# Foreword

lSO ltbe International Organization for Standardization) and IEC (the Inter national Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization 'to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organ izations, governmental and non-governmental, in liaison with ISO and IEC, also take part 'n the work.

In the field of information technology, ISO and IEC have established a joint technical committee, 'SO/IEC JTC 1. D'aft International Standards adopted by the joint technical committee are circulated to national bodies for voting. Publication as an International Standard requires-app'oval by at least 75% o' the national bodies casting a vote. '

International Standard ISO/IEC 11172-2 was prepared by Joint Technical Committee ISO/IEC JTC 1, Information technology, Sub-Committee SC 29, Coded representation of audio, picture, multimedia and hypermedia infcrmation.

ISD/EC 11172 consists of the following parts, under the general title information technology  $-$  Coding of moving pictures and associated audio for digital storage media at up to about 1,5 MbiVs:

- '— Part 1': Systems
- Part 2: "Video
- Part 3: Audio
- —— Part 4: Compliance testing

Annexes A, B and C form an integral part of this part of ISOAEC 11172. Annexes  $D$ ,  $E$  and  $F$  are for information only.

# Introduction

Note -- Readers interested in an overview of the MPEG Video layer should read this Introduction and then proceed to annex D, before returning to clauses I and 2.

#### 0.1 Purpose

This part ofISDIIEC <sup>11</sup> 172 was developed in response to the growing need for a common format for representing compressed video on various digital storage media such as CDs, DATs, Winchester disks and optical drives. This part of lSO/[EC 11172 specifies a coded representation that can be used for compressing video sequences to bitrates around 1,5 Mbit/s. The use of this part of ISO/IEC 11172 means that motion video can be manipulated as a form of computer data and can be transmitted and received over existing and future networks. The coded representation can be used with both 625-line and 525-line television and provides flexibility for use with workstation and personal computer displays.

This part of ISO/IEC 11172 was developed to operate principally from storage media offering a continuous transfer rate of about 1.5 Mbit/s. Nevertheless it can be used more widely than this because the approach taken is generic.

#### 0.1.1 Coding parameters

The intention in developing this part of ISO/IEC 11172 has been to define a source coding algorithm with a large degree of flexibility that can be used in many different applications. To achieve this goal, a number of the parameters defining the characteristics of coded bitstreams and decoders are contained in the bitstream itself. This allows for example, the algorithm to be used for pictures with a variety of sizes and aspect ratios and on channels or devices operating at awide range of bitrates

Because of the large range of the characteristics of bitstreams that can be represented by this part of ISO/IEC 11172. a sub-set of these coding parameters known as the "Constrained Parameters" hasbeen defined. The aim in defining the constrained parameters is to offer guidance about a widely useful range ofparameters. Conforming to this set of constraints is not a requirement of this part of ISO/IEC 11172. A flag in the bitstream indicates whether or not it is a Constrained Paraneters bitstream.

#### Summary of the Constrained Parameters:

#### 0.2 Overview of the algorithm

with intraframe coding alone. The need for random access, however, is best satisfied with pure in Harange Exhibit 2005 with intraframe coding alone. The need for famous access, however, is best sansfied with pure muarianity Exhibit 2005 4 of 124 The coded representation defined in this part of ISO/IEC 11172 achieves a high compression ratio while preserving good picture quality. The algorithm is not lossiess as the exact pcl values are not preserved during coding. The choice of the techniques is based on the need to balance a high picture quality and compression ratio with the requirement to make random access to the coded bitstream. Obtaining good picture quality at the bitrates of interest demands a very high compression ratio, which is not achievable recursive temporal redundancy reduction.

iv

A number of techniqucsare used to achieve a high compression ratio. The first, which is almost independent from this part of ISO/IEC 11172, is to select an appropriate spatial resolution for the signal. The algorithm then uses block-based motion compensation to reduce the temporal redundancy. Motion compensation is used for causal prediction of the current picture from a previous picture, for non-causal prediction of the current picture from a future picture, or for interpolative prediction from past and future pictures. Motion vectors are defined for each 16-pel by 16-line region of the picture. The difference signal, the prediction error. is further compressed using the discrete cosine transform (DCI') to remove spatial correlation before it is quantized in an irreversible process that discards the less important information. Finally, the motion vectors are combined with the DCT information, and coded using variable length codes.

#### 0.2.1 Temporal processing

Because of the conflicting requirements of random access and highly efficient compression, three main picture types are defined. Inna-coded pictures(I-Pictures) are coded without reference to other pictures. They provide access points to the coded sequence where decoding can begin, but are coded with only a moderate compression ratio. Predictive coded pictures (P-Pictures) are coded more efficiently using motion compensated prediction from a pastintraor predictivecoded picture and are generally used as a reference for further prediction. Bidirectionally-predictive coded pictures (B-Pictures) provide the highest degree of compression but require both past and future reference pictures for motion compensation. Bidirectionallypredictive coded pictures are never used as references for prediction. The organisation of the three picture types in a sequence is very flexible. The choice is left to the encoder and will depend on the requirements of the application. Figure 1 illustrates the relationship between the three different picture types.

Figure l -- Example of temporal picture structure

The fourth picture type defined in this part of ISO/IEC 11172, the D-picture, is provided to allow a simple, but limited quality, fast-forward playback mode.

# 0.2.2 Motion representation - macroblocks

The choice of 16 by 16 macroblocks for the motion-compensation unit is a result of the trade-off between increasing the coding efficiency provided by using motion information and the overhead needed to store it. Each macroblock can be one of a number of different types. For example, intra-coded, forward-predictivecoded, backward-predictive coded, and bidirectionally-predictive-coded macroblocks are permitted in hidirectionally-predictive coded pictures. Depending on the type of the macrohlock, motion vector information and other side information are stored with the compressed prediction error signal in each macroblock. The motion vectors are encoded differentially with respect to the last coded motion vector, using variable-length codes. The maximum length of the vectors that may be represented can be programmed, on a picture-by-picture basis, so that the most demanding applications can be met without compromising the performance of the system in more normal situations.

It is the responsibility of the encoder to calculate appropriate motion vectors. This part of ISO/IEC 11172<br>does not specify how this should be done.

Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016.—01135 5 of 124 <sup>5</sup> of 124

#### 6.2.3 Spatial redundancy reduction

Both original pictures and prediction error signals have high spatial redundancy. This part of lSO/lEC 11172 usesa block-based DCT method with visually weighted quantization and run—length coding. Each 8 by 8 block of the original picture for intra-coded macroblocks or of the prediction error for predictive-coded macroblocks is transformed into the DCT domain where it is scaled before being quantized. After quant'zation many of the coefficients are zero in value and so live—dimensional run—length and variable length coding is used to encode the remaining coefficients efficiently.

# 0.3 Encoding

This part of ISOIIBC 11172 does not Specify an encoding process. Itspecifies the syntax and semantics of the bitstream and the signal proceSsing in the decoder. As a result, many options are left open to encoders to trade-off cost and speed against pieture quality and coding efficiency. This clause is abrief description of the functions that need to be performed by an encoder. Figure 2 shows the main functional blocks.

where

DCT is discrete cosine transform  $DCT^{-1}$  is inverse discrete cosine transform Q is quantization  $Q^{-1}$  is dequantization VLC is variable length coding

Figure 2 -- Simplified video encoder block diagram

The input video signal must be digitized and represented as a luminance and two colour difference signals  $(Y, C_b, C_r)$ . This may be followed by preprocessing and format conversion to select an appropriate window, resolution and input format. This part of ISO/IEC 11172 requires that the colour difference signals ( $C_p$  and  $C_r$ ) are subsampled with respect to the luminance by 2:1 in both vertical and horizontal directions and are reformatted, if necessary, as a non-interlaced signal.

The encoder must choose which picture type to use for each picture. Having defined the picture types, the encoder estimates motion vectors for each 16 by 16 macroblock in the picture. In P-Pictures one vector is needed for each non-intra macroblock and in B-Pictures one or two vectors are needed.

If B-Pictures are used, some reordering of the picture sequence is necessary before encoding. BecaBdeNA Exhibit 2005 Pictures are coded using bidirectional motion compensated prediction, they can only ppdecoded index hdPR2016-01135 6 of 124 subsequent reference picture (an I or P-Picture) has been decoded. Therefore the pictures are reordered by the

encodersothat the pictures arrive at the decoder in the order fordecoding. The correct d'splay order is recovered by the decoder;

The basic unit of coding within a picture is the macroblock. Within each picture, macroblocks are encoded in sequence, left to right, top to bottom. Each macrnblock consists of six 8 by <sup>8</sup> blocks: four blocks of luminance, one block of Cb chrominance, and one block of Cr chrominance. See figure 3. Note that the picture area covered by the four blocks of luminance isthe same as the area covered by each of the chrominance blocks. This is due to subsampling of the chrominance information to match the sensitivity of the human visual system. -

Firstly, for a given macroblock, the coding mode is chosen. It depends on the picture type, the effectiveness ofmotion compensated prediction in that local region, and the nature of the signal within the block. Secondly, depending on the coding mode, amotion compensated prediction of the contents ofthe block based on past and/or future reference pictures is formed. This prediction is subtracted from the actual data in the current macroblock to form an error signal. Thirdly, this error signal is separated into 8 by 8 blocks (4 luminance and 2 chrominance blocks in each macroblock) and a discrete cosine transform is performed on each block. Each resulting 8 by 8 block of DCT coefficients is quantized and the twodimensional block is scanned in a zig-zag order to convert it into a one-dimensional string of quantized DCT coefficients. Fourthly, the side-information for the macroblock (mode, motion vectors etc} and the quantized coefficient data are encoded. For maximum efficimcy, a number of variable length code tables are defined for the different data elements. Run-length coding is used for the quantized coefficient data.

A consequence of using different picture types and variable length coding is that the overall datarate is variable. In applications that involve a fixed-rate channel, a FIFO buffer may be used to match the encoder output to the channel. The status of this buffer may be monitored to control the number of bits generated by the encoder. Controlling the quantization process is the most direct way of controlling the bitrate. This part of ISO/IEC 11172 specifies an abstract model of the buffering system (the Video Buffering Verifier) in order to constrain the maximum variability in the number of bits that are used for a given picture. This ensures that abitstrearn can be decoded with a buffer of known size.

At this stage, the coded representation of the picture has been generated. The final step in the encoder is to regenerate I—Pictures and P-Pictures by decoding the data so that they can be med as reference pictures for. subsequent encoding. The quantized coefficients are dequantized and an inverse 8 by 8 DCT is performed on each block. The prediction error signal produced is then added back to the prediction signal and limited to the required range to give a decoded reference picture.

#### 0.4 Decoding

Decoding is the inverse of the encoding operation. it is considerably simpler than encoding as there is no need to perform motion estimation and there are many fewer options. The decoding process is defined by this part of ISOJIEC 11172. The descripticn that follows is a very brief overview ofone possible way of decoding abitstream. Other decoders with different architectures are possrblc. Figure 4 shows the main functional blocks.

 $Q^{-1}$  is dequantization

 $MUX^{-1}$  is demultiplexing<br>VLD is variable length is variable length decoding

Figure 4 -- Basic video decoder block diagram

For fixed-rate applications, the channel fills a FIFO buffer at a constant rate with the coded bitstream. The decoder reads this buffer and decodes the data elements in thebitstream according to the defined syntax.

As the decoder reads the bitstream, it identifies the start of a coded pictureand then the type of the picture. It decodes each macrohlock in the picture in turn. Themacrohlodt type and the motion vectors, if present, are used to construct a prediction of the current macroblock based on past and future reference pictures that have been stored in the decoder. The coefficient data are decoded and dequantized. Each 8 by 8 block of coefficient data is transformed by an inverse  $DCT$  (specified in annex A), and the result is added to the prediction signal and limited to the defined range.

After all the macroblocks in the picture have been processed, the picture has been reconstructed. If it is an Ipicture or aP—picture it is a reference picture for subsequent pictures and is stored, replacing the oldest stored reference picture. Before the pictures are displayed they may need to be re-ordered from the coded order to their natural display order. After reordering, the pictures are available, in digital form, for post-processing and display in any manner that the application chooses.

## 0.5 Structure of the coded video bitstream

This part of ISOHEC 11172 spedfics a syntax for acoded video bitstrearn. This syntax contains six layers, each of which either supports a signal processing or a system function:

#### 0.6 Features supported by the algorithm

PLUMA Exhibit 2005 Applications using compressed video on digital storage media need to be able to perform anumber of operations in addition to normal forward playback of the sequence. The coded bitstream has been designed to support a number of these operations.

Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 8 of 124 <sup>8</sup> of 124

#### 0.6.1 Random access

Random access is an essential feature for video on a storage medium. Random access requires that any picture can be decoded in a l'mited amount of time. It implies the existence of access points in the bitstream - that is segments of information that are identifiable and can be decoded without reference to other segments of data. A spacing of two random access points (Intra-Pictures) per second can be achieved without significant loss of picture quality.

#### 0. 6. <sup>2</sup> Fast search

Depending on the storage medium, it is possible to scan the access points in a coded bitstream (with the help of an application specific directory or other knowledge beyond the scope of this part of ISO/IEC ]] 172) to obtain a last—forward and fast—reverse playback effect

#### 0.6.3 Reverse playback

Some applications may require the video signal Lobe played in reverse order. This canbe achieved in a decoder by using memory to store entire groups of pictures after they have been decoded before being. displayed in reverse order. An encoder can make this feature easier by redrcing the length of groups of pictures.

#### 0.5.4 Error robustness

Most digital storage media and communication channels are not error-free. Appropriate channel coding schemes should be used and are beyond the scope of this part of ISO/IEC 11172. Nevertheless the compression scheme defined in this part of ISO/IEC-11172 is robust to residual errors. The slice structure allows a decoder to recover after a data error and to resynchronize its decoding. Therefore, bit errors in the compressed data will cause errors in the decoded picmres to be limited in area. Decoders may be able to use concealment strategies to disguise these errors.

#### 0.6.5 Editing

Thereis a conflict between the requirement for high coding efficiency and easy editing. The coding structure and syntax have not been designed with the primary aim of simplifying editing at any picture. Nevertheless a number of features have been included that enable editing of coded data

Information technology  $-$  Coding of moving pictures and associated audio for digital storage media at up to about  $1.5$  Mbit/s  $-$ 

Part 2:

Video

#### Section 1: General

1.1 Scope

This part of lSOlIEC 11172 specifies the coded representation of video for digital storage media and specifies the decoding process. The representation supports normal speed forward playback, as well as special functions such as random access, fast forward playback, fast reverse playback, normal speed reverse playback, pause and still pictures. This part of ISO/IEC 11172 is compatible with standard 525- and 625line television formats, and it provides flexibility for use with personal computer and workstation displays.

lSO/IBC 11172 is primarily applicable to digital storage media supporting a continuous transfer rate up to about 1,3 Mbit/s, such as Compact Disc, Digital Audio Tape. and magnetic hard disks. Nevertheless itcan be used more widely than this because of the generic approach taken. The storage media may be directly connected to the decoder, or via communications means such as busses,LANs, or telecommunicatious links. This part of ISO/IEC 11172 is intended for non-interlaced video formats having approximately 288 lines of 352 pets and picture rates around 24 Hz to 30 Hz.

#### 1.2 Normative references

The following International Standards contain provisions which, through reference in this text, constitute provisions ofthis part of ISOIIEC 11172. At the time of publication, the editionsindicated were valid. All standards are subject to revision, and parties to agreements based on this part of ISOIJEC <sup>1</sup> 1172 are encouraged to investigate the possibility of applying the most recent editions of the standards indicated below. Members of IEC and ISO maintain registers of currently valid International Standards.

#### Section 2: Technical elements

#### 2.1 Definitions

For the purposes of ISOflEC 11172, the following definitions apply. If Specific to a part. this is noted in square brackets.

2.1.1 ac coefficient Ivideo]: Any DCT coefficient for which the frequency in one or both dimensions is non-zero.

2.1.2 access unit [system]: In the case of compressed audio an access unit is an audio access unit. In the case of compressed video an access unit is the coded representation of a picture.

2.1.3 adaptive segmentation {audio}: A subdivision of the digital representation of an audio signal in variable segments of time.

2.1.4 adaptive bit allocation [audio]: The assignment of bits to subbands in a time and frequency varying fashion according to a psychoacoustic model.

2.1.5 adaptive noise allocation [audio]: The assignment of coding noise to frequency bands in a time and frequency varying fashion according to a psychoacoustic model.

2.1.6 alias [audio]: Mirrored signal component resulting from sub-Nyquist sampling.

2.1.7 analysis filterbank [audio]: Filterbank in the encoder that transforms a broadband PCM audio signal into a set of subsampled suhband samples.

**2.1.3 audio access unit [audio]:** For-Layers I and II an audio access unit is defined as the smallest part of the encoded bitstream which can be decoded by itself, where decoded means "fully reconstructed sound'. For Layer III an audio access unit is part of the bitstream that is decodable with the use of previously acquiredmain information

2.1.9 audio buffer [audio]: A buffer in the system target decoder for storage of compressed audio data.

2.1.10 audio sequence [audio]: A non-interrupted series of audio frames in which the following parameters arenot diangcd:

- ID — layer

- Sampling Frequency

- For Layer I and II: Bitrate index

2.1.11 backward motion vector [video]: A motion vector that is used for motion compensation from a reference picture at a later time in display order.

2.1.12 Bark {audio}: Unit of critical baud rate. The Bark scale is anon-linear mapping of the frequency scale over the audio range closely corresponding with the fiequency selectivity of the human ear across the band.

2.1.13 bidirecfionally predictive-coded picture; B-picture [video]: A picture that is coded using motion compensated prediction froma past and'or future reference picture.

2.1.14 bitrntc: The rate at which the compressed bitsiream is delivered from the storage medium to the input of a decoder.

2.1.15 block companding [audio]: Normalizing of the digital representation of an audio signal within a certain time period.

2.1.18 byte aligned: A bit in a coded bitstream is byte-aligned if its position is a multiple of 8-bits from the firstbit in the stream.

2.1.19 byte: Sequence of 8-bits.

2.1.20 channel: A digital medium that stores or transports an ISO/IEC 11172 stream.

2.1.2} channel [audio]: The left and right channels of a stereo signal

2.1.22 chrominance (component) [video]: A matrix, block or single pel representing one of the two colour difference signals related to the primary colours in the manner defined in CCIR Rec 601. The symbols used for the colour difference signals are Cr and Cb.

2.1.23 coded audio bitstream [audio]: A coded representation of an audio signal as specified in [SOIIEC 11172-3.

2.1.24 coded video bitstream [video]: A coded representation of a series of one or more pictures as specified in this part of  ${SO/IEC}$  11172.

2.1.25 coded order [video]: The order in which the pictures are stored and decoded. This order is not necessarily the same as the display order.

2.1.26 coded representation: A data elementas represented in its encoded form.

2.1.27 coding parameters [video]: The set of user-definable parameters that characterize a coded video bitstream. Bitstreams are characterised by coding parameters. Decoders are characterised by the bilstreams that they are capable of decoding.

2.1.23 component [video]: A matrix, block or single pal. from one of the three matrices (luminance and two chrominance) that make up a picture.

2.1.29 compression: Reduction in the number of bits used to represent an item of data.

2.1.30 constant bitrate coded video [video]: A compressed video bitstream with a constant averagebitrate.

2.1.31 constant bitrate: Operation where the bitrate is constant from start to finish of the compressad bitstream.

2.1.32 constrained parameters [video]: The values of the set of coding parameters defined in 2.4.3.2.

2.1.33 constrained system parameter stream (CSPS) [system]: An ISO/IEC 11172 multiplexed stream for which the constraints defined in 2.4.6 of ISO/IEC 11172-1 apply.

2.1.34 CRC: Cyclic redundancy code.

2.1.35 critical band rate [audio]: Psychoacoustic function of frequency. At a given audible frequency it is proportional to the number of critical bands below that frequency. \_ The units of the critical band rate scale areBarks.

2.1.36 critical band [audio]: Psychoacoustic measure in the spectral domain which corresponds to the frequency seiedivity of the human ear. This selectivity is expressed in Bark.

2.1.37 data element: An item of data as represented before encoding and after decoding.

2.1.38 dc-coefficient [video]: The DCT coefficient for which the frequency is zero in bothPUMA Exhibit 2005 dimensions. Apple v. PUMA, IPR2016-01135 14 of 124  $\frac{11}{11}$  14 of 124

> Apple Exhibit 1009 Apple Exhibit 1009 Page 14 of 124 Page 14 of 124

2.1.39 dc-coded picture; D-picture [video]: A picture that is coded using only information from itself. Of the DCT coefficients in the coded representation, only the dc-coefficients are present.

2.1.40 DCT coefficient: The amplitude of a specific cosine basis funcriou.

2.1.41 decoded stream: The decoded reconstruction of a compressed bitstream.

2.1.42 decoder input buffer [video]: The first-in first-out (FIFO) buffer specified in the video buffering verifier.

2.1.43 decoder input rate [video]: The data rate specified in the video buffering verifier and encoded in the coded video bitstream.

2.1.44 decoder. An embodiment of a decoding process.

2.1.45 decoding (process): The process defined in ISO/IEC 11172 that reads an input coded bitstream and produces decoded pictures or audio samples.

2.1.46 decoding time-stamp; DTS [system]: A field that may be present in a packet header that indicates the time that an access unit is decoded in the system target decoder.

2.1.47 de-emphasis {audio}: Filtering applied to an audio signal after storage or transmission to undo a linear distortion due to emphasis.

2.1.48 dequantization [video]: The process of rescaling the quantized DCT coefficients after their representation in the bitstream has been decoded and before they are presented to the inverse DCT.

2.1.49 digital storage media; DSM: A digital storage or transmission device or system.

2.1.50 discrete cosine transform; DCT [video]: Either the forward discrete cosine transform or the inverse discrete cosine transform. The DCT is an invertible, discrete orthogonal transfonnation. The inverse DCT is defined in annex A.

2.1.51 display order [video]: The order in which the decoded pictures should be displayed. Normally this is the same order in which they were presented at the input of the encoder.

2.1.52 dual channel mode [audio]: A mode, where two audio channels with independent programme contents (cg. bilingual) are encoded within one bitstream. The coding process is the same as for the stereo mode.

2.1.53 editing: The process by which one or more compressed bitstreams are manipulated to produce a new compressed bitstream. . Conforming edited bitstreams must meet the requirements defined in this part of ISO/EEC l1172.

2.1.54 elementary stream [system]: A generic term for one of the coded video, coded audio or other coded bitstreams.

2.1.55 emphasis [audio]: Filtering applied to an audio signal before storage or transmission to improve the signal—to—noise ratio at high frequencies.

2.1.56 encoder: An embodiment of an encoding process.

2.1.57 encoding (process): A process, not specified in lSO/IEC 1l172, that reads asueam of input pictures or audio samples and produces a valid coded bitstream as defined in ISO/IEC 11172.

21.58 entropy coding: Vanable length lossless coding of the digital representation of a signal to Exhibit 2005<br>reduce redundancy.

Apple v. PUMA, IPR2016-01135 Apple v. PUMA, IPR2016-01135

**2.1.59 fast forward playback [video]:** The process of displaying a sequence, or parts of a sequence,  $15$  of  $124$ ofpictures in display-order faster than real-time.

> Apple Exhibit 1009 Apple Exhibit 1009 Page 15 of 124 Page 15 of1245

2.1.60 FFT: Fast Fourier Transformation. A fast algorithm for performing a discrete Fourier transform (an orthogonal transform). '

2.1.61 filterbank [audio]: A set of band-pass filters covering the entire audio frequency range.

2.1.62 fixed segmentation [audio]: A subdivision of the digital representation of an audio signal into fired segments of time.

2.1.63 forbidden: The term "forbidden" when used in the clauses defining the coded bilstream indicates that the value shall never be used. This is usually to avoid emulation of start codes.

2.1.64 forced updating [video]: The process by which macroblocks are intra-coded from time-to-time to ensure that mismatch errors between the inverse DCT processes in encoders and decoders cannot build up excessively.

2.1.65 forward motion vector [video]: A motion vector that is used for motion compensation from areferenoe picture at an earlier time in display order.

2.1.66 frame (audio): A part of the audio signal that corresponds to audio PCM samples from an Audio Access Unit.

21.67 free format [audio]: Any bitrate other than the defined bitrates that is less than the maximum valid bitrate for each layer.

2.1.68 future reference picture [video]: The future reference picture is the reference picture that occurs at a later time than the current picture-in display order.

2.1.69 granules [Layer II] [audio]: The set of 3 consecutive subband samples from all 32 subbands thatare considered together before quartization. They correspond to 96 PCM samples.

2.1.70 granules [Layer III] [audio]: 576 frequency lines that carry their own side information.

