer the audio information that is inputted to  
30 monitor, 202M, also to divider, 202D. In so doing, receiving said message causes the apparatus of said station to combine to the computer system of said program originating studio. Automatically, controller, 20, causes a control information communication link to be established that links controller, 20, and the controller, 39, of decoder, 203, then inputs an  
35

interrupt signal of new-channel-input information to said controller, 39. In so doing, receiving said message causes the decoder, 203, of said station to delete all previously received SPAM information and commence discarding all  
5 received SPAM information until an end of file signal is detected. Automatically, controller, 20, causes matrix switch, 258, to configure its switches so as to cease transferring audio information inputted from said tuner, 215, to monitor, 202M, and video information inputted from said  
10 tuner, 215, to monitor, 202M. Automatically, controller, 20, causes matrix switch, 258, to configure its switches so as to commence transferring audio information inputted from said microcomputer, 205, to monitor, 202M, and video information inputted from said microcomputer, 205, to monitor, 202M. In  
15 so doing, receiving said message causes matrix switch, 258, to interconnect the apparatus of said station in the fashion of Fig. 7E.

(Receiving said align-URS-microcomputers-205 message (#10) at the stations of said second subscriber and of said  
20 third subscriber causes apparatus at said stations to function in the station of Figs. 7 and 7F, apparatus of said stations to combine to the computer system of said program originating studio, to discard received SPAM information, and to interconnect at each of said stations in the fashion of  
25 Fig. 7E.)

After an interval that is sufficient to allow apparatus at each subscriber station so to combine and interconnect, said studio transmits said synch-SPAM-reception message (#10), embedded in the transmission of said  
30 programming. Said message consists of a "01" header, information of the aforementioned pseudo-command execution segment, appropriate meter-monitor information that includes the "program unit identification code" information of said programming of Q, any required padding bits, an information  
35 segment that contains no binary information, and information

of a SPAM end of file signal.

Receiving said message at the station of Figs. 7 and 7F causes decoder, 203, to detect the end of file signal of said message and to process the next received SPAM information as information of the header of a SPAM message, thereby causing said decoder, 203, to commence identifying and processing the individual SPAM messages of the SPAM information subsequently embedded in the transmission of the programming of Q. In so doing, receiving said message causes decoder apparatus of the station of Figs. 7 and 7F to commence executing controlled functions in response to SPAM messages transmitted by said program originating studio. (In the fashions described above, receiving said message at decoders, 145 and 282, causes said decoders, 145 and 282, to process the meter-monitor information of said message and to transmit meter-monitor information to the onboard controller, 14A, of signal processor, 200, and causes said onboard controller, 14A, to initiate signal record information of said programming of Q and process in the fashions described above that include transferring recorded signal record information to one or more remote auditing stations.)

Then immediately, said studio transmits said control-invoking message (#10), embedded in the transmission of said programming. Said message consists of a "00" header, information of a particular control-invoking execution segment that is addressed to URS decoders, 203, appropriate meter-monitor information that includes the "program unit identification code" information of said programming of Q, any required padding bits.

Receiving said message at the station of Figs. 7 and 7F causes decoder, 203, to input the aforementioned control invoking instructions to its microcomputer, 205, thereby causing microcomputer, 205, to come under control of the computer system of the transmission of said studio.

(Decoder, 203, has capacity to turn power on to microcomputer, 205, and receiving said message may cause decoder, 203, first to turn power on to microcomputer, 205, before inputting control invoking instructions.)

5 Automatically, decoder, 203, also transfers meter-monitor information, causing to said onboard controller, 14A, to increment its signal record information of Q in the fashion described above.

(Receiving said synch-SPAM-reception message (#10) and  
10 said control-invoking message (#10) at the stations of said second subscriber and of said third subscriber causes apparatus at said stations, in the same fashion, to come under control of the computer system of said program originating studio.)

15 (At other stations that lack microcomputer, 205, capacity, that display only the conventional programming of the transmission of Q at a monitor, 202M, and that are preprogrammed to collect monitor information, receiving said messages at decoders, 145 and 282, causes decoders, 145 and  
20 282, and onboard controllers, 14A, of signal processors, 200, to process the meter-monitor information of said message, to initiate signal record information of said programming of Q, and at selected ones of said stations where recorders, 16, record signal record information and equal or exceed  
25 predetermined capacity, to transfer recorded signal record information to one or more remote auditing stations.)

Then said studio transmits said transmit-data-module-set message (#10), causing each intermediate transmission station, including the station of Fig. 6 and said second  
30 intermediate transmission station, to transmit its specific data-module-set message (#10), as described above.

Receiving the specific data-module-set message (#10) of its intermediate transmission station causes each ultimate receiver station to record one instance of the DATA\_OF.ITS  
35 information in said message in a particular file, named

"DATA\_OF.ITS" at so-called "RAM disk" memory of the microcomputer, 205, of said station. At the station of Figs. 7 and 7F, receiving the data-module-set message (#10) transmitted by the intermediate transmission station of Fig. 6 causes said message to be detected at decoder, 203, and causes decoder, 203, to load and execute at microcomputer, 205, the information segment of said message (which includes complete information of the aforementioned data file, DATA\_OF.ITS, of said station). Executing said information causes microcomputer, 205, to place said complete information at a so-called "D:" RAM disk at the RAM of said microcomputer, 205, in a file entitled, at the directory of said disk, "DATA\_OF.ITS". (Simultaneously, the microcomputer, 205, at the station of said second subscriber [which station is a also subscriber station of the intermediate transmission station of Fig. 6] receives the same data-module-set message (#10) and is caused, in the same fashion, to place complete information said aforementioned data file, DATA\_OF.ITS, at the "D:" RAM disk at said microcomputer, 205, in a file entitled "DATA\_OF.ITS". And the microcomputer, 205, at the station of said third subscriber [which station is a subscriber station of said second intermediate transmission station] receives the data-module-set message (#10) of said second intermediate station and is caused, in the same fashion, to place complete information the data file, DATA\_OF.ITS, of said second intermediate station at the "D:" RAM disk at said microcomputer, 205, in a file also entitled "DATA\_OF.ITS".) (Alternately, receiving the specific data-module-set message (#10) of its intermediate transmission station may cause each ultimate receiver station to record one instance of the DATA\_OF.ITS information in said message in a particular file, named "DATA\_OF.ITS", on appropriate recording medium of a peripheral disk drive, designated drive D:, of the microcomputer, 205, of said station.)

Then said studio transmits said transmit-and-execute-program-instruction-set message (#10), causing each intermediate transmission station, including the station of Fig. 6 and said second intermediate transmission station, to 5 transmit its specific program-instruction-set message (#10), as described above.

Receiving the specific program-instruction-set message (#10) of its intermediate transmission station causes each ultimate receiver station to record one instance of the 10 PROGRAM.EXE information in said message at particular RAM and execute the information so loaded as a machine language job. At the station of Figs. 7 and 7F, receiving the program-instruction-set message (#10) transmitted by the intermediate transmission station of Fig. 6 causes said message to be 15 detected at decoder, 203, and causes decoder, 203, to load and execute at microcomputer, 205, the information segment of said message (which is the program instruction set of Q.1 and is the output file, PROGRAM.EXE, of said station). As described above, the information of said segment includes 20 formula-and-item-of-this-transmission information of the higher language line of program code:

$$Y = 1000.00 + 62.21875 + (2.117 * X)$$

25 compiled and linked to other compiled information. (Simultaneously, the microcomputer, 205, at the station of said second subscriber receives the same program-instruction-set message (#10) and is caused, in the same fashion, to load and execute said program instruction set of Q.1 that is the information of the information segment of said message. And 30 the microcomputer, 205, at the station of said third subscriber receives the program-instruction-set message (#10) of said second intermediate station and is caused, in the same fashion, to load and execute the complete instructions of the output file, PROGRAM.EXE, of said second intermediate 35

station which is the information of the information segment  
of said last named message and is the program instruction set  
of Q.2. Said instructions so executed include formula-and-  
item-of-this-transmission information of the higher language  
5 line of program code:

$$Y = 1000.00 + 132.2362 + (2.0882 * X)$$

compiled and linked to other compiled information.)

10 Executing the specific program instruction set  
instructions received at each subscriber station causes the  
microcomputer, 205, of said station to generate its own  
specific information of a series of outputs.

Under control of the instructions of said program  
15 instruction set of Q.1, the microcomputer, 205, of Figs. 7  
and 7F generates image information of a first video overlay  
and generates selected information of subsequent overlays in  
the following fashion. Automatically, in a fashion well  
known in the art, microcomputer, 205, accesses its file  
20 A:DATA\_OF.URS and locates the aforementioned information  
of the particular address of the subscriber station of Figs.  
7 and 7F the accesses its file D:DATA\_OF.ITS and locates the  
aforementioned information of the particular street addresses  
of each of the markets of said supermarket chain that is in  
25 the locality of the intermediate station of Fig. 6. Then  
automatically, microcomputer, 205, accesses the  
aforementioned distance-and-relative-location module that,  
when accessed, computes the shortest vehicle driving distance  
between any two locations in the local vicinity of the  
30 station of Fig. 6 when passed two street addresses of said  
vicinity and passes to said module and passes to said module  
the address of said subscriber station and, one at a time,  
the address of each of said markets. Automatically, under  
control of the instructions of said module, microcomputer,  
35 205, computes the shortest vehicle distance and the relative

direction between said subscriber station and each of said markets. Then automatically, by comparing distance information, microcomputer, determines which market is closest to said subscriber station, that the distance between  
5 said subscriber station and said market is 4.3 miles, and that said subscriber station is southwest of said market. Automatically, microcomputer, 205, stores particular southwest-quadrant information at particular 1st working memory of said microcomputer, 205. Then automatically, on a  
10 machine language basis and in a fashion well known in the art, said microcomputer, 205, substitutes the value 4.3 for the variable X in the equation:

$$Y = 1000.00 + 62.21875 + (2.117 * X)$$

15 computes the value of Y that is specific the the station of Figs. 7 and 7F to be: 1071.32 (rounded in a fashion well known in the art); and stores 1071.32 information at particular 2nd working memory of said microcomputer, 205. Automatically, microcomputer, 205, clears video RAM; causes  
20 the background color of video RAM to be a color such as black that is transparent when combined with transmitted video by the PC-MicroKey System; causes binary image information of "\$1,071.32" to be placed at bit locations of video RAM that  
25 produce video image information in the upper left hand of a video screen when video RAM information is transmitted to said screen. (Simultaneously, under control of the instructions of said program instruction set of Q.1, the microcomputer, 205, at the station of said second subscriber  
30 computes and determines that the distance between said last named station and the market closest to said station is 8.7 miles and that said station is northwest of said market; stores particular northwest-quadrant information at particular 1st working memory of said microcomputer, 205;  
35 substitutes the value 8.7 for the variable X in its received

information of said last named equation and computes the value of Y that is specific the station of said second subscriber to be 1080.64 (rounded); stores 1080.64 information at particular 2nd working memory of said  
5 microcomputer, 205; clears and sets video RAM to said transparent background color; and causes binary image information of "\$1,080.64" to be placed at particular upper left hand video screen bit locations of video RAM. And under control of the instructions of said program instruction set  
10 of Q.2, the microcomputer, 205, at the station of said third subscriber computes and determines that the distance between said last named station and the closest selected market in the vicinity of said second intermediate transmission station is 3.2 miles and that said subscriber station is southeast of  
15 said market; stores particular southeast-quadrant information at particular 1st working memory of said microcomputer, 205; substitutes the value 3.2 for the variable X in its received information of the equation:

$$20 \quad Y = 1000.00 + 132.2362 + (2.0882 * X)$$

and computes the value of Y that is specific to the station of said third subscriber to be 1138.92 (rounded); stores 1138.92 information at particular 2nd working memory of said  
25 microcomputer, 205; clears and sets video RAM to said transparent background color; and causes binary image information of "\$1,138.92" to be placed at particular upper left hand video screen bit locations of video RAM.)

Then, under control of said instructions that  
30 constitute the specific program instruction set of the microcomputer, 205, of the station of Figs. 7 and 7F, said microcomputer, 205, generates and stores additional information of subsequent outputs, selects sound image information of a first audio overlay, and places said  
35 selected information at audio RAM. At the station of Figs.

7 and 7F, microcomputer, 205, computes the amount that the subscriber of said station will save by buying an untrimmed pork belly unit as compared with buying a trimmed pork belly unit at the aforementioned local market selected at said station. Automatically, microcomputer, 205, locates the aforementioned cost-of-a-trimmed-pork-belly-unit information in its file, D:DATA\_OF.ITS. Then, by subtracting the information stored at said 2nd working memory of said microcomputer, 205, (which is 1071.32) from said cost-of-a-trimmed-pork-belly-unit information (which is 1987.25), microcomputer, 205, automatically computes said amount to be 915.93 and saves information of 915.93 at particular 3rd working memory of said microcomputer, 205. Then microcomputer, 205, selects audio information that represents the percentage saving that said subscriber can save by buying an untrimmed pork belly unit in comparison to a trimmed pork belly unit at said market. Automatically, microcomputer, 205, clears its audio RAM. Then automatically, by dividing the information at said 3rd working memory (which is 915.93) by said cost-of-a-trimmed-pork-belly-unit information (which is 1987.25), microcomputer, 205, computes information of .4609 (rounded), which is the decimal equivalent of the percentage saving; determines that said information is greater than .4600 and less than .4700; and selects the audio information of an announcer's voice saying "forty-six" from among the information of said file, D:DATA\_OF.ITS; and places said information at audio RAM. (In similar fashion, the microcomputer, 205, at the station of said second subscriber computes information of the amount that the subscriber of said station will save by buying an untrimmed pork belly unit by subtracting the information stored at the aforementioned 2nd working memory of said microcomputer, 205, [which information is 1080.64] from the cost-of-a-trimmed-pork-belly-unit information of the program instruction set instructions received by said microcomputer, 205, [which

information is 1987.25]; stores the difference information so  
computed [which is 896.61] at particular 3rd working memory  
of said microcomputer, 205; clears the audio RAM of said  
microcomputer, 205; by dividing the information at said 3rd  
5 working memory [which is 896.61] by the cost-of-a-trimmed-  
pork-belly-unit information [which is 1987.25] at its file,  
D:DATA\_OF.ITS, computes information of .4562 [rounded], which  
is the decimal equivalent of the percentage saving of said  
second subscriber; determines that said information of .4562  
10 is greater than .4500 and less than .4600; selects the  
aforementioned audio information of an announcer's voice  
saying "forty-five" from its file, D:DATA\_OF.ITS; and places  
said information at said audio RAM. And the microcomputer,  
205, at the station of said third subscriber computes  
15 information of the amount that said subscriber will save by  
buying an untrimmed pork belly unit by subtracting the  
information stored at the 2nd working memory of said  
microcomputer, 205, [which is 1138.92] from the cost-of-a-  
trimmed-pork-belly-unit information of its file,  
20 D:DATA\_OF.ITS, [which information is 2021.42]; stores the  
difference information so computed [which is 882.50] at  
particular 3rd working memory of said microcomputer, 205;  
clears the audio RAM of said microcomputer, 205; computes  
information of .4366 [rounded], which is the decimal  
25 equivalent of the percentage saving of said second subscriber  
by dividing the information at said 3rd working memory [which  
is 882.50] by said cost-of-a-trimmed-pork-belly-unit  
information [which is 2021.42]; determines that said  
information of .4366 is greater than .4300 and less than  
30 .4400; selects the audio information of an announcer's voice  
saying "forty-three" from its file, D:DATA\_OF.ITS; and places  
said information at said audio RAM.)