2.1.71 group of pictures [video]: A series of one or more coded pictures intended to assist random access. The group of pictures is one of the layers in the coding syntax defined in this part of ISO/IEC 11 172.

2.1.72 Harm window [audio]: A time function applied sample-oy-sample to a block of audio samples before Fourier transformation.

2.1.73 Huffman coding: A specific method for entropy coding.

2.1.74 hybrid filterbank [audio]: A serial combination of subband filterbank and MDCT.

2.1.75 IMDCT [audio]: Inverse Modified Discrete Cosine Transform.

2.1.76 intensity stereo [audio]: A method of exploiting stereo irrelevance or redundancy in stereophooic audio programmes based on retaining at high frequencies only the energy envelope of the right and left channels.

**2.1.77 interlace [video]:** The property of conventional television pictures where alternating lines of the picture represent different instances in time.

**2.1.78 intra coding [video]:** Coding of a macroblock or picture that uses information only from that marroblock or picture.

2.1.79 intra-coded picture; I-picture [video]: A picture coded using information only from  $R_{\text{eff}}^{\text{PL}}$ Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 16 of 124 16 of 124

2.1.80 ISO/IEC 11172 (multiplexed) stream [system]: A bitstream composed of zero or more elementary streams combined in the manner defined in ISO/IEC 11172-1.

2.1.81 joint stereo coding [audio]: Any method that exploits stereophonic irrelevance or stereophonic redundancy.

2.1.32 joint stereo mode [audio]: A mode of the audio coding algorithm using joint stereo coding.

2.1.83 layer [audio]: One of the levels in the coding hierarchy of the audio system defined in ISO/IEC 11172-3.

2.1.84 layer [video and systems]: One of the levels in the data hierarchy of the video and system specifications defined in ISO/IEC 11172-1 and this part of ISO/IEC 11172.

2.1.85 luminance (component) [video]: A matrix, block or single pol representing a monochrome representation of the signal and related to the primary colours in the manner defined in CCIR Rec 601. The symbol used for luminance is Y.

2.1.86 macroblock [video]: The four 8 by 8 blocks of luminance data and the two corresponding 8 by 8 blocks. of chrominance data coming from a 16by 16 section of the luminance component of the picture. Macroblock is sometimes used to refer to the pel data and sometimes to the coded representation of the pel values and other data elements defined in the macroblock layer of the syntax defined in this part of ISO/IEC 11172. The usage is dear from the context.

2.1.87 mapping [audio]: Conversion of an audio signal from time to frequency domain by subband filtering and/or by MDCT.

2.1.88 masking [audio]: A property of the human auditory system by which an audio signal cannot be perceived in the presence of another audio signal.

2.1.89 masking threshold [audio]: A function in frequency and time below which an audio signai' cannot be perceived by the human auditory system.

2.1.90 MDCT [audio]: Modified Discrete Cosine Transform.

2.1.91 motion compensation [video]: The use of motion vectors to improve the efficiency of the prediction of pel values. The prediction uses motion vectors to provide offsets into the past and/or future reference pictures containing previously decoded pet valuesthat are used to form the prediction error signal

2.1.92 motion estimation [video]: The process of estimating motion vectors during the encoding process.

2.1.93 motion vector [video]: A two-dimensional vector used for motion compensation that provides an offset from the coordinate position in the current picture to the coordinates in a reference picture.

2.1.94 MS stereo [audio]: A method of exploiting stereo irrelevance or redundancy in stereophonic audio programmes based on coding the sum and difference signal instead of the left and right channels.

2.1.95 non—intra coding [video]: Coding of a macroblock or picture that uses information both from itself and from macrobiocks and pictures occurring at other times.

2.1.96 non-tonal component [audio]: A noise-like component of an audio signal.

2.1.97 Nyquist sampling: Sampling at or above twice the maximum bandwidth of a signal.

PUMA Exhibit 2005 2.1.98 pack [system]: A pack consists of a pack header followed by one or more packets. It is a layer in the system coding syntax described in  $\text{ISO}/\text{IEC}$  11172–1.

> Apple v. PUMA, IPR2016-01135 Apple v. PUMA, IPR2016-01135

2.1.99 packet data Isystem]: Contiguous bytes of data from an elementary stream present in a packet.  $17$  of  $124$ 

Page 17 of 124 Page 17 of 124

ISO/IEO 11172-2: 1993 (E) © [so/[EC

2.1.100 packet header [system]: The data structure used to convey information about the elementary stream data contained in the packet data.

2.1.101 packet [system]: A packet consists of a header followed by a number of contiguous bytes from an elementary data stream. It is a layer in the system coding syntax described in ISO/IEC 11172-1.

2.1.102 padding [audio]: A method to adjust the average length in time of an audio frame to the duration of the corresponding PCM samples, by conditionally adding a slot to the audio frame.

2.1.103 past reference picture [video]: The past reference picture is the reference picture that occurs at an earlier time than the current picture in display order.

2.1.104 pel aspect ratio [video]: The ratio of the nominal vertical height of pel on the display to its nominal horizontal width.

2.1.105 pel [video]: Picture element.

2.1.106 picture period [video]: The reciprocal of the picture rate.

**2.1.107 picture rate [video]:** The nominal rate at which pictures should be output from the decoding process.

2.1.108 picture [video]: Source, coded or reconstructed image data. A source or reconstructed picture consists of three rectangular matrices of 8-bitnumbers representing the luminance and two chrominance signals. The Picture layer is one of the layers in the coding syntax defined in this part of ISO/IEC 11172. Note that the term "picture" is always used in ISO/IEC 11172 in preference to the terms field or frame.

2.1.109 polyphase filterbank [audio]: A set of equal bandwidth filters with special phase interrelationships allowing foran efficient implementation of the filterbank.

2.1.110 prediction [video]: The use of a predictor to provide an estimate of the pel value or data element currently beingdecoded.

2.1.111 predictive-coded picture; P-picture [video]: A picture that is coded using motion compensated prediction from the past reference picture.

2.1.112 prediction error [video]: The difference between the actual value of a pel or data element and its predictor.

2.1.113 predictor [video]: A linear combination of previously decoded pel values or data elements.

2.1.114 presentation time-stamp; PTS [system]: A field that may be present in a packet header that indicates the time that a presentation unit is presented in the system target decoder.

2.1.115 presentation unit; PU [system]: A decoded audio access unit or a decoded picture.

2.1.116 psychoacoustic mode] [audio]: A madiematical model of the masking behaviour of the human auditory system.

2.1.117 quantization matrix [video]: A set of sixty-four 8-bit values used by the dequantizer.

2.1.118 quantized DCT coefficients [video]: DCT coefficients before dequantizatiou. A variable length coded representation of quantized DCT coefficients is stored as part of the compressed video

PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 18 of 124 18 of 124 2.1.119 quantizer scalefactor [video]: A data element represented in the bitstream and used by the  $2005$ decoding process to scale the dequantization. Apple V. PUMA, IPR2016-01135

2.1.120 random access: The process of beginning to read and decode the coded bilstream at an arbitrary point

2.1.121 reference picture [video]: Reference pictures are the nearest adjacent I- or P-pictures to the current picture in display Order.

**2.1.122 reorder buffer [video]:** A buffer in the system target decoder for storage of a reconstructed  $I$ picture or a reconstructed P-picture.

**2.1.123 requantization** [audio]: Decoding of coded subband samples in order to recover the original quantized values.

2.1.124 reserved: The term "reserved" when used in the clauses defining the coded bitstream indicates that the valuemay be used in the future for [SO/{EC defined extensions.

2.1.125 reverse playback [video]: The process of displaying the picture sequence in the reverse of display order.

**2.1.126** scalefactor band [audio]: A set of frequency lines in Layer III which are scaled by one scalefactor.

2.1.127 scalefactor index [audio]: A numerical code for a scalefactor.

2.1.128 scalefactor [audio]: Factor by which a set of values is scaled beftne quantization.

**2.1.129 sequence header [video]:** A block of data in the coded bitstream containing the coded representation of anumher of data elements.

2.1.130 side information: Information in the bitstream necessary for controlling the decoder.

2.1.131 skipped macroblock [video]: A macroblock for which no data are stored.

2.1.132 slice [video]: A series of macroblocks. It is one of the layers of the coding syntax defined in this part of ISO/IEC 11172.

2.1.133 slot [audio]: A slot is an elementary part in the bitstream. In Layer I a slot equals four bytes, in Layers II and III one byte.

2.1.134 source stream: A single non-multiplexed stream ofsamples before compression coding.

2.1.135 spreading function [audio]: A function that describes the frequency spread of masking.

2.1.136 start codes [system and video}: 32-bit codes embedded in that coded bitstream that are unique. They are used for several purposes including identifying some of the layers in the coding syntax.

2.1.137 STD input buffer [system]: A first-in first-out buffer at the input of the system target decoder for storage of compressed data from elementary streams-before decoding.

2.1.138 stereo mode [audio]: Mode, where two audio channels which form a stereo pair (left and right) are encoded within one bitstream. The coding process is the same as for the dual channel mode.

2.1.139 stuffing (bits); stuffing (bytes) : Code-words that may be inserted into the compressed bitstream that are discarded in the decoding process. Their purpose is to increase the biuate of the stream.

2.1.140 subliand [audio]: Subdivision ol the audio frequency band.

PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 19 of 124  $P$ UMA Exhibit 2005 2.1.141 subband filterbank [audio]: A set of band filters covering the entire audio frequency parts of 135<br>In ISO/IEO 11172.2 the orbland filter bord is a solution filter had. In ISO/IEC 11172-3 the subband filterbank is a polyphase filterbank.  $\blacksquare$  $\mu$  phase filterbank. The set of 124

2.1.142. suhband samples [audio]: The subband filterhank within the audio encoder creates a filtered and subsampled representation of the input audio stream. The filtered samples are called subband samples. From 384 time-consecutive input audio samples, 12 time-consecutive subband samples are generated within each of the 32 subbands.

2.1.143 syncword [audio]: A 12-bit code embedded in the audio bitstream that identifies the start of a frame.

2.1.141 synthesis filterbank [audio]: Filteibank in the decoder that reconstructs a PCM audio signal from subband samples.

2.1.145 system header [system]: The system header is a data structure defined in ISO/[EC 11172—1 that carries information summarising the system diaracteristics ofthe ISO/IEC 11172 multiplexed stream.

2.1.146 system target decoder, STD [system]: A hypothetical reference model of a decoding process used to describe the semantics of an ISOllEC 11172 multiplexed bitstream.

2.1.147 time-stamp [system]: A term that indicates the time of an event.

2.1.148 triplet [audio]: A set of <sup>3</sup> consecutive subhand samples from one subband. A triplet from each of the 32 suhbands forms a granule.

2.1.149 tonal component [audio]: A sinusoid—like component of an audio signal.

2.1.150 variable bitrate: Operation where the bitrate varies with time during the decoding of a compressed bitstream.

2.1.151 variable length coding; VLC: A reversible procedure for coding that assigns shorter codewords to frequent events and longer code-words to less frequent events.

2.1.152 video buffering verifier; VBV [video]: A hypothetical decoder that is conceptually connected to the output of the encoder. Its purpose is to provide acoustrainton the variability of the data rate that an encoder or editing process may produce.

2.1.153 video sequence [video]: A series of one or more groups of pictures. It is one of the layers of the coding syntax defined in this part of ISO/IEC  $11172$ .

2.1.154 zig-zag scanning order [video]: A specific sequential ordering of the DCT coefficients from (approximately) the lowest spatial frequency to the highest.

# 2.2 Symbols and abbreviations

The mathematital operators used to describe this Intemaional Standard are similar in those used in the C programming language- However, integer division with truncation and rounding are specifically defined. The bitwise operators are defined assuming twos-complement representation of integers. Numbering and counting loops generally begin from zero.

### <sup>2</sup> . 2 .1 Arith metic operators

<< Shift left with zero fill.

# 2 .2 .5 Assignment

= Assignment operator.

#### 2.2.6 Mnemonics

The following mnemonics are defined to describe the different data types used in the coded bit-stream.

#### 2.2.? Constants

# 2.3 Method of describing bitstream syntax

The bitstream retrieved by the decoder is described in 2.42. Each data item in the bitstream is in bold type. It is described by its name, its length in bits, and a mnemonic for its type and order of transmission.

The action caused by adecoded data element in abitstream depends on the value of that data element and on data elements previously decoded. The decoding of the data elements and definition ofthe state variables used in their decoding are described in 2.4.3. The following constructs are used to express the conditions when data elements are present, and are in normal type:

Note this syntax uses the 'C'-code convention that a variable or expression evaluating to a nonzero value is equivalent to acondition that is true.

2005

#### iSO/IEC 11172-2: 1993 (E) © iSO/lEC

for (exprl; expr2; expr3) { cxprl is an expression specifying the initialization of the loop. Normally it  $data$  $e$ lernent specifies the initial state of the counter.  $exp(2)$  is a condition specifying a test - . . made before each iteration of the loop. The loop terminates when the condition is not true. expr3 is an expression that is performed at the end of each iteration of the loop, normally it increments a counter.

Note that the most common usage of this construct is as follows:

As noted, the group of data elements may contain nested conditional constructs. For compactness, the  $\{\}$ may be omitted when only one data element follows.

 $data$ -element  $[m..n]$  is the inclusive range of bits between bit m and bit n in the data element.

While the syntax is expressed in procedural terms, it should not be assumed that 2.4.3 implements a safisfactorydeeoding procedure. In particular, it defines a correct and error-free input bitstream. Actual decoders must include a means to look for start codes in order to begin decoding correctly, and to identify errors. erasures or insertions while decoding. The methods to identify these situations, and the actions tobe taken, are not standardized.

#### Definition of hytealigned function

The function hytealigned 0 returns <sup>1</sup> it the current position is on a byte boundary, that is the next bit in the bitstream is the first bit in a byte. Otherwise it returns 0.

#### Definition of nextbits function

The function nextbits 0 permits comparison of a bit string with the next bits to be decoded in the bitstream.

#### Definition of next\_start\_code function

The next\_start\_code function removes any zero bit and zero byte stuffing and locates the next start code.

After that any number of zero bytes may be present before the start-code. Therefore start-codes aBUMfore Exhibit 2005 Apple v. PUMA, IPR2016-01135 This function checks whether the current position is bytealigned. If it is not, zero stuffing bits are present. bytealigned and may be preceded by any number of zero stuffing bits.

#### 2.4 Requirements

#### 2.4.1 Coding structure and parameters

#### Video sequence

A coded video sequence commences with a sequence header and is followed by one or more groups of pictures and is ended by a sequence\_end\_codc. Immediately before each of the groups of pictures there may be a sequence header. Within each sequence, pictures shall be decodable continuously.

In each of these repeated sequence headers all of the data elements with the permitted exception of those defining the quantization matrices (load\_intra\_quantizer\_matrix, load\_non\_intra\_quantizer\_matrix and Optionally intra\_quantizer\_rnatrix and non\_intra\_qnantizer\_rnatrix) shall have the same values as in the first sequence header. 'Ihequantization matrices may be redefined each time that a sequence header occurs in the bitstream. Thus the data elements load\_intra\_quantizer\_matrix, load\_non\_intra\_quantizer\_matrix and optionally intra\_quantizer\_matrix and non\_intra\_quantizer\_matrix may have any (non-forbidden) values.

Repeating the sequence header allowsthe data elements of the initial sequence headerto berepeated in order that random access into the video sequence is possible. In addition the quantization matrices may be daanged ins'de the video sequence as required.

#### Sequence header

A video sequence header commences with a sequence\_header\_code and is followed by a series of data elements.

#### Group of pictures

A group of pictures is a series of one or more coded pictures intended to assist random access into the sequence. In the stored bitstream, the first coded picture in a group of pictures is an l-Picture. The order of the pictures in the coded stream is the order in which the decoder processes them in normal playback In particular, adjacent B-Pictures in the coded stream are in display order. The last coded picture, in display order, of a group of pictures is either an I-Picture or a P-Picture.

The following is an example of groups of pictures taken from the beginning ofa video sequence. In this example the first group of pictures contains seven pictures and subsequent groups of pictures contain nine pictures. There are two B—pictnres between successive P-pictnres and also two B—picturcs between successive I- and P-pictures. Picture '11' is used to form a prediction for picture '4P'. Pictures '4P' and '11' are both used to form predictions for pictures 2B' and '3B'. Therefore the order of pictures in the coded sequence shall be "11', '4P', '2B', '3B'. However, the decoder should display them in the order 'lI', '23', '3B', '4P'.

At the encoder input,

At the encoder output, in the stored hitstrearn, and at the decoder input;

where the double vertical bars mark the group of pictures boundaries. Note that in this example, the fust group of pictures is two pictures shorter than subsequent grorrps of pictures, since atthe beginning of video coding there are no B—pictures preceding the first I-Picture. However, in genera], in display order, there may be B-Pictures preceding the first I-Picture in the group of pictures, even for the first group of pictures to be decoded.

> PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 25 of 124 25 of 124

At the decoder output,

#### 1234567391011l2i314i516171819202122232425

A group of pictures may be of any length. A group of pictures shall contain one or more I-Pictures. Applications requiring random access, fast-forward playback, or fast and normal reverse playback may use relatively short groups of pictures Groups of pictures may also be started at scene cuts or other cases where motion compensation is ineffective.

The number of consecutive B-Pictures is variable. Neither B- nor P-Pictures need be present.

A video sequence of groups of pictures that is read by the decoder may be different from the one at the encoder output due to editing.

#### Picture

A source orreconstructed picture ccns'sts of three rectangular matrices of eight-bit numbers; a luminance matrix  $(Y)$ , and two chrominance matrices (Cb and Cr). The Y-matrix shall have an even number of rows and columns, and the Cb and Cr matrices shall be one half the size of the Y-matrix in both horizontal and vertical dimensions.

The Y, Cb and Cr components are related to the primary (analogue) Red, Green and Blue Signals ( $E_R$ ,  $E_G$ and  $E_D$ ) as described in CCIR Recommendation 601. These primary signals are gamma pre-corrected. The

assumed value of gamma is not defined in this part of [SOHEC 11172 but may typically be in the region approximately 2,2 to approximately 2,8. Applications which require accurate colourreproduction may <sup>I</sup> choose to specify the value of gamma more accurately, but this is outside the scope of this part of ISO/IEC<br>11.172

The luminance and chrominance samples are positioned as shown in figure 5, where " $x$ " marks the position of the luminance (Y) samples and "0" marks the position of the chrominance (Cb and Cr) samples:

Figure  $5 -$  The position of luminance and chrominance samples.

There are four types of coded picture that use different coding methods.

An Intra-coded picture (I-picture) is coded using information only from itself.

A Predictive-coded picture (P-picture) is a picture which is coded using motion compensated prediction from a pastI-Picture or P—Picture.

A Bidirectionally predictive-coded picture (B-picture) is a picture which is coded using motion compensated prediction from a past andlor future I-Picture or P—Pictnre.

dc ones are present. The D-Pictures shall not be in a sequence containing any other picture lypes  $\mu$ UMA Exhibit 2005 A dc coded (D) picture is coded using information only from itself. Of the DCT coefficients only the

Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 26 of 124 26 of 124

#### Slice

A slice is a series of an arbitrary number of macroblocks with the order of macroblocks starting from the upper-left ofthe picture and proceeding by raster-scan order from left to right and top to bottom. The first and last macroblocks of a slice shall not be skipped macroblocks (see 2.4.4.4]. Every slice stall contain-at least one macroblock. Slices shall not overlap and there shall be no gaps between slices. The position of slices may change from picture to picture. The first slice shall start with the first macroblock in the picture and the last slice shall end with the lastmacroblock in the picture.

#### Macrobloek

A macroblock contains a 16-pel by 16-line section of luminance component and the spatially corresponding 8-pel by 8-line section of each chrominance component. A macroblock has 4 luminance blocks and 2 chrominance blocks. The term "macroblock' can refer to source or reconstructed data or to scaled, quantized coefficients. The order of blocks in a macroblock is top-left, top-right, bottom-left. bottom-right blocks for Y, followed by Cb and Cr. Figure 6 shows the macroblock is top-left, top-right, bottom-left, bottom-right blocks for Y, followed by Cb and Cr. Figure 6 arrangement of these blocks. A skipped macroblock is one for which no information is stored (see 2.4.4.4).

Figure  $6 -$  The arrangement of blocks in a macroblock.

#### Block

A block is an orthogonal 8-pel by 8-line section of a luminance or chrominance component.

The term "block" can refer either to source and reomslructed dataorto the corresponding coded data elements.

#### Reserved, Forbidden and Marker bit

The terms "reserved" and "forbidden" are used in the description of some values of several fields in the coded bitstream.

The term 'reserved" indicates that the value may be used in the future for ISO/IEC-defined extensions.

The tenn "forbidden" indicates a value that shall never be used (usually in order to avoid emulation ofstart codes)-

The term 'marker\_bit" indicates a one bit field in which the value zero is forbidden. These marker bits are introduced at several points in the syntax to avoid start-code emulation.

### 2.4.3 Semantics for the video bitstream syntax

#### 2 .4 .3.'I Video sequence layer

sequence\_end\_code -- The sequence\_end\_code is the bit string 000001B7 in hexadecimal. It terminates a video sequence.

#### 2.4.3.2 Sequence header

sequence\_header\_code — The sequence\_header\_code is the bit string 000001 B3 in hexadecimal. It identifiesthe beginning of a sequence header.

horizontal size -- The horizontal size is the width of the displayable part of the luminance component in pels. The width of the encoded luminance component in macroblocks, mb<sub>u</sub>width, is (horizontal\_size+15)/16. The displayable part of the picture is left-aligned in the encoded picture.

vertical\_size  $-$  The vertical\_size is the height of the displayable part of the luminance component in pels. The height of the encoded luminance component in macroblocks, mb\_height. is (vettical\_size+15l/16. The displayahle part of the pictwe is tap—aligned in the encoded picture.

pel\_aspect\_ratio -- This is a four-bit integer defined in the following table.

picture\_rate —— This isa four-bit integer defined in the following table.

PUMA Exhibit 2005 Applicatiors and encoders should take into account the fact that 23,976, 29,97 and 59,94 are not exact representations of the nominal picture rate. The exact values are found from 24 000/1 001, 30 000/1 001, and  $600001001$  and can be derived from CCIR Report  $624.4$ .

Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 34 of 124 34 of 124

bit\_rate  $-$  This is an integer specifying the bitrate of the bitstream measured in units of 400 bits's, rounded upwards. The value zero is forbidden. The value 3FFFF (11 1111 1111 1111 1111) identifies variable bit rate operation.

 $$ 

vbv\_buffer\_size -- This is a 10—bit integer defining the size of the VBV (Video Buffering Verifier, See annex C) buffer needed to decode the sequence. It is defined as:

 $B = 16 * 1024 * vbv_buffer_size$ 

where  $B$  is the minimum VBV buffer size in bits required to decode the sequence (see annex  $C$ ).

constrained parameters flag  $\sim$  This is a one-bit flag which may be set to "1' if the following data elements meet the following constraints:

horizontaLsize <= 768 pols, verticaLsize <= 576 pels, ((horizontal\_size+15)/16) \*((vertical\_size+15)/16) <= 396,  $((horizontal_size+15)/16)$  " $((vertical_size+15)/16)$ "picture\_rate <= 396\*25, picture\_rate  $\leq$ =30 pictures/s. forward  $f\text{-code} \leq 4$  (see 2.4.3.4) backward\_f\_code  $\leq 4$  (see 2.4.3.4)

If the constrained\_parameters\_flag is set, then the vbv\_buffer\_size field shall indicate a VBV buffer size less than or equal to 327 680 bits  $(20*1024*16; i.e. 40 \text{ kbytes}).$ 

If the constrained\_parameters\_flag is set, then the bit\_rate field shall indicate a coded data rate less than or equal to 1 856 000 bits/s.

load intra-quantizer matrix  $-$  This is a one-bit flag which is set to "1' if an intra-quantizer\_matrix follows. If itis set to "0' then the default values defined belowin raster-scan order, are used until the next occurence of the sequence header. '

intra\_quantizer\_matrix  $\sim$  This is a list of sixty-four 8-bit unsigned integers. The new values, stored in the zigzag scanning order shown in  $2.4.4.1$ , replace the default values shown above. The value zero is forbidden. The value for intra<sub>nd</sub>uant[0][0] shall always be 8. The new values shall be in effect until the next occurence of a sequence header.

load\_non\_intra\_quantizer\_matrix – This is a one-bit flag which is set to "1" if a non\_intra\_quanlizer\_mahix follows. If it is set to "D" then the defauit values defined below are used until the nextoccuience of the sequence header.

Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 35 of 124 35 of 124

nongintra-quantizer matrix  $\sim$  This is a list of sixty-four 8-bit unsigned integers. The new values, stored in the zigzag scanning order shown in 2.4.4.1, replace the default values shownabove. The value zero is forbidden. The new values shall be in effect until the next occurence of a sequence header.

extension\_start\_code -- The extension\_start\_code is the bit string 000001135 in hexadecimal. It identifies the beginning of extension data The extension data continue until receipt of another start code. It is a requirement to parse extension data correctly.

#### sequence\_extension\_data —- Reserved

user\_data\_start\_code -- The user\_data\_start\_code is the bit string 000001B2 in hexadecimal. It identifies the beginning of userdata. The user data continues until receipt of another Stan code.

user\_datn — The user\_data is defined by the users for their specific applications. The user data shall not contain a string of 23 or more zero hits.

#### 2-4.3.3 Group of pictures layer

group\_start\_mcle -- The group\_start\_code is the bit string 000001138 in hexadecimal. It identifies the beginning of a group of pictures.

time\_code  $-$  This is a 25-bit field containing the following: drop\_frame\_flag, time\_code\_hours, time\_code\_minutes, marker\_bit, time\_code\_seconds and time\_code\_pictures. The fields correspond to the fields defined in the IEC standard (Publication 461) for "time and control codes for video tape recorders" (see annex E). The code refers to the first picture in the group of pictures that has a temporal reference of zero.<br>The drop frame flag can be set to either "0" or "1". It may be set to "1" only if the picture rate is The drop\_frame\_flag can be set to either  $"0"$  or  $"1"$ . It may be set to  $"1"$  only if the picture rate is  $29,97$ Hz. If it is  $"0"$  then pictures are counted assuming rounding to the nearest integral number of pictures per second, for example 29,97 Hz would be rounded to and counted as 30 Hz. If it is "1" then picture numbers 0 and 1 at the start of each minute, except minutes 0, 10, 20, 30, 40, 50 are omitted from the

closed\_\_gop -- This is a one-bit flag which may be set to "1" if the group of pictures has been encoded without motion vectors pointing to the previous group of pictures.

This bit is provided for use during any editing which occurs after encoding. If the previous group of pictures is removed by editing, broken\_link may be set to "1" so that a decoder may avoid displaying the  $\overline{B}$ -Pictures immediately following the first I-Picture of the group of pictures. However if the closed\_gop hit indicatesthat there areno prediction references to the previous group of pictures then the editor may choose not to set the broken\_link bit as these B~Pictures can be correctly decoded in this case.

broken\_link — This is aone—hit flag which shall be set to "0" during encoding. It is set to "l" to indicate that the B—Pictures immediately following the first l—Picture of a group of pictures cannotbe correctly decoded because the other I—Picture or P-Picture which is used for prediction is not available (because of the action of editing).

A decoder may use this flag to avoid displaying pictures that cannotbe ccrrectly decoded.

extension\_start\_code -- See 2.4.3.2.

group\_extension\_data -- Reserved.

user\_data\_start\_code  $-$  See 2.4.3.2.

user\_data  $-$  See 2.4.3.2.

PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 36 of 124
#### 2.4.3.4 Picture layer

picture\_start\_code — The picture\_start\_code is a string of  $32$ -bits having the value  $00000100$  in hexadecimal.

temporal\_reference -- The temporal\_reference is a 10-bit unsigned integer associated with each input picture. It is incremented by one, modulo 1024, for each input picture. For the earliest picture (in display order) in each group of pictures, the temporal\_reference is reset to zero.

The temporal\_reference is assigned (in sequence) to the pictures in display order, no temporal\_reference shall be omitted from the sequence.

picture\_coding\_type -- The picture\_coding\_type identifies whether a picture is an intra-coded picture(I), predictive-coded picture(P), bidirectionally predictive-coded picture(B), or intra-coded with only dc coefficients picture(D) according to the following table. D-pictures shall never be included in the same video sequenceas the other picture coding types.

vbv\_delay -- The vbv\_delay is a 16-bit unsigned integer. For constant bitrate operation, the vbv\_delay is used to set the initial occupancy of the decoder's buffer at the start of decoding the picture so that the decoder's buffer does not overflow or underflow. The vbv delay measures the time needed to fill the VBV buffer from an initially empty state at the target bit rate, R, to the correct level immediately before the current picture is removed from the buffer.

The value of vbv\_delay is the number of periods of the 90kHz system clock that the VBV should wait after receiving the final byte of the picture start code. It may be calculated from the state of the VBV as follows:

$$
v_{\rm v}^2 = 90\,000 \cdot B_n^* / R
$$

where:

 $n>0$ 

 $=$  VBV occupancy, measured in bits, immediately before removing picture n from the

buffer but after removing any group of picture layer data, sequence header data and the picturc\_start\_code tint immediately precedes the data elements of picture n.

 $R =$  bitrate measured in bits/s. The full precision of the bitrate rather than the rounded value encoded by the bit\_rate field in the sequence header shall be used by the encoder in the VBV model.

For non-constant bitrate operation vbv\_delay shall have the value FFFF in hexadecimal.

full\_pel\_forward\_vector —- If set to "1", then the motion vector values decoded represent integer pel offsets (rather than half-p61 units) as reflected in the equations of 2.4.4.2.

forward\_f\_code -— An unsigned integer taking values <sup>1</sup> through 7. The value zero is forbidden. The variables forward\_r\_size and forward\_r used in the process of decoding the forward motion vectors are derived from forward\_f\_code as described in 2.4.4.2

PUMA Exhibit 2005<br>**Full\_pel\_backward\_vector** -- If set to "1", then the motion vector values decoded represent integer pel Apple v. PUMA, IPR2016-01135 37 of 124 offsets (rather than half pel units) as reflected in the equations of  $2.4.4.3$ .

#### ISO/IEC 11172-2: 1993 (E) o tSO/IEC 11172-2: 1993 (E)

backward f\_code -- An unsigned integer taking values 1 through 7. The value zero is forbidden. The variables backward\_r\_size and backward\_f used in the process of decoding the backward motion vectors are derived from backward  $f_{\perp}$  code as described in 2.4.4.3.

extra\_bit\_picture ~- A bit indicates the presence of the following extra information. If extra\_bit\_picture is set to "1", extra\_information\_picture will follow it. If it is set to "0", there are no data following it.

extra\_information\_picture —- Reserved-

extension\_start\_code -- See 2.4.3.2.

picture\_extension\_data - Reserved.

userglatagstartgode — See 2.4.3.2.

user\_daia —— See 2.4.3.2.

2.4.3.5 Slice layer

slice\_start\_code —- The slice\_start\_code is a string of 32-bits. The first 24-bits have the value 000001 in hexadecimal and the last 8-hits are the slice vertical position having a value in the range 01 through AF hexadecimal inclusive.

slioe\_vertical\_position -— This is given by the last eight hits of the Slicc\_start\_codc. It is an unsigned integer giving the vertical position in macroblock units of the firstmacroblock in the siice. The slice vertical position of the first row of macroblocks is one. Some slices may have the same slice\_vcrtical\_position since slices may start and finish anywhere. Note that the slice\_Vertical\_position is constrained by 2.4.1 to define non-overlapping slices with no gaps between them. The maximum value of slice\_vertical\_position is 175.

quantizer\_scale —- An unsigned integer in the range <sup>1</sup> to 31 used to scale the reconstruction level ofthe retrieved DCT coefficient levels. The decoder shall use this value until another quantizer\_scale is encountered either at the slice layer or the macroblock layer. The value zero is forbidden.

extra\_bit\_slice  $-$  A bit indicates the presence of the following extra information. If extra bit slice is set to "1", extra information slice will follow it. If it is set to "0", there are no data following it.

extra\_information\_slice -— Reserved.

### 2.4.3.6 Macroblock layer

macroblock stuffing  $-$  This is a fixed bit string "0000 0001 111" which can be inserted by the encoder to increase the bit rate to that required of the storage or transmission medium. It is discarded by the decoder.

macroblock\_escape -- The macroblock\_escape is a fixed bit-string "0000 0001 COC" which is used when the difference between macroblock\_address and previous\_macroblock\_address is greater than 33. It causes the value of macroblock\_address\_increment to be 33 greater than the value that will be decoded by subsequent macroblock\_escapes and the macrobiock\_address\_increment codewords.

For example, if there are two macroblock\_escape codewords preceding the macroblock\_address\_increment, then 66 is added to the value indicated by macroolock\_address\_increment

maeroblock\_adtlress\_increment — This is a variable length coded integer coded as per table B.1 which indicates the difference between macroblock\_address and previous\_macroblock\_address. The maximum value of macroblock\_address\_increment is 33. Values greater than this can be encoded using the macroblock\_escape codeword.

PUMA Exhibit 2005 The macroblock\_address is a variable defining the absolute position of the current matroblock. The macroblock\_address of the top-left macroblock is zero.

Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 38 of 124 38 of 124

The previous\_macroblock\_address is a variable defining the absolute position of the last non-skipped macroblock (see 2.4.4.4 for the definition of skipped macroblocks) except at the start of a slice. At the start ofa slice, previous\_macroblock,addressis reset as follows:

previous\_macroblock\_aidress=(slice\_vertical\_position-1)\*mb\_width-1;

The spatial position in macroblock units of a macroblock in the picture (mb\_row, mb\_column) can be computed from the macrobiock\_address as follows:

> mb  $row = macroblock$  address I mb width  $mb_{\perp}$ column = macroblock address %  $mb_{\perp}$ width

where mb\_width is the number of macroblocks in one row of the picture.

NOTE - The slice\_vertical\_position differs from mb\_row by one.

macroblock\_type ~— Variable length coded indicator which indicates the method of coding and content of the macrobiock according to the tables B.2a through B.2d.

macroblock\_quant-- Derived from macroblock\_type.

macroblock\_motion\_forward -- Derived from macroblock\_type.

macroblock\_motion\_backward -- Derived from macroblock\_type.

 $m$ acrob $\text{lock}\_\text{pattern}$  -- Derived from  $m$ acrob $\text{lock}\_\text{type}$ .

 $macroblock\_mtra - Derived from macroblock type.$ 

quantizer\_scale  $-$  An unsigned integer in the range 1 to 31 used to scale the reconstruction level of the retrieved DCT coefficient levels. 'ihe value zero is forbidden. The decoder shall use this value on til another quantizer\_scale is encountered either at the slice layer or the macroblock layer. The presence of quantizer\_scale is determined from macroblock\_type.

motion\_horizontal\_forward\_code -- motion\_horizontal\_forward\_code is decoded according to table 34. The decoded valueis required (aiong with forward\_f— see 2.4.42) to decide whether or not motion\_horizontal\_forward\_r appears in the bitstream.

motion\_horizontal\_forward\_r  $~\sim~$  An unsigned integer (of forward\_t\_size bits - see 2.4.4.2) used in the process of decoding forward motion vectors as described in 2.4.4.2.

motion\_vertical\_forward\_code -- motion\_vertical\_forward\_code is decoded according to table B.4. The decoded value is required (along with forward  $f$  - see 2.4.4.2) to decide whether or not motion\_vertical\_forward\_r appearsin the bitstrearn.

motion\_vertical\_forward\_r — An unsigned integer (of forward\_t\_size bits  $\cdot$  see 2.4.4.2) used in the process of decoding forward motion vectors as described in 2.4.4.2.

motion\_horizontal\_backward\_code -- motion\_horizontal\_backward\_code is decoded according to table B.4. The decoded value is required (along with backward  $f$  - see 2.4.4.2) to decide whether or not motion\_horizontal\_backward\_r appears in the bitstrcarn.

motion\_horizontal\_backward\_r -- An unsigned integer (of backward\_r\_size bits - see 2.4.4.2) used in the process of decoding backward motion vectors as described in 2.4.4.2.

 $mational\_backward\_code$  — motion vertical backward code is decoded according to table  $B.A$ . The decoded value is required (along with backward  $_f$ ) to decide whether or not motion vertical backward  $_f$ appears in the bitstream.

 $\text{motion\_vertical\_backward\_r -- An unsigned integer}$  (of backward\_r\_size bits) used in t $\mathbb{R}$   $\mathbb{W}$ as $\mathbb{S}$  anibit 2005 Apple v. PUMA, IPR2016-01135 decoding backward motion vectors as described in  $2.4.4.3$ .

39 of 124 - 39 of 124

ISONEC 11172-22 1993 © [SO/[EC

coded\_block\_pattern -- coded\_block\_pattern is a variable length code that is used to derive the variable cbp according to table B.3. If macroblock intra is zero, cbp=0. Then the pattern code[i] for  $\neq$  0 to 5 is derived from cbp using the following:

pattern  $code[i] = 0$ ;

if ( cbp &  $(1 \ll (5-1))$  ) pattern code [i] = 1; if ( macroblock\_intra ) pattern  $\c{code[i] = 1}$  ;

pattern\_code $[0]$  – If 1, then the upper left luminance block is to be received in this macroblock.

pattern\_code[1]  $-$  If 1, then the upper right luminance block is to be received in this macroblock.

pattern\_code $[2]$  – If 1, then the lower left luminance block is to be received in this macroblock.

pattern\_code[3]  $-$  If 1, then the lower right luminance block is to be received in this macroblock.

pattern code<sup>[4]</sup>  $-$  If 1, then the chrominance block Cb is to be received in this macroblock.

patiern\_code[5]  $-$  If 1, then the chrominance block Cr is to be received in this macroblock.

end\_of\_macroblock  $-$ - This is a bit which is set to "1" and exists only in D-Pictures.

### 2.4.3.7 Block layer

 $dct_dc_size_l$  luminance —- The number of bits in the following  $dct_dc_d$  differential code, dc\_size\_luminance, is derived according to the VLC table B5a. Note that this data element is used in intra coded blocks.

 $dct_dc_ssize_{chrominance}$  -- The number of bits in the following dct  $dc_d$  differential code, dc\_size\_chrominance, is derived according to the VLC table B.5b. Note that this data element is used in intna coded blocks.

dct\_dc\_differential -- A variable length unsigned integer. If dc\_size\_luminance or dc\_size\_chrominance (as appropriate) is zero, then dct\_dc\_differential is not present in the bitstream, dct\_zz [} is the array of quantized DCT coefficients in zig-zag scanning order.  $dct_zz[i]$  for i $\approx 0.63$  shall be set to zero initially. If dc\_size\_luminance or dc\_size\_chronunance (as appropriate) is greater than zero, then dct\_zz[0] is computed as follows from det dc differential:

#### For luminance blocks:

if  $(\text{dct_dc_differential} \& (1 << (\text{dc_size_luminance-1}))) \& (1 << 0) = \text{dct_dc_differential}$ ; else dct\_zz $[0] = (1) \ll (d \cdot \text{size\_luminance})$  ) | (dct\_dc\_differential+1);

#### For chrominance blocks:

if ( $dct_dc_d$ cifferential  $&(1 << (dc_size_cthrominance-1))$ ) dct<sub>rz</sub>z[0] = dct<sub>r</sub>dc<sub>r</sub>differential; else dct\_zz $[0] = ((-1) \ll (de\_size\_chrominance))$ l (dct\_dc\_differential+1) ;

Note that this data element is used in intia coded blocks.

dct\_coeff\_first -- A variable length code according to tables B.5c through B.5f for the first coopticion Exhibit 2005 The variables run and level are derived according to these tables. The zigzag-scanned quantized  $\Gamma$ CE<sup>NTT</sup> EXILIOTLE coefficient list is updated as follows. 40 of 124 40 of 124

 $i = run$ ; if  $(s = 0)$  dct\_zz[i] = level; if  $(s = 1)$  dct\_zz[i] = - level ;

The terms det\_coeff\_first and dct\_coeff\_next are run-length encoded and dct\_zz[i], i>=0 shall be set to zero initially. A variable length code according to tables  $B.5c$  through B.5f is used to represent the run-length and level of the DCT coefficients. Note that Ibis data element is used in non—intracoded blocks.

det\_coeff\_next m A variable length code according to tables B.5c through B.5f for coefficients following the first retrieved. The variables run and level are derived according to these tables. The zigzag-scanned quantized DCT coefficient list is updated as follows.

 $i = i + \text{mn} + l$ ; if  $(s=0)$  dct\_zz[i] = level; if  $(s == 1) det_zz[i] = - level$ ;

If macroblock intra  $= 1$  then the term i shall be set to zero before the first det coeff next of the block. The decoding of dct\_coeff\_next shall not cause i to exceed 63.

end\_of\_block -- This symbol is always used to indicate that no additional non-zero coefficients are present. It is used even if dct\_zz[63] is non-zero. Its value is the bit-string "10" as defined in table B.5c.

#### 2 . 4 .4 The video decoding process

Compliance requirements for decoders are contained in ISO/IEC 11172-4.

#### 2.4.4.1 Intra-coded macroblocks

In l-pictures all macroblocks are intra-coded and stored. In P-pictures and B-pictures, some macroblocks may be intra-coded as identified by macroblock\_type, Thus, macroblock\_intra identifies the intra-coded maeroblocks.

The variables mb row and mb\_column locate the macroblock in the picture. They are defined in 2.4.3.6. The definitions of dct\_dc\_differential, and dct\_coeff\_next also have defined the zigzag-scanned quantized DCT coefficient list, dct\_zz[]. Each dct\_zz[] is located in the macroblock as defined by pattern\_code[].

Define dct recon $[m]$ [n] to be the matrix of reconstructed DCT coefficients of the block, where the first index identifies the row and the second the column of the matrix. Define dct\_dc\_v\_past, dct\_dc\_cb\_past and dct\_dc\_cr\_past to be the dct\_recon[0][0] of the most recently decoded intra-coded Y. Cb and Cr blocks respectively. The predictors dct\_dc\_y\_past, dct\_dc\_cb\_past and dct\_dc\_cr\_past shall all be reset at the start of a slice and at non-intra—coded macroblocks (including skipped maaohlocks) to the value <sup>1</sup> 024 (128\*8).

Define intra\_quant $[m][n]$  to be the intra quantizer matrix that is specified in the sequence header.

Note that intra\_quant $[0][0]$  is used in the dequantizer calculations for simplicity of description, but the result is overwritten by the subseqient calculation for the dc coefficient.

Define  $\operatorname{scan}[\![n]\!]$  to be the matrix defining the zigzag scanning sequence as follows:

Where **n** is the horizontal index and m is the vertical index.

Define past\_intra\_address as the macroblock\_address of the most recently retrieved intra-coded macroblock within the slice. It shall be reset to -2 at the beginning of each slice.

Then dct\_recon [m][n] shall be computed by any means equivalent to the following procedure for the first luminance block:

```
PUMA Exhibit 2005 
for (m=0; m<8; m++) {
            for (n=0; n<8; n++) {
                       i = \operatorname{scan}[m][n];
                       dct_recon[m][n] = (2 * det_zz[i] * quantizer_scale * intra_quant[m][n] )/16;
                       if ((dct_recon[m][n] \alpha 1) = 0)
                                   \det_{\mathbf{r}} \text{econ}[\mathbf{m}][n] = \det_{\mathbf{r}} \text{econ}[\mathbf{m}][n] - \text{Sign}(\det_{\mathbf{r}} \text{econ}[\mathbf{m}][n]);
                       if (\text{det\_recon}[m][n] > 2047) \text{ det\_recon}[m][n] = 2047;
                       if (\text{det\_recon[m][n]} < -2.048) det recon[m][n] = -2.048;
} }
dct_recon[0][0] = dct_zz[0] * 8;
if ( (macroblock address \cdot past intra address > l) ]
            dct_recon[0][0] = (128 * 8) +dct_recon[0][0];
else
            \det_{a} recon[0][0] = \det_{a} dct_\det_{a} y_past + \det_{a} recon[0][0] ;
\text{det}_\text{L} \text{dc}_\text{y} past = \text{det}_\text{L} \text{recon}[0][0] :
```
 $\Delta$ pple v. PUMA, IPR2016-01135

42 of 124 Note that this process disallows even valued numbers. This has been found to prevent accumulation of mismatch errors.

For the subsequent luminance blocks in the macroblock, in the order of the list defined by the array pattem\_codel]:

```
for (m=0; m<8; m++) {
                     for (n=0; n<8; n++) {
                                \mathbf{i} = \text{scan}[m][n];
                                dct_recon[m][n] = (2 * det_zz[i] * quantizer_scale * intra_quant[m][n] )/16;
                                if ( ( dct_recon[m][n] & 1 ) == 0)
                                            dct_recon[m][n] = dct_recon[m][n] - Sign(dct_recon[m][n]);
                                if (det\_recon[m][n] > 2047) dct_recon[m][n] = 2047;
                                if (dct_recon[m] [n] < -2048) dct_recon[m] [n] = -2048;
           } I
          \det_{\mathbf{r}} \text{recon}[0][0] = \det_{\mathbf{r}} \text{d}c_{\mathbf{r}} past + (\det_{\mathbf{r}} zz[0] * 8) ;
          \det_\alpha dct_dc<sub>ive</sub> past = dct_recon[0][0] ;
For the chrominance Cb block,:
           for (m=0; m<8; m++) {
                      for (n=0, n<8; n++) {
                                i = scan[m][n];
                                dct_recon[m][n] = (2 * d c \cdot zz[i] * qwzizz] intra_quant[m][n] ) /16 ;
                                if ( (dct_recon[m][n] \& 1 ) = 0 )
                                            det\_recon[m][n] = det\_recon[m][n] - Sign(det\_recon[m][n]);
                                if (dct_recon[m][n] > 2 047) dct_recon[m][n] = 2 047;
                                if (\text{det\_recon}[m][n] < -2.048) \text{ det\_recon}[m][n] = -2.048;
                      }
           }
           dct_recon[0][0] =dct_zz{0} * 8;
          if ( ( macroblock_address - past_intra_address ) > 1 )
                      dct_recon[0][0] = (128 * 8) + dct_recon[0][0];
           else
                      \text{det\_recon}[0][0] = \text{det\_dc\_cb\_past} + \text{det\_recon}[0][0];
           dct_dc_cb_past = dct_recon[0][0] ;
For the chrominance Cr block,:
           for (m=0; m<8; m++) {
                      for (n=0; n<8; n++) {
                                 i = \operatorname{scan}[m][n]dct_recon;m|[n] = (2 * d d_2z[i] * quantizer_scale * intra_quant[m][n]' /16;
                                 if ( (dct\_recon[m][n] \& 1) = 0 )
                                            \det_{\mathbf{r}} \text{recon}[\mathbf{m}][\mathbf{n}] = \det_{\mathbf{r}} \text{recon}[\mathbf{m}][\mathbf{n}] - \text{Sign}(\det_{\mathbf{r}} \text{recon}[\mathbf{m}][\mathbf{n}]);
                                 if (dct_recon[m][n] > 2 047) dct_recon[m][n] = 2 047;
                                 if (\text{det\_recon}[m][n] < -2.048) \text{ det\_recon}[m][n] = -2.048;<sup>1</sup>
            } }
           det\_recon[0][0] = det\_zz[0] * 8;if ( ( macroblock_address - past_intra_address) > 1 )dct_recon[0][0] = (128 * 8) + dct_recon[0][0];
           else
                      \text{det\_recon}[0][0] = \text{det\_dc\_cr\_past} + \text{det\_recon}[0][0] ;
           \text{dct\_dc\_cr\_past} = \text{dct\_recon}[0][0];
```
After all the blocks in the macroblock are processed:

rast\_intra\_address = memblock\_address ;

PUMA Exhibit 2005 values in the coded data elements leading to dct\_recon[0][0] < Oor dct\_recon[0][0] > 2 047 are not permitted.<br>Apple v. PUMA, IPR2016-01135

Once the DCT coefficients are reconstructed, the inverse DCT transform defined in annex A shall be appliefly of 124 to Obtain the inverse transformed pel values in the range {-256, 255]. These pel values shall be limitcd'lo

the range  $[0, 255]$  and placed in the luminance and chrominance matrices in the positions defined by mb\_row, mb\_column, and the list defined by the array pattern code.[].

#### 2 .4 .4 .2 Predictive-coded macroblocks in P-pictures

Predictive-coded macroblocks in P-Pictures are decoded in two steps.

First, the value of the forward motion vector for the macroblock is reconstructed and a prediction macroblock is formed, as detailed below.

Second, the DCT coefficient information stored for some or all of the blocks is decoded, dequantized, inverse DCT transformed, and added to the prediction macroblock.

Let recon\_right\_for and recon\_down\_for be the reconstructed horizontal and vertical components of the motion vector for the current macroblock, and recon\_right\_for\_prev and recon\_down\_for\_prev be the reconstructed motion vector for the previous predictive-coded macroblock. Ifthe current macroblock is the first macroblock in the slice, or if the last macroblock that was decoded contained no motion vector information (cither because it was skipped or macroblock\_motion\_forward was zero), then recon\_right\_for\_prev and recon\_down\_for\_prev shall be set to zero.