As each subscriber station microcomputer, 205,  
completes placing selected information of an announcer's  
voice at audio RAM, the program instruction set instructions  
35

received by said microcomputer, 205, cause said microcomputer, 205, to pause, in a fashion well known in the art, and wait for an input instruction.

Meanwhile, in the conventional television programming transmission of Q, the video conveys television picture information of a large outdoor barbecue party, and the audio transmits information of an announcer saying:

"Think how much your friends enjoy outdoor barbecues."

Said studio transmits television picture information of the upper torso of a person and audio information of an announcer saying,

"For a limited time only, Super Discount Supermarkets make this special offer to you. Super Discount Supermarkets will deliver to you, at cost, all the pork you need to entertain five hundred people for this low, low price ... "

Said studio transmits television picture information of the right hand and arm of said person pointing moving to point at the upper left hand corner of the television screen.

At this moment, said studio embeds and transmits said 1st commence-outputting message (#10). Said message consists of a "00" header; execution segment information that is identical to the execution segment of the second message of the "Wall Street Week" example, appropriate meter-monitor information including "program unit identification code" information and overlay number field information, and any required padding bits. And each intermediate transmission station (including the intermediate station of Fig. 6 and said second intermediate station) receives and retransmits said message.

Receiving said message causes each subscriber station

that has completed the generation of first overlay image information at video RAM to combine its specific image information with the conventional video information transmitted by said studio and cause its specific monitor, 5 202M, to display the combined specific image information and transmitted video information. At the station of Fig. 7 and 7F, decoder, 203, detects the information of said message, and receiving said 1st commence-outputting message (#10) causes decoder, 203, to execute "GRAPHICS ON" at the PC- 10 MicroKey system of microcomputer, 205. Automatically, microcomputer, 205, combines its specific video RAM binary image information of "\$1,071.32" with its received conventional video information. And automatically \$1,071.32 is displayed at the upper left hand corner of the picture 15 screen of monitor, 202M, which is the corner to which the image of the person shown at said screen is pointing. (Simultaneously and in the same fashion, apparatus at the station of said second subscriber causes the specific video RAM image information of said station, which is "\$1,080.64", 20 to be displayed at the upper left hand corner of the picture screen of the monitor, 202M, of said station and said subscriber can see the image said person pointing at \$1,080.64. And at the station of said third subscriber, in the same fashion, apparatus causes the specific video RAM 25 image information of said station, which is "\$1,138.92", to be displayed at the upper left hand corner of the picture screen of the monitor, 202M, of said station and said third subscriber can see the image said person pointing at \$1,138.92.)

30 Said studio then transmits audio information of the announcer saying:

35 "Super Discount Supermarkets makes this offer--today only--at cost, and this offer represents a saving to you of over."

Then said program originating studio embeds and transmits said 2nd commence-outputting message (#10). Said message consists of a "00" header; particular audio-overlay execution segment information that is addressed to URS microcomputers, 205, appropriate meter-monitor information including "program unit identification code" information and overlay number field information, and any required padding bits. And each intermediate transmission station (including the intermediate station of Fig. 6 and said second intermediate station) receives and retransmits said message.

Receiving said 2nd commence-outputting message (#10) causes each subscriber station that has completed the generation of first audio image information at audio RAM to combine its specific image information to the conventional audio information transmitted by said studio and to emit sound of its combined specific audio information and its received conventional audio information at its specific monitor, 202M. At the station of Fig. 7 and 7F, decoder, 203, detects the information of said message, and receiving said 2nd commence-outputting message (#10) causes decoder, 203, to execute "SOUND ON" at the microcomputer, 205 of said station. Automatically, microcomputer, 205, transmits to monitor, 202M, via audio information transmission means, one instance of the information at the audio RAM of said microcomputer, 205, causing the emission of sound of said audio information, and the subscriber of said station can hear said announcer's voice saying:

"forty-six".

(Simultaneously, the microcomputer, 205, at the station of said second subscriber transmits to the monitor, 202M, of said station, via audio information transmission means, one instance of the information at the audio RAM of said

microcomputer, 205, causing emission of sound of said audio information, and said second subscriber can hear said announcer's voice saying:

5 "forty-five".

And the microcomputer, 205, at the station of said third subscriber transmits to the monitor, 202M, of said station, one instance of the information at the audio RAM of said  
10 microcomputer, 205, causing emission of sound of said audio information, and the sound of said announcer's voice saying:

"forty-three"

15 is what said third subscriber can hear.)

Then after an interval that is long enough for each subscriber station to emit sound of its specific audio RAM information, said studio transmits audio information of the announcer saying:

20 "percent."

Receiving said 2nd commence-outputting message (#10) causes each subscriber station that outputs audio information  
25 in this fashion, immediately after so transmitting one instance of its specific information at audio RAM, to continue executing instructions of its specific program instruction set at the next instruction following the aforementioned pause. Automatically, after outputting one  
30 instance of audio RAM information, each subscriber station clears its audio RAM, selects sound image information of a second audio overlay, and places said selected information at audio RAM. At the station of Figs. 7 and 7F, microcomputer, 205, clears its audio RAM then determines, in the  
35 predetermined fashion of said program instruction set of Q.1,

that the shopping list information at particular shopping-list memory at said station includes information of Patak's low-salt Vindaloo Curry Paste. So determining causes said microcomputer, 205, in said predetermined fashion, to select  
5 particular sound image information of an announcer's voice saying "low-salt Vindaloo" from among the information of its D:DATA\_OF.ITS file and to place said selected information at said audio RAM. (In similar fashion, at the station of said second subscriber, the microcomputer, 205, clears its audio  
10 RAM; determines that the shopping list information at the shopping-list memory at said station includes information of Patak's Quick Curry Paste (Mild); selects particular sound image information of an announcer's voice saying "Mild version Quick" from its D:DATA\_OF.ITS file; and places said  
15 selected information at said audio RAM. And at the station of said third subscriber, the microcomputer, 205, clears its audio RAM; determines that the information at its shopping-list memory includes information of Patak's Quick Curry Paste (Hot); selects particular sound image information of "Hot  
20 version Quick" from its D:DATA\_OF.ITS file; and places said selected information at said audio RAM.)

As each subscriber station microcomputer, 205, completes placing selected information of an announcer's voice at audio RAM, the program instruction set instructions  
25 received by said microcomputer, 205, cause said microcomputer, 205, to pause a second time and wait for an input instruction.

Meanwhile, as said studio continues to transmit television picture information of the person pointing to the upper left hand corner of the television screen, said studio  
30 transmits audio information of an announcer saying,

"To confirm this very special limited offer to you in writing, we are now printing, at your printer ..."

35

Then said program originating studio embeds and transmits said 3rd commence-outputting message (#10). Said message consists of a "00" header; particular print-output execution segment information that is addressed to URS  
5 microcomputers, 205; appropriate meter-monitor information including "program unit identification code" information and overlay number field information; and any required padding bits. And each intermediate transmission station (including the intermediate station of Fig. 6 and said second  
10 intermediate station) receives and retransmits said message.

Receiving said 3rd commence-outputting message (#10) causes each subscriber station to commence printing specific offer and coupon information at its printer, 221. At the station of Figs. 7 and 7F, decoder, 203, detects the  
15 information of said message, and receiving said 3rd commence-outputting message (#10) causes decoder, 203, to execute "PRINT OUT" at the microcomputer, 205 of said station. Under control of said program instruction set instructions received by said microcomputer, 205, microcomputer, 205,  
20 commences to generate print output information and to transmit said information to printer, 221. Automatically, microcomputer, 205, transmits to printer, 221, particular print information (that is transmitted to intermediate stations in the generate-set-information message (#10) as  
25 generally applicable information of the intermediate generation set of Q and is compiled and/or linked to become part of said program instruction sets of Q.1 and Q.2) of "Super Discount Supermarkets offers to deliver at cost one unit of untrimmed pork belly product, suitable for a large  
30 outdoor barbecue party, to:". Automatically, microcomputer, 205, accesses the file A:DATA\_OF.URS, selects information of the aforementioned particular address of the subscriber station of Figs. 7 and 7F, and causes said information to be printed at printer, 221. Automatically, microcomputer, 205,  
35 transmits additional print information of said program

instruction set of Q.1 to printer, 221, causing printer, 221, to print: "in exchange for this coupon and the sum of" and "\$". Automatically, microcomputer, 205, selects information of the aforementioned 1071.32 at said 2nd working memory and 5 transmits said information to printer, 221, causing printer, 221, to print: "1,071.32". Automatically, microcomputer, 205, transmits additional print information of said program instruction set of Q.1 including information of "15 cents off" and of "Nabisco Zweiback Teething Toast" (incorporated 10 into said generally applicable information at the station of Fig. 6).

At printer, 221, the printed so-called "hard copy" of said offer and coupon information emerges as:

15 . . . . .  
.  
Super Discount Supermarkets offers to deliver at .  
cost one unit of untrimmed pork belly product, .  
suitable for a large outdoor barbecue party, to: .  
20 .  
111 First St. .  
Anytown, Massachusetts .  
.  
in exchange for this coupon and the sum of: .  
25 .  
\$1,071.32 .  
.  
.  
.  
30 15 cents off . 15 cents off .  
.  
Nabisco Zweiback Teething Toast .  
.  
.  
35 . . . . .

(Simultaneously, at the station of said second subscriber, the decoder, 203, executes "PRINT OUT" at the 5 microcomputer, 205; said microcomputer, 205, transmits to the printer, 221, of said station the same print information of program instruction set of Q.1 together with selected information of the particular address of said second station and of the aforementioned 1080.64 at said 2nd working memory 10 of said microcomputer, 205; and printed hard copy offer and coupon information emerges at said printer, 221, as:

. . . . .  
.  
15 . Super Discount Supermarkets offers to deliver at .  
. cost one unit of untrimmed pork belly product, .  
. suitable for a large outdoor barbecue party, to: .  
.  
. 222 Second St. .  
. Anytown, Massachusetts .  
20 .  
. in exchange for this coupon and the sum of: .  
.  
. \$1,080.64 .  
25 .  
. . . . .  
. 15 cents off 15 cents off .  
.  
30 . Nabisco Zweiback Teething Toast .  
. . . . .

35

And at the station of said third subscriber, the decoder, 203, executes "PRINT OUT" at the microcomputer, 205; said microcomputer, 205, transmits to the printer, 221, of said station its received program instruction set print  
5 information [including information of "Cheerios Toasted Oat Cereal" that was incorporated at said second intermediate station into the generally applicable of the said intermediate generation set of Q instead of "Nabisco Zweiback Teething Toast"] together with selected information of the  
10 particular address of said second station and of the aforementioned 1138.92 at said 2nd working memory of said microcomputer, 205; and:

.....  
15 . Super Discount Supermarkets offers to deliver at .  
. cost one unit of untrimmed pork belly product, .  
. suitable for a large outdoor barbecue party, to: .  
.....  
20 . 333 Third St. .  
. Anothertown, Florida .  
.....  
. in exchange for this coupon and the sum of: .  
.....  
25 . \$1,138.92 .  
.....  
.....  
. 15 cents off . 15 cents off .  
30 . Cheerios Toasted Oat Cereal .  
.....  
.....

35

is the printed hard copy offer and coupon information that emerges at said printer, 221, at the station of said third subscriber.)

5           Then, having transmitted audio of an announcer saying, "To confirm this very special limited offer to you in writing, we are now printing, at your printer ..." (whereupon said 3rd commence-outputting message (#10) was transmitted and offer and coupon printing commenced), said studio then  
10 transmits audio of said announcer saying,

          "the current specials and coupon offers of Super Discount Supermarkets which include a special coupon for you with which you can buy enough pork for your  
15 own barbecue party."

(As said announcer makes this statement, the transmitted video image is of said person pointing to the upper left hand corner of the television screen where \$1,071.32 continues to  
20 be displayed at the station of Figs. 7 and 7F [while, simultaneously, \$1,080.64 is displayed at the station of said second subscriber, and \$1,138.92 is displayed at the station of said third subscriber].)

          Then said program originating studio embeds and transmits said 1st cease-outputting message (#10). Said  
25 message is identical to the aforementioned third message of the "Wall Street Week" example.

          Receiving said 1st cease-outputting message (#10) causes each subscriber station to cease combining and to  
30 display only the transmitted video information at its monitor, 202M. At the station of Figs. 7 and 7F, decoder, 203, detects the information of said message, and receiving said 1st cease-outputting message (#10) causes decoder, 203, to execute "GRAPHICS OFF" at the PC-MicroKey System of  
35 microcomputer, 205. In so doing, decoder, 203, causes said

PC-MicroKey to cease combining its specific image information with the conventional video information transmitted by said studio, to commence transmitting only the transmitted video information to monitor, 202M.

5 Receiving said message causes each subscriber station then temporarily to stop generating and outputting said print output information, to prepare to combine a second specific video overlay image, then to resume generating and outputting said print output information. At the station of Figs. 7  
10 and 7F, receiving said 1st cease-outputting message (#10) causes decoder, 203, after so executing "GRAPHICS OFF", to input the aforementioned clear-and-continue instruction to the CPU of microcomputer, 205. In the preferred embodiment, said instruction is inputted to said CPU as an interrupt  
15 signal. Receiving said clear-and-continue instruction as an interrupt signal causes microcomputer, 205, in a fashion well known in the art, to cease its current function, to store particular information at particular instruction-at-which-to-resume memory that identifies the location of the particular  
20 instruction at which to resume said function, and to execute a particular when-interrupted portion of said program instruction set of Q.1. Automatically, microcomputer, 205, ceases generating and transmitting said print output information, having just outputted information of "in  
25 exchange for this coupon and the sum of:" which causes printer, 221, to stop printing after printing "of:". (Simultaneously, receiving the interrupt signal of its station's clear-and-continue instruction at the microcomputer, 205, of the station of said second subscriber  
30 causes said microcomputer, 205, to cease generating and outputting its specific print output information, having just outputted information of "222 Second St." which causes the printer, 221, of said station to stop printing after printing "St.". And receiving its station's clear-and-continue  
35 instruction at the microcomputer, 205, of the station of said

third subscriber causes said microcomputer, 205, to cease generating and outputting its specific print output information, having just outputted information of "\$1,138.92" which causes the printer, 221, of said station to stop  
5 printing after printing ".92".) Then, under control of the instructions of said when-interrupted portion, microcomputer, 205, determines that said clear-and-continue instruction is the first instance of a clear-and-continue instruction that  
10 microcomputer, 205, has received while under control of said program instruction set of Q.1. So determining causes microcomputer, 205, to place "0" at particular Flag-interrupt register memory of said CPU that is normally "1" then to jump to a particular first-clear-and-continue address of the  
15 instructions of said program instruction set of Q.1 and to commence executing first-clear-and-continue instructions at said address. Automatically, under control of said instructions, microcomputer, 205, clears video RAM; sets the background color of video RAM to a transparent overlay black; determines that the aforementioned 1st working memory of said  
20 microcomputer, 205, holds southwest-quadrant information; selects from said D:DATA\_OF.ITS file information of the aforementioned southwest delivery route telephone number, "456-1414", and causes binary image information of said number to be placed at bit locations that produce video image  
25 information in the lower middle portion of a video screen. (Under control of the first-clear-and-continue instructions of its station's program instruction set of Q.1, the microcomputer, 205, of the station of said second subscriber clears video RAM; sets background to transparent black;  
30 determines that the 1st working memory of said microcomputer, 205, holds northwest-quadrant information; and causes binary information of the selected northwest delivery route telephone number, "224-3121", to be placed at particular lower middle video screen bit locations. And under control  
35 of the first-clear-and-continue instructions of its station's

program instruction set of Q.2, the microcomputer, 205, of the station of said third subscriber clears video RAM; sets background to transparent black; determines that the 1st working memory of said microcomputer, 205, holds southeast-  
5 quadrant information; and causes binary information of the selected southeast delivery route telephone number, "623-3000", to be placed at particular lower middle video screen bit locations.) Then said first-clear-and-continue instructions cause microcomputer, 205 to determine that the  
10 information at said Flag-interrupt register memory is "0", to place "1" at said Flag-interrupt register memory, and to resume generating and transmitting said print output information by executing the instruction located at the location identified by the information at said instruction-  
15 at-which-to-resume memory. Automatically, microcomputer, 205, commences generating and transmitting its specific output information, starting immediately after the aforementioned "of:", thereby causing printer, 221, to print:

20 .  
 . \$1,071.32 .",  
and the information that follows. (At the station of said second subscriber, the microcomputer, 205, resumes generating and transmitting its specific print output information, executing the instruction whose location is identified by the  
25 information at the instruction-at-which-to-resume memory of said microcomputer, 205, thereby causing the printer, 221, of said station to print:  
 .  
 . Anytown, Massachusetts .  
 .",

30 and the information that follows. And at the station of said third subscriber, the microcomputer, 205, resumes generating and transmitting its specific print output information, executing the instruction identified by the information at  
35 its instruction-at-which-to-resume memory, thereby its

printer, 221, to print: " .  
.  
.....  
."

5 and the information that follows.)

(In example #10, receiving said 1st cease-outputting message (#10) causes each subscriber station to cease combining and to display only the transmitted video information at its monitor, 202M; to stop generating and outputting particular output information; to generate second video overlay image information; then to resume generating and outputting said particular output information. The fact that the particular output information generated and outputted is print information that is outputted to a printer is only incidental to the present invention. Receiving said 1st cease-outputting message (#10) could as easily cause each subscriber station to stop generating and outputting then to resume generating and outputting any form of computer output information, outputted to any appropriate computer peripheral device. Said output could be data and/or computer program instructions outputted to a disk drive and caused to be recorded or outputted to a modem and caused to be transmitted. Said output could be audio and/or video information outputted to a monitor, 202M, and caused to be emitted as sound and/or displayed as picture information.)

25 Then, having caused locally generated video images to cease appearing in the the upper left hand corner of subscriber station television screens (including "\$1,071.32" at the station of Figs. 7 and 7F, "\$1,080.64" at the station of said second subscriber, and "\$1,138.92" at the station of said third subscriber), immediately said studio ceases transmitting a video image of of said person pointing to the upper left hand corner of the television screen.

30 Promptly said program originating studio commences transmitting the video image of the so-called "talking head"  
35

of said person standing in front of a background image of the logo of said program, "Exotic Meals of India," and transmits audio information of said announcer saying:

5 "Super Discount Supermarkets is proud to sponsor the television series, 'Exotic Meals of India.' Being truly exotic, many of the ingredients, can't be found in average supermarkets, but your friendly Super Discount manager is happy to supply all of these ingredients to your family. Tonight your personal recipe and shopping list call for Patak's"

10 Then said program originating studio embeds and transmits said 4th commence-outputting message (#10). Said message consists of a "00" header; said audio-overlay execution segment information that is addressed to URS microcomputers, 205; appropriate meter-monitor information including "program unit identification code" information and overlay number field information; and any required padding bits. And each intermediate transmission station (including the intermediate station of Fig. 6 and said second intermediate station) receives and retransmits said message.

20 Receiving said 4th commence-outputting message (#10) causes apparatus at each subscriber station that has completed the generation of second audio image information at audio RAM to combine its specific audio information to the transmitted audio and to emit sound of its combined audio. At the station of Fig. 7 and 7F, decoder, 203, receiving said 4th commence-outputting message (#10) causes decoder, 203, to execute "SOUND ON" at the microcomputer, 205 of said station. Automatically, microcomputer, 205, transmits to monitor, 202M, via audio information transmission means, one instance of the information at the audio RAM of said microcomputer, 205, causing the emission of sound of said audio information, and the subscriber of said station can hear said announcer's

35

voice saying:

"low-salt Vindaloo".

5 (Simultaneously, the microcomputer, 205, at the station of  
said second subscriber transmits to the monitor, 202M, of  
said station, via audio transmission means, one instance of  
its information at audio RAM, and said second subscriber can  
hear said announcer's voice saying

10

"Mild version Quick".

And at the station of said third subscriber, emission at the  
monitor, 202M, of sound of said announcer's voice saying

15

"Hot version Quick"

is caused by the microcomputer, 205.)

(The instructions of the program instruction sets of  
20 Q.1 and Q.2 do not cause subscriber stations to clear audio  
RAM after the audio combining caused by receiving said 4th  
commence-outputting message (#10).)

Then after an interval that is long enough for each  
subscriber station to emit sound of its specific audio RAM  
25 information, said studio transmits audio information of the  
announcer saying:

30 "Curry Paste. Your local Super Discount Supermarket  
has a complete line of Patak's Curry Paste products  
in stock. Call the telephone number,"

At this moment, said program originating studio embeds  
and transmits said 5th commence-outputting message (#10).  
Said message consists of a "00" header; execution segment  
35 information that is identical to the execution segment of the

second message of the "Wall Street Week" example, appropriate meter-monitor information including "program unit identification code" information and overlay number field information, and any required padding bits. And each  
5 intermediate transmission station (including the intermediate station of Fig. 6 and said second intermediate station) receives and retransmits said message.

Receiving said message causes each subscriber station that has completed the generation of second overlay image  
10 information at video RAM to combine its specific image information with the conventional video information transmitted by said studio and cause its specific monitor, 202M, to display the combined video information. At the station of Fig. 7 and 7F, receiving said 5th commence-  
15 outputting message (#10) causes decoder, 203, to execute "GRAPHICS ON" at the PC-MicroKey system of microcomputer, 205. Automatically, microcomputer, 205, combines its specific video RAM binary image information of "456-1414" with its received conventional video information. And  
20 automatically 456-1414 is displayed in the lower middle portion of the picture screen of monitor, 202M.

(Simultaneously and in the same fashion, apparatus at the station of said second subscriber causes the specific video RAM image information of said station, which is "224-3121",  
25 to be displayed in the lower middle portion of the picture screen of the monitor, 202M, of said station. And at the station of said third subscriber, in the same fashion, apparatus causes the specific video RAM image information of said station, which is "623-3000", to be displayed in the  
30 lower middle portion of the picture screen of the monitor, 202M, of said station.)

Said studio then transmits audio information of the announcer saying,

35 "that you see on your screen to have your order

delivered to your door. Or if you enter on your Widget Signal Generator and Local Input the information that you see here on your screen,"

5           Said studio transmits video information of said person pointing to the upper left hand corner of the video screen, and the image of "TV568\*" appears in said corner. Thus each viewer--including the subscriber of the station of Figs. 7 and 7F, said second subscriber, and said third subscriber--  
10 can see TV568\* in the upper left hand corner of the picture on the monitor, 202M, of his station.

          Said studio then transmits audio information of the announcer saying,

15           "your Super Discount manager will see that all the ingredients that you need for your personal 'Exotic Meals of India' fish curry recipe are delivered to you in time for dinner tomorrow. And as a special inducement to enter "TV568\*" on your Widget Signal  
20 Generator and Local Input now, your manager promises to include one jar of Patak's"

          Then said program originating studio embeds and transmits said 6th commence-outputting message (#10). Said  
25 message is identical to the 4th commence-outputting message (#10) except for different overlay number field information.

          In the same fashion that applied to receiving the 4th commence-outputting message (#10), receiving the 6th  
30 commence-outputting message (#10) causes apparatus at each subscriber station that has completed the generation of second audio image information to combine its specific audio information to the transmitted audio and to emit sound of its combined audio. At the station of Fig. 7 and 7F, decoder, the monitor, 202M, emits sound of said announcer's voice  
35 saying:

"low-salt Vindaloo".

(Simultaneously, the monitor, 202M, of the station of said  
5 second subscriber emits sound of said announcer's voice  
saying:

"Mild version Quick".

10 And at the station of said third subscriber, sound of said  
announcer's voice saying:

"Hot version Quick"

15 is emitted at the monitor, 202M.) After causing emission of  
audio information of the information at audio RAM once, the  
instructions of said program instruction sets of Q.1 and Q.2  
cause a microcomputer, 205, to clear audio RAM then pause.

Then after an interval that is long enough for each  
20 subscriber station to emit sound of its specific audio RAM  
information, said studio transmits audio information of the  
announcer saying:

25 "Curry Paste. Do it now! Enter 'TV568\*' on your  
Widget Signal Generator and Local Input or call the  
telephone number that you see on your television  
screen."

At the station of Figs. 7 and 7F, the subscriber  
30 enters TV568\* at the keyboard of local input, 225, which  
causes said input, 225, to transmit the aforementioned  
process-local-input instruction and said TV568\* information  
to the controller, 20, of the signal processor, 200, of said  
station. (And at the station of said third subscriber, said  
35 third subscriber enters TV568\* at the keyboard of his local

input, 225.)

Receiving said instruction and information causes the controller, 20, at each station where TV568\* is entered, in a predetermined fashion, to retain said TV568\* information at 5 particular last-local-input-\* memory.

Coincidentally, said program originating studio embeds and transmits said 2nd cease-outputting message (#10). Said message is identical to the aforementioned third message of the "Wall Street Week" example.

10 Receiving said 2nd cease-outputting message (#10) causes each subscriber station to cease combining and to display only the transmitted video information at its monitor, 202M. At the station of Figs. 7 and 7F, receiving said 2nd cease-outputting message (#10) causes decoder, 203, 15 to execute "GRAPHICS OFF" at the PC-MicroKey System of microcomputer, 205. Automatically, said PC-MicroKey ceases combining its specific image information with the conventional video information transmitted by said studio, and the image of 456-1414 disappears from the lower middle 20 portion of the picture screen of monitor, 202M. (Simultaneously and in the same fashion, at the station of said second subscriber, the image of 224-3121 disappears from the lower middle portion of the picture screen of the monitor, 202M, and at the station of said third subscriber, 25 the image of 623-3000 disappears from the lower middle portion of the picture screen of the monitor, 202M.)

Receiving said 2nd cease-outputting message (#10) causes each subscriber station then to clear video RAM and continue executing instructions of its specific program 30 instruction set of Q.1 or Q.2.

In due course, said studio ceases transmitting programming of said program unit of Q and recommences transmitting programming of said "Exotic Meals of India" program.

35 Subsequently, so continuing executing instructions of

its specific program instruction set of Q.1 or Q.2 causes apparatus at each subscriber station where where TV568\* has been inputted to a local input, 225, automatically to telephone a shopping list order. At the station of Figs. 7  
5 and 7F, under control of said program instruction set of Q.1, microcomputer, 205, measures elapsed time, in a fashion well known in the art, and determining that ninety seconds have passed from receiving said 2nd cease-outputting message (#10) causes microcomputer, 205, to input particular check-for-  
10 entered-TV568\*-and-respond instructions to the controller, 20, of signal processor, 200. Receiving said instructions causes controller, 20, to determine that TV567\* information exists at said last-local-input-\* memory and to transmit particular TV567\*-entered information to microcomputer, 205.  
15 Receiving said information causes microcomputer, 205, under control of said program instruction set of Q.1, to access said D:DATA\_OF.ITS file; to select information from said file of the aforementioned local-automatic-order-taking telephone number of the supermarket chain applicable in the vicinity of  
20 the intermediate transmission station of Fig. 6 which is 1-(800) 247-8700; to transmit to controller, 20, particular call-this-number-and-respond-with-"A:SHOPPING.EXE" instructions and information of 1-(800) 247-8700; and to record particular instructions at the recording medium of the  
25 disk at the A: disk drive of microcomputer, 205, in a file named "SHOPPING.EXE". Receiving said call-this-number-and-respond-with-"A:SHOPPING.EXE" instructions and information of 1-(800) 247-8700 causes controller, 20, in the fashion described above, to cause auto dialer, 24, to dial the  
30 telephone number, 1-(800) 247-8700. Automatically, in the fashion described above, controller, 20, establishes telephone communications with a computer of said super market chain at a remote station. Then said call-this-number-and-respond-with-"A:SHOPPING.EXE" instructions cause controller,  
35 20, to cause the instruction "A:SHOPPING.EXE" to be entered

to microcomputer, 205. Entering said instruction causes microcomputer, 205, to execute the instructions of said file, "SHOPPING.EXE" as a machine language job. Under control of said instructions, microcomputer, 205, transmits via  
5 controller, 20, to said computer at a remote station information of the street address of the station of Figs. 7 and 7F (selected from the file, A:DATA\_OF.URS) and complete information of the aforementioned file, A:SHOPPING.LST, which is the shopping list of the subscriber of said station. (At  
10 the station of said second subscriber where TV567\* has not been entered at the local input, 225, the controller, 20, does not transmit TV567\*-entered information to the microcomputer, 205, and all apparatus cease functioning under control of program instruction set of Q.1 instructions. And  
15 at the station of said third subscriber where TV567\* has been entered at the local input, 225, in similar fashion, the instructions of the program instruction set of Q.2 cause apparatus to telephone the aforementioned local-automatic-order-taking telephone number of the vicinity of said second  
20 intermediate station which is 1-(800) 371-2100 and to transmit information of the street address and shopping list of said third subscriber.)

In due course, after sufficient time has elapsed for each subscriber station where TV567\* has been entered at a  
25 local input, 225, to record information of a file named "SHOPPING.EXE" at a disk drive, said program originating studio embeds and transmits the aforementioned disband-URS-microcomputers-205 message (#10). Said message consists of a "10" header, information of a particular SPAM separate-  
30 subscriber-station-microcomputers-from-programming-transmission execution segment that is addressed to URS signal processors, 200, and any required padding bits.

Receiving said message at the station of Figs. 7 and 7F causes TV signal decoder, 203, to detect said message and  
35 input said message to the controller, 20, of signal

processor, 200.