If no iorward motion vector data exists for the current macroblock [either because it was skipped or macroblock\_motion\_forward  $= 0$ ), the motion vectors shall be set to zero.

If forward motion vector data exists for the currentmacmblock, then any means emiralent to the following procedure shall be used to reconstruct the motion vector horizontal and vertical components.

forward\_ $r$ \_size and forward\_f are derived from forward  $f$  code as follows:

```
forward_r_size = forward_f_code - 1
forward f = 1 \ll forward r size
```

```
if ( (forward f = 1) \| (motion horizontal forward code = 0)) [
         complement_horizontal_forward_r = 0;
} else {
         complement_horizontal_forward_t =forward_f - 1 - motion_horizontal_forward_r;
t
if ( (forward_f == 1) \mathbb{I} (motion_vertical_forward_code == 0)) {
         complement_vertical_forward_t = 0;
} else { .
         complement_vertical_forward_r = forward_f - 1 - motion_vertical_forward_r;
}
right_little = motion_horizontal_forward_code * forward f;
if (right_little = 0) {
         right_big = 0;
} else {
         if (right_little > 0) {
                  right_little = right_little \cdot complement_horizontal_forward_r;
                  right_big = right_little - (32 * forward f);
         \} else \{
```
right\_little = right\_little + complement\_horizontal\_forward\_r; right\_big = right\_little +  $(32 * forward_f);$

34

ł

```
down\_little = motion\_vertical\_forward\_code* forward_f;if \text{(down\_little = 0)} {
         down\_big = 0;
} else { .
         if (down_llittle >0) {
                  down_little = down_little - complement_vertical_forward_r;
                  down_big = down_little - (32 * forward_f);1 else {
                  down\_little = down\_little + complement\_vertical\_forward_r;
                  down_big = down Iittle + (32 * forward f);
         l,
}
```
Values of forward\_f, motion\_horizontal\_forward\_code and if present, motion\_horizontal\_forward\_r shall be such that right\_little is not equal to forward  $f * 16$ .

Values of forward\_f, motion\_vertical\_forward\_code and if present, motion\_vertical\_forward\_r shall be such that down little is not equal to forward  $f * 16$ .

```
max = (16 * forward_f) - 1:
min = (-16 * forward f);
new\_vector = recon\_right\_for\_prev + right\_litle;
if ( (new\_vector \leq max) && (new\_vector \geq min) )
recon\_right\_for = recon\_right\_for\_prev + right\_little;else.
         recon\_right\_for = recon\_right\_for\_prev + right\_big;recon_right_for_prev = recon_right_for ;
if ( full_pel_forward_vector ) recon_right_for = recon_right_for << 1 ;
new\_vector = recon\_down\_for\_prev + down\_little;
if ( (new\_vector \le max) && (new_vector \ge min) )
         recon_down_for = recon_down for prev + down little ;
else
         recon_down_f for = recon_down_f for prev + down_big;
recon_down_for\_prev = recon_down_for;if ( full\_pel\_forward\_vector) recon_down_for = recon_down_for << 1;
```
The motion vectors in whole pel units for the macroblock, right for and down for, and the half pel unit flags, right\_balf\_for and down\_half\_for, are computed as follows:

Motion vectors leading to references outside a reference picture's boundaries are not allowed.

A positive value of the reconstructed horizontal motion vector (right\_for) indicates that the referenced area of the past reference picture is to the right of the macroblock in the coded picture.

A positive value of the reconstructed vertical motion vector (down\_for) indicates that the referenced area of the past reference picture is below the macroblock in the coded picture.

Defining pel\_past[][] as the pel values of the past picture referenced by the forward motion vector, and pel[][] as the predictors for the pel values of the block being decoded, then:

if (  $\ell$  right\_half\_for)&& (! down\_half\_for))<br>pel[i] j] = pel\_past[i+down\_for][j+right\_for];

PUMA Exhibit 2005 pequility = pel\_past[i+down\_tor]{j+right\_tor];<br>Apple v. PUMA, IPR2016-01135 45 of 124 45 of 124

#### **ISO/IEC 11172-2: 1993 (E)** C) ISO/IEC **ISO/IEC** ISO/IEC

}

if ( (I right\_half\_for) && down\_half\_for)  $pel[i][j] = (pel_past[i+down_fof[i+right_fof] +$ pel\_past[i+down\_for+1][j+right\_for])  $// 2;$ 

- if ( right half for && (! down half for) )  $pel[i][j] = (pel past[i+down-for][j+right_fof] +$ pel\_past[i+down\_for][j+right\_for+1]  $)//2$ ;
- if  $(\int$  night half for && down half for )  $pel[i][j] = (rel\_past[i+down\_for][j+right\_for] + pel\_past[i+down\_for+1][j+right\_for] +$ pel\_past[i+down\_for][j+right\_for+1] + pel\_past[i+down\_for+l][j+right\_for+1]) // 4;

Define non\_imra\_quant[m][n] to be the non-intra quantizer matrix that is specified in the sequence header.

The DCT coefficients for each block present in the macroblock shall be reconstructed by any means equivalent to the following procedure:

```
for (m=0; m<8; m++) {
                for (n=0; n<8; n++) {
                                i = \text{scan}[m][n];
                                \det_{\mathbf{z}} \text{recon}[\text{m}][\text{n}] = ((2 * \det_{\mathbf{z}} z[i]) + \text{Sign}(\det_{\mathbf{z}} z[i])) *quantizer_scale * non_intra_quant[m][n]) / 16;
                                if ( (\det_{\mathbf{r}} \text{econ}[m][n] \& 1) = 0 )
                                                \det_{\mathbf{r}} \text{recon}[\text{m}][\text{n}] = \det_{\mathbf{r}} \text{recon}[\text{m}][\text{n}] - \text{Sign}(\det_{\mathbf{r}} \text{recon}[\text{m}][\text{n}]);
                                if (\det_{\mathbf{r}} \text{recon}[\mathbf{m}][\mathbf{n}] > 2047) \ \text{dct\_recon}[\mathbf{m}][\mathbf{n}] = 2047;if (dct_recon[m][n] < -2048) dct_recon[m][n] = -2048 ;<br>if ( dct_zz[i] == 0 )
                                if (\det_z z[i] = 0)<br>\det_z z[\text{mean}][n] = 0;\cdot
```
dct\_recon{m}[n] = 0 for all–in, n in skipped macroblocks and when pattern[i] = 0.

Once the DCT coefficients are reconstructed, the inverse DCT transform defined in annex A shall be applied to obtain the inverse transformed pel values in the interval [-256, 255]. The inverse DCT pel values shall he added to the pelfi] [j] which were computed above using the motion veerors'. The result of the addition shall be limited to the interval  $[0,255]$ . The location of the pels is determined from mb\_row, mb\_column and the pattern\_code list

#### 2.4.4.3 Predictive-coded macroblocks in B-pictures

Predictive-coded macroblocks in B-Pictures are decoded in four steps.

First, the value of the forward motion vector for the macroblock is reconstructed from the retrieved forward motion vector information, and the forward motion vector reconstructed for the previous macroblock, using the same procedure as for calculating the forward motion vector in P-pictures. However, for B-pictures the previous reconstructed motion vectors shall be reset only for the first macroblock in a slice, or when the last macroblock that was decoded was an intra-coded macroblock. If no forward motion vector data exists for the current macroblock, the motion vectors shall be obtained by:

 $recon\_right\_for = recon\_right\_for\_prev$ , recon\_down\_for= recon\_dowu\_for\_prev.

PUMA Exhibit 2005 PUMA Exhibit 2005 Second, the value of the backward motion vector for the rnacroblock shall be reconstructed from the retrievedbackward motion vectorinformation, and the backward motion vector reconstructed for the previous macroblock using the same procedure as for calculating the forward motion vector in B-pictures. In this procedure, the variables needed to find the backward motion vector are substituted for the variables needed to find the forward motion vector. The variables and coded data elements used to calculate the backward motion vector are:

recon\_right\_back\_prev, recon\_down\_back\_prev, backward\_f\_code, full\_p<mark>Appalkward'\leVd</mark>dx, IPR2016-01135 46 of 124 motion\_horizontal\_backward\_code, motion\_horizontal\_backward\_r, motion\_vertical\_backward\_code, motion\_vertical\_backward\_r,

backward rusize and backward fare derived from backward foode as follows:

 $backward_r_size = backward_fcode - 1$  $backward_f = 1 \ll$  backward  $r$  size

The following variables result from applying the algorithm in 2.4.4.2, modified as described in the previous paragraphs in this clause:

> right\_for right\_half\_for down\_for down\_half\_for right\_back right\_half\_back down\_back down\_half\_back

They define the integral and halfpe] value of the rightward and downward components of the forward motion vector (which referencesthe past picture in display order) and the backward motion Vector (which references the future picture in display order).

Third, the'predictors of the pel values of the block being decoded, pel HI], are calculated. If only forward motion vector information was retrieved for the macroblock, then pel $\prod$  of the decoded picture shall be calculated according to the formulas in 2.4.4.2. If only backward motion vector information was retrieved for the macroblock, then pel[][] of the decoded picture shall be calculated according to the formulas in the predictive-coded macroblock clause, with "hack" replacing "for", and pel\_future[][] replacing pel\_past[][]. If both forward and backward motion vectors information are retrieved, then let pel  $[$  for  $]$ [] be the value calculated from the past picture by use of the reconstructed forward motion vector, and let pel\_back $[1]$  be the value calculated from the future picture by use of the reconstructed backward motion vector. Then the value of pel $[]$  shall be calculated by:

 $pel[] = (pel_for[]] + pel_back[]$  //2;

Define non\_intra\_quant $[m][n]$  to be the non-intra quantizer matrix that is specified in the sequence header.

Fourth, the DCT coefficients foreaeh block present in the rmcroblock shall be reconstructed by any means equivalent to the following procedure:

```
for (m=0; m<8; m++) {
          for (n=0, n<8; n++)i = \operatorname{scan}[m][n];
                     dct_recon [n][n] = ((2 * det_z z[i]) + Sign(det_z z[i])) *quantizer_scale * non_intra_quant{\rm [m][n]} ) / 16 ;
                     if ((det\_recon[m][n] \& 1) = 0)
                                det\_recon[m][n] = det\_recon[m][n] - Sign(det\_recon[m][n]);
                     if (dct_recon[m}[n] > 2 047] dct_recon[m}[n] = 2 047 ;
                     if (\text{dct\_recon[m]}[n] < 2.048) dct_recon[m][n] = -2.048;
                     if (dct_zz[i] = 0 )\det_{\mathbf{r}} \operatorname{recon}[\mathbf{m}][\mathbf{n}] = 0;
          <sup>}</sup>
}
```
dct\_recon[m][n] = 0 for all m, n in skipped macroblocks and when pattern  $[i] = 0$ .

Once the DCT coefficients are reconstructed, the inverse DCT transform defined in annex A shall be applied to obtain the inverse transformed pel values in the range [-256, 255]. The inverse DCI' pel values shall be added to pel[][], which were computed above from the motion vectors. The result of the addition shall be limited to the interval [0,255]. The location of the pels is determined from mb\_row, mb\_column and the pattem\_code list

### 2.4.4.4 Skipped macroblocks

greater than 1. PUMA Exhibit 2005 For some macroblocks there are no coded data, that is neither motion vector information nor DCT information is available to the decoder. These macroblocks are called skipped macroblocks and are indicated when the macroblock address increment is greater than 1.

In I-pictures, all macroblocks shall be coded and there shall be no skipped magnephbeks.  $\rm PUMA, IPR2016\text{-}01135$ 47 of 124

In P-pictures, the skipped macroblock is defined to be a macroblock with a reconstructed motion vector equal to zero and no DCT coefiicients.

In B-pictures, the skipped macroblock is defined to have the same macroblock\_type (forward, backward, or both motion vectors) as the prior macroblock, differential motion vectors equal to zero, and no DCT coefficients. In a B-pictune, a skipped macrobiock shall not foliow an intra~coded maeroblock.

### <sup>2</sup> 4.4.5 Forced updating

This function is achieved by forcing the use of an intra-coded macroblock. The update pattern is not defined. For control of accumulation of IDCT mismatch-error, each macroblock-shall be intra-coded at least once per every 132 times it is coded in a P-picture without an intervening I-picture.

> PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 48 of 124 48 of 124

### Annex A

## (normative)

### 8 by <sup>B</sup> Inverse discrete cosine transform

The 8 by 8 inverse discrete cosine transform for I-pictures and P-pictures shall conform to IEEE Draft Standard, P1180/D2, July 18, 1990. For B-pictures this specification may also be applied but may be unnecessarily stringent. Note that clause 2.3 of P1180/D2 'Considerations of Specifying IDCT Mismatch Errors" requires the specification of periodic intra-coding in order to control the accumulation of mismatch errors. The maximum refresh period requirement for this part of ISO/IEC 11172 shall be 132 intra-coded pictures or predictive-coded pictures as stated in 2.4.4.5, which is the same as indicated in P1 I8O/D2 for visual telephony according to CCITT Recommendation H.251 [5].

### Variable length code tables

### Introduction

This annex contains the variable length code tables for macroblock addressing, macroblock type, macroblock pattern, motion vectors, and DCT coefficients.

### **B.1 Macroblock addressing**

PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 50 of 124 50 of 124

### 8.2 Macroblock type

The properties of the macroblock are determined by the macroblock type VLC according to these tables.

Table B.2a. -- Variable length codes for macroblock\_type in intra-coded pictures {I-pictures).

Table B.2b. -- Variable length codes for macroblock\_type in predictive-coded pictures (P-pictures).

Table B.2c. -- Variable length codes for macroblock\_type in bidirectionally predictive-coded pictures ( $\tilde{B}$ -pictures).

Table B.2d. -- Variable length codes for macroblock\_type in dc intra-coded pictures (D-pictures).

PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 51 of 124 51 of 124

### Annex C

### (normative)

### Video buffering verifier

Constant rate coded video bitstreams shall meet constraints imposed through a Video Buffering Verifier (VBV) defined in clause C.I.

The VBV is a hypothetical decoder which is conceptually connected to the output of an encoder. Coded data are placed in the input buffer of the model decoder at the constant bitrate thatis being used. Coded data is removed from the buffer as defined in C.1.4, below. It is a requirement of the encoder (or editor) that the bitstream it produces will not cause the VBV input bufferto either overflow or underflow.

### C.1 Video buffering verifier

C-1.1 The VBV and the video encoder have the same clock frequency as well as the same picture rate, and are operated synchronously. '

C.1.2 The VBV has an input buffer of size B, where B is given in the vbv\_buffer\_size field in the sequence header.

C.1.3 The VBV input buffer is initially empty. After filling the input buffer with all the data that precedes the first picture start code and the picture start codeitself, the input buffer is filled from the bitstream for the time specified by the vbv\_delay field in the video bitstream.

C.l.4 All ofthe picture datafor the picture that has been in the buffer longest is instantaneously removed. Then after each subsequent picture interval all of the picture data for the picture which at that time has been in the bufferlongest is instantaneously removed.

For the purposes of this annex picture data includes any sequence header and group of picture layer data that immediately precede the picture start code as well as all the picture data elements and any trailing stuffing bits or bytes. For the first coded picture in the video sequence, any zero bit or byte stuffing immediately preceding the sequence header is also included in the picture data.

The VBV buffer is examined immediately before removing any picture data and immediately after this picture data is removed. Each time the VBV is examined its occupancy shall lie between zero bits and B bits where, B is the size of the VBV buffer indicated by vbv, buffer size in the sequence header.

This is a requirement for the entire video bitstream.

To meet these requirements the number of bits for the  $(n+1)'$ th coded picture d<sub>n+1</sub> shall satisfy

$$
d_{n+1} > B_n + (2R/P) - B
$$
  
d\_{n+1}  $< B_n + (R/P)$ 

 $d_{n+1} \leq B_n + (R/P)$  Real-valued arithmetic is used in these inequalities.

where

 $n >= 0$ 

 $B = VBY$  receiving buffer size given by vbv\_buffer\_size  $* 16 384$  bits.

 $B_n$  = the buffer occupancy (measured in bits) just after time  $t_n$ 

 $R =$  bitrate measured in bits/s. The full precision of the bitrate rather than the rounded value encoded by the bit\_rate field in the sequence header shall be used by the encoder in the VBV model.

 $P =$  nominal number of pictures per second

 $t_{\rm n}$  = the time when the n'th coded picture is removed from the VBV buffer PUMA Exhibit 2005

### Annex D

#### (informative)

### Guide to encoding Video

### D.1 Introduction

This annex provides background material to help readers understand and implement this part of ISO/IEC 11172. The normative clauses of this part of ISO/IEC 11172 do not specify the design of a decoder. They provide even lessinformation about encoders; they do not specify what algorithms encoders should employ in order to produce a valid bitstream. The normative material is written in aconcise form and contains few examples; consequently is not easy to understand. This annex attempts to address this problem by explaining coding methods, giving examples, and discussing encoding and decoding algorithms which are not directly covered by this part of ISO/IEC 11172.

The normative clauses specify the bitstream in such a way that it is fairly straightforward to design a compliant decoder. Decoders may differ considerably in architecture and implementation details, but have very few choices during the decoding process: the methods and the results of the decoding process are closely specified. Decoders do have some freedom in methods of postprocessing and display, but the results of such postprocessing cannot be used in subsequent decoding steps.

The situation is quite different for encoders. This part of ISO/IEC 11172 does not specify how to design or implement an encoder which produces good quality video. This annex devotes a maior part to discussing encoder algorithms.

This part of ISO/IEC 11172 was developed by ISO/IEC ITC1/SC29/WG11 which is widely known as MPEG (Moving Pictures Expert Group). This part of [SO/JEC 11172 was developed in response to industry needs for an efficient way of storing and retrieving audio and video information on digital storage media (DSM). CD-ROM-is an inexpensive medium which can deliver data at approximately 1,2 Mbits/s, and this partofISOIEEC 11172 was aimed at approximately this data rate. The "corstrained parameters bitstream', a subset of all permissible bitstreams that is expected to be widely used, is limited to data rates up to <sup>1</sup> 856 000 hits/s. However, it should be noted that this part of lSO/IEC 11112 is not limited to this value and may be used at higher data rates.

Two other relevant International Standards were being developed during the work ofthe MPEG video committee: H.261 by CCi'IT aimed at telecommunicadons applications {5], and iSO/lEC 10918 by the ISOII'EC JTCIISC29 (IPEG) committee aimed at the coding of still pictures [6]. Elements of both of these standards were incorporated into this part of ISO/IEC 11172, but subsequent development work by the committee resulted in coding elements that are new to this part of ISO/IEC 11172. Le Gall [2] gives an account of the method by which ISO/IEC JTC1/SC29/WG11 (MPEG) developed this part of ISO/IEC 11172, and a summary of this part of ISO/IEC 11172 itself.

### D.2 Overview

### D.2.1 Video concepts

This part of ISO/IEC 11172 defines a format for compressed digital video. This annex describes some ways in which practical encoders and decoders might be implemented.

before coding. After decoding, the decoder may optionally produce an interlaced format for displayMA Exhibit 2005 Although this part of ISO/IEC 11172 is quite flexible, the basic algorithms have been tuned to work well. at data rates of about 1 to 1,5 M bits/s, at spatial resolutions of about 350 pels horizontally by about 250 pcls vertically, and picture rates of about 24 to 3G pictures/s. The use of the word "picture" as opposed to "frame" is deliberate. This part of ISO/IEC 11172 codes progressively-scanned images and does not recognize the concept of interlace. Interlaced source video must be converted to a non-interlaced format

Apple v. PUMA, IPR2016-01135<br>This part of ISO/IEC 11172 is designed to permit several methods of viewing coded video which are normally associated with VCRs such as forward playback, freeze picture, fast forward, fast reverse, and slow $61$  of  $124$ 

forward. In addition, random access may be possible~ The ability of the decoder to implement these modes depends to some extent on the nature of the digital storage medium on which the coded video is stored-

The overall process of encoding and decoding is illustrated below:

Figure DJ -- Coding and decoding process

Figure D.1 shows a typical sequence of operations that must be performed before moving pictures can be seen by a viewer. The unemoded source may exist in many forms, such as the CCIR 601 format. Clause D.3 describes how such a source may be converted into the appropriate resolution for subsequent encoding. in the encoding step, the encoder must be aware ofthe decoder buffer capacity, and the need of the decoder to match the rate of the media to the rate of filling the picture buffer with arch successive picture. To this end, amodel of the decoder buffer and its overflow and underflow problem is introduced in DA, and rate control is described in  $D.6.1$  The structure of an ISO/IEC 11172-2 bitstream is covered in D.5, as are the coding operations that compress the video. Following the encoding process, the bitstream may be copied to a storage medium. To view the moving pictures, the decoder accesses the 180/IBC 11172-2 bitstrearn, and decodes it as described in D.7. Postprocessing for display is described in D.8.

### 0-2.2 MPEG video compression techniques

Video is represented as a succession of individual pictures, and each picture is treated as a two-dimensional array of picture elements (pols). The colour representation for each pel consists of three components: Y (luminance), md two chrominanoe components Cb and Cr.

Compression of digitized video comes from the use of several techniques: subsampling ofthe chrominance information to match the sensitivity of the human visual system (HVS), quantization, motion compensation (MC) to exploit temporal redundancy, frequency transformation by discrete cosine transform {DCT} to exploitspatial redundancy, variable length coding (VLC), and picture interpolation.

### {1.2.2.1 Subsampling of chrominance information

The HVS is most sensitive to the resolution of an image's luminance component, so the Y pel values are encoded at full resolution. The HVS is less sensitive to the chrominance information. Subsampling reduces the number of pel values by systematically combining them with a type of averaging process. This reduces the amount of information to be compressed by other techniques. The International Standard retains one set of chrominanoe pels for each 2x2 neighbourhood of luminance pols.

#### 0.2.2.2 Quantization

the actual value and the quantized value is called the quantization noise. Under some circumstances, that A Exhibit 2005 HVS is less sensitive to quantization noise so such noise can be allowed to be lapppply in preaxing coping 016-01135 62 of 124 Quantization represents a range of values by a single value in the range. For example, converting areal number to the nearest integer is a form of quantization. The quantized range can be concisely represented as an integer code, which can be used to recover the quantized value during decoding. The difference between efficiency.  $62$  of 124

### D.2.2.3 Predictive coding

Predictive coding is atechnique to improve the Compression through statistical redundancy. Based on values ofpols previously decoded, both the encoder and decoder can estimate or predict the value of a pol yetto be encoded or decoded. The difference between the predicted and actual values is encoded. This difference value is the prediction error which the decoder can use to correct the prediction. Most error values will be small and cluster around the valueO since pol values typically do not have large changes within asmall spatial neighbourhood. The probability distribution of the prediction error is skewed and compresses better than the distribution of the pel values themselves. Additional information can be discarded by quantizng the prediction error. In this International Standard predictive coding is also used for the dc-values of successive luminance or chrominance blocks and in the encoding of motion vectors.

#### D.2.2.4 Motion compensation and interframe coding

Motion compensation (MC) predicts the values of a block petsin a picture by relocating a block of neighbouring pel values from a known picture. The motion is described as a two-dimensional motion vector thatspecifia where to retrieve a block of pel values from apreviously decoded picture that is used to predict pel values of the current block. The simplest example is a scene where the camera is not moving, and no objects in the scene are moving. The pel values at each image location remain the same. and the motion vector for each block is 0. In general however, the encoder may transmit a motion vector for each macroblock. The translated block from the known picture becomes a prediction for the block in the picture tobeencoded. The technique relies on the fact that within ashortsequence of pictures of the same general scene, many objects remain in the same location while others move only a short distance.

#### D.2.2.5 Frequancy transformation

The discrete cosine transform (DCT) converts an 8 by 8 block of pel values to an 8 by 8 matrix of horizontal and vertical spatial frequency coefficients. An <sup>8</sup> by 8 block of pa] values can be reconstructed by performing the inverse discrete cosine transform (IDCT) on the spatial frequency coefficients. In general, most of the energy is concentrated in the low frequency coefficients, which are conventionally written in the upper left corner of the transformed matrix. Compression is achieved by aquantization step, where the quantization intervals are identified by an index. Since the encoder identifies the interval and not the exact value within the interval, the pel values of the block reconstructed by the IDCT have reduced accuracy.