Receiving said message causes controller, 20, to separate microcomputer, 205, from the computer system of said program originating studio and to cause the video and audio 5 output transmissions of tuner, 215, to be inputted to monitor, 202M. Automatically, controller, 20, executes particular controlled functions and determines, in a predetermined fashion, that microcomputer, 205, is outputting television audio and video to monitor, 202M, that 10 microcomputer, 205, receives from tuner, 215. Automatically, controller, 20, causes matrix switch, 258, to configure its switches so as to cease transferring audio information and video information inputted from said microcomputer, 205, to monitor, 202M, then to commence transferring audio 15 information and video information inputted from said tuner, 215, to monitor, 202M. Then automatically, controller, 20, causes matrix switch, 258, to cease transferring audio information and video information inputted from tuner, 215, to dividers, 202D and 4, respectively. Automatically, 20 decoder, 203, ceases receiving SPAM information.

Receiving said disband-URS-microcomputers-205 message (#10) may also cause controller, 20, (under control of information and instructions preprogrammed at controller, 20) to cause the microcomputer, 205, of the station of Figs. 7 25 and 7F to combine to and commence processing the SPAM information of the computer system of a second program originating studio that is different from said studio that originates the transmission of program unit Q (or in the case of example #9, that is different from the recorder, 76, that 30 transmits the prerecorded programming of Q). In this case, controller, 20, causes appropriate receiver apparatus to receive the transmission of said second studio; causes matrix switch, 258, to input audio and video information of the transmission of said programming to dividers, 202D and 4, 35 respectively; and inputs an interrupt signal of new-channel-

input information to the controller, 39, of decoder, 203.

Alternatively, receiving said disband-URS-  
microcomputers-205 message (#10) may also cause controller,  
20, (under control of information and instructions  
5 preprogrammed at controller, 20) to cause the microcomputer,  
205, revert from broadcast control to local control. In this  
case, in a predetermined fashion that is functionally the  
reverse of invoking broadcast control, controller, 20, causes  
microcomputer, 205, to clear all RAM (except for that portion  
10 of RAM containing operating system information) and all CPU  
registers and any other designated processors; then to load  
at RAM the information of a particular file such as  
"INTERUPT.BAK" that exists at a designated place on a  
particular disk at a particular disk drive; then to record  
15 at particular CPU registers selected information at  
designated locations at RAM; then to cause said CPU to  
resume processing in the fashion of a resumption that follows  
an interrupt and that is well known in the art. In so doing,  
controller, 20, causes microcomputer, 205, to revert from  
20 broadcast control to local control; to commence processing  
the particular job that was interrupted when broadcast  
control was invoked; and to commence so processing said job  
at the particular instruction at which invoking broadcast  
control interrupted the processing of said job.  
25 (Hereinafter, the steps associated with returning a  
microcomputer, 205, from broadcast control to local control  
are called "revoking broadcast control.")

(Receiving said disband-URS-microcomputers-205 message  
(#10) at the stations of said second subscriber and of said  
30 third subscriber causes apparatus at said stations to  
separate the microcomputers, 205, of said stations from the  
transmission of said studio that originates the transmission  
of program unit Q [or in the case of example #9, from the  
transmission of said recorder, 76] and may cause apparatus at  
35 either station, in the preprogrammed fashion of said

apparatus, to cause a microcomputer, 205, to combine to and commence processing the SPAM information of the computer system of a program originating studio that is different from said studio [or in the case of example #9, that is different from said recorder, 76] or may cause said apparatus to revoke broadcast control [thereby causing said apparatus to resume processing a station specific local job].)

(NOTE: Except for the content of their meter-monitor information, the messages transmitted in example #9 by the intermediate transmission station of Fig. 6 to the subscriber stations of its field distribution system, 93, are identical to the messages transmitted to the same field distribution system, 93, in example #10 and cause the same functioning. More precisely, except for their meter-monitor information content, said align-URS-microcomputers-205 message (#9), synch-SPAM-reception message (#9), data-module-set message (#9), program-instruction-set message (#9), 1st commence-outputting message (#9), 2nd commence-outputting message (#9), 3rd commence-outputting message (#9), 1st cease-outputting message (#9), 4th commence-outputting message (#9), 5th commence-outputting message (#9), 6th commence-outputting message (#9), 2nd cease-outputting message (#9), and disband-URS-microcomputers-205 message (#9) are all identical to the messages of like name of example #10. Furthermore, said program instruction set of Q of example #9 is identical to said program instruction set of Q.1 of example #10. Thus except as regards the collection of meter-monitor record information, transmitting the messages of example #9 causes precisely the same functioning at the stations of Figs. 7 and 7F and of said second subscriber as is caused by transmitting the messages of example #10.)

(In addition to the above described functioning, transmitting said messages in examples #9 and #10 causes apparatus at subscriber stations of particularly slow microcomputers, 205, said field distribution system, 93, to

function in the restoring efficiency fashion described above. Receiving each of said commence-outputting messages causes a decoder, 203, of at least one of said stations to input particular second-condition-test-failed instructions to its associated microcomputer, 205, causing said microcomputer, 205, to jump to and commence processing additional instructions of its received program instruction set of Q.1 rather than to commence outputting locally generated combined medium programming. For example, receiving said 1st  
10 commence-outputting message (#10) (or (#9)) causes at least one decoder, 203, of at least one station to input the aforementioned second-condition-test-failed instructions to a microcomputer, 205, causing at least one microcomputer, 205, to jump to and execute the instructions caused to be  
15 executed by the aforementioned clear-and-continue instructions described above. Automatically, said microcomputer, 205, ceases its current function; stores particular information at particular instruction-at-which-to-resume memory that identifies the location of the particular  
20 instruction at which to resume said function; executes the aforementioned when-interrupted portion of said program instruction set of Q.1 [or of Q in the case of example #9]; and determines, under control of the instructions of said portion, that said second-condition-test-failed instructions  
25 constitute the first instance of video overlay second-condition-test-failed instructions that microcomputer, 205, has received while under control of said program instruction set of Q.1 [or of Q]. So determining causes said microcomputer, 205, to jump to the aforementioned first-  
30 clear-and-continue address of the instructions of said program instruction set of Q.1 [or of Q] and to commence executing first-clear-and-continue instructions at said address. Automatically, said microcomputer, 205, clears video RAM; sets the background color of video RAM to  
35 transparent black; determines that 1st working memory of said

microcomputer, 205, holds particular quadrant information; and causes selected binary image information of said number a telephone number to be placed at bit locations that produce video image information in the lower middle portion of a  
5 video screen. Automatically, said microcomputer, 205, places information at particular Flag-interrupt register memory which information causes said microcomputer, 205, subsequently to jump over and not reexecute said first-clear-and-continue instructions. Then automatically, said  
10 microcomputer, 205, resumes executing instructions of said program instruction set of Q.1 [or of Q] at the location identified by the information at said instruction-at-which-to-resume memory.)

15 PREPROGRAMMING RECEIVER STATION OPERATING SYSTEMS

So-called "operating systems" are well known in the art and generally comprise the most basic form of processor control instructions. In order to control fundamental aspects of the processing of any given data file, such as a  
20 DATA\_OF.ITS or DATA\_OF.URS file, under control of any given computer program, such as a PROGRAM.EXE program, a computer is usually preprogrammed with an operating system that controls such fundamental aspects as, for example, so-called  
25 "input/output" functions. One such system that is commonly known as "PC-DOS" or "MS-DOS" is an operating system of the IBM personal computer, commonly known as the "IBM PC." (PC-DOS or MS-DOS is described in Disk Operating System of the IBM Personal Computer Computer Language Series.)

Many computers are designed to hold operating system  
30 instructions at RAM. The IBM PC is one such computer. When power is turned on to an IBM PC, under control of particular instructions that are permanently recorded at ROM and are commonly known as "ROM BIOS", said PC accesses a disk at a particular disk drive and loads the instructions of a  
35 particular prerecorded file from said disk to particular

locations of RAM in a fashion well known in the art that is commonly known as "booting."

One advantage of recording operating system instructions at memory such as RAM that can be conveniently  
5 overwritten relates to expanding system functions. New so-called "routines" can easily be entered into a given system to control existing apparatus of said system in new functions, and the operating system of a given system can be expanded easily to control newly installed apparatus. Thus  
10 many versions usually exist of any given operating system which versions have greater or lesser capacities. For example, versions 1.00, 1.10, 2.00, etc. exist of PC-DOS and MS-DOS. Each version has capacity for controlling the operation of an IBM PC, and later versions generally have  
15 expanded capacities in comparison to earlier versions.

Efficient operation of any given computer system of the present invention requires capacity to control the preprogramming of the operating system software of receiver station apparatus.

20 Receiver station apparatus of the present invention is extensive and can vary greatly from station to station. For example, apparatus that requires preprogramming at the station of Fig. 7, includes microcomputer, 205; controllers, 12 and 20, of signal processor, 200; the RAMs associated with  
25 the processors, 39B and 39D, and with the control processor, 39J, of decoder, 30, of signal processor, 200; and the RAMs associated with the processors, 39B and 39D, and with the control processor, 39J, of other decoders of said station such as decoders, 203 and 282. Other ultimate receiver  
30 stations can include less apparatus, more apparatus, or simply different apparatus. (For example, one receiver station may have the decoder, 203/SPAM controller, 205C, apparatus of example #1 while another station has the preferred decoder, 203, apparatus of example #3.)  
35 Furthermore, the complete computer system of a remote network

origination and control station such as the program originating studio that transmits the program unit of Q in example #10 involves apparatus not only at ultimate receiver stations but also at intermediate transmission stations.

5           One objective of the unified system of programming communication of the present invention is standardization of receiver station operating systems. With standardization, any given transmission station such as the program originating studio of example #10 can assemble and take  
10 control of a computer system of the computers of selected subscriber stations in the fashion described above in example #7 without any need to preprogram system software at any apparatus of said selected subscriber stations.

          Another objective of the present invention is  
15 flexibility and convenience in reprogramming operating systems in order to expand system functions.

          The present invention provides means and methods whereby one remote system master control station can preprogram all intermediate transmission stations and  
20 ultimate receiver station in a given geographical area (such as, for example, the continental United States of America) by transmitting a given sequence of SPAM messages that contain operating system instructions which sequence is received at and processed by all receiver stations and from which  
25 selected stations select selected messages that contain instructions of specific relevance. Each message is addressed to specific station SPAM control apparatus such as ITS computers, 73, in the case of intermediate transmission stations and URS signal processors, 200, in the case of  
30 ultimate receiver stations. Each message consists of a "01" header; execution segment information addressed to the appropriate station SPAM control apparatus; meter-monitor information that identifies not only a specific preprogrammable apparatus such as URS decoders, 203, but also  
35 the particular version of said apparatus (for example, URS

decoders, 203, of the version illustrated above in example #1 rather than example #3); padding bits as required; an information segment that consists, itself, of a particular SPAM message without an end of file signal; and an end of  
5 file signal. The information of each information segment consist of a "01" header; execution segment information addressed to said specific preprogrammable apparatus version which segment information causes said apparatus version to invoke its ROM preprogramming instructions; appropriate  
10 meter-monitor information that may include particular meter instructions; padding bits as required; and an information segment that contains the operating system instructions of said specific apparatus version.

Each appropriate receiver station apparatus that  
15 receives and processes a SPAM message of said sequence is preprogrammed with the necessary controlled-function-invoking information and controlled function instructions invoked by said message, and the information and instructions so invoked are preprogrammed at ROM.

20 Likewise, each specific receiver station SPAM control apparatus has access to specific information that is preprogrammed at non-volatile memory that identifies not only the specific preprogrammable apparatus (such as URS decoders, 203) of said station but also the particular version of said  
25 apparatus (for example, URS decoders, 203, of the version illustrated above in example #3).

Fig. 8 illustrates the installation of the station specific non-volatile memory apparatus that identifies specific preprogrammable apparatus of the station of Fig. 7.  
30 Said specific non-volatile memory apparatus is station specific EPROM, 20B. Station specific EPROM, 20B, is reprogrammed whenever apparatus is installed at or removed from the station of Figs. 7 and 8 and contains not only information that identifies specific preprogrammable  
35 apparatus of said station but also switch control

instructions that identify which particular apparatus input to the specific inputs of matrix switch, 259; that identify which particular outputs of said matrix switch, 259, output to which particular station apparatus; and that control  
5 switch controller, 20A, in causing matrix switch, 259, to configure its switches to transfer information from one given station apparatus to another. Station specific EPROM, 20B, is mounted in a cartridge and inserted manually into switch controller, 20A, in a fashion well known in the art, at a  
10 port in the equipment case of signal processor, 200. Station specific EPROM, 20B, is also preprogrammed with information of a specific operating system master control frequency of the station of Fig. 7. (Fig 8 also illustrates other selected apparatus and programming and control information  
15 transmission means that process SPAM information in the course of the preprogramming of operating system instructions at selected apparatus of the station of Fig. 7.)

At other ultimate receiver stations, other station specific EPROMs, 20B, are installed in the same fashion with  
20 each station specific EPROM, 20B, containing programmed information of the specific apparatus and apparatus versions of its specific station and a specific operating system master control frequency. (Similar station specific non-volatile memory apparatus is installed at each computers, 73,  
25 of an intermediate station such as the station of Fig. 6 which non-volatile memory apparatus identifies the specific preprogrammable apparatus of said station.)

An example that focuses, in particular, on preprogramming operating system instructions at the station  
30 of Figs. 7 and 8 illustrates preprogramming receiver station operating systems.

At a particular time such as, for example, 4:00 AM Eastern Standard Time on January 3, 1989, the controller, 20,  
of the signal processor, 200, of said station causes the  
35 oscillator, 6, switch, 1, and mixer, 3, of the signal

processor, 200, of the station of Fig. 7 to input a selected frequency to the decoder, 30, and causes said decoder, 30, to commence processing the information of said frequency. Said selected frequency is the specific operating system master control frequency of the information preprogrammed at station specific EPROM, 20B. (Said controller, 20, may be caused so to function in any of the fashions described above that cause a controller, 20, to function. For example, said remote system master control station may transmit particular SPAM message information that causes apparatus at each receiver station, in the fashion of the news items of "AUTOMATING U. R. STATIONS ... RECEIVING SELECTED PROGRAMMING" above, to tune to and commence processing SPAM information embedded in its preprogrammed specific operating system master control frequency at a selected decoder which decoder is said decoder, 30. Controller, 20, may also cause selected station apparatus such as earth station, 250, and satellite receiver circuitry, 251, to receive the transmission of said frequency and cause selected station apparatus such as matrix switch, 258, to input said transmission to a selected contact of said switch, 1.)

At 4:01 AM, said remote system master control station transmits a SPAM end of file signal causing each receiver station, including the station of Figs. 7 and 8, to commence identifying and processing the individual SPAM messages embedded in said transmission.

Then said remote master control station commences transmitting said sequence of SPAM messages that contain operating system instructions causing each receiver station to select those specific SPAM messages that contain information applicable to specific preprogrammable apparatus and to program said apparatus.

Said remote station transmits a first SPAM message that contains meter-monitor information of an APPLE II microcomputer, 205, apparatus version and an information

segment that contains SPAM message information of APPLE II microcomputer operating system instructions. (APPLE II microcomputers are well known in the art.)

Receiving said message causes the apparatus of the station of Figs. 7 and 8 to determine that the microcomputer, 205, of said station is not an APPLE II microcomputer and to discard all information of said message. Automatically, decoder, 30, detects said message and executes particular controlled function instructions that cause decoder, 30, to transfer all information of said message, via buffer/comparator, 8, to controller, 12. Automatically, controller, 12, loads the command information (and associated padding bits) of said message at its SPAM-input-signal register memory, executes particular controlled functions, selects the particular meter-monitor information that identifies a specific preprogrammable apparatus version, and inputs to controller, 20, a particular preprogrammed operating-instructions-received-for-specific-apparatus instruction as an interrupt signal together with said information that identifies a specific apparatus version. Receiving said instruction and information causes controller, 20, to transfer said instruction and information to switch controller, 20A, causing switch controller, 20A, to determine, in a predetermined fashion, that no information of an APPLE II microcomputer, 205, exists at station specific EPROM, 20B. So determining causes switch controller, 20A, to transmit a particular preprogrammed discard-operating-system-message instruction to controller, 20, causing controller, 20, to transmit said instruction to controller, 12. Receiving said instruction causes controller, 12, to discard all information of said first SPAM message. (Simultaneously, at stations where the microcomputers, 205, are APPLE II microcomputers, receiving said first message causes apparatus, in a fashion described more fully below, to cause the operating system instructions of said message to be

recorded at disk drives of said APPLE II microcomputers, 205, and so-called "booted" at said APPLE II microcomputers, 205.)

Then said remote station transmits a second SPAM message that contains meter-monitor information of an IBM PC 5 microcomputer, 205, apparatus version and an information segment that contains SPAM message information of IBM PC microcomputer operating system instructions.

Receiving said message causes apparatus of the station of Figs. 7 and 8 to determine that the microcomputer, 205, of 10 said station is an IBM PC microcomputer and to input the contained SPAM message information of said second SPAM message to decoder, 203. Automatically, decoder, 30, detects said message and transfers all information of said message to controller, 12. Automatically, controller, 12, loads at its 15 SPAM-input-signal memory the command information of said message and any padding bits immediately following said command information, selects the meter-monitor information that identifies a specific preprogrammable apparatus version--that is, an IBM PC--and inputs to controller, 20, 20 said operating-instructions-received-for-specific-apparatus instruction together with said information that identifies an apparatus version. Receiving said instruction and information causes controller, 20, to transfer said instruction and information to switch controller, 20A, 25 causing switch controller, 20A, to determine, in a predetermined fashion, that said meter-monitor information that identifies a specific preprogrammable apparatus version matches information that is preprogrammed at station specific EPROM, 20B, and that identifies specific preprogrammable 30 apparatus of the station of Figs. 7 and 8--in other words, to determine that an IBM PC is the microcomputer, 205, of said station. So determining causes switch controller, 20A, in a predetermined fashion, to cause matrix switch, 259, to configure its switches so as to transfer information inputted 35 from controller, 12, to decoder, 203, then causes switch

controller, 20A, to transmit a particular preprogrammed transfer-operating-system-message instruction to controller, 20, causing controller, 20, to transmit said instruction to controller, 12. Receiving said instruction causes  
5 controller, 12, to transmit to matrix switch, 259, all information of said second SPAM message after said command and padding bit information recorded at said SPAM-input-signal register memory. In so doing, controller, 12, transfers the information segment and end of file signal of  
10 said second message to matrix switch, 259, and causes said switch, 259, to input said information to decoder, 203. (Simultaneously, at stations where the microcomputers, 205, are APPLE II microcomputers, receiving said second message causes the controllers, 12, [functioning with controllers, 20  
15 and 20A, and with EPROMs, 20A] to cause all information of said message to be discarded.)

Said information that is inputted to decoder, 203, is the contained SPAM message of said second SPAM message, and having been separated from the command information and  
20 immediately following padding bits of said second SPAM message, said contained SPAM message is a SPAM message in its own right. Said contained message consists of a "01" header; execution segment information that is addressed to URS decoders, 203, of IBM PCs and that causes said decoders,  
25 203, each to invoke its ROM instructions for entering operating system instructions into its microcomputer, 205; appropriate meter-monitor information that may include particular meter instructions; padding bits as required; and an information segment that contains the SPAM operating  
30 system instructions of an IBM PC microcomputer. Immediately following the last bit of said information segment is the end of file signal of said second SPAM message which is also the end of file signal of said contained SPAM message. (Another benefit of the message composition fashion of the present  
35 invention, which places distinctive signals at the end of

messages rather than the beginning, is capacity to transmit any number of contained SPAM messages within the information segment of any given SPAM message that has an information segment and thus that ends with an end of file signal. Said  
5 contained messages may be sequential messages or may be nested in the sense of each being contained in the information segment of its preceding message.)

Receiving said contained SPAM message causes decoder, 203, to cause the operating system instructions of said  
10 message to be recorded on the recording medium of a disk at a particular disk drive of microcomputer, 205, and to cause microcomputer, 205, to boot the operating system so recorded. Automatically, decoder, 203, executes the controlled functions of its ROM instructions for entering operating  
15 system instructions into microcomputer, 205. Automatically, decoder, 203, interrupts the operation of the CPU of microcomputer, 205, and inputs particular instructions to said CPU that cause microcomputer, 205, to load received information in a file at RAM. Automatically, decoder, 203,  
20 commences inputting the information segment information of said contained message to microcomputer, 205, and microcomputer, 205, records said inputted information in said file at RAM. Then receiving said end of file signal causes decoder, 203, to cease inputting information segment  
25 information to microcomputer, 205, and to cause microcomputer, 205, to record the information of said file in a designated file such as "COMMAND.COM" on a disk at a designated disk drive such as drive A:. In so doing, receiving said message causes the operating system  
30 instructions in said message to be recorded at the particular disk drive and in the particular file from which the ROM BIOS of said microcomputer, 205, is preprogrammed to load the operating system of said microcomputer, 205, at boot time. When microcomputer, 205, completes recording the information  
35 of said file at said disk drive, microcomputer, 205, inputs

particular preprogrammed file-recorded information to decoder, 203. Receiving said file-recorded information causes decoder, 203, under control of said ROM instructions for entering operating system instructions, to turn power to 5 said microcomputer, 205, off then on (which decoder, 205, has capacity to do). Automatically, microcomputer, 205, under control of the instructions of said ROM BIOS, boots the instructions of the disk drive file A:COMMAND.COM in a fashion well known in the art, loads the operating system 10 instructions of said file (which are the operating system instructions of said contained SPAM message) at operating system memory, and commences to function at so-called "operating system level" under control of said instructions. (Simultaneously, at other stations where the microcomputers, 15 205, are IBM PC microcomputers, receiving said contained SPAM message of said second SPAM message causes other decoders, 203, and microcomputers, 205, to cause the operating system instructions of said contained message to be recorded and booted in the same fashion.)

20 Then said remote station transmits a third SPAM message that contains meter-monitor information of a decoder, 203, apparatus of the example #3 version and an information segment that contains SPAM message information of decoder, 203, of example #3 operating system instructions. (The 25 operating system of a SPAM apparatus such as a decoder, 203, contains all instructions required at said apparatus to control the operation of said apparatus. SPAM apparatus operating system instructions include, in particular, the controlled function instructions and controlled-function- 30 invoking information of said apparatus. Permanent operation system instructions of any given SPAM apparatus are recorded at the ROM of said apparatus.)

Receiving said third message causes apparatus of the station of Figs. 7 and 8 to determine that a decoder, 203, 35 apparatus of the example #3 version exists at said station

and to input the contained SPAM message information of said third SPAM message to decoder, 203. Automatically, decoder, 30, detects said message and transfers all information of said message to controller, 12. Automatically, controller, 5 12, selects the meter-monitor information that identifies a specific preprogrammable apparatus version--that is, an example #3 version of a decoder, 203--and inputs to controller, 20, said operating-instructions-received-for-specific-apparatus instruction together with said information 10 that identifies an apparatus version. Automatically, controller, 20, transfers said instruction and information to switch controller, 20A, causing switch controller, 20A, to determine, in a predetermined fashion, that said information that identifies an apparatus version matches information that 15 is preprogrammed at EPROM, 20B, and that identifies the decoder, 203, of said station. Automatically, switch controller, 20A, causes matrix switch, 259, to configure its switches so as to transfer information inputted from controller, 12, to decoder, 203, then transmits said 20 transfer-operating-system-message instruction to controller, 20, causing controller, 20, to transmit said instruction to controller, 12, and causing controller, 12, to transmit to matrix switch, 259, all information of the information segment and end of file signal of said third SPAM message. 25 In so doing, controller, 12, inputs said information segment and end of file signal to decoder, 203. (Simultaneously, at stations where the decoders, 203, are of the version of example #1, receiving said third message causes controllers, 12, [functioning with controllers, 20 and 20A, and with 30 EPROMs, 20A] to discard all information of said message.)

Said information that is inputted to decoder, 203, is the contained SPAM message of said third SPAM message and is a complete SPAM message in its own right. Said contained message consists of a "01" header; execution segment 35 information that is addressed to URS decoders, 203, of the

example #3 version and that causes said said decoders, 203, each to invoke its ROM instructions for entering operating system instructions into its RAM; appropriate meter-monitor information that may include particular meter instructions; 5 padding bits as required; and an information segment that contains the SPAM operating system instructions of an example #3 version decoder, 203. Immediately following the last bit of said information segment is the end of file signal of said third SPAM message which is also the end of file signal of 10 said contained SPAM message.

Receiving said contained SPAM message causes decoder, 203, to record the operating system instructions of said message at particular operating system locations at the RAMs of decoder, 203, and to commence operating under control of 15 said instructions. Automatically, control processor, 39J, compares the execution segment information of said message to controlled-function-invoking information and determines that said execution segment information matched particular load-operating-system-of-203 information that is preprogrammed at 20 the ROM associated with control processor, 39J, and that invokes particular load-operating-system-of-203 instructions that are are preprogrammed at the ROM associated with control processor, 39J. Automatically, control processor, 39J, executes said instructions and, under control of said 25 instructions, causes processor, 39B, to cease receiving information from buffer, 39A, then loads all information of the information segment of said message sequentially at the RAM associated with control processor, 39J, (which has capacity to contain all information of an operating system of 30 an example #3 version decoder, 203) starting at the first bit location of said RAM and overwriting, if necessary, the information of all bit locations of said RAM. Then, receiving interrupt information of an end of file signal from EOFs valve, 39F, causes control processor, 39J, 35 automatically, under control of said load-operating-system-

of-203 instructions, to load all information so loaded at selected operating system locations of decoder, 203. Automatically, control processor, 39J, selects particular information at particular first bit locations of said RAM 5 (which information is particular first binary information of the information segment of said contained SPAM message) and determines the composition of the operating system information so recorded at RAM by processing said information in a predetermined fashion under control of said load- 10 operating-system-of-203 instructions. Automatically, control processor, 39J, inputs particular commence-loading-operating-system instructions to processor, 39B; selects the binary information of particular bit locations at said RAM; and inputs said information to processor, 39B, thereby causing 15 processor, 39B, to record said information sequentially at particular operating system locations of the RAM associated with said processor, 39B, beginning at the first bit location of said RAM. Automatically, control processor, 39J, then inputs said commence-loading-operating-system instructions to 20 processor, 39D; selects the binary information of particular bit locations at said RAM associated with said control processor, 39J; and inputs said information to processor, 39D, thereby causing processor, 39D, to record said information sequentially at particular operating system 25 locations of the RAM associated with said processor, 39D, beginning at the first bit location of said RAM. Automatically, control processor, 39J, then selects the binary information of a particular first signal word of bit locations and a particular second signal word of bit 30 locations at said RAM associated with said control processor, 39J; and inputs said selected information separately to EOFS valves, 39F and 39H, thereby causing said valves, 39F and 39H, each to record at its EOFS Standard Word Location the information of said first signal word of bit locations and at 35 its EOFS Standard Length Location the information of said

second signal word of bit locations. In so doing, receiving said third messages may causes said decoder, 203, subsequently to commence detecting end of file signals of new composition and/or length. (In other words, thereafter said valves, 39F and 39H, may detect end of file signals that are composed of, for example, fifteen sequential instances of "11101110" binary information rather than eleven sequential instances of "11111111" binary information.) Automatically, control processor, 39J, then moves selected binary information of particular bit locations at said RAM associated with said control processor, 39J, to particular operating system locations of said RAM, beginning at the first bit location of said RAM. In so doing, control processor, 39J, completes causing all operating system instructions of said contained SPAM message to be located at the appropriate operating system RAM locations of said decoder, 203. Then automatically, under control of said commence-loading-operating-system instructions, control processor, 39J, causes all buffer, non-operating system RAM, and non-operating system register locations of decoder, 203, (except for buffer, 39A) to be cleared; causes all other apparatus of decoder, 203, to commence processing under control of the new operating system instructions; causes processor, 39B, to commence receiving and processing information from buffer, 39A; and commences waiting for information of a SPAM header under control, first, of a particular new operating system instruction that is located at a predetermined location said RAM associated with control processor, 39J. (Simultaneously, at other stations where the decoders, 203, are of the example #3 version, receiving said third SPAM message causes other apparatus to load the operating system instructions of the contained SPAM message of said third message at the appropriate operating system RAM locations of said decoders, 203, and causes said decoders, 203, to come under control of said instructions in the same

fashion.)

Subsequently, said remote station transmits additional operating system SPAM messages until one SPAM message has been transmitted that is addressed to each separate version 5 of SPAM apparatus. Each message contains meter-monitor information of its apparatus version and an information segment that contains SPAM message information operating system instructions of said version.

Receiving each message causes apparatus of each 10 receiving station, in the fashions described above, to determine whether an apparatus of the apparatus version identified by the meter-monitor information of said message exists at said station, to input a contained SPAM message to an apparatus of said apparatus version if an apparatus of 15 said apparatus version exists at said station, and to discard all information of said message if no apparatus of said apparatus version exists at said station. (Said contained messages that are addressed to apparatus such as decoder, 30, PRAM controller, 20, and switch controller, 20A, that exist 20 within the equipment case of a signal processor, 200, are inputted to said apparatus from controller, 12, via controller, 20, rather than via matrix switch, 259.)

Receiving each contained SPAM message causes the apparatus version of said message, in the fashion described 25 above, to record the operating system instructions and information of said message to at particular operating system locations at the RAMs and EOFs valves that control the operation of said apparatus and to commence operating under control of said instructions and information.

Following the transmission of each message, for a 30 particular interval of time no SPAM information is transmitted that is causes any processing at any apparatus of the apparatus version of message. Said interval is the length of time required for the slowest apparatus of said apparatus version to receive said message, record the 35

operating system instructions and information of said message, and commence operating under control of said instructions and information.

5 THE PREFERRED SPAM HEADER

An important feature of the preferred embodiment of the present invention is flexibility for expansion while continuing to accommodate, within the unified system, existing information requirements. Subscribers who have  
10 simple information demands must have capacity to receive and process simple SPAM messages with simple subscriber station apparatus. Such simple messages may contain, for example, only sixty-four alternate instances of SPAM execution segment  
15 binary information, and the optimal length of SPAM execution segment information for such subscribers would be six binary digits. Simultaneously, subscribers who have complex information demands must have capacity to receive and process more complex SPAM messages that control more extensive subscriber station apparatus. Controlling the subscriber  
20 station apparatus of subscribers who have complex information demands far more execution segment capacity than is provide by a system that has only six binary digits of execution segment information transmission capacity. And invariably, many different classes of subscriber will exist with  
25 different information demands and different optimal SPAM execution segment lengths.