The DCI' coefficient in location (0,0) (upper left) of the block represents the zero horizontal and zero vertical frequency and is called the dc coefficient The dc coefficient is proportional to the average pel value ofthe 8 by 8 block. and additional compression is provided through predictive coding since the difference in the average value of neighbouring 8 by 8 blocks tends to be relatively small. The other coefficients represent me ormore nonzero horizontal ornonzero vertical spatial frequencies, and are called ac coefficients. The quantization level of the coefficients corresponding to the higher spatial frequencies favors the Creation of an ac coefficient of <sup>D</sup> by choosing a quantization step size such that the HVS is unlikely to perceive the loss of the particular spatial frequency unless the coefficient value lies above the particular quantization level. The statistical encoding of the expected runs ofconsecutive zero-valuedcoefftcients of higher–order coefficients accounts for considerable compression gain. To cluster nonzero coefficients early in the series and encode as many zero coefficients as possible following the last nonzero coefficient in the ordering, the coefficient sequence is specified to be a zig-zag ordering; see figure D.30. The ordering omemtrates the highestspatial frequencies at the end of the series

#### D.2.2.6 Variable-length coding

Variable—length coding (VLC) is a statistical coding technique that assigns codewords to values to be encoded. Values of high frequency of occurrence are assigned short codewords, and those ofinfrequent occurrence are assigned long codewords. On average, the more frequent shorter codewords dominate, such that the code string is shorter than the original data. '

#### 0.2.2.7 Picture interpolation

intermediate pictures can be forward and backward predicted and translated by means of moucle UMA Exhabibit  $2005$ decoder may reconstruct pel values belonging to a given block as an average of polites from the aastrarch 016-01135<br>Europe is to see 63 of 124 If the decoder reconstructs a picture from the past and a picture from the future, then the intermediate pictures can be reconstructed by the technique of interpolation, or bidirectional prediction. Blocks in the future pictures.  $\frac{63 \text{ of } 124}{ }$ 

### D.2.3 Bitstream hierarchy

The ISO/EEC 11172-2 coding scheme is arranged in layers corresponding to a hierarchical structure. A sequence is the top layer of the coding hierarchy and consists of a header and some number of groupsof-pictures(COPS). The sequence header initializes the state of the decoder. This allows decoders to decode any sequence without being affected by past decoding hislory.

<sup>A</sup> GOP is arandorn access point, i.e iris the smallest coding unit that can be independently decoded within a sequence, and consists of a header and some number of pictures- The GOP header contains time and editing information.

A picture corresponds to a single frame of motion video, or to <sup>a</sup> movie frame. There are four picture types: I-pictures, or intra coded pictures, which are coded without reference to any other pictures; Ppictures, or predictive coded pictures, which are coded using motion compensation from a previous I or P~ picture; B-pictures, or bidirectionally predictive coded pictures, which are coded using motion compensation from a previous and a future I or P-picture, and D pictures, or  $D$  pictures, which are intended only for a fast forward search mode. A typical coding scheme contains a mix of I,  $P<sub>i</sub>$  and B-pictures. pictures inserted between each pair of I or P-picturcs.

Figure D.2 -— Dependency relationship between I, B, and P-pictures

Figure D.2 illustrates a number of pictures in display order. The arrows show the dependency relationship of the predictive and bidirectionally predictive coded pictures.

Note that because of the picture dependencies, the bitstream order, i.e. the order in which pictures are transmitted, stored, or retrieved, is not the display order, but rather the order which the decoder requires them to decode the bitstream. An example of a sequence of pictures, in display order, might be:

> {BBPB'BPBBPBBIBBPBBP t}123456789101112131415161718

Figure D.3 -- Typical sequence of pictures in display order

whereas the bitstream order would be as shown below:

PBBPBBPBBIBEPBBPBB 3 1  $\mathbf{I}$ <sup>0</sup> 12645978121011151314181617

Figure DA -- Typical sequence of pictures in bitstream order

Because the B-pictures depend on the following (in display order) I or P-picture, the I or P-picture must be transmittal and decoded before the dependent B-pictures.

Pictures consist of a header and one or more slices. The picture header contains time, picture type, and coding information.

picture, the decoder should be able to recover by waiting for the next slice, without having to droppen pair exhibit 2005 Apple v. PUMA, IPR2016-01135 pictm- Apple V. PUMA, IPR2016-01135 A slice provides some immunity to data corruption. Should the bitstream become unreadable within a

64 of 124 64 of 124

Slices consist of a header and one or more macroblocks. At the start of each slice all of the predictors, for do values and motion vectors, are reset. The slice header contains position and quantizer scale information. This is sufficient for recovery from local corruption.

A macroblock is the basic unit for motion compensation and quantizet scale changes

Each macroblock consists of a header and six component 8 by 8 blocks: four blocks of luminance, one block of Ch chrominance, and one block of Cr chrominance. See figure D.5. The macroblock header contains quantizer scale and motion compensation information.

Figure D.5 -- Macroblock structure

A macroblock contains a 16-pel by 16-Iine section of luminance component and the spatially oonesponding 8-pe] by 31ine section of each chrominance component. A skipped macrohlock is one for which no information is stored (see 2.4.4.4).

Note that the picture area covered by the four blocks of luminance is the same as the area covered by each of the chrominance blocks. This is due to subsampling of the chrominance information.

Blocks are the basic coding unit, and the DCT is applied at this block level. Each block contains 64 component pels arranged in an 8 by 8 array as shown in figure D.6.

'Figure D.6 -- Block structure

### D.2.4 Decoder overview

A simplified block diagram of a possible decoder implementation is shown below:

It is instructive to follow the method which the decoder uses to decode a bitstream containing the sequenceof pictures given in Fig DA, and display them in the order given in Fig D.3. The following description is simplified for clarity.

The input bitstream is accumulated in the Input Buffer until needed. The Variable Length Code (VLC) Decoder decodes the header of the fust picture, picture 0, and determines that it is an 1-picture. The VLC Decoder prodices quantized coefficients corresponding to the quantized DCT coefficients These are assembled for each 8 by 8 block of pels in the image by inverse zig-zag scanning. The Inverse Quantizer produces the actual DCT coefficients using the quantization Step size. The coefficients are then transformed into pel values by the Inverse DC'T transformer and stored in the Previous Picture Store and the Display Buffer. The picture may be displayed at the appropriate time.

The VLC Decoder decodes the header of the next picture, picture 3, and determines that it is a P-picture. For each block, the VLC Decoder decodes motion vectors giving the displacement from the stored previous picture, and quantized coefficients corresponding to the quantized DCT coefficients of the difference block. These quantized coefficients are inverse quantized to produce the actual DCT coefficients. The coefficients are then transformed into pel difference values and added to the predicted block produced by applying the motion vectors to blocks in the stored previous picture. The resultant block is stored in the Future Picture Store and the Display Buffer. This picture cannot be displayed until B-pictures 1 and 2 have been received. decoded and displayed.

Ihe VLC Decoder decodes the header of the next picture, picture I. and determines that it is aB-picture. For each biodc, the VLC decoder decodes motion vectors giving the displacement from the stored previous or future pictures or both, and quantized coefficients corresponding to the quantized DCT coefficients ofthe diffemnce block These quantized coefficients are inverse quantized to produce the actual DCT coefficients. The coefficients are then inverse transformed into difference pel values and added to the predicted block produced by applying the motion vectors to the stored pictures. The resultant block is then stored in the Display Buffer. Itmay be displayed at the appropriate time.

The VLC Decoder decodes the header of the next picture, picture 2, and determines that it is a B-picture. It is decoded using the same method as for picture 1. After decoding picture 2, picture 0, which is in the Previous Picture Store, is no longer needed and may be discarded.

The VLC Decoder decodes the header of the next picture, picture 6, and determines that it is a P-picture. The picture in the Future Picture Store is copied into the Previous Picture Store, the ppble otting bMcA<sub>3</sub>dPR2016-01135 66 of 124 for picture 3. Picture 6 should not be displayed until pictures 4 and 5 have been received and displayed.

The VLC Decoder decodes the header of the next picture, picture 4, and determinesthat it is a B—picture. It is decoded using the same method as for picture 1.

The VLC Decoder decodes the header of the next picture, picture- 5, and determines that it is a B-picture. It is decoded using the same method as for picture 1.

The VLC Decoder decodes the header of the next picture, picture 9, and determines that it is a P—picture. It then proceeds as for picture 6.

The VIC Decoder decodes the header of the next picture, picture 7, and determines that it is. a B—picture. It is decoded using the same method as for picture 1.

The VIC Decoder decodes the header of the next picture, picture 8, and determines that it is a B—picture. It is decoded using the same method as for picture 1.

The VLC Decoder decodes the header of the next picture, picture 12, and determines that it is an I-picture. It is decoded using the same method as for picture 0. This process is repeated for the subsequent pictures.

### D.3 Preprocessing

The source material may exist in many forms, cg. computer files or CCIR 601 format, but in general, it mustbe processed before being encoded. This clause discusses some aspects of preprocessing.

For a given data rate and source material, there is an optimum picture rate and spatial resolution at which to code ifthe bestperceived quality is desired. It the resolution is too high, then too many bits will be expended on the overhead associated with each block leaving too few to code the values of each pel accurately. If the resolution is too low, the pel values will be rendered accurately, but high frequency detail will be lost. The optimum resolution represents a tradeoff between the various coding artifacts (e.g. noise and blockiness) and the perceived resolution and sharpness ofthe image. This tradeoff is further complicated by the unknowns of die final viewing conditions, eg, screen brightness and the distance ofthe viewer from the screen.

At data rates of 1 to 1,5 Mbits/s, reasonable choices are: picture rates of 24, 25 and 30 pictures/s, a horizontal resolution of between 250 and 400 pels, and a vertical resolution of between 200 and 300 lines. Note that these values are not normative and other picture rates and resolutions are valid.

### D.3.1 Conversion from CCIR 601 video to MPEG SIF

The two widely used scanning standards for colour television are 525 and 625 lines at 29,97 and 25 frames/s respectively. The number of lines containing picture information in the transmitted signal is 484 forthe  $525$ -line system and  $576$  for the  $625$ -line system. Both use interlaced scanning with two fields per picture.

CCIR Recommendation 601 defines standards for the digital coding of colour television signals in component form. Of these the 4:2:2 standard has become widely adopted; the sampling frequency used for the luminance signal, Y, is  $13,5$  MHz and the two colour difference signals, Cb or B-Y and Cr or R-Y, are both sampled at 6.75 MHz. The number of luminance samples in the digital active line is 720 but only about 702 will be used in practice by the analogue active line.

The number of picture elements in the height and width of the picture, in the standards defined above, are too large for effective coding at data rates between 1 and 1,5 Mbit/s. More appropriate values are obtained by decreasing the resolution in both directions to a half. This reduces the pel rate by a factor of four. Interlace should be avoided as it increases the difficulties in achieving low data rates.

One way to reduce the vertical resolution is to use only the odd or the even fields. If the other field is simply discarded, spatial aliasing will be introduced, and this may produce visible and objectionable artifacts. More sophisticated methods of rate conversion require more computational power, but can perceptibly reduce the aliasing artifacts.

Exhibit 2005 the 4:2.2 format. See the CCIR 601 sampling pattern of figure D.8(a). Such PRIending pattern Hap  $\frac{30}{100}$  16-01135 converted to the SIF sampling pattern of figure D.3(b) as follows. The odd field only may be extracted,  $67$  of  $124$ The horizontal and vertical resolutions may be halved by filtering and subsampling. Consider a picture reducing the number of lines by two, and then a horizontal decimation filter used on the remaining lines to

> Apple Exhibit 1009 Apple Exhibit 1009 Page 67 of 124 Page 67 of 124**ל**

#### lSO/lEC 11172-2: 1993 (E) (Q lSO/IEC

reduce the horizontal resolution by a factor of two. In addition the chrominance values may be vertically decimated. The filters for luminance and chrominance have to be chosen carefully since particular attention relationship between. luminance and chrominancemust also be correct.

(a) Sampling pattern for 4:2:2 (CCIR 601) (b) Sampling pattern for MPEG (SIF) Circles represent luminance; Boxes represent Chrominance

Figure D.8 -- Conversion of CCIR 601 to SIF

The following 7-tap FIR filter has been found to give good results in decimating the luminance:

Figure D3 -- Luminance subsampling filter tap weights

Use of a power of two for the divisor allows a simple hardware implementation.

'lhe chrominance samples have to appear in the between the luminance samples both horizontally and vertically. The following linear filter with a phase shift of half a pet may be found useful.  $\frac{6}{138}$   $\frac{138}{138}$   $\frac{88}{10}$   $\frac{1}{10}$ <br>Complement of allows a simple hardware implementation<br>the vith a phase shift of balf a pel<br>Chrominance subsampling<br>Chrominance subsampling

Figure  $D.10$   $\cdot$  Chrominance subsampling filter tap weights

To recover the samples consistent with the CClR 601 grid of figure D.8(a), the process ofinterpolation is used. The interpolation filter applied to a zero-padded signal can be chosen to be equal to the decimation filter employed for the luminance and the two chrominance values in the encoder.

Note that these filters are not part of the International Standard, and other filters may be used.

At the end of the lines some special technique such as renormalizing the filter or replicating the last pel, must be adopted. The following example shows a horizontal line of 16 luminance pels and the same line after filtering and subsampling. In this example the data in the line is reflected at each end.

PÜMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 68 of 124 so 90 92 90 . 12 32 23 9 12 49 95 {hxhlblt 2005 <sup>10</sup> <sup>12</sup> <sup>20</sup> <sup>30</sup> 35. ### © ISO/IEO ESQ/EEC 11172—2: 1993 (E)

The result of this filtering and subsampling is a source input format {81F} which has a luminance resolution of  $360 \times 240$  or  $360 \times 288$ , and a chrominance resolution which is half that of the luminance in each dimension.

#### (b) Chrominance

The SiF is not quite optimum for processing by MPEG video coders. MPEG video divides the luminance component into macroblocks of 16x16 pels. The horizontal resolution, 360, is not divisible by 16. The same is true of the vertical resolution,  $242$ , in the case of 525-line systems. A better match is obtained in the horizontal direction by discarding the 4 pels at the end of every line oi the suhsampled picture. Care must be taken that this results in the correct configuration of lum'mance and chrominance Samples in Ihe macroblock. The remaining picture is called the significant pe] area, and corresponds to the dark area in figure D.13:

The conversion process is summarized in table D.1.

| Picure Rate (Hz)                    | 29.97            | 25               |
|-------------------------------------|------------------|------------------|
| Picture Aspect Ratio (width:height) | 4:3              | 4:3              |
| Luminance (Y)                       |                  |                  |
| CCIR Sample Resolution              | 720 x 484        | $720 \times 576$ |
| SIF                                 | 360 x 242        | $360 \times 288$ |
| Significant Pel Area                | 352 x 240        | $352 \times 288$ |
| Chrominance (Cb Cr)                 |                  |                  |
| <b>CCIR Sample Resolution</b>       | 360 x 484        | $360 \times 576$ |
| SIF                                 | 180 x 121        | 180 x 144        |
| Significant Pel Area                | $176 \times 120$ | 176 x 144        |

Table D.1 -- Conversion of source formats

The preprocessing into the SIF format is not normative, other processing steps and other resolutions may be used. The picture size need not even be a multiple of 16. In this case an MPEG video coder adds padding pels to the right or bottom edges of a picture in order to bring the transmitted resolution up to a multiple of 16, and the decoder discards these after decoding the picture. For example, a horizontal resolution of 360 pels could be coded by adding 8 padding pels to the right edge of each horizontal row bringing the total up to 368 pols. 23 macroblocks would be coded in each row. The decoder would discard the extra padding pels after decoding, giving a final decoded horizontal resolution of 360 pels.

## 0,3.2 Conversion from film

If film material can be digitized at 24 pictures/s, then it forms an excellent source for an ISO/IEC  $\rm \mu\mu_{22}$ Exhibit 2005 bitstream. It may be digitized at the desired spatial resolution. The picture\_rate fielppihethe WdBMeequ4RR2016-01135 70 of 124 header, see 2.4.2.3, allows the picture rate of 24 pictures to be specified exactly.

Sometimes the source material available for compression consists of film material which has been converted to video at some otherrate. The encoder may detect this and recode at the original film rate. For example, 24 pictures/s film material may have been digitized and converted to a 30 frame/s system by the technique of 3:2 pulldown. In this mode digitized pictures are shown altemately for <sup>3</sup> and for 2television field times. This alternation may not be exact since the actual frame rate might be 29,97 frames/s and not the 30 frames/s that the 3:2 pulldown technique gives. In addition the pulldown timing might have been changed by editiugand splicing after the conversion. A sophisticated encoder might detectthe duplicated fields, average them to reduce digitization noise, and code the result at the original 24 pictures/s rate- This should give a significant improvement in quality over coding at 30 pictures per second, since direct coding at 30 pictures/s destroys the 3:2 pulldown timing and gives a jerky appearance to the final decoded video.

### 0.4 Model decoder

## 0.4.1 Need for a decoder model

A coded bitstrearn contains different types of pictures, and each type ideally requires adifferent number of. hits to encode. in addition. the video may vary in complexity with time, and an encoder may wish to devote more coding bits to one part of a sequence than to another. For constant bitrate coding, varying the number ofbits allocated to each picture requires that the decoder have differing to store the bits notneeded todeeode the immediate picture; The extent to which an encoder can vary the number of bits allocated to each picture depends on the amount of this buffering. If the amount of the buffering is large an encoder can use greater variations, increasing the picture quality, but at the cost of increasing theldecoding delay. Encoders need to know the size of the amount of the decoder's buffering in order to determine to whatextent they can vary the distribution of coding bits among the pictures in the sequence.

The model decoder is defined to solve two problems. It constrains the variability in the number of hits that may be allocated to different pictures and it allows a decoder to initialize its buffering when the system is started. It should be noted that Part 1 of this International Standard addresses the initialisation of buffers and the maintenance of synchronisation during playback in the case when two ormore elementary streams (for example one audio and one video stream) are multiplexed together. The tools defined in ISO/IEC 11172-1 for the maintenance of synchronisation should be used by decoders when multiplexed streams are beingplayed.

### 0.4.2 Decoder model

Annex C contains the definition of <sup>a</sup> parameterizcd mode] decoder for this purpose. It is known as a Video Buffer Verifier (VBV). The parameters used by a particular encoder are defined in the bitstream. This really defines a model decoder that is needed if encoders are to be assured that the coded bitstreams they produce will be decodable. The model decoder looks like this:

Figure D.14 -- Model decoder

A fixed-rate channel is assumed to put hits at a constant rate into the. Input Buffer. At regular intervals, set by the picture rate, the Picture Decoder instantaneously removes all the bits for the next picture from the Input Buffer. If there are too few bits in the Input Buffer, i.e. all the bits for the next picture have not been received, then the Input Buffer underflows and there is an underflow error. If, during the time between picture starts, the capacity of the Input Buffer is exceeded, then there is an overflow error.

PUMA Exhibit 2005 PUMA Exhibit 2005

Practical decoders differ from this model in several important ways. They may just demon their period of 6-01135 a different point in the decoder, or distribute it throughout the decoder. They may not remove all the bits 71 of 124<br>required to decode a picture from the Input Buffer instantaneously, they may not be able to control the

of decoding very preciselyasrequired by the butter fullness parameter in the picture header, and they take a finite time to decode. They may also be able to delay decoding for a short time to reduce the chances of underflow occuring- But these differences depend in degree and kind on the exact method of implementation. To satisfy requirements of different unplementations, the MPEG video committee (lSO/IEC JTC] SC29/WG11) chose a very simple model for the decoder. Practical implementations of decoders must ensure that they can decode the bitstream constrained by this model. In many cases this will be achieved by using an Input Buffer that is larger than the minimum required, and by using a decoding delay that is larger than the value derived from the vbv\_delay parameter. The designer must compensate for differences between the actual design and the model in order to guarantee that the decoder can handle any bitstream that satisfies the model.

Encoders monitor the status of the model to control the encoder so that overflow problems do not occur. The calculated buffer fullness is Iransrnitted at the start of each picture so that the decoder can maintain synchronization.

### D.4.3 Buffer size and delay

For constant bit rate operation each picture header contains a vbv<sub>-</sub>delay parameter to enable decoders to start their decoding correctly. This parameter defines the time needed to fill the Input Buffer of figure D.14 from an empty'state to the correct level immediately before the Picture Decoder removes all the bits for the picture. This time is thus a delay and is measured in units of  $1/90,000$  s. This number was chosen because it is almost an exact multiple of the picture durations:  $1/24$ ,  $1/25$ ,  $1/29$ ,  $97$  and  $1/30$ , and because it is comparable in duration to an audio sample.

The delay is given by

#### $D = vbv$  delay / 90 000 s

For example, if vbv\_delay were 9 000, then the delay would be 0,1 sec. This means that at the start of a picture the Input Buffer of the model decoder should contain exactly 0,1 s worth of data from the-input bitstream.

The bit rate,  $R$ , is defined in the sequence header. The number of bits in the Input Buffer at the beginning of the picture is thus given by:

$$
B = D * R = vby_dday * R / 90 000 bits
$$

For example, if vbv\_delay were 9 000 and R were 1,2 Mbits/s, then the number of bits in the Input Buffer would be 120 000.

The constrained parameter bitstream requires that the Input Buffer have a capacity of 327 680 bits, and B should neverexceed this value.

### D.5 MPEG video bitstream syntax

This clause describes the video bitstream in a top-down fashion. A sequence is the top level of video coding. It begins with a sequence header which defines important parameters needed by the decoder. The sequence header is followed by one or more groups of pictures. Groups of pictures, as the name suggests, consist of one or more individual pictures. The sequence may contain additional sequence heado's. A sequence is terminated by a sequence end code. ISO/IEC 11172-1 allows considerable flexibility in specifying application parameters such as bit rate, picture rate, picture resolution, and picture aspect ratio. These parameters are specified in the sequence header.

Ifthese parameters, and some others, fall within certain limits, then the bitstream is called acoustrained parameterbitstream.

### D.5.l sequence

A video sequence commences with a sequence header and is followed by one or more groups of pictures  $q$  and  $E$ xhibit 2005  $\Delta$ pple $\sim$  PUMA, IPR2016-01135 72 of 124 A video sequence commences with a sequence neader and is rotiowed by one or more groups of propugglap  $q_{\text{ex}}$  this it 2005<br>is ended by a sequence\_end\_code. Additional sequence headers may appear within the sequence  $\mu$ quantization matrices (load\_intra\_quantizer\_matrix, load\_non\_intra\_quantizer\_matrix and optionally

62
intra\_quantizer\_matrix and non\_intra\_quantizer\_matrix) shall have the same values as the first sequence header. Repeating the sequence header with its data elements makes random access into the video sequence possible. The quantization matrices may be redefined as required with each repeated sequence header.

The encoder may set such parameters as the picture size and aspect ratio in the sequence header, to define the resources that adecoder requires. In addition, userdata may be included

# D.5.1.1 Sequence header code

A coded scquencebegins with <sup>a</sup> sequence header and the headerstarts with the sequence start code. Its value is:

hex:  $00\ 00\ 01\ B3$ binary: 0000 0003 0000 0000 00000001101] 0011

This is a unique string of 32 bits that cannot be emulated anywhere else in the bitstream, and is bytealigned, as are all start codes. To achieve byte alignment the encodermay precede the sequence start code with any nurnber of zero bits. These can have a secondary function of preventing decoderinput buffer underflow. This procedure is called bit stuffing, and may be performed before any start code. The stuffing bits must all be zero. The decoder discards all such stuffing bits.

The sequence start code, like all video start codes, begins with a string of 23 zeros. The coding scheme ensures that such a string of consecutive zeros cannot be produced by my other combination of codes, i.e. it cannot be emulated by other codes in the video bitstream. This string of zeros can onlybe produced by a start code,or by stuffing bits preceding a start code.

#### 0.5.1 .2 Horizontal size

This is a 12-bit number representing the width of the picture in pels, i.e. the horizontal resolution. It is an unsigned integer with the most significant bit first. A value of zero is not allowed (to avoid start code emulation) so the legal range is from T to 4 095. In practice values are usually a multiple of 16. At 1,5-Mbits/s, apopular horizontal resolution is 352 pels. The value 352 is derived from half the CCIR 601 horizontal resolution of 720, rounded down to thenearestmultiple of 16 pels. Otherwise the encoder must fill out the picture on the right to the next higher multiple of  $16$  so that the last few pels can be coded in a macroblock. The decoder should discard these extra pels before display.

For efficient coding of the extra pels, the encoder should add pel values that reduce the number of bits generated in the transformed block. Replicating the last column of pels is usually superior to filling in the remaining pels widi a gray level.

## D.5.1.3 Vertical size

This is a 12-bit number representing the height of the picture in pels, i.e. the vertical resolution. It is an unsigned integer with the mostsignificantbit first A value of zero is not allowed (to avoid start code emulation} so the legal range is from <sup>1</sup> to4 095. In practice values are usually a multiple of 16. Note that the maximum value of slice\_vertical\_position is 175 (decimal), which corresponds to a picture height of 2 800 lines. At 1,5 Mbits/s, a popular vertical resolution is 240 to 288 pels. Values of 240 pels are convenient for interfacing to 525-line NTSC systems, and values of 288 pels are more appropriate for 625line PAL and SECAM systems.