Two objectives of the unified system of the present invention are to provide capacity whereby any given transmission can transmit SPAM messages to all classes of  
30 subscribers and capacity whereby the apparatus of subscribers with complex information demands can process not only complex messages but also simple messages. More precisely, the present invention provides means and methods whereby SPAM messages of different execution segment lengths can be  
35 transmitted, intermixed on one transmission, and complex SPAM

receiver apparatus with capacity to process long SPAM execution segment information can also process short SPAM execution segment information.

In the preferred embodiment these objectives are realized by having SPAM header information identify not only the four alternate message compositions of the simplest preferred embodiment specified above but also many alternate versions of message composition.

In the preferred embodiment, the length of a SPAM header--and of the SPAM-header register memory of any given SPAM apparatus--is the length of one signal word which is one byte of eight binary digits. SPAM messages are composed of varying numbers and sequences of segments of highest priority, intermediate priority, and lowest priority segment information. Complex SPAM receiver apparatus have means and are preprogrammed to process at register memory execution segment information of varying lengths of binary information. And simple SPAM receiver apparatus are preprogrammed to process at RAM and/or ROM SPAM messages that are too complex to be processed at their register memories (if only to discard said messages).

#### A SUMMARY EXAMPLE #11 ... AND THE GENERAL CASE

The full scope of the unified system of programming communication of the present invention comprehends and includes all of the above described apparatus and methods in all of their variations.

An example #11 that focuses on generating and communicating information of farmers at a time in the future illustrates a few features of the full scope of the present invention.

In February, 2027, farmers all over Europe make plans regarding which crops to plant for the 2027 growing season. Each farmer is confronted with the problem of deciding what mix of crops is most profitable to grow on his property,

given his resources. Each farmer has a subscriber station that is identical to the station of Fig. 7 except that each station has two television recorder/players that are recorder/players, 217 and 217A; two television tuners, 215 and 215A; and a laser disk player, 232. Particular farm information of the specific farm of each farmer is recorded  
5 in a file named MY\_FARM.DAT on a disk at the A: disk drive of the microcomputer, 205, of each station. The recorded data includes, for example, data of the number and size of the individual parcels of property of the farmer's farm, the soil conditions of said parcels, the aspects of said parcels with  
10 respect to sunlight and shade, the history of crop rotation of said parcels, the farm equipment of said farmer, and the financial resources of said farmer. Each farmer's laser disc player, 232, is loaded with a so-call "optical disk" on which is recorded a file named "PROPRIET.MOD" that contains  
15 encrypted information of a proprietary software module. When accessed, the instructions of said module cause a microcomputer, 205, to analyze any given crop planting plan and generate information of a recommended planting plan and growing method that minimizes the expense of insect and other  
20 crop pest damage given maximum revenue.

Elsewhere and at the same time, national planners of each member nation of the European Economic Community seek to formulate agricultural policy for the 2027 growing season and to communicate information of that policy to farmers, thereby  
25 influencing the farmers' decisions regarding which crops to plant. Each nation has a national intermediate transmission station that is identical to the intermediate station of Fig. 6 except that it transmits output information of several individual television channels to receiver stations via a  
30 satellite in geosynchronous orbit over Europe rather than via a cable field distribution system. At the computer, 73, of each national intermediate transmission station is local-formula-and-item information of specific data, in a file

35

named NATIONAL.AGI, regarding proposed subsidy formulas and items regarding the various alternate crops that farmers of the nation may choose to grow.

5 Simultaneously, other national planners of each nation seek to formulate other economic policies including tax and revenue raising policies and monetary policies. At the computer, 73, of each national intermediate transmission station, in a file named NATIONAL.TAX, is local-formula-and-item information of specific proposed tax formulas and items  
10 regarding, for example, taxes on farm incomes and proposed depreciation schedules of farm equipment. And in a file named NATIONAL.MON is local-formula-and-item information of specific proposed money supply growth rates and interest rates.

15 Each nation also has a plurality of local governments at which local planners seek to formulate local tax and revenue raising policies and welfare and subsidized employment policies. Each local government has a local intermediate transmission station that is identical to the  
20 intermediate station of Fig. 6 and that transmits multiplexed output information of several separate television channels via a cable field distribution system. At the computer, 73, of each local intermediate transmission station, in a file named LOCAL.TAX, is local-formula-and-item information of  
25 specific proposed tax formulas and items regarding, for example, income taxes that relate to farmers and property taxes that relate to farm land and equipment. And in a file named LOCAL.EMP is local-formula-and-item information of specific proposed employment subsidy formulas relating to  
30 local unemployed persons which formulas vary with respect to the specific education levels of the unemployed.

Just as government planners wish to communicate policy information to and receive response information from farmers, so too, businessmen wish to advertise to farmers the benefits  
35 of their goods and proprietary information services and to

persuade farmers to respond by ordering their goods and services.

Each farmer's station has capacity and is preprogrammed to receive programming transmitted via  
5 satellite by a particular European master network origination and control station and the specific national intermediate transmission station of the specific nation of said farmer and is a subscriber station in the field distribution system of the local intermediate transmission station of the  
10 farmer's local government.

At 3:00 AM Greenwich Mean Time on Monday, February 15, 2027, the signal processor of each receiver station in the nations of the European Economic Community--including each national and each local intermediate transmission station and  
15 each ultimate receiver station of a farmer--commences receiving information of the particular master transmission of said European master network station. Automatically, the controller, 20, of the signal processor of each receiver station in said nations causes its oscillator, 6, switch, 1,  
20 and mixer, 3, to input a selected frequency to its decoder, 30, and causes said decoder, 30, to commence processing the information of said frequency. Said selected frequency is the specific operating system master control frequency of the information preprogrammed at its station specific EPROM, 20B.  
25 Automatically each receiver station that is equipped with a satellite earth station (50 in Fig. 6 or 250 in Fig. 7) receives and inputs to its switch, 1, information of a particular master transmission of said European master network station. Then the controller, 20, of the signal  
30 processor of the signal processor system, 71, of each intermediate transmission station (of Fig. 6) in said nations causes the computer, 73, of said station to cause apparatus of said station also to retransmit information of said master transmission on the frequency of a selected master channel  
35 transmission. Automatically each receiver station that is

not equipped with a satellite earth station commences receiving and inputting to its switch, 1, information of said master transmission that is retransmitted on the frequency of a selected master channel transmission of a selected intermediate transmission station.

At 3:10 AM, GMT, said European master network station transmits particular SPAM message information, embedded in the information of said master transmission, including a SPAM end of file signal and the aforementioned sequence of SPAM messages that contain operating system instructions. In so doing, said European master network station inputs operating system instructions to all SPAM apparatus and receiver station computers, 73, and microcomputers, 205, thereby causing said apparatus and computers, 73 and 205, as described above in "PREPROGRAMMING RECEIVER STATION OPERATING SYSTEMS," to commence operating under control of the instructions of said operating systems.

Causing each signal processor at every receiver station in said nations to commence operating under control of its specific operating system instructions causes apparatus of each signal processor to commence processing sequentially information of a plurality of specific frequencies in the fashion of example #5 to detect program unit identification signal information. One frequency that is processed at each receiver station is the specific operating system master control frequency of the information preprogrammed at the station specific EPROM, 20B, of said station. Said frequency is either said master transmission of said European master network station or a selected master channel transmission of a selected intermediate transmission station upon which information of said master transmission is retransmitted. Thus information of said master transmission is processed at each receiver station for program unit identification information of interest.

In due course, various transmission stations commence

embedding program unit identification signal information in programming transmissions and transmitting the transmissions.

Transmitting the programming with said embedded program unit identification information causes signal  
5 processors at selected receiver stations each to commence selecting and receiving specific programming of interest in the fashion of "AUTOMATING U. R. STATIONS ... RECEIVING SELECTED PROGRAMMING." Automatically receiver stations all over said nations commence tuning to different transmissions  
10 and receiving selected programming that differs from receiver station to receiver station.

At 3:59 PM, GMT on Monday, February 15, 2027, said European master network station commences embedding in the information of said master transmission and transmitting  
15 program unit identification information of a particular combined medium television program, "Farm Plans of Europe."

Farmers and government planners all over Europe wish to receive and interact with the information of said program and have preprogrammed the apparatus of their stations to  
20 receive and combined to the programming transmission of said program. Thus so transmitting said program unit identification information of said "Farm Plans of Europe" program causes apparatus at the ultimate receiver stations of farmers in all of said nations to interconnect display (or  
25 other output apparatus) to the transmission of said program and to combine to the computer system of said transmission in the fashions described in example #10 and in "AUTOMATING U. R. STATIONS ... MORE ON EXAMPLE #7 ... RECEIVING SELECTED PROGRAMMING AND COMBINING SELECTED URS MICROCOMPUTERS, 205,  
30 AUTOMATICALLY TO THE COMPUTER SYSTEM OF A SELECTED PROGRAMMING TRANSMISSION." Automatically each ultimate receiver station that is equipped with a satellite earth station, 250, commences transferring received information of said master transmission, via its matrix switch, 258, to its  
35 divider, 4, (thereby inputting said received information to

its computer, 205, and its decoder, 203) and commences transferring the television output information of its microcomputer, 205, to its television monitor, 202M, thereby causing display and emission of the television images and sound of said output information. Automatically each receiver station that is not equipped with a satellite earth station tunes its tuner, 215, to receive the specific master channel transmission of its specific selected local intermediate transmission station (which retransmits the master transmission of said European European master network station on its master channel transmission) and commences transferring received information of said master channel transmission, via its matrix switch, 258, to its divider, 4, (thereby inputting said received information to its computer, 205, and its decoder, 203) and commences transferring the television output information of its microcomputer, 205, to its television monitor, 202M, thereby causing display and emission of the television images and sound of said output information.

At 3:59:45 PM, GMT said European master network station embeds in the information of said master transmission and transmits a SPAM message that is addressed to the ITS computers, 73, of intermediate stations that are local stations.

Receiving said message causes each of said local intermediate station automatically to tune selected receiver apparatus to the specific satellite transmission that is the particular second television channel output transmission of its specific national intermediate transmission station and to input the embedded SPAM information of said transmission to its computer, 73, thereby causing said computer, 73, to come under control of the output transmission of the computer, 73, of its national intermediate station.

At 3:59:55 PM, GMT, said European master network station transmits end of file signal information then invokes

broadcast control of each national intermediate transmission station computer, 73, and each ultimate receiver station microcomputer, 205, that receives SPAM information of said master transmission. Automatically said European master network station commences controlling directly the computers, 73, of said national intermediate stations and the microcomputers, 205, of said ultimate receiver stations. And said master station causes each national intermediate station computer, 73, to embed in its particular second television channel transmission and to transmit end of file signal information then to invoke broadcast control of the computers, 73, of its specific local intermediate transmission stations.

At 4:00 PM, GMT, said European master network station commences transmitting the conventional television information of said "Farm Plans of Europe" program.

Immediately, said European master network station causes ultimate receiver stations to obscure all video information of said master transmission and display only locally generated information and causes all national intermediate station computers, 73, and ultimate receiver station microcomputers, 205, that are combined to the transmission of said master station to commence receiving SPAM information embedded in the full frame video of said master transmission. Said master station transmits SPAM information that is addressed to URS microcomputers, 205, that causes said microcomputers, 205, to commence combining and displaying locally titles information (while sound is emitted of transmitted audio theme music) in the fashion described in "CONTROLLING COMPUTER-BASED COMBINED MEDIA OPERATIONS." Then said master station transmits SPAM information that is addressed to ITS computers, 73, of intermediate stations that are national stations and to URS microcomputers, 205, which SPAM information causes decoder apparatus to commence receiving SPAM information embedded in

the full frame video of said master transmission at each national intermediate station and each ultimate receiver station where a microcomputer, 205, is combined to the computer system of said master transmission.

5           Then said European master network station causes said ultimate receiver stations each to commence receiving and emitting at its speaker system, 261, sound information of a selected transmission that transmits audio language information of said "Farm Plans of Europe" program in the  
10 specific language that is the primary language of its subscriber. On a selected secondary transmission, said master station transmits, in a fashion well known in the art, a spectrum of radio frequencies containing a plurality of individual frequency transmission each of which expresses the  
15 audio of said program in a separate European language including minority languages such as Flemish, Welsh, Basque, etc. (Each local intermediate station receives and retransmits said spectrum on a particular channel frequency spectrum.) Particular specific primary language information  
20 is preprogrammed at specific SPAM apparatus (such as, for example, radio decoders, 211). Said master station embeds and transmits particular specific-language SPAM information addressed to said specific SPAM apparatus, and receiving said specific-language information causes said specific apparatus  
25 at each ultimate receiver station to tune and emit the sound of the specific primary language of the subscriber of said station (for example, in the fashion of AUTOMATING U. R. STATIONS ... COORDINATING A STEREO SIMULCAST."

Next said European master network station transmits in  
30 the full frame video of said master transmission a SPAM message that is addressed to ITS computers, 73, of intermediate stations that are national stations and that contains information segment information of a particular national level intermediate generation set. Receiving said  
35 message causes each national intermediate transmission

station to input to and execute at its computer, 73, the information of said set. (The information of said set and the processing and functioning caused by executing said information are described more fully below.)

5 Said European master network station then transmits a series of SPAM messages that cause ultimate receiver stations to commence processing combined medium programming of said "Farm Plans of Europe" program and displaying (or otherwise outputting) combined medium information in a particular  
10 fashion. First, said master station transmits a SPAM message that causes the signal processor, 200, of each ultimate receiver station to cause its oscillator, 6, switch, 1, and mixer, 3, to input the specific operating system master control frequency of its EPROM, 20B, continuously to its  
15 decoder, 30, thereby causing said decoder, 30, to commence processing the information of said frequency continuously. (In so doing, said master station causes SPAM information embedded in said master transmission to be inputted to said signal processor, 200, continuously irrespective of the  
20 transmissions inputted to decoders, 145, 203, or 282, and prevents signal processor, 200, from identifying any other programming of interest at its station.) Then said master station embeds and transmits in the full frame video of said master transmission a SPAM message that is addressed to URS  
25 microcomputers, 205, that contains information segment information of a particular first program instruction set. Transmitting said message causes the all ultimate receiver station microcomputers, 205, that are combined to the computer system of the transmission of said master station to  
30 commence executing the instructions of said set and to commence generating local video, audio, and print overlay and output information in the fashions described above. Then said master station transmit a SPAM message that causes all SPAM decoder apparatus of all national intermediate stations and all ultimate receiver stations with microcomputers, 205,  
35

combined to the transmission of said master station to commence receiving SPAM information embedded in only the normal transmission location of said master transmission; commences embedding SPAM information only in the normal transmission location; and commences transmitting the conventional video of said "Farm Plans of Europe" program. And as said master station transmits conventional video and audio information that shows visually and describes aurally information of general interest to farmers in all of said nations, said master station commences periodically embedding and transmitting SPAM messages that are addressed to URS microcomputers, 205, and that cause specific information of each farmer to be generated, under control of the instructions of said program instruction set, at each ultimate receiver station and that cause locally generated information periodically to be displayed or emitted as sound or printed in the fashion of example #10 at each ultimate subscriber station whose microcomputer, 205, is combined to the computer system of said master transmission.