If the vertical resolution is not a multiple of 16 lines, the encoder must fill out the picture at the bottom to the next higher multiple of 16 so that the last few lines can be coded in a macroblock The decoder should discard these extra lines before display.

For efficient coding, replicating the last line of pels is usually better than filling in the remaining pels with a grey level.

# D.5.1.4 Pel aspect ratio

PCMA Exhibit 2005 This is a four-bit number which defines the shape of the pel on the viewing screen. This is neploy apply the shape of the displayed ricture.<br>horizontal and vertical picture sizes by themselves do not specify the shape of t This is a four-bit number which defines the shape of the pel on the viewing screen. This is nepled an expediate 2005

73 of 124 The pel aspect ratio does not give the shape directly, but is an index to the following look up table:

# ISO/IEC 11172-2: 1993 © lSO/IEC

| 1010        | 1.0255          |                            |
| 1011        | 1,0695          |                            |
| 1100        | 1.0950          | $711x487$ at $43 = 1,0950$ |
| 1101        | 1,1575          |                            |
| 1110        | 1,2015          |                            |
| 1111        | undefined       | reserved                   |

Table D.2 -- Pei aspect ratio

The code 0000 is forbidden to avoid start code emulation. The code 0001 has square pels. This is appropriate for many computer graphics systems. The code 1000 is suitable for displaying pictures on the 625-line 50Hz TV system (see CCIR Recommendation 601).

height / width = 
$$
0.75 * 702 / 575 = 0.9157
$$

The code 1100 is suitable for displaying pictures on the 525-line 60Hz TV system (see CCIR Recommendation 601).

height / width = 
$$
0.75 * 711 / 487 = 1.0950
$$

The code 1111 is reserved for possible future extensions to this part of ISO/IEC 11172.

The remaining points in the table were filled in by interpolating between these two points 1000'and 1100 using the formula:

#### aspect ratio =  $0,5855 + 0,044N$

where N is the value of the code in table D.2. These additional-pel aspect ratios might be useful for HDTV where ratios of 16:9 and 5:3 have been proposed.

It is evident that the specification does not allow all possible pel aspect ratios to be specified. We therefore presume that a certain degree of tolerance is allowable. Encoders will convert the actual pel aspect ratio to the nearest value in the table, and decoders will display the decoded values to the nearest peI aspect ratio of which they are capable.

## 0.5.1.5 Picture rate

This is a four-bit integer which is an index to the following table:

PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 74 of 124 74 of 124

| <b>CODE</b> | PICTURES PER SECOND |
|-------------|---------------------|

| 1001        | Reserved            |
|             |                     |
|             |                     |
| 1111        | Reserved            |

Table D3 -- Picture rate

The allowed picture rates are oommoniy available sources of analog or digital sequences. One advantage in not allowing greater flexibility in picture rates is thatstandard techniques may be used to convert to the display rate of the decoderif it does not match the coded rate.

#### D.5.1.6 Bit rate

The bit rate is an 18-bit integer giving the bit rate of the data channel in units of 400 bits/s. The bit rate is assumed to be constant for the entire sequence. The actual bit rate is rounded up to the nearest multiple of 400 bits/s. For example, a bit rate of 830 100 bits/s would be rounded up to 839 400 bits/s giving a coded bit rate of 2 076 units.

If all 18 bits are 1 then the bitstream is intended for variable bit rate operation. The value zero is forbidden.

For constant bit rate operation, the bit rate is used by the decoder in conjunction with the vbv\_delay parameterin the picture header to maintain synchronization of the decoder with a constant rate data channel. If the stream is multiplexed using  $[SO/IEC 11172-1]$ , the time-stamps and system clock reference information defined in  $ISO/IEC$  11172–1 provide a more appropriate tool for performing this function.

#### 0.5.1.7 Marker bit

The bitrate is followed by asiugle reserved bit which is always set to 1. This bit prevents emulation of start codes.

# 0.5.1.3 VBv buffer size

The buffer size is a 10-bit integer giving the minimum required size of the input buffer in the model decoder in units of 16 384 bits (2 048 bytes). For example, a buffer size of 20 would require an input buffer of 20  $x$  16 384 = 327 680 bits (= 40 960 bytes). Decoders may provide more memory than this, but if they provide less they will probably run into buffer overflow problems while the sequence is being decoded.

#### D.5.1.9 Constrained Parameter flag

If certain parametersspecified in the bitstream fall within predefined limits, then the bitsuearn is called a constrained parameter bitstream. Thus the constrained parameter bitstream is a standard of performance giving guidelines to encoders and decoders to facilitate the exchange of bitstrenms.

The bitrate parameter allows values up to about 100 Mbits/s, but a constrained parameter bitstream must have abit rate of 1,856 Mbits/s or less. Thus the bit rate parameter must be 3 712 or less.

The picture rate parameter allows picture rates up to 60 picturesis, but a constrained parameter bitstream must have a picture rate of  $30$  pictures/s or less.

PUMA Exhibit 2005 PUMA Exhibit 2005<br>The resolution of the coded picture is also specified in the sequence header. Horizontal resolutions-unted to<br>4095 pels are allowed by the syntax, but in a constrained parameter bitstream the resolution i 75 of 124 768 pels or less. Vertical resolutions up to 4095 pels are allowed, but that in a constrained parameter

# [SO/EEC 11172—2:1993(E) © lSO/IEC

bitstream is limited to 576 pels or less. In a constrained parameter bitstream, the total number of macrobiooks per picture is limited to 396. This sets a limit on the maximum area of the picture which is only about one quarter of the area of a  $720x576$  pel picture. In a constrained parameter bitstream, the pel rate is limited to 2 534 400 pels/s. For a given picture rate, this sets another limit on the maximum area ofthe picutre. [f the picture has the maximum area of 396 macroblocks, then the picture rate is restricted to 25 pictures/s or less. If the picture rate has the maximum constrained value of 30 pictures/s the maximum area is limited to 339 macrohlocks

A constrained parameter bitstrearn can be decoded by a model decoder with a buffer size of 327 680 bits without overflowing or underflowing during the decoding process. The maximum buffer size that can be specified for a constrained parameter bitstream is 20 units.

A constrained parameter bitstream uses a forward  $\bar{f}$  code or backward  $\bar{f}$  code less than or equal to 4. This constrains the maximum range of motion vectors that can be represented in the bitstream (see table D.7).

If all these conditions are met, then the bitstream is constrained and the constrained parameters flag in the sequence header should be set to 1. If any parameter is exceeded, the flag shall be set to 0 to inform decoders that more than a minimum capability is required to decode the sequence.

#### 0.5.1.10 Load intra quantizer matrix

This isa one~bit flag. if it is set to 1, sixty—four 8-bit integers follow. These define an <sup>8</sup> by <sup>8</sup> set of weights which are used to quantize the DCT coefficients. They are transmitted in the zigzag scan order shown in figure D.30. None of these weights can be zero. The first weight must be eight which matches the fixed quantization level of the dc coefficient.

If the flag is set to zero, the intra quantization matrix must be reset to the following default value:

### Figure  $D.15 - Default$  intra quantization matrix

The default quantization matrix is based on work performed by ISO/IEC JTC: SC29/WG10 (JPEG) [6]. Experience has shown that it gives good results over a wide range of video material. For resolutions close to  $350x250$  there should normally beno need to redefine the intra quantization matrix. If the picture resolution departs significantly from this nominal resolution, then some other matrix may give perceptibly better results.

The weights increase to the right and down. This reflects the human visual system which is less sensitive to quantization noise at higher frequencies.

#### D.5.1.11 Load non—intra quantize: matrix

This is a one—bit flag. If it is set to 1, sixty—four 8-bit integers follow in zigzag scan order. None of these integers can be zero.

If the flag is set to zero. the non-intra quantization matrix must be reset to the following default value which consists of all 16s.

> PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 76 of 124 76 of 124

# Figure D.16 -- Default non-intra quantization matrix

This flat default quantization matrix was adopted from H.261 which uses a flat matrix for the equivalent of P-pictures [5]. Little work has been performed to determine the optimum non-intra matrix for MPEG video coding, but evidence suggests that it is more dependent on video material than is the intra matrix. The optimum non-intra matrix may be somewhere between the flat default non-intra matrix and the strongly frequency-dependent values of the default intra matrix.

# D.5.1.12 Extension data

This start code is byte-aligned and is 32 bits long. Its value is

hex:  $000001B5$ binary: 0000 0000 0000 0000 0000 0001 10110101

It may be preceded by any number of zeros. If it is present then it will be followed by an undetermined number of data bytes terminated by the next start code. These data bytes are reserved for future extensions to this part of ISO/IEC 11172, and should not be generated by encoders. MPEG video decoders should have the capability to discard any extension data found.

#### D.5.1.13 User data

A user data start mde may follow the optional extension data. This start code is byte-aligned and is 32 bits long. Its value is

> hex: 00 00 01 B2 binary: 0000 0000 0000 0000 0000 0001 1011 0010

It may be preceded by any number of zeros. If it is present then it will be followed by an undetermined number of data bytes terminated by the next start code. These data bytes can be used by the encoder for any purpose. The only restriction on the data is that they cannot emulate a start code, even if not byte-aligned. This means that astring of 23 consecutive zeros must not occur. One way to prevent emulation is to force the most significant bit of alternate bytes to be a  $1$ .

In closed encoder-decoder systems the decoder may be able to use the data. In the more general case, decoders should be capable of discarding the user data.

# D.5.2 Group of pictures

Two distinct picture orderings exist, the display order and the bitstrearn order (as they appear in the video bitstream). A group of pictures (gop) is a set of pictures which are contiguous in display order. A group of pictures must contain at least one I-picture. This required picture may be followed by any number of I and P-pictures. Any number of B-pictures may be interspersed between each pair of I or P-pictures, and may also precede the firstI-picture.

Property 1. A group of pictures, in bitstream order, must start with an I-picture and may be followed by any number of 1, P or B—pictures in any order.

picture, and must end with an I or a P-picture. The smallest group of pictures consists of a sightly  $\phi$  diverges 2005 whereas the largest size is unlimited. Apple V. PUMA, IPR2016-01135 Property 2. Another property of a group of pictures is that it must begin, in display order, with an I or a  $B$ -

77 of 124 77 of 124

# lSO/IEC 11172-2: 1993 (E) on later than the control of th

The original concept of a group of pictures was a set of pictures that could be coded and displayed independently of any other group. In the final version of this part of ISO/IEC 11172 this is not always true, and any B-pictures preceding (in display order) the first I-picture in a group may require the last picture in the previous group in order to be decoded. Nevertheless encoders can still construct groups of pictures which are independent of one another. One way to do this is to omit any B-pictures preceding the first Ipicture. Another way is to allow such B-pictures, but to code them using only backward motion compensation.

Property 3. From a coding point of view, aconcisely stated property is that a group of pictures begins with a group of pictures header, and either ends at the next group of pictures header or at the next sequence header or at the end of sequence, whichever comes first.

Some examples of groups of pictures are given below: I

Figure D.17 -- Examples of groups of pictures in display order

These examples illustrate what is possible, and do not constitute a suggestion for structures of groups of pictures.

#### Group of pictures start code

The group of pictures header starts with the Group of Pictures start code. This code is byte-aligned and is 32 bits long. Its value is

> hex: 00 00 01 B8 binary: 0000 0000 0000 0000 0000 0001 1011 1000

It may be preceded by any number of zeros. The encoder may have inserted some zeros to get byte alignment, and may have inserted additional zeros to prevent buffer underflow. An editor may have inserted zeros in order to match the vbv\_delay parameter of the first picture in the group.

#### Time, code

A time code of 25 bits immediately follows the group of pictures start code. This encodes the same information as. the SMPTE time code [4].

The time code can be broken down into six fields as shown in table DA.

Table 0.4 — Time code fields

The time code refers to the first picture in the group in display order, i.e. the first picture with a temporal reference of zero. The SMPTE time code is included to provide a video time identification to applications. It may be discontinuous. The presentation time-stamp in the System layer (Part 1) has a much higher precision and identifies the time of presentation of the picture.

PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 78 of 124 78 of 124

#### Closed GOP

A one bit Hag follows the time code. It denotes whether the group of pictures is open or closed. Closed groups can be decoded without using decoded pictures of the previous group for motion compensation, whereas open groups require such pictures to be available.

# Figure D.18 -- Example groups of pictures in display order

A less typical example of a closed group is shown in figureD.18b. in this example, the B-picmres which precede the first I—picture must use backward motion compensation only, i.e. any motion compensation must be based only on picture number 2 in the group.

If the closed\_gop flag is set to 0 then the group is open. The first B-pictures that precede the first [-picture inthe group may have been encoded using the last picture in the previous group for motion compensation.

#### Broken link

A one bit flag follows the closed\_gop flag. It denotes whether the B-pictures which precede the first Ipicture in the GOP can be correctly decoded. If it is set to 1, these pictures cannot be correctly decoded because the I-picture or P-picmre from the previous group pictures that is required to form the predictions is not available (presumably because the preceding group of pictures has been removed by editing). The decoder will probably choose not to display these B-pictures

Ifthe sequence is edited so that the original group of pictures no longerprecedes the current group of pictures then this flag normally will be set to 1 by the editor. However, if the closed\_gop flag for the current group of pictures is set, then the editor should not set the broken\_link flag. Because the group of pictures is closed, the first B-pictures (if any) can still be decoded correctly.

#### Extension data

This start code is byte—aligned and i532 bits long. Its value is

hex:  $00\,00\,01\,B_2$ binary: 0000 0000 0000 0000 0000 0001 1011 0101

It may be preceded by any number of zeros If it is present then it will be followed by an undetermined number ofdaa'oytesterminated by the next start code. These data bytes are reserved for future extensions to this part of ISO/IEC 11172, and should not be generated by encoders MPEG video decoders should have the capability to discard any extension data found.

#### User data

A user data start code may follow the optional ex tension data. This start code is byte—aligned and is 32 bits long. Its value is

> PUMA Exhibit 2005 hex: 00 00 01 B2 binary: 0000 0000 0000 0000 0000 0001 1011 0010

It may be preceded by any number of zeros. If it is present then it will be follopped by an UNA star phone  $2016$ -01135 number of data bytes tenninated by the next start code. These data bytes can be used by the encoder for any o of 124<br>number allowed a poly restriction on the data is that they cannot enulate a stert and a symptop of byte a purpose. The only restriction on the data is that they cannot emulate a start code, even if not byte-aligned.

This means that a string of 23 consecutive zeros must not occur. One way to prevent emulation is to force the most significant bit of alternate bytes to be a 1.

In closed encoder-decoder systems the decoder may be able to use the data. In the more general case, decoders should be capable of discarding the user data.

# D.5.3 Picture

The picture layer contains all the coded information {or one picture. The header identifies the temporal reference of the picture, the picture coding type, the delay in the video buffer verifier (VBV) aid. if appropriate, the range of motion vectors used.

# 0.5.3.1 Picture header and start code

A picture begins with a picture header. The header starts with a picture start code. This code is byte~aligned and is 32 bits long. Its value is:

> hex: 00 00 01 00 binary: 0000 0000 0000 0000 0000 0001 0000 0000

It may bepreceded by any number of zeros.

# D.5.3.2 Temporal reference

The Temporal Reference is a ten-bit number which can be used to define the order in which the pictures must be displayed. It may be useful since pictures are not transmitted in display order, but rather in the order which the decoder needs to decode them. The first picture, in display order, in each group must have Temporal Reference equal to zero: This is incremented by one for each picture in the group.

Some example groups of pictures with their Temporal Reference numbers are given below.

# Figure D.19 -- Examples of groups of pictures and temporal references

If there are more than 1024 pictures in a group, then the Temporal Reference is reset to zero and then increments anew. This is illustrated below:

Figure  $D.20 - Example$  group of pictures containing 1500 pictures

PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 80 of 124 80 of 124

# D.5.3.3 Picture coding type

A three bit number follows the temporal reference. This is an index into the following table defining the type of picture.

| CODE. | PICTURE TYPE      |
|-------|-------------------|
| 000   | Forbidden         |
| 001   | 1-picture         |
| 010   | P-picture         |
| 011   | <b>B</b> -picture |
| 100   | D Picture         |
| 101   | Reserved          |
| 110   | Reserved          |
| 111   | Reserved          |

Tabie D5 -- Picture types

The various types of pictures are described in D.2.3. Codes 101 through 111 are reserved for future extensions to this part of ISO/IEC 11172. Decoders should be capable of discarding all pictures of this type, and scan for the next picture start code, group start code or sequence start code. Code 000 will never be used to avoid start code emulation.

## D.5.3.4 VBV deiay

For constant bit rate operation, vbv\_delay can be used at the start of decoding and after a random access to ensure that the correct number of bits have been read by the decoder before the first picture is displayed.

The buffer fullness is not specified in bits but rather in units of time. The vbv\_delay is a 16-bit number defining the time needed in units of 1/90000 s to fill the input buffer of the model decoder from an empty state to the correct state at the hitrate specified in the sequence headen

For example, suppose the vbv\_delay had a decimal value of 30000, then the time delay would be:

$$
D = 30\,000\,190\,000 = 1\,13\,s
$$

If the channel bit rate were 1,2 Mbits/s then the contents of the buffer before the picture is decoded would be:

$$
B = 1200.000 / 3 = 400 000 bits
$$

If the decoder determined that its actual buffer fullness differed significantly from this value, then it would have to adopt some strategy for regaining synchronization.

The meaning of vbv\_delay is undefined for variable bit rate operation.

# D.5.3.5 Full pei forward vector

This is a one bit flag giving the precision of the forward motion vectors. If it is 1 then the precision of the vectors is in integer pels, if it is zero then the precision is half a pel. Thus if the flag is set to one the vectors have twice the range than they do if the flag set to zero.

This flag is present only in the headers of P-pictures and B-pictures. It is absent in I-pictures and D pictures.

# D.5.3.6 Forward f-code

maximum size of the forward vectors that can be coded. It can take only values of 1 through 7 a value of<br>zero is forbidden. This is a three-bit number and, like the full pel forward vector flag, is present only in the headers of Ppictures and B-pictures. It provides information used for decoding the coded forward vectors and controls the

Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 81 of 124 81 of 124

ISO/IEO 11172—2 1993 (E) © ISO/1E0

I'wo parameters used in decoding the forward motion vectors are derived from forward\_f\_code, forward\_r\_size and forward f.

The forward r\_size is one less than the forward  $\dot{\tau}$  code and so can take values 0 through 6.

The forward f parameter is given by table D.6:

#### Table D.6 -- f\_codes

### 0.5.3.7 Full pel backward vector

This is a one bit flag giving the precision of the backward motion vectors. Ifit is <sup>1</sup> then the precision of the vectors is in integer pets, if it is zero then the precision is half a pel. 'lbus if the flag is set to one the vectors have twice the range than they do if the flag set to zero.

This flag is only present in the headers of B-pictures. It is absent in I-pictures, P-pictures and D pictures.

## D.5.3.8 Backward f-code

This is a three-bit number and, like the full pel backward vector flag, is present only in the headers of  $B$ pictures. It provides information used for decoding the coded backward vectors. It can take only values of 1 through  $7$ ; a value of zero is forbidden.

The backward  $_1$  parameter is derived from the backward  $_1$  code and is given by table D.6

### D.5.3.9 Extra picture information

Extra picture information is the next field in the picture header. Any number of information bytes may be present. An information byte is preceded by a flag bit which is set to 1. Information bytes are therefore generally not byte-aligned. The last information byte is followed by a zero bit. The smallestsize of this field is therefore one bit, a 0, that has no information bytes. The largest size is unlimited. The following example has l6bits of extra information denoted by E:

#### lEEEEEEEElEEEEEEEEO

Where E is an extra infonnation bit.

The extra information bytes are reserved for future extensionsto this part of ISOIIEC 11171. The meaning of these bytes is currently undefined, so encoders must not generate such bytes and decoders must be capable of discarding them.

# D.5.3.10 Extension data

This start code is byte-aligned and is 32 bits long. Its value is:

hex: 00 0001 B5 binary: 0000 0000 0000 0000 0000 0001 1011 0101

number of data bytes terminated by the next start code. These data bytes are reserved for future extensions Exhibit 2005<br>to this regt of ISO/IEC 11.172, and should not be concepted by encoders. MPEG video deedeen was EA Ex Apple v. PUMA, IPR2016-01135 82 of 124 82 of 124 It may be preceded by any number of zeros. ## D.5.3.11 User data

This start code is byte-aligned and is 32 bits long. Its value is

hex: 00 00 01 B2 binary. 0000 0000 0000 0000 0000 0001 1011 0010

Itmay be preceded by any number of zeros. [f it is present then it will be followed by an undetermined number of data bytes terminated by the next start code. These data bytes can be used by the encoder for any purpose. The only restriction on the data is that they cannot emulate a start code, even if not byte—aligned. One way to prevent emulation is to force the most significant bit of alternate bytes to be a 1.

In closed encoder-decoder systems the decoder may be able to use the data. In the more general case, decoders should be capable of discarding the user data.

# D.5.4 Slice

Pictures are divided into slices. Each slice consists of an integral number of macroblocks in raster scan order. Slices can be of different sizes within a picture, and the division in one picture need not be the same as the division in any other picture. Slices can begin and end at any macroblock in a picture subject to the following restrictions. The first slice must begin at the top left of the picture, and the end of the last slice must be the bottom right maeroblock of the picture. There can be no gaps between slices, nor can slices overlap. The minimum number of slices in a picture is one, the maximum number is equal to the number of macroblocks.

Each slice starts with a slice start code, the exact value of which defines the vertical position of the slice. This is followed by a code thatsets the quantization step-size At the start of each slice the predictors for the dc coefficient values and the predictors for the vector decoding are all reset. The horizontal position of the start of the slice is given by the macrohlock address of the first macroblook in the slice. The result of all this is that, within apicture, a slice can be decoded without information from the previous slices. Therefore, if a data error occurs, decoding can begin again at the subsequent slice.

If the data are to be used in an error free environment, then one slice per picture may be appropriate. If the environment is noisy, then one slice per row ofmacroblocks may be more desirable, as shown in figure D21.

Figure D.21 -- Possible arrangement of slices in a  $\frac{1}{2}$  Methra, IPR2016-01135 83 of 124 83 of 124 In this figure and in the next, each strip is one macroblock high, i.e. 16 pels high.

Since each slice header requires 40 hits, there is some penalty for including more than the minimum number of slices. For example, a sequence with a vertical resolution of 240 lines coded at 30 pictures/s requires approximately  $40x30 = 1200$  bits/s for the slice headers using one slice per picture, and  $40x15x30$  $=$  18 000 bits/s with one slice per row, an additional overhead of 16 800 bits/s. The calculation is approximate and underestimates the impact, since the inclusion of a slice imposes additional requirements that the macroblock immediately before the slice header be coded, as well as the first macroblock in the slice.

The coding structure permits great flexibility in dividing a picture up into slices. One possible arrangement is shown in figure  $D.22$ .

Figure D.22 -- Possible arrangement of slices in a 256x192 picture

This division into slices is given for illustrative purposes only. it is not intended as a suggestion on how to divide a picture into slices.

## D.5.4.1 Slice header and start code

Slices start with a slice header. Each slice header starts with a slice start code. This code is byte-aligned and is 32 bits long. The last eight bits can take on a range of values which define the vertical position of the slice in the picture. The permitted slice start codes are:

Each slice start code may be preceded by any number of zeros.

The last <sup>8</sup> bits ofthe slice start code give the slice vertical position, ie the vertical position of the first macroblock in the slice in units of macrobiocks starting with position <sup>1</sup> at the top of the picture. A useful variable is macroblock row. This is similar to slice vertical position except that row  $\theta$  is at the top of the picture. Thus

slice vertical position = macroblock  $row + 1$ 

PUMA Exhibit 2005

For example, a slice start code of 00000101 hex means that the first macroblock hpmle slice is alvertical 2016-01135 84 of 124 position 1 or macroblock row 0, i.e. at the top of the picture. A slice start code of  $00000120$  hex means

that the first macroblock is at vertical position 32 or macroblock row 31, i.e. at the 495th row of pels. It is possible for two or more slices to have the same vertical position.

The maximum vertical position is 175 units. A slice with this position would require a vertical size of  $175x16 = 2800$  pels.

The horizontal position of the first macroblock in the slice can be calculated from its macroblock address increment. Thus its position in the picture can be determined without referring to any previous slice or marroblock Thus a decoder may decode any slicein a picture without having decoded any other slice in the same picture. Thisfeature allows decoders to recover from bit errors by searching for the next slice start code and then resuming decoding.