20 In the mean time, executing their inputted information of said national level intermediate generation set causes the computers, 73, of said national intermediate stations each to generate information of a specific local level intermediate generation set in the fashion that receiving the intermediate generation set of Q caused different intermediate stations to compute and incorporate specific formula-and-item-of-this-transmission information into generally applicable information of the program instruction sets of Q.1 and Q.2 in example #10. Said national level intermediate generation set includes generally applicable information of national agriculture and economic policy information, of local tax formulas and items and employment subsidy formulas, and of farmers' recommended crop planting plans. Said national level set also contains a particular projected market price at which farmers are projected to be able to sell each

alternate crop. Each price is projected on the basis of projected demand for each crop and the aggregate quantity that European farmers are projected to supply. In addition, said national level set contains information of the aggregate amount of farm borrowing. Executing the information of said set causes the computer, 73, of each national intermediate transmission station to access its specific NATIONAL.AGI, NATIONAL.TAX, and NATIONAL.MON files and to compute formula-and-item-of-this-transmission information specific subsidy formulas and items regarding each alternate crop that national farmers may grow, regarding specific tax formulas and depreciation schedules, and regarding specific monetary growth and interest rates, all given the specific market price information of said national level intermediate generation set and the projected aggregate amount of farm borrowing. Having computed said formula-and-item-of-this-transmission information, each computer, 73, is caused to incorporate said information selectively into selected generally applicable information of said national level set, thereby generating at each of said computers, 73, a specific local level intermediate generation set that applies to the local intermediate transmission stations of its nation.

After an interval of time that is long enough for each national intermediate generation station to generate its specific local level intermediate generation set, said European master network station embeds and transmits a SPAM message that is addressed to ITS, computers, 73, of intermediate stations that are national stations and that instructs said stations to embed and transmit their specific local intermediate sets.

Receiving said message causes the computer, 73, of each national intermediate station to embed in the normal location of its particular second television channel transmission and to transmit a particular SPAM message that is addressed to ITS computers, 73, and that contains

information segment information of its specific local level intermediate generation set.

Receiving the specific SPAM message of its national intermediate station causes the computer, 73, of each  
5 local intermediate station to execute the contained local level intermediate generation set of said message and to generate information of a specific program instruction set in the fashion that executing the intermediate generation set of Q caused different intermediate stations in example #10 to  
10 generate their specific program instruction sets of Q.1 or Q.2. Executing the information of its local level set causes the computer, 73, of each local intermediate station to access its specific LOCAL.TAX and LOCAL.EMP files and to compute formula-and-item-of-this-transmission information of  
15 specific local income and property tax formulas and local employment subsidy formulas, all given the specific market price information, the projected aggregate amount of farm borrowing, the specific national subsidy formulas and items regarding each alternate crop that national farmers may grow,  
20 the specific national tax formulas and depreciation schedules, and the specific national monetary growth and interest rates that are information of its local level intermediate generation set. Automatically, each computer, 73, of a local intermediate station incorporates its computed  
25 information selectively into selected generally applicable information of said local level intermediate generation set, compiles information, and links information, thereby generating its specific program instruction set.

At 4:29:50 PM, GMT, after an interval of time that is  
30 long enough for each local intermediate generation station to generate its specific program instruction set, said European master network station transmits a particular SPAM first-master-cueing message (#11) that is addressed to ITS computers, 73, of intermediate stations that are national  
35 stations. Receiving said message causes each national

intermediate station to generate and embed in the normal location of its particular second television channel transmission a particular SPAM first-national-cueing message (#11) that is addressed to ITS computers, 73, of intermediate 5 stations that are local stations.

Receiving said message causes each local intermediate station to commence playing prerecorded programming loaded at its recorder, 76, and transmitting said programming to its field distribution system, 93, on the television channel 10 transmission that is the master channel transmission of said intermediate station. In so doing, each local intermediate station commences transmitting television information of a national and local segment of the "Farm Plans of Europe" program. (Each national intermediate station can have 15 transmitted said prerecorded programming to its local intermediate stations and caused said stations to organize said programming in the fashion of examples #8 and #9 or, alternatively, said first-national-cueing message (#11) could cause each local station to commence transmitting on its 20 master channel transmission the its received television transmission of the second television channel output transmission of its specific national intermediate transmission station.)

Automatically each ultimate receiver station that is 25 not equipped with a satellite earth station (and which is, as a consequence, receiving the master transmission of said European master station retransmitted on the master channel transmission of its local intermediate transmission station) commences receiving the programming transmitted by the 30 recorder, 76, of its local intermediate station.

At 4:29:55 PM, GMT, said European master network station embeds in its master transmission and transmits a particular SPAM second-master-cueing message (#11) that is addressed to URS microcomputers, 205.

35 Only ultimate receiver stations that are equipped with

and that receive the information of said master transmission directly by means of satellite earth station apparatus receive said second-master-cueing message (#11), and receiving said message causes said stations each to receive  
5 and process the combined medium programming of the television channel transmission that is the master channel transmission of its particular local intermediate transmission station (of which transmission information is preprogrammed at its EPROM, 20B). Automatically, a tuner, 215, is tuned at each of said  
10 stations to receive the particular master channel transmission of the EPROM, 20B, of said station and apparatus of said station interconnects to input the received master channel transmission to the microcomputer, 205, and the decoder, 203, of said station.

15 In due course, each recorder, 76, transmits prerecorded end of file information then a particular transmit-program-instruction-set SPAM message (#11) addressed to ITS computers, 73.

In the fashion of example #9, each local intermediate  
20 station detects the particular SPAM message of its recorder, 76, at its decoder, 77, and receiving its particular message causes each station to embed and transmit end of file signal information then a particular first SPAM message that is addressed to URS microcomputers, 205, and that contains  
25 complete information of its particular program instruction set. (In example #11, the local stations are preprogrammed in such a fashion that receiving its specific transmit-program-instruction-set message (#11) causes each station to transmit the program instruction set generated by the local  
30 intermediate generation set of its national intermediate station rather than by a prerecorded intermediate generation set previously transmitted by its recorder, 76.)

Subsequently, additional SPAM messages that are embedded in said prerecorded programming and that are addressed to URS  
35 microcomputers, 205, are transmitted by said recorder, 76.

Receiving the particular first SPAM message of its local intermediate station causes apparatus of the subscriber station of each farmer to execute the contained program instruction set of said message at the microcomputer, 205, of  
5 said station and to commence generating the specific combined medium output information of its subscriber station. And receiving said additional SPAM messages causes apparatus at each subscriber station of a farmer to display or otherwise output (or to cease displaying or otherwise outputting)  
10 combined medium program of said national and local segment of the "Farm Plans of Europe" program. Automatically, the display and output apparatus of each farmer's station commences displaying and outputting television picture image, sound, and print information of the national and local  
15 agricultural, economic, tax, and employment subsidy policies combined periodically with related locally generated information of specific relevance to each farmer.

So executing a specific contained program instruction set causes each microcomputer, 205, to generate a specific  
20 so-called "optimal" solution for its particular farmer's problem of deciding what mix of crops is most profitable to grow on his property, given his resources.

First, each microcomputer, 205, accesses the specific information of its particular farmer. Automatically, under  
25 control of its specific received program instruction set, each microcomputer, 205, accesses the file, MY\_FARM.DAT, that is prerecorded on the disk loaded at its A: disk drive and also accesses the encrypted "PROPRIET.MOD" file that is prerecorded at the laser disc player, 232, of each farmer's  
30 station (the information of which last named file is prerecorded by any one of a plurality of proprietary services companies whose information any given farmer may acquire and the information of which varies from farmer's station to farmer's station).

35 To access the information of its encrypted

"PROPRIET.MOD" file, the instructions of its particular program instruction set cause each microcomputer, 205, to decrypt the information of said file and enter the decrypted information of said file at particular RAM. In so doing, 5 said instructions also cause each signal processor, 200, to retain meter information of the decryption of said file. (Selected stations that are preprogrammed to retain monitor information are also caused to retain monitor information.) The information of said file is embedded in the so-called 10 "full frame" video at a laser disc loaded at the disk player, 232, of each station intermixed with SPAM messages that control the decryption and metering of the information of said file. Automatically, at the beginning of a particular interval during which its local intermediate station 15 transmits no SPAM message information to URS microcomputers, 205, instructions of its particular program instruction set cause each microcomputer, 205, to instruct its signal processor, 200, to cause its laser disk player, 232, to play. Then, in the fashion of example #7, apparatus of each station 20 are caused to decrypt and retain meter information of the decryption of the encrypted information of said file. (At each station, in a predetermined fashion that is controlled by the instructions of its program instruction set, apparatus is caused, to input the received television information 25 transmitted by the recorder, 76, of its local intermediate station directly from its tuner, 215, to its TV monitor, 202M then to input the decrypted information of its "PROPRIET.MOD" file to its microcomputer, 205, via its decoder, 203, then to recommence inputting inputting said received television 30 information from its tuner, 215, to its TV monitor, 202M, via its divider, 4, and microcomputer, 205.)

Then using linear programming techniques that are well known in the art, each farmer's microcomputer, 205, under control of the particular program instruction set generated and transmitted by its local intermediate station, computes 35

its particular farmer's "optimal" crop planting plan by making reference to said farmer's specific data that includes, for example, the number and size of the individual parcels of property of the farmer's farm, the soil conditions  
5 of said parcels, the aspects of said parcels with respect to sunlight and shade, the history of crop rotation of said parcels, the farm equipment of said farmer, and the financial resources of said farmer; by using said data as so-called "constraints"; and by applying information of said program  
10 instruction set. Said information that is applied includes the specific market price information and projected aggregate amount of farm borrowing transmitted by said European master network control station as generally applicable information in its outputted national level intermediate generation set;  
15 the specific national subsidy formulas and items regarding each alternate crop that national farmers may grow, the specific national tax formulas and depreciation schedules, and the specific national monetary growth and interest rates that were incorporated at the national intermediate station  
20 of each farmer into the generally applicable information of said national level intermediate generation set to generate its local level intermediate generation set; and the specific local income and property tax formulas and local employment subsidy formulas that were incorporated at the local  
25 intermediate station of each farmer into the generally applicable information of its received local level intermediate generation set to generate its program instruction set (which is the program instruction set received at said farmer's station).

30 The specific "optimal" crop planting plans so computed vary from station to station and include budget information of projected revenues, expenses, and profits. The plan of one particular farmer calls for planting forty acres of oats and sixty acres of wheat and projects profits of fifteen  
35 thousand units of local currency. The plan of a particular

second farmer calls for planting fifteen acres of broad beans and five acres of tomatoes and projects profits of thirty thousand units of local currency. The plan of a particular third farmer calls for planting ten acres of red tulips and  
5 two acres of blue tulips and projects profits of twenty thousand units of local currency.

Each specific "optimal" crop planting plan may also include so-called "sensitivity analyses" that are well known in the art and information of alternate planting plans that  
10 are close to but not quite optimal.

Automatically, under control of its received program instruction set, the microcomputer, 205, of its farmer's station records complete information of said farmer's crop planting plan at its A: disk in a file named PLANTING.DAT.

15 Then automatically, under control of its particular program instruction set, each farmer's microcomputer, 205, computes and retains information of a particular schedule of spot commercials. Information of twenty-six specific potential commercials of any given schedule are included in  
20 the information of its set, and the specific commercials include, for example, commercials for a particular new farm truck, a particular new farm tractor, a particular new farm disk harrow, software of a particular new "PROPRIET.MOD" module for analyzing crop planting plans and generating  
25 recommended planting plans in a "new improved fashion," etc. Under control of the instructions of its particular set, by analyzing the budget information of its farmers crop planting plan, each microcomputer, 205, automatically identifies four commercial spots that are of a particular possible highest  
30 potential value to its farmer. For example, by analyzing equipment depreciation information, one microcomputer, 205, determines that its farmer has an old truck, a new tractor, and a new disk harrow and selects, as one of its four commercials, the commercial of the new truck. Meanwhile,  
35 another microcomputer, 205, determines that its farmer has an

old truck, a new tractor, and a old disk harrow and selects the commercial of the new truck because a new truck is costlier than a disk harrow and may be more valuable to its farmer. Automatically, the microcomputer, 205, of each station inputs to the signal processor, 200, of its station particular schedule information of its four identified commercial spots.

In due course, the recorder, 76, of each local intermediate station transmits further additional SPAM messages that are embedded in its prerecorded programming and that are addressed to URS microcomputers, 205, then transmits a particular local-second-cueing message (#11) that is addressed to ITS computers, 73.

Receiving the further additional SPAM messages of its local intermediate station causes apparatus at each subscriber station of a farmer to display or otherwise output (or to cease displaying or otherwise outputting) further combined medium programming of said national and local segment of the "Farm Plans of Europe" program. Automatically, in the fashion of example #10, the display and output apparatus of each farmer's station commences displaying and outputting generally applicable television picture image, sound, and print information of a crop planting plan combined periodically with related locally generated specific crop planting plan information of its specific farmer. Automatically, crop and budget information of the aforementioned optimal crop planting plan of each farmer is explained in the outputted the generally applicable programming and is displayed, emitted in sound, and printed at the station of each farmer.

Then so transmitting a particular local-second-cueing message (#11) at each local intermediate station causes a decoder, 77, at each station to detect the local-second-cueing message (#11) transmitted at its station and input said message to the computer, 73.

Receiving its local-second-cueing message (#11) causes the computer, 73, of each local intermediate station to embed SPAM message information that is addressed to URS signal processors, 200, in the normal location of its master  
5 channel transmission then after a particular interval to cause the video recorder/player, 78, of its station to commence playing and to cause apparatus of its station to transmit the output of said recorder/player, 78, to the field distribution system of said station on the television  
10 transmission of a particular second television channel.

Transmitting said SPAM message information at its local intermediate station causes apparatus of each farmer's station to receive and input said information to the signal processor, 200, of said station, and receiving said  
15 information causes the signal processor, 200, of said station to cause its tuner, 215A, to commence receiving the transmission of the particular second television channel of its local intermediate station; to cause apparatus of said station to interconnect to transfer the transmission received  
20 at said tuner, 215A, to a selected video recorder/player, 217 or 217A; and to cause said video recorder, 217 or 217A, to prepare to record selected programming.

Then after an interval that is long enough for each of its subscriber stations to prepare a selected  
25 recorder/player, 217 or 217A, to record selected programming, each computer, 73, causes said recorder, 78, to commence playing. In so doing, each computer, 73, causes twenty-six program units of commercial spot programming to be transmitted, in series, to its subscriber stations. Each  
30 program unit is preceded by embedded program unit identification information of its own that is addressed to URS signal processors, 200.