## D.5.4.2 Quantizer scale

The quantizer scale is a five-bit integer which is used by the decoder to calculate the DCT coefficients from the transmitted quantized coefficients. A value of  $\theta$  is forbidden, so the quantizer scale can have any value between 1 and 31 inclusive.

Note in addition that the quantizer scale may be set at any macroblock.

#### D.5.4.3 Extra slice information

Extra slice information forms the lastfield in the slice header. Any number of information bytes may be present. An information byte is preceded by a flag bit which is set to 1. Information bytes are therefore generally not byte-aligned. The last information byte is followed by a zero biL The smallest size of this field is therefore one bit, a 0, that has no information bytes. The largest size is unlimited. The following example has 24 bits of extra information denoted by E: '

# IEEEEEEEEIEEEEEEEE <sup>l</sup> EEEEE'EEEO

The extra information bytes are reserved for future extensions to this part of ISO/IEC 11172. The meaning. of these bytes is currently undefined, so encoders must not generate such bytes and decoder; must discard them.

The slice header is followed by code defining the macroblocks in the slice.

# D.5.5 Macroblock

Slices are divided into macroblocks of 16 x 16 pels. Macroblocks are coded with a header that contains information on the macroblock address, macroblock type, and the optional quantizer scale. The header is followed by data defining each of the six blocks in the macrobiock It is convenient to discuss the macroblock header fields in the order in which they are coded.

#### 0.5.5.1 Macrohlock stuffing

The first field in the macrobiock header is "macroblock stuffing". This is an optional field, and may be inserted or omitted at the discretion of the encoder. If present it consists of any number of 11-bit strings with the pattern "0000 0001 111". This stuffing code is used by the encoder to prevent underflow, and is discarded by the decoder. If the encoder determines that underflow is about to occur, then it can insert as many stuffing codes into the first field of the macroblock header it likes.

Note that an encoder has other strategies to prevent buffer underflow. It can insert stuffing bits immediately before a start code. It can reduce the quantizer scale to increase the number of coded coefficients. It can even

# 0.5.5.2 Macrobiock address increment and macroblock escape

Macrobiocks have an address which is the number of the macroblock in raster scan order. The tap left<br>macroblock in a picture has address 0 the next one to the right has address 1 and so on. If than 2005 macrobiock in a picture las address 0, the next one to the right has address 1 and so on. If there are M<br>macroblocks in a picture, then the bottom right macroblock has an address M-Apple V. PUMA, IPR2016-01135 85 of 124 85 of 124

# ISO/1E0 11172-2: 1993 (E) (0 ISO/IEC

The address of a macroblock is indicated by transmitting the difference between the addresses of the current macroblock and the previously coded macroblock. This difference is called the macroblock address increment. In I-pictures, all macroblocks are coded and so the macroblock address increment is nearly always one. There is one exception. At the beginning of each slice the macroblock address is set to that of the right hand macrohlock of the previous row. At the beginning of the picture it is set to -1. lfa slice does notstart at the left edge of the picture, then themacroblock address increment for the firstmacroblodt in the slice will be larger than one. For example, the picture of figure  $D22$  has 16 macroblocks per row. At the start of slice2 the macroblock address is set to 15 which is the address of the macroblock at the right hand edge of the top row of macroblocks. If the first slice contained 26 macroblocks, 10 of them would be in the second row, so the address of the first macroblock in slice 2 would be 26 and the macroblock address increment would be 11.

Macroblock address increments are coded using the VLC codes in the table in B.1.

It can be seen that there is no code to indicate a maooblock adiress increment of zero. This is why the macroblock address is set to  $-1$  rather than zero at the top of a picture. The first macroblock will have an increment of one making its address equal to zero;

The macroblock address increments allow the position of the macroblock within the picture to be determined. For example, assume that a slice header has the start code equal to  $00\ 00\ 01\ 0A$  hex, that the picture width is 256 pals, and that a macroblock address increment code 0000111 is in the macroblock header of the first macroblock in the slice. A picture width of 256 pels implies that there are 16 macroblocks per row in this picture. The slice start code tells us that the slice vertical position is 10, and so the macroblock row is 9. The slice header sets the previous macroblock address to the last macroblock on row 8, which'has address 143. The macrobioch address increment VLC leads to amacroblodc address increment of B, and so the macrobiock address of the first macrobiock in the slice is  $143 + 8 = 151$ .

The macroblock row may be calculated from the address:

macroblock row = macroblock address / macroblock width

$$
= 151 / 16
$$

 $\overline{a}$ 

The division symbol signifies integer truncation, not rounding.

The macroblock column may also be calculated from the address:

macroblock column = macroblock address % macroblock width  $= 151$  % 16<br>= 7

Columns are numbered from the left of the picture starting at 0.

There are two special codewords: escape and stuffing.

The escape code means "add 33 to the following macroblock address increment". This allows increments greater than 33 to be coded. For example, an increment of 40 would be coded as escape plus an increment of 7:

#### 0000 0031 0000 0010

An increment of 70 would be coded as two escape codes followed by the code for an increment of 4:

#### 00000001000000€D0010000011

The stutfing code is included since the decoder must be able to distinguish it from increment codes.' Itis used by the encoder to prevent underflow, and is discarded by the decoder.

#### D.5.5.5 Motion horizontal/vertical forward/backward R

The interpretation of these codes is explained in D.6.2.3.

#### D.5.5.6 Coded block pattern

This code describes which blocks within the macroblock are coded and transmitted. The interpretation of this code is explained in  $D.6.4.2$ .

# 0.5.5.7 End of macrobloek

This code is used only in D-pictures and is described in D.6.6.

# D.5.6 Block

A block is an array of 8 by 8 componentpet values, treated as a unit and input to the Discrete Cosine Transform (DCT). Blocks of 8 by 8 pels are transformed into arrays of 8 by 8 DCT coefficients using the<br>two dimensional discrete cosine transform.

# D.6 Coding MPEG video

# D.6.1 Rate control and adaptive quantization

The encoder must control the bitrate so that the model decoder 'tnputbuffer neither overflows nor underflows. Since the model decoder removes all the hits associated with a picture from the input buffer instantaneously, it is necessary to control oniy the total number of bits per picture. The encoder should allocate the total numbers of hits among the various types of pictures so that the perceived quality is suitably balanced. The distribution will vary with the scene content and with the particular distribution of the three picture types (I, P and B-pictures).

Within a picture the encoder should allocate the total number of bits available among the macroblocks to maximize the visual quality of the picture.

One method by which an encoder controls the bit rate is to vary the quantizer scale. This is set in each slice header, and may be set at the beginning of any macroblock, giving the encoder excellent control over the bit rate within a picture.

#### D.6.1.1 Rate control within a sequence

For atypical coding scheme represented by the following group of pictures in display order:

### BBIBBPBBPBEPBBP

it has been found that good results can be obtained by matching the visual quality of the I and P—pictures, and by reducing the code size ofthe B-pictures to save bits giving a generally lower quality for the 8 pictures.

PUM A<sup>l</sup> Exhibit 2005  $\frac{1}{4}$ 87 of 124 The best allocation of bits among the picture types depends on the scene cement. Work of the MPEG video committee suggests that allotting P-pictures about 2-5 times as many bits as B-picturepland Allerging bit 2005 If the motion or change in the video, then a greater proportion of the bits should be allotted to the 1-pictures  $\frac{8}{7}$  of

If there is a lot of motion or change, then the proportion allotted to l-pictures should be reduced and most of the savings given to the P-pictures.

A reasonable encoder algorithm is to start with the foregoing estimates, then reallocate bits dynamically depending on the nature of the video.

## 0.6.1.2 Rate control within a picture

If the buffer is heading toward overflow, the quantizer stale should be increased. Ifthis action is not sufficient to prevent an impending overflow then. as a last resort, the encoder could discard high frequency DCT coefficients and transmit only low frequency ones. Although this would probably produce visible artifactsin the decoded video, it would in no way compromise the validity of the coded bitstream.

Ifthebuffer is heading toward underflow, the quantizer scale should be reduced. if this isnot sufficient, the encodercan insert macroblock stuffing into the bitstrearn, or add leading zeros to start codes.

Under normal circumstances, the encoder calculates and monitors the state of the model decoder buffer aid changes the quantizer Scale to avert both overflow and underflow problems.

One simple algorithm that helps accomplish this is to monitor the buffer fullness. Assume that the bits have been allocated among the various picture types, and that an average quantizer scale for each picture type has been established. The actual buffer fullness at any macroblock in a picture can be calculated and compared with the nominal fullness, ie. the value that would beobtained if the hits were uniformly distributed among all the macroblocks in the picture. If the buffer fullness is larger than the nominal value, then the quantizer scale should be set higher than the average, whereas ifthe buffer fullness is smaller than the nominal, the quantizer scale should be set lower than the average.

If the quantizer scale is kept constant over a picture, then, for a given number of coding bits, the total mean square error of the coded picture will tend to be close to the minimum. However, the visual appearance of most pictures can be improved by varying the quantizer scale over the picture, making it smaller in smooth areas of the picture and larger in busy areas. This technique reduces the visibility of blockiness in smooth areas at the expense of increased quantization noise in the busy areas where, however, it is masked by the image detail.

Thus a good algorithm for controlling the bitrate within a picture adjusts the quantizer scale depending on both the calculated buffer fullness and on the local image. content Examples of techniques for rate control and quantization may be found in  $[7] [8]$ .

## D.6.1.3 Buffer fullness

To give the best visual quality, the encodershould aimed fill the inputbuffer before instructing the decoder to start decoding.

# D.6.2 Motion estimation and compensation

### D.5.2.1 Motion compensation

P-pictures use motion compensation to exploit temporal redundancy in the video. Decoders construct a predicted block of pels from pels in a previously transmitted picture. Motion within the pictures (e.g. a pan) usually implies that the pels in the previous picture will bein a different position from the pek in the current block, and the displacement is given by motion vectors encoded in the bitstream. The predicted block is usually a good estimate of the current block, and it is usually more efficient to transmit the motion vector plusthe difference between the predicted block and the current block, than to transmit a description of the current block by itself.

Consider the following typical group of pictures.

PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 88 of 124 88 of 124

© ISO/IEC - [SO/IEC 11172-2: 1993 (E)

Figure  $D.23 - Grow$  of pictures in display order

The J-picture, picture 2, is decoded without requiring any motion vectors. The first P-picture, number 5, is decoded using motion vectors from picture 2. This motion compensation is called forward motion compensation since it is forward in time. Motion vectors define the motion of a macroblock, i.e. the motion of a-16x16 block of luminance pels and the associated chrominance components. Typically, most macroblocks in a P-picture use motion compensation. Non-zero motion vectors are transmitted differentially with reference to the last trammitred motion vector.

The transmitted vectors usually have a precision of halfa pet. The maximum range of the vector is set by the forward f parameter in the picture header. Sometimes, if the motion is unusually large, the range may be doubled and the accuracy reduced to integer pels, by the full\_pel\_forward\_vector bitin the picture header.

A positive value of the horizontal or vertical component of the motion vector signifies that the prediction is formed frompels in the referenced picture which are spatially to the right or below the pets being predicted.

Not all macroblocks in a P-picture necessarily use motion compensation. Some macroblocks, as defined by the transmitted macroblock type (see table B.2b), may be intra-coded, and these are reconstructed without motion compensation. Full details defining the method of decoding the vectors and constructing the motion-compensated macroblock are given in 2.4.4.2

P—picture <sup>8</sup> in figure D23 uses forward motion compensation from picture 5. P-pictures always use forward motion compensation from the last transmitted I or P-picture.

B-pictures may use motion compensation from the previous I or P-picture, from the next (in display order) I or P-picture, or both; i.e., from the last two transmitted I or P-pictures.

Prediction is called forward if reference is made to a picture in the past and called backward if reference is made- to a picture in the future. For example, B-picnre <sup>3</sup> in figure D23 uses forward motion compensation from I-picture 2, and backward motion compensation from P-picture 5. B-pictures may use both forward and backward motion compensationand average the result. This operation is called interpolative motion compensation.

All three types of motion compensation are useful, and typically are used in coding B-pictures. Interpolative motion compensation has the advantage of averaging any noise present. Forward or backward motion compensation may be more useful near the edges of pictures, or where a foreground object is passing in front of a fixed or slow moving background.

Note that this technique of coding with P and B-pictures increases the coding efficiency. B-pictures can have greater errors of reconstruction than I or P-pictures to conserve coding bits, but since they are not used as the basis of motion compensation for future pictures, these errors may be tolerated.

## 0.6.2.2 Motion estimation

Motion compensation in a decoder is straightforward, but motion estimation which includes determining the best motion vectors and which must be performed by the encoder, presents a formidable computational challenge.

better results, so there is tradeoff to be made in the encoder: computational power, and hence BBM A Exhibit 2005 Apple v. PUMA, IPR2016-01135 Various methods are available to the encoder. The more computationally intensive methods tend to give

89 of 124 89 of 124

lSO/IEC 11172-2: 1 993 © lSO/IEC

Using a search strategy the encoder attempts to match the peis in <sup>a</sup> macroblock with those in a previous or future picture. The vector corresponding to the best match is reported after the search is completed.

#### D.6.2.2.1 Block matching criteria

in seeking a match, the encoder must decide whether to use the decoded past and future pictures as the reference, or the the original pastand future pictures. Formotion estimation, use of the decoded pictures by the encoder gives the smallest error in the error picture, whereas use of the original pictures gives the most accurate motion vectors. The choice depends on whether the artifacts of increased noise, or greater spurious motion are judged to be the more objectionable. There is usually little or no difference in quality between the two methods. Note that the decoder does not perform motion estimation. It performs motion compensated prediction and interpolation using vectors calculated in the encoder and stored in the bitstream. In motion compensated prediction and interpolation, both the encoder and decoder must use the decoded pictures as the references.

Several matching criteria are available. The mean square error of the difference between the motioncompensated block and the current block is an obvious choice. Another possible criterion is the mean absolute difference between the motion-compensated block and the current block.

For half pel shifts, the pel values could be interpolated by several methods. Since the decoder uses a simple linear interpolation, there is little reason to use a more complex method in the encoder. The linear interpolation method given in this partof ISO/[EC <sup>11</sup> 172 is equivalent to the following. Consider four peis having values A, B, D and E as shown in figure D24:

Figure D.24 -- Interpolation of half pel shifts

The value of the horizomally interpolated pel is

$$
h = (A + B) \, \text{if} \, 2
$$

where the double division symbol means division with rounding to the nearest integer. Half integer values are to be rounded to the next higher value. Thus if  $A = 4$  and  $E = 9$  then  $h = 6.5$  which is rounded up to 7.

The value of the vertically interpolatedpel is

 $v = (A + D) / I$  2

The value of the central interpolated pel is

$$
c = (A + B + D + E) / 4
$$

0.6.21.2 Search range

Once a block matching criterion has been selected, some kind of search strategy mustbe adopted. This must recognize the limitations ofthe VLC tables used to code the vectors. The maximum range of the vector depends upon forward\_f\_code or backward\_f\_code. The motion vector ranges are given in table D.7.

> PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 90 of 124 90 of 124

The range depends on the value of full\_pel\_fcrward\_vector or full\_pel\_backward\_vector in the picture header. Thus if all the motion vectors were found to be 15 pels or less, the encoder would usually select half pel accuracy and a forward\_f\_code or backward\_f\_code value of 2.

The search must be constrained to take place within the boundaries of the decoded reference picture. Motion vectors which refer to pels outside the picture are not allowed. Any bitstream which refers to such pels does not conform to this part of ISO/IEC 11172.

#### D.6.2.2.3 2-D search strategy

There are many possible methods of searching another picture for the best match to a current block, and a few simple ones will be descnbed.

The simplest search is a full-search. Within the chosen search range all possible displacements are evaluated using the block matching criterion.

The full search is computationally expensive, and practical encoders may not be able to afford the time required for a full seach.

A simple modification of the full-search is to search using only integer pel displacements. Once the best integermatch has been found, the eight neighbouring half-integer pel displacements are evaluated, and the best one selected as illustrated below:

Figure D25 -- Integer pel and half pel displacements

Assume that the position  $x+2$ ,  $y+2$  gives the best integer displacement matching using the selected block matching criterion, then the encoder would evaluate the eight positions with half pel displacements marked  $by + signs$  in figure D.25. If one of them were a better match then it would become the motion vector, otherwise the motion vector would remain that of the integer displacement  $x+2,y+2$ .

If during the integerpel search, two or more positions have the same block matching value, the encoder can adopt a consistent tie—breaking rule.

factor of four. In addition, the evaluations are simpler since the pel differences can be calculated fuelelly and<br>do not have to be internolated The modified full search algorithm is approximately an order ofmagnitude simpler than the full search. Using only integer displacements forthe first stage of the search reduces the number of evaluations by a do not have to be interpolated.

Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 91 of 124 91 of 124

For some applications even the modified full search may be too time consuming, and a faster search method may be required. One such method is the logarithmic search.

## D.6.2-2.4 Logarith mic search

in this search method, grids of 9 displacements are examined, and the reach continued based on a smaller grid centered on lheposition of the'best match. Ifthe grids are reduced in size by afactor of 3 at each step then the search is maximally efficient in the sense that any integershift has a unique selection path to it. This method will find the bestmatch only for a rather limited set of image types. A more robust method is to reduce the size of the grids by a smaller factor at each step, e.g. by a factor of  $2$ . The scaling factors can also be adjusted to match the search ranges of table D7.

The method will be illustrated with an example. Consider the set of integer shifts in figure D26:

Figure D.26 -- Logarithmic search method for integer pel shifts

The first grid has a spacing of 4 pels. The first step examines pels at shifts of  $0, 4$ , or  $-4$  pels in each direction. marked 1 in figure  $D.26$ . The best position is used as the center point of the second grid. Assume it is the pel marked 1 directly to the left of the center pel. The second grid has a spacing of 2 pels. The second step examines pels atshifts oi 0, 2, or —2 pels in each direction from the center of the new grid, marked 2 in the figure. The best position is used as the center point of the third grid, assume it is the lower right pel of the second grid. The third grid hasa spacing of <sup>1</sup> psi. The third step examines peis at shifts of 0, 1, or -i peis in each direction from the center of the grid. The best position is used asthe center point of the fourth grid. The fourth grid has a spacing of  $1/2$  pel. The fourth step examines pels at shifts of 0,  $1/2$ , or —1/2 pclsin each direction from the centerofthe grid using the same method as in the modified full search. The best position determines the motion vector.

Some possible grid spacings for various search ranges are given in table DB.

For P—pictures only forward searches are performed. but B-pictnres require both forward and backward searches. Not all the vectors calculated during the search are necessarily used. In B—pictures either forward or backward motion compensation might be used instead of interpolated motion compensation, and in both P and B~pictures the encoder might decide that a block is better codedas intra, in which case no vectors are transmitted.

## D.6.2.2.5 Telescopic search

#### PUMA Exhibit 2005

Even with the faster methods of the modified full search, or the logarithmic search publission Hublight,  $HPR2016-01135$ 92 of 124 quite expensive. For example, if the encoder decides to use a maximum search range of 7 pels per picture

interval, and ifthere are 4 B—pictures preceding aP-pidnre, then the full search range for the P-picture would be 35 pels. This large search range may exceed the capabilities of the encoder.

One way of reducing the search range is to use a telescopic search technique. This is best explained by illustrating with an example. Consider the group of pictures in figure D.27.<br>  $[AB \quad B \quad B \quad P \quad B \quad B \quad P \quad B \quad B \quad P$ 

1 B B B P B B B P B B B P B 1 2 3 4 5 6 7 8 9 10 11 12

Figure D37 -- Example group of pictures in display order

The encoder might proceed using its selected block matching criterion and D search strategy. For each Ppicture and thepreceding B-pictures, it first calculates all the forward vectors, then calculates all the backward vectors. The first set of pictures consists of pictures 0 through 4.

To calculate the complete set of forward vectors, the encoder first calculates all the forward vectors from picture 0 to picture 1 using a 2-D search strategy centered on zero displacement. It next calculates all the forward vectors from picture 0 topicture 2 using a 2—D search strategy centered on the displacements calculated for the corresponding block of picture 1. It next calculates all the forward vectors from picture 0 to picture 3- using a 2—D search strategy centered on the displacements calculated for the corresponding block of picture 2. Finally, it calculates all the forward vectors from picture 0 to picture 4 using a  $2$ -D search strategy centered on the displacements calculated for the corresponding block of picture 3.

To calculate the complete set of backward vectors, thecncoder first calculates all the backward vectors from picture 4 to picture 3 using a 2-D search strategy centered on zero displacement. It next calculates all the backward vectors from picture 4 to picture 2 using a 2-D search strategy centered on the displacements calculated for the corresponding block of picture 3. Finally, it calculates all the backward vectors from picture 4 to picture 1 using a 2-D search strategy centered on the displacements calculated for the corresponding block of picture 2.

Further methods of motion estimation are given by Netravali and Haskell [1].

# D.6.2.3 Coding of motion vectors

The motion vector of amacrohlork tends tobewcll correlated with the vector of the previous macroblock. For example, in apan all vectors would be roughly the same. Motion vectors are coded using a DPCM technique to make use of this correlation.

In P-pictures the motion vector used for DPCM, the prediction vector, is set to zero at the start of each slice and at each intra-coded macroblock. Note that macroblocks which are coded as predictive but which have no motion vector, also set the prediction vector to zero.

In B-pictnres there are two motion vectors, forward and backward. Each vectoris coded relative to the predicted vector of the same type. Both motion vectors are set to zero at the start of each slice and at each intra-coded macroblock. Note that predictive macroblocks which have only a forward vector do not affect the value of the predicted backward vector. Similarly, predictive macrohlocks which have only a backward vector do not atfect the value of the predicted forward vector.

The range of the vectors is set by two parameters. The full\_pel\_fomard\_vector and full\_pel\_backward\_vector flags in the picture header determine whether the vectors are defined in half-pel or integer-pol units.

A second parameter, forward for backward for code, is related to the number of bits appended to the VLC codes in table D.9.

Table D9 —- Differential motion code.

Advantage is taken of the fact that the range of displacemert vector values is constrained. Each VLC represents a pair of difference values. Only one of the pair will yield a motion vector falling within the permitted range,

The range of the vector is limited to the values shown in table D.7. The values obtained by decoding the differential values must bekept within this range by adding or subtracting amodulus which depends on the f value as shown in table D.10.

PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 94 of 124 94 of 124

The use of the modulus, which refers only to the numbers in tables  $D.8$  through  $D.10$ , will be illustrated by an example. Assume that a slice has the following vectors, expressed in the units set by the full pel flag.

3 10 30 30 —]4 —16 27 24

The range is such that an  $f$  value of  $2$  can be used. The initial prediction is zero, so the differential values

3720 0—44—2436

The differential values are reduced to the range -32 to +31 by adding or subtracting the modulus 64 corresponding to the forward 1 code of 2.

37 <sup>20</sup> <sup>0</sup> <sup>20</sup> —2-21-3-

To create the codeword, ( $mvd + (sign(mvd)*(forward_f-1))$ ) is divided by forward f. The signed quotient of this division is used to find a variable length codeword from table D.9. Then the absolute value of the remainder is used to generate a fixed length code that is concatenated with the variable length code. The codes generated by this example are shown below:

# D.6.3 Coding l-pictures

in coding I-pictures, the encoder has two main decisions to make that are not mandated by this partof [SO/IEC 11 112. These are: how to divide the picture up into slices, and how to set the quantizer scale.

#### 0.6.3.1 Slices in l-pictures

Division of the picture into slices is described in D.5.4.

9.3.3.2 Macroblocks in I-pictures

#### 13.6.3.2.1 Macroblock types in I~pictures

There are two types of macroblock in l-pictures. Both use intra coding. One uses the current quantizer scale, whereas the other defines anew value for the cprantizerscale. They are identified in the coded bitstream by the VLC codes given in table D.11.

The types are referred to names in this annex. Intra-d is the default type where the quantizer scale is not changed. Intra-q sets the quantizer scale.

Additional types could be added to this table without interfering with the existing entries. The VLC table is<br>thus open for future additions, and not closed. A policy of making the coding tables open in **Phistopher Exh**ib adopted by in developing this part of ISO/IEC 11172. The advantage of future experiency by indeveloping this part of ISO/IEC 11172. The advantage of future experiency is worth the slight coding inefficiency. 95 of 124 In order to allow for possible future extension to MPEG video, the VLC for intra-q is 01 rather than 0. Additional types could be added to this table without interfering with the existing entries. The VLC table is

> Apple Exhibit 1009 Apple Exhibit 1009 Page 95 of 124 Page 95 of 12485

## D.6.3.2.2 Quantizer scale

If the macroblock type is intra-q, then the macroblock header contains a five-bit integer which defines the quantizer scale. This is used by the decoder to calculate the DCT coefficients from the transmitted quantized coefficients. A value of 0 isforbidden, so the quantizer scale can have any value between <sup>1</sup> and 31 inclusive.