Automatically, the signal processor, 200, of each station causes its recorder/players, 217 and 217A, in the  
35 fashion that applied to computer, 73, and recorders, 76 and

78, in example #8, to record and then to organize to play the selected programming of the selected commercial spots of its station. Automatically, a decoder, 282A, at the tuner, 215A, of each station detects each datum of program unit  
5 identification information received at its tuner, 215A, and inputs each datum to the signal processor, 200, of its station. Automatically, said signal processor, 200, causes a selected recorder/player, 217 or 217A, to record selected programming then, after a particular last unit is received,  
10 to organize the recorded programming to play according to its schedule previously inputted by its microcomputer, 205.

In due course, the instructions of the program instruction set received at each farmer's station cause a particular module, TELEPHON.EXE, to be recorded at a  
15 particular disk drive of the microcomputer, 205, of each farmer's station (in the fashion of the file, "SHOPPING.EXE" in example #10) which, when executed, will permit the farmer to modify the information of his specific crop planting plan and associated budget and to transmit the specific  
20 information of his plan (as modified if modified) to a particular data collection computer at a remote station.

Then a particular second-cueing message (#11) that is embedded at the end of the prerecorded national and local segment of the "Farm Plans of Europe" programming at the  
25 recorder, 76, of each local intermediate station and that is addressed to URS signal processors, 200, is transmitted and causes the signal processor, 200, of each farmer's station to separate the apparatus of its station from the master channel transmission and second television of its local intermediate  
30 station; to cause its recorder/players, 217 and 217A, to commence playing their prerecorded commercial spot programming in the fashion of example #8, and to cause apparatus of its station to interconnect so as to commence generating and displaying (or otherwise outputting) combined  
35 medium programming of the programming transmitted by its

selected recorder/player, 217 or 217A.

Playing each commercial spot causes the combined medium information of said spot to display information of a particular commercial product such as a truck or a particular service such as a software package; to access the prerecorded "A:PLANTING.DAT" disk file information of a farmer's crop planting plan; in a fashion well known in the art, to generate cost/benefit financial analysis of the incremental benefit of acquiring and using the displayed product or service (by comparison with the farmer's existing product or service of like kind); and to display (or otherwise output) information of said analysis (if said analysis results in a positive net present benefit).

After studying his specific crop planting plan and associated budget projections, his associated sensitivity analyses, and the output information of the selected commercial spots of his station, each farmer loads and runs his prerecorded module, TELEPHON.EXE, in a fashion well known in the art. Under control of the instructions of the TELEPHON.EXE module of his station controlling the operation of his signal processor, 200, each farmer enters information at his local input, 225, that modifies the information of his file, "PLANTING.DAT," to suit his own wishes and inclinations then executes particular information of said TELEPHON.EXE module that causes the instructions of said module to cause his signal processor, 200, to transmit the information of his "PLANTING.DAT" file, via telephone network in the fashion of example #10, to a computer at a particular remote data collection station.

Over the course of a particular time such as two days, computers at remote data collection stations receive data automatically from each farmer of said nations which data indicates the specific quantity of each crop that each farmer expects to harvest during the 2027 growing season. Automatically, the received data is aggregated, in a fashion

well known in the art, at the computer of said European master network origination and control station which allows planners at said station to modify and refine the variables of the national intermediate generation set of said station, 5 especially the projected market prices at which farmers are projected to be able to sell each alternate crop.

The aggregated data is also distributed automatically to computers at the national and local intermediate transmission stations, enabling national and local planners 10 to vary and refine the policy variables of their stations' local-formula-and-item information.

Then, at 3:59 PM, on Thursday, February 18, 2027, the cycle of generating and communicating information of farmers is repeated using the refined variables. Once again farmers 15 receive optimal planting plans, given the new refined variables, and respond with their own plans, causing data to be aggregated at the computer of said European master network origination and control station.

In an iterative fashion well known in the art, this 20 cycle is repeated several times until a satisfactory European master agricultural plan is achieved. Invariable early cycles result in excessive planned planting, but as projected variables are refined in subsequent planning cycles, the excesses are eliminated. Ultimately the planners 25 are able to establish policy formula and item variables at levels that yield socially beneficial economic conditions while enabling farmers individually to maximize the profitability of their planting plans, subject to their individual resources.

30 In this fashion, the unified system of programming communication of the present invention facilitates efficient economic planning and decision making.

It is obvious to one of ordinary skill in the art that the foregoing is presented by way of example only and that 35 the invention is not to be unduly restricted thereby since

modifications may be made in the structure of the various parts or in the methods of their functioning without functionally departing from the spirit of the invention. Any SPAM message and any other programming transmission can  
5 be caused, through encryption/decryption and other SPAM regulating techniques of the present invention, to take affect fully only selected stations and station apparatus. Because any transmission station can invoke any SPAM controlled function by transmitting a SPAM message with  
10 meter-monitor segment information, invoking any given SPAM controlled function can also cause meter information and or monitor information to be processed in the fashions described above at apparatus and stations where said controlled function is invoked. Intermediate transmission stations can  
15 be equipped with SPAM regulating capacity such as that illustrated in Fig. 4, monitoring capacity such as that illustrated in Fig. 5, and control information switching and bus communications capacity such as that illustrated in Figs. 7 and 8. Controlling such capacity by means of transmitted  
20 SPAM messages, a remote network origination and control station can transmit programming to intermediate transmission stations, regulate and meter the use of said programming at said stations, monitor the use and usage of said programming at said stations, and control communication of control  
25 information at said stations all in the fashions that apply above to ultimate receiver stations. And any given transmission station can cause its receiver stations to function automatically not only in the fashions described above in the sections on automating ultimate receiver  
30 stations but in any appropriate fashion that a network origination and control station can cause intermediate transmission stations to function automatically.

35

WHAT IS CLAIMED IS:

1           1.    A method of controlling the communication of  
2 television programming at a television transmission station,  
3 said method comprising the steps of:  
4            receiving television programming from a plurality of  
5 television programming sources;  
6            receiving programming communication instructions  
7 designating for each unit of television programming at least  
8 one from the group consisting of:  
9            (a) an output channel to be used in communicating  
10           said unit of television programming; and  
11           (b) the time said unit of television programming is  
12           to be communicated; and  
13           communicating each unit of television programming from  
14 said transmission station to at least one subscriber according  
15 to said programming communication instructions.

ABSTRACT

A unified system of programing communication. The system encompasses the prior art (television, radio, broadcast hardcopy, computer communications, etc.) and new user specific mass media. Within the unified system, parallel processing computer systems, each having an input (e.g., 77) controlling a plurality of computers (e.g., 205), generate and output user information at receiver stations. Under broadcast control, local computers (73, 205), combine user information selectively into prior art communications to exhibit personalized mass mediaprogramming at video monitors (202), speakers (263), printers (221), etc. At intermediate transmission stations (e.g., cable television stations), signals in network broadcasts and from local inputs (74, 77, 97, 98) cause control processors (71) and computers (73) to selectively automate connection and operation of receivers (53), recorder/players (76), computers (73), generators (82), strippers (81), etc. At receiver stations, signals in received transmissions and from local inputs (225, 218, 22) cause control processors (200) and computers (205) to automate connection and operation of converters (201), tuners (215), decryptors (224), recorder/players (217), computers (205), furnaces (206), etc. Processors (71, 200) meter and monitor availability and usage of programming.

**DECLARATION AND POWER OF ATTORNEY - ORIGINAL APPLICATION**

ATTORNEY'S DOCKET NO.  
5634/8

As a below named inventor, I hereby declare that:

My residence, post office address, and citizenship are as stated below next to my name.

I believe I am an original, first, and joint inventor of the subject matter that is claimed and for which a patent is sought on the invention entitled **Signal Processing Apparatus and Methods**, the specification of which is attached hereto.

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, § 1.56(a).

**PRIOR UNITED STATES APPLICATION(S)**

I hereby claim the benefit under Title 35, United States Code, § 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, § 112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, § 1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

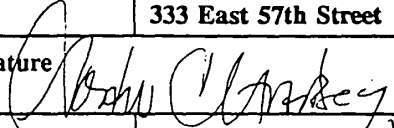

APPLICATION NUMBER	FILING DATE (day, month, year)	STATUS (i.e. Patented, Pending, Abandoned)
08\056,501	3 May 1993	Pending
07\849,226	10 March 1992	Patented
07\588,126	25 September 1990	Patented
07\096,096	11 September 1987	Patented
06\829,531	14 February 1986	Patented
06\317,510	3 November 1981	Patented

**POWER OF ATTORNEY:** As a named inventor, I hereby appoint the following attorneys with full power of substitution and revocation, to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith:  
James F. Davis (Reg. No. 21,072); Joel M. Freed (Reg. No. 21,501); Alan M. Grimaldi (Reg. No. 26,599); Thomas J. Scott, Jr. (Reg. No. 27,836); Richard H. Kjeldgaard (Reg. No. 30,186); Joseph P. Lavelle (Reg. No. 31,036); William J. Griffin (Reg. No. 31,260); Richard S. Meyer (Reg. No. 32,541); James W. Inskeep (Reg. No. 33,910) and C. Scott Talbot (Reg. No. 34,262).

SEND CORRESPONDENCE, AND DIRECT TELEPHONE CALLS TO:

Thomas J. Scott, Jr.  
**HOWREY & SIMON**  
 1730 Pennsylvania Avenue, N.W.  
 Washington, D.C. 20006

UNITED STATES PATENT AND TRADEMARK OFFICE

PATENT

In Re Rule 1.60 Application of :  
**John C. Harvey and James W. Cuddihy** : Examiner  
Serial No: **TO BE ACCORDED** : Group Art Unit  
Filed: **HEREWITH** : Atty Dkt 5634.174  
For: **SIGNAL PROCESSING APPARATUS AND METHODS**

REQUEST FOR FILING OF DIVISIONAL-CONTINUATION APPLICATION  
PURSUANT TO 37 C.F.R. 1.60

Honorable Commissioner  
of Patents and Trademarks  
Washington, DC 20231

Sir:

This is a request for filing:  
a  continuation application  
a  divisional application  
under 37 C.F.R. 1.60, of pending prior application:

Serial No. 08/113,329; Filed August 30, 1993  
of John C. Harvey and James W. Cuddihy  
for SIGNAL PROCESSING APPARATUS AND METHODS

The following are enclosed:

1.  A complete copy of the prior application, comprising:  
 a total of 558 numbered pages (557 pages of  
Specification, 1 page of Claims), a 1 page Abstract and  
22 sheets of drawings).  
 the Oath or Declaration as originally filed

2.  The filing fee was calculated as follows:

Claims filed in the Prior Application Less any Claims Cancelled by Amendment Below

Fee	Claims in Prior Filed Application, <i>less</i> claims cancelled by Preliminary Amendment plus claims added by Preliminary Amendment					No Extra	Small Entity		Large Entity	
							Rate	Fee		
Basic Fee							\$365	\$365		
Total Claims	<u>1</u>	- <u>1</u>	+ <u>1</u>	= <u>1</u>	- <u>20</u>	=	-0-	11	-0-	
Independent Claims	<u>1</u>	- <u>1</u>	+ <u>1</u>	= <u>1</u>	- <u>3</u>	=	-0-	38	-0-	
1st Multi Dependent								120	-0-	
<b>Total for Small Entity</b>								<b>\$ 365</b>		

\*If the difference is less than zero, enter zero.

3.  HOWREY & SIMON Check No. 98555 in the amount of \$365.00 is enclosed.

4.  The Commissioner is hereby authorized to charge  
 any additional fees listed below  
 37 CFR 1.16 (filing fees)  
 37 CFR 1.16 (presentation of extra claims)  
 37 CFR 1.17 (extension of time)  
 which may be required by this paper or to credit any overpayment to Account No. 08-3038. A Duplicate copy of this sheet is enclosed.

5.  The prior application is assigned of record to: PERSONALIZED MASS MEDIA CORPORATION and is so recorded on August 30, 1993 in the U.S. Patent Office at Reel 6686 and Frames 0319.

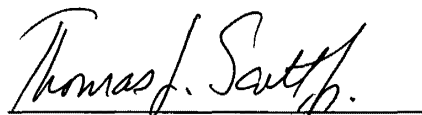

6.  The Power of Attorney in the application is Thomas J. Scott, Jr., Registration No. 27,836.  
 address all future communications to Thomas J. Scott, Jr., HOWREY & SIMON, 1299 Pennsylvania Avenue, NW, Washington, D.C. 20004. Tel: (202) 383-6614.

7.  A Preliminary Amendment is enclosed.

8. [X] I hereby verify that the attached papers are a true copy of prior application serial no. 08/113,329, as originally filed on August 30, 1993.

The undersigned declares further that all statements made herein of his own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18, United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

Date: May 24, 1995

WHAT IS CLAIMED IS:

1           1. A method of controlling the communication of  
2 television programming at a television transmission station,  
3 said method comprising the steps of:  
4           receiving television programming from a plurality of  
5 television programming sources;  
6           receiving programming communication instructions  
7 designating for each unit of television programming at least  
8 one from the group consisting of:  
9           (a) an output channel to be used in communicating  
10           said unit of television programming; and  
11           (b) the time said unit of television programming is  
12           to be communicated; and  
13           communicating each unit of television programming from  
14 said transmission station to at least one subscriber according  
15 to said programming communication instructions.

For **SIGNAL PROCESSING APPARATUS AND METHODS**

PRELIMINARY AMENDMENT

Honorable Commissioner of  
 Patents and Trademarks  
 Washington, D.C. 20231

Sir:

Prior to initiating the Examination of the above-described continuation application, Applicants herewith submit the following Preliminary Amendment.

IN THE CLAIMS

Please cancel claim 1 and add the following claim:

- 1 *Sub*  
 2. A method for decrypting data from a storage device using a computer  
 2 operatively connected to said storage device, said storage device having encrypted data  
 3 stored thereon, and a decryptor operatively connected to said computer to receive data  
 4 from said storage device and control instructions from said computer comprising the  
 5 steps of:  
 6 selecting data on said storage device;

*A/cont*

1 transferring said selected data from said step of selecting from said storage  
2 device to said decryptor;  
3 identifying information in said selected data from said step of selecting; and  
4 decrypting said selected data from said step of transferring in response to the  
5 information in said selected data from said step of identifying.

IN THE SPECIFICATION

On page 1, please rewrite the paragraph in the "Cross-Reference to Related Applications" as follows:

This is a continuation of application serial no. 08/113,329, filed August 30, 1993, herein incorporated by reference in its entirety, which is a continuation of application serial no. 056,501, filed May 3, 1993, now U.S. Patent 5,335,277, which was a continuation of application serial no. 849,226, filed March 10, 1992, now U.S. Patent No. 5,233,654, which was a continuation of application serial no. 588,126, filed Sept. 25, 1990, now U.S. Patent No. 5,109,414, which was a continuation of application serial no. 096,096, filed Sept. 11, 1987, now U.S. Patent No. 4,965,825, which was a continuation-in-part of application serial no. 829,531, filed Feb. 14, 1986, now U.S. Patent No. 4,704,725, which was a continuation of application serial no. 317,510, filed Nov. 3, 1981, now U.S. Patent No. 4,694,490.

Respectfully submitted,

Thomas J. Scott, Jr.