Note thatalso the quantizer scale is set in a slice header.

If the block type is intra—d, then no quantizer scale is transmitted and the decoder uses the previously set value. For a discussion on strategies encoders might use to set the quantizer scale, see D.6.1.

Note that the cost of transmitting anew quantizer scale is six bits: one for the extra length of the macrohlocktype code, and five to define the value. Although this is normally a small fraction of the hits allocated to coding each mauohlock, the encoder should exercise some restraint and avoid making a large number of very small Changes.

# D.G.3.3 DCT transform

The DCT is illustrated in figure D28.

The pels are shown in raster scan order, whereas the coefficients are arranged in frequency order. The top left coefficient is the dc term and is proportional to the average value of the componentpei values. The other coefficients are called ac coefficients, The ac coefficients to the right of the dc coefficientrepresent increasing horizontal frequencies, whereas ac coefficients below the dc coefficient represent increasing vertical frequencies. The remaining ac coefficients contain borh horizontal and vertical frequency components. Note that an image containing only vertical lines contains only horizontal frequencies.

The coefficient array contains all the information of the pel array and the pel array can be exactly reconstructed from the coefficient array, exceptfor information lost by the use of finite arithmetic precision.

The two—dimensional DCT is defined as

$$
F(\mathbf{u}, \mathbf{v}) = \frac{1}{4} \sum_{x=0}^{7} \sum_{y=0}^{7} f(x, y) \cos(\pi(2x+1)\mathbf{u}/16) \cos(\pi(2y+1)\mathbf{v}/16)
$$

PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 96 of 124 96 of 124

with: u, v, x,  $y = 0, 1, 2, ... 7$ where  $x, y =$  spatial coordinates in the pel domain  $u, v =$  coordinates in the transform domain  $C(u) = 1/\sqrt{2}$  for  $u=0$  $C(v) = 1/\sqrt{2}$  for  $v=0$ 1 otherwise

This transform is separable, i.e. a one-dimensional DCT transform may be applied first in the horizontal direction and then in the vertical direction. The formuia for the one dimensional transform is:

> 7  $\mathbf{F}(\mathbf{u}) = \frac{1}{2} \mathbf{C}(\mathbf{u}) \sum_{n=0}^{\infty} f(x) \cos(\pi(2x+1)\mathbf{u}/16)$  $C(u) = 1/\sqrt{2}$  for  $u = 0$ otherwise  $=1$

Fast DCT transforms exist, analogous to fast Fourier transforms. See reference [3].

The input pel values have a range from 0 to 255. giving a dynamic range for the dc coefficient from 0 to 2040. The maximum dynamic range for any ac coefficient is about -1 000 to 1 000. Note that for P and . B-pictures the component pels represent difference values and range from -255 to 255. This gives a maximum dynamic range for any coefficient of about -2 U00 to 2 DO). The encoder may thus represent the coefficients using 12 bits whose values range from -2 048 to 2 047.

### [1.6.3.4 Quantization

Each array of <sup>8</sup> by 8 coefficients produced by the DCT transform operation is quantized to produce an 8 by 8 array of quantized coefficients. Normally the number of non-zero quantized coefficients is quite small, and this is one of the main reasons why the compression scheme works as well as it does.

The coefficients are quantized with a uniform quantizer. The characteristic of this quantizer, only for Iblocks, is shown below:

Figure D.29. -- Uniform quantizer characteristics

The value of the coefficient is divided by the quantizer step size and rounded to the nearest whole number to<br>produce the quantized coefficient. Half integer values may be rounded up or down without directly after the un image quality. However, rounding towards zero tends to give the smallest codespire and sP is wide feat RR POH 6-01135 97 of 124 produce the quantized coefficient. Half integer values may be rounded up or down without directly affecting hibit  $2005$ example, with a step size of 16 all coefficients with values between 25 and 40 inclusive would give a quantized coefficient of 2,

> Apple Exhibit 1009 Apple Exhibit 1009 Page 97 of 124 Page 97 of 12487

**ISO/IEC 11172-2: 1993 (E)**  $\bullet$  **SO/IEC** 

The quantizer step size is derived from the quantization matrix and the quantizer scale. It can thus be different for different coetfidents, and may change between macroblocks. The only exception is the dc coefficient which is treated differently.

The eye is quite sensitive to large area luminance errors, and so the accuracy of coding the dc value is fixed. The quantizer step size for the dc coefficients of the luminance and chrominance components is fixed at eight. The dc quantized coefficient is obtained by dividing the dc coefficient by eight and rounding to the nearest whole number. This effectively quantizes the average dc value to one part in 256 for the reconstructed pels.

For example, a dc coefficient of 21 is quantized to a value of 3, independent of the value of the quantizer scale.

The ac coefficients are quantized using the intra quantization matrix. The quantized coefficient i[u,v] is produced by quantizing the coefficient  $c[u,v]$  for I-blocks. One equation is given by the formula:

$$
i[u, v] = 8 * c[u, v] // (q * m[u, v])
$$

where  $m[u, v]$  is the corresponding element of the intra quantization matrix, and q is the quantizer scale. The quantized coefficient is limited to the range -255 to +255.

The intra quantization matrix might be the default matrix, or it might have been downloaded in the sequence header.

# D.6.3.5 Coding of quantized coefficients

The top left coefficient in figure D.28b is called the dc coefficient, the remainder are called ac coefficients. The dc coefficient is correlated with the dc coefficient of the preceding block, and advantage is taken of this in coding. The ac coefficients are not well correlated, and are coded independently.

After the dc coefficient of a block has been quantized it is coded losslessly by a DPCM technique. Coding of the luminance blocks within a macroblock follows the raster scan order of figure D.5, 0 to 3. Thus the dc value of block 3 becomes the dc predictor for block 0 of the following macroblock. The dc value of each chrominance block is coded using the dc value of the corresponding block of the previous macrohlook as a predidor. At the beginning of each slice, all threedc predictorsfor Y, Cb and Cr, are set to <sup>1</sup> 024 (123\*8).

The differential dc values thus generated are categorized according to their dosolute value as shown in table D.12.

| DIFFERENTIAL DC<br>(absolute value) | <b>SIZE</b> | <b>VLC CODE</b><br>(luminance) | <b>VLC CODE</b><br>(chrominance) |

Table D.13. -- Differential dc additionai code

For example, a luminance dc change of 10 would be coded as 1101010. table D.12 shows that the first threebits 110 indicate that the size is 4. This means that few additional bits are required to define the exact value. The next bit is a 1, and table D.13 shows that the differential dc value must be somewhere between-8 and 15 inclusive. The last three bits, 010, show that the exact value is 10.

The decoder reconstructs dc quantized coefficients by following the inverse procedure.

The ac quantized coefficients are coded using a nm length and level technique. The quantized coefficients are first scanned in the zigzag order shown in figure D.30.

Figure D.30. -- Quantized coefficient block in zigzag scan order

The scanning order starts at 1, passes through 2, 3 etc in order, eventually reaching 64 in the bottom right corner. The length of a run is the number ofzero quantized coefficients skipped ever. For example, the quantized coefficients in figure D.31 produce the list of run lengths and levels in table D.14.

# Figure D31. -- Example quantized coefficients

## Table D.14. -- Example run lengths and levels

The scan starts at position 2 since the top left quantized coefficient is coded separately as the dc quantized coefficient.

Using a zig zag scan rather than a raster scan is more efficient as it gives fewer runs and can be coded with shorter VLC codes.

The list of run lengths and levels is coded using table D.15 Not all possible combinations of run length and level are in Ihese tables, only the more common ones. For combinations not in the tables, an escape sequence is used. In table D.15, the last bit 's' denotes the sign of the level; 0 means a positive level and 1 means a negative level. The escape code is used followed by the run length derived from table D.15 and then<br>the level from table D.17

# Table D.16. - Zero run length codes

# Table D.17. -- Level codes for DCT quantized coefficients

Using tables  $D.15$  through  $D.17$  we can derive the VLC codes for the example of table  $D.14$ :

Table D.18. -- Example run lengths, values, and VLC codes

| RI IN | J I IF | VLC CODE                           | <b>IMMENT</b> |
|-------|--------|------------------------------------|---------------|
|       |        | 0001 100                           |               |
|       |        | 0000 1100                          |               |
|       |        | 0010 11                            |               |
| 3     |        | -5 0000 0100 0011 1111 1011        | esc seq       |
|       |        | 110                                |               |
| 14    | 130    | 0000 0100 1110 0000 0000 1000 0010 | esc seq       |
| F∩R   |        |                                    |               |

The first three codes in table D.18 are derived directly from table D.15. The next code is derived indirectly since table D.15 does not contain an entry corresponding to a run length of 3 and alevel of5. Instead the escape code 000001 is used. This is followed by the six-hit code 000011 from table D.16 indicating arm length of 3. Lastly the eight-bit code from table D.17 (1111011 - indicating a level of -5) is appended.

coefficient is at the bottom right of the block. PUMA Exhibit 2005 After the last coefficient has been coded, an EOB code is used to inform the decoder that there are no more quantized coefficients in the current 8 by 8 block. This EOB code is used even if the last quantized coefficient is at the bottom right of the block.

There are two codes for the 0,1 run length, level combination, as indicated in tableTDlPSV In  $\mu$  Mook IPR2016-01135 coding always has the first quantized coefficient, the dc quantized coefficient, coded using the dc size method 102 of 124 Consequently intrablocks always use the code <sup>1</sup> Is to denote a run length, level combination of0,1. It will

be seen Iaterthat predictivcly ccded blocks code the dc quantized coefficient differently, andmay use the shorter code.

# D.6.4 Coding P-pictures

As in I-pictures, each P-picture is divided up into one or more slices, which are, in turn, divided into macroblocks. Coding is more complex than for I-pictures, since motion—compensated macroblocks maybe constmcted. The difference between the motion compensated macroblock and the current macroblock is transformed with a two-dimensional DCT giving an array of 8 by 8 transform coefficients. The coefficients are quantized to produce aser of quantized coefficients. The quantized coefficients are then encoded usinga rum-length value technique.

As in I-pictures, the encoder needs to store the decoded P-picture since this may be used as the starting point for motion compensation. Therefore, the encoder will reconstruct the image from the quantized coefficients.

In coding P-pictuies. the encoder has more decisions to make than in the case ofI-pictures. These decisions are: how to divide the picture up into slices, determine thebest motion vectors to use, decide whether to code each macroblock as intra or predicted, and how to set the quantizer scale.

## 0.6.4.1 Slices. in P-pictures

P—pictures are divided into slices in the same way as [—pictures. The same considerations as to the best method of dividing a picture into slices apply, see D.5.4.

#### 0.6.4.2 Maoroblocks in F—pictures

Slices are divided into macroblocks in the same way as for I-pictures. The major difference is the complexity introduced bymotion compensation.

The macroblock header may contain stuffing. The position of the macroblock is determined by the macroblock address. Whereas the macroblock address increment within a slice for l–pictures is restricted to one, it may be larger for P-pictures. Any macroblocks thus skipped over are called "skipped macroblocks". The decoder copies them from the previous picture into the currentpicture. Skippcd macroblocks are as predicted macroblocks with a zero motion vector for which no additional correction is available. They require very few bits to transmit.

The next field in the macroblock header defines the macroblock type.

## D.6.4.2.1 Macrobiock types in P-pictures

There are eight types of macroblock in P-pictures:

| <b>TYPE</b> | <b>VLC</b> | <b>INTRA</b> | <b>MOTION</b><br><b>FORWARD</b> | <b>CODED</b><br><b>PATTERN</b> | <b>QUANT</b> |
|-------------|------------|--------------|---------------------------------|--------------------------------|--------------|
| pred-mc     |            |              |                                 |                                |              |
| pred-c      | 01         |              |                                 |                                |              |
| pred-m      | 001        |              |                                 |                                |              |
| intra-d     | 00011      |              |                                 |                                |              |
| pred-mcq    | 00010      |              |                                 |                                |              |
| predcq      | 00001      |              |                                 |                                |              |
| intra-q     | 000001     |              |                                 |                                |              |
| skipped     | 'N/A       |              |                                 |                                |              |

Table 9.19 -- Macrobiock type VLC for P-pictures (table B.2b)

Not all possible combinations of motion compensation, coding, quantization, and intra coding oocnr. For example, with intracoded macroblocks, intra-d and intra-q, motion vectors are not transmitted.

Skipped macroblocks have no VLC code. Instead they are coded by having the macroblock address A Exhibit 2005 increment code skip over them. Apple V. PUMA, IPR2016-01135

103 of 124 103 of 124

# D.6.4.2.2 Quantizar scale

If the macroblock type is pred-mcq, pred-cq or intra-q, i.e. if the QUANT column in table D.19 has a 1, then a quantizer scale is transmitted. If the macroblock types are pred–mc, pred–c or intra–d, then the DCT correction is coded using the previously established value for the quantizer scale.

# D.6.4.2.3 Motion vectors

1f the macroblock type is pied-111, prod-Inc 0r pred—tnq, ie. if Ihe MOTION FORWARD column in table D.19 has a 1, then horizontal and vertical forward motion vectors are transmitted in succession...

## 0.6.4.2.4 Coded block pattern

If the macroblock type is pred-c, pred-mc, pred-cq or pred-mcq, i.e. if the CODED PATTERN column in table D.19 has a 1, then a coded block pattern is traasmitted. This informs the decoder which of the six blocks in the macroblock are coded, i.e. have transmitted DCT quantized coefficients, and which are not coded, i.e. have no additional correction after motion compensation,

The coded block pattern is a number from  $0$  to 63 that indicates which of the Blocks are coded, i.e. have at least one transmitted coefficient, and which are not coded. To understand the structure ofthe coded block pattern, we refer to figure D.5 and introduce the variables PN to indicate the status of each of the six blocks. If block N is coded then PN has the value one, if itis not coded then PN is zero. The coded block pattern is defined by the equation:

$$
CBP = 32^*P0 + 16^*P1 + 8^*P2 + 4^*P3 + 2^*P4 + P5
$$

This is equivalent to the definition given in 24.3.6.

For example, if the top two luminance blocks and the Cb block are coded, and the other three are not, then  $P0 = 1$ ,  $P1 = 1$ ,  $P2 = 0$ ,  $P3 = 0$ ,  $P4 = 1$ , and  $P5 = 0$ . The coded block pattern is:

$$
CBP = 32*1 + 16*1 + 8*0 + 4*0 + 2*1 + 0 = 50
$$

Certain patterns are more common than others. Advantage is taken of this fact to increase the coding efficiency and transmit a VLC representing the coded block pattern, rather than the coded block pattern itself. The VLC code; are given in table D20.

Table D.20 -- VLC table for coded block pattern

| $\rm CBP$ | <b>I</b> VLC CODE |                 | <b>CBP   VLC CODE</b> | CBP I | <b>VLC CODE</b>                            |  |

104 of 124 104 of 124

Thus the coded block pattern of the previous example, 50, would be represented by the code "00010110".

Note that there is no code representing the state in which none of the blocks are coded, a coded block pattern equal to zero. Instead, this state is indicated by the macroblock type.

For macroblocks in l-pictures, and for intra coded macroblocks in P and B-pictures, the coded block pattern is not transmitted, but is assumed to have a value of 63, ie. all the blocks in the macroblock are coded.

The use of coded block patterns instead of transmitting end of block codes for all blocks follows the practice in CCITT Recommendation H.261.

# 0.6.4.3 Selection of macroblock type

An encoder has the diflicnlt task of droosing between the different types of macroblocks.

An exhaustive method is to try coding a macroblock to the same degree of accuracy using each type, then choose the type that requires the least number of coding bits.

A simpler method, and one that is computationally less expensive, is to make a series of decisions. One way to order these decisions is:

- 1: motion compensation or no motion compensation, to is a motion vector transmitted or is it assumed to be zero
- 2: intra or non inlra coding, i.e. is the macroblock type intra or is it predicted using the motion vector found in step 1.
- 3. if the macroblock type is non-intra, is it coded or not coded, i.e. is the residual error large enough to be coded using the DCT transform.
- 4: decide if the quantizer scale is satisfactory or should be changed.

These decisions are summarized in figure D.32.

The four decision steps are discussed in the next four clauses

#### D.6.4.3.1 Motion compensation decision

algorithm is to search for the best match and compare the error of the predicted block with that formed with illit  $2005$ <br>a zero ypotor. If the mation compared allock is an used that the the unconvenient of the Hallit  $\frac$ a zero vector. If the motion-compensated block is only slightly better than the uncompensated block negligited  $\sim$ The encoder has an option whether to transmit morion vector; or not for predictive-coded macroblocks. If the motion vector is zero lhen some code may he saved by nottransmitting the motion vectors. Thus one the selected block matching criterion, then the zero vector might te used to savelebrang bits.  $11.2$ , if  $12.2$  if  $124$ 

105 of 124

An algorithm used in the development of both CCITT Recommendation H.261 and this part of ISO/IEC 11172 was as follows.

The block–matching criterion is the sum of absolute differences of all the luminance pels in a macroblock, when compared with the motion-compensated macroblock. If the sum is M for the motion-compensated block, and Z for the zero vector, then the decision of whether to make use of the motion vector is defined by Figure D33.

Figure D.33 -- Characteristic MC/No MC

Points on the line dividing the No MC (no motion compensation, i.e. zero vector), from the MC (motion compensation) regions, are regarded as belonging to the no motion compensation region.

It can be seen that if the error is sufficiently low, then no motion compensation should be used. Thus a way to speed up the decision is to examine the zero vector first and decide if it is good enough.

The foregoing algorithm was designed for telecommnications sequences in which the camera was fixed, and in which any movement of the background caused by the 'drag along effect" of nearby moving objects was very objectionable. Great care was taken to reduce this spurious motion, and this accounts for the curious shape of the boundary between the two regions in figure D.33.

### D.6.4.3.2 Intra/non-intra coding decision

Afterthe encoder has determined the best motion vector, it is in a position to decide whether to use it, or disregard it entirely and code the macroblock as intra. The obvious way to do this is to code the block as intra, and compare the total number of bits required when coded as motion compensated plus correction with the same quantizer scale. Themethod using the fewest bits may be used.

This may he too computationally expensive for the encoder to do, and afaster algorithm may he required One such algorithm, used in the simulation model during the development of this part of ISO/IEC 11172, was tased on the variance of the luminance component of the macroblock. The variance of the current macroblock and of the difference macroblock (current - motion-compensated previous) is compared. It is calculated using the method represented by the following C program fragment. Note that in calculating the variance of the difference macroblock, the average value is assumed to be zero.

> PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 106 of 124 106 of 124

```
int pelp[16][16]; \frac{1}{2} Pel values in the Previous macroblock after motion compensation */<br>int pelc[16][16]; \frac{1}{2} Pel values in the Current macroblock */
                                \frac{1}{2} Pel values in the Current macroblock \frac{1}{2}long dif; \sqrt{\frac{1}{2}} Difference between two pel values */
long sum; \frac{1}{2} from of the current pel values */
long vard; \frac{1}{2} Variance of the Difference macroblock */
long varc; {\sqrt{\frac{4}{2}}} /*Variance of the Current macroblock */
int x,y; \sqrt{\frac{1}{2}} \cdot \frac{1}{2} (oordinates */
sum = 0;vard = 0;
varc = 0;
for (y=0; y<16; y++) {
           for (x=0;x<16;x++) {
                     sum = sum + pcl(y)[x];varc= varc + (pelc[y][x]*pelc[y][x]);
                     dif = \text{pelc}[y][x] - \text{pelp}[y][x];vard = vard + (dif<sup>*</sup>dif);
           }
}
vard = vard/256; \frac{1}{7} assumes mean is close to zero */
varc = (varc/256) - (\frac{\text{sum}}256)*(sum/256));
```
The decision as to whether to code as intra or non intra is then based on figure D.34.

Figure D.34 -- Characteristic intra/non—intra

Points on the line dividing the non-intra from the intra regions, are regarded as belonging to the non-intra region.

# D.6.4.3.3 Coded/not coded decision

The choice of coded or not coded 's a result of quantization; when all coefficients are zero then a block is not coded. A macroblock is not coded ifno block in it is coded, else itis coded.

## 0.6.4.3.! Ouanlizerlno quantizer decision

Generally the quantizer scale is changed based on local scene content to improve the picture quality, and on the buffer fullness of the model decoder to prevent overflow and underflow.

# D.6.4.4 DCT transform

set to TO24 (128\*8) for intrablocks in P and B-pictures, unless the previous block was intralgoded.<br>PUMA Exhibit 2005 Coefficients of intra blocks are transformed into quantized coefficients in the same way that they were for intra blocks in I-pictures. Prediction of the dc coefficient differs, however. The dc predicted values are all

PUMA, Exhibit 2005<br>Coefficients of non-intra blocks are coded in a similar way. The main differemption in the coefficients 2016-01 107 of 124 be transformed represent differences between pel values rather than the pel values themselves. The differences are obtained by subtracting the motion-compensated pe] values from the previous picture from

the pel values in the currentmacroblodc. Since the coding is of differences, there is no spatial prediction of the dc term.

## D.6.4.5 Quantization of P-pictures

Intra macroblocks in P and B-pictures are quantized using the same method as described for I-pictures.

Non-intra macroblocks in P and B-pictures are quantized using the quantizer scale and the non-intra quantization matrix. Both dc and the ac coefficients are quantized the same way,

The following quantization formula was derived by inverting the reconstruction formula given in 2.4.4.2.<br>Note that the divisor indicates truncation towards zero.

coeffqant =  $(8 * \text{coefforig})$  / (quantscale \* niqmatrix);

The process is illustrated below:

The last line shows the reconstructed coefficient values. The following diagram shows the characteristics of this quantizer. The flat spot around zero gives this type of quantizer its name: a dead-zone quantizer.

Figure D.35 -- Dead zone quantizer characteristic

# 05.4.6 Coding oi quantized coefficients

# D.6.4.6.1 Coding of inira blocks

Intra blocks in P-pictures are coded the same way as intra blocks in I-pictures. The only differBIdMies Exhibit 2005 the prediction of the dc coefficient. The dc predicted value is 128, unless the approximately blook mass in the prediction of the dc coefficient. The dc predicted value is 128, unless the approximately proper prediction of 108 of 124
#### D.6.4.6.2 Coding of non-intra blocks

The coded block pattern is transmitted indicating which blocks have coefficient data. These are coded in a similar way to the coding of intra blocks except that the dc coefficient is coded in the same way as the ac coefficients.

## D.6.5 Coding B-pictures

As in I and P-pictures, each B-picture is divided up into one or more slices, which are, in turn, divided into macroblocks. Coding is more complex than for P-pictures, since several types of motion compensated macroblock may be constructed: forward, tackward, and interpolated. The difference between the motioncompensated macroblock and the current macroblock is transformed with a two-dimensional DCT giving an array of 8 by 8 transform coefficients. The coefficients are quantized to produce a set of quantized coefficients. The quantized coefficients are then encoded using a run-length value technique.

The encoder does not need to store the decoded B-pictnres since they will notbe used for motion compensation.

In coding B-pictures, the encoder has more decisions to make than in the case of P-pictures. These decisions are: how to divide the picture up into slices, determine the best motion vectors to use, decide whether to use forward or backward or interpolated motion compensation or to code as intra, and how to set the quantizer scale.

#### D.6.5.1 Slices in B-pictures

B-pictures are divided into slices in the same way as I and P-pictures. Since B-pictures are not used as a reference for motion compensation, enors in B-pictures are slightly less imponant than in I or P—pictures. Consequently, itmight be appropriate to use fewer slices for B-pictures.

### D.6.5.2 Macroblocks in B-pictunes

Slices are divided into macroblocks in the same way as for I-pictures.

The macroblock header may contain stuffing. The position of the macroblock is determined by the macroblock address. Whereas the macroblock address increment within a slice for I-pictures is restricted to one, it may be larger for B-pictures. Any macroblocks thus skipped over are called "skipped macroblocks". Skipped macroblocks in B-pictures differ from skipped macroblocks in P-pictures. Whereas in P-pictures skipped macroblocks have a motion vector equal to zero, in B-pictures skipped macroblocks have the same motion vector and the same macroblock type as the previous macroblock, which cannot be intra coded. As there is no additional DCT correction, they require very few hits to transmit.

The next field in the macroblock header defines the macroblock type.

PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 109 of 124 109 of 124

#### D.6.5.2.1 Macroblock types in B-pictures

There are  $12$  types of macroblock in B-pictures:

Table D.21 -- Macroblock type VLC for B-pictures (table B.2d)

| <b>TYPE</b> | <b>VLC</b> | <b>INTRA</b> | <b>MOTION</b><br><b>FORWARD</b> | <b>MOTION</b><br><b>BACKWARD</b> | <b>CODED</b><br><b>PATTERN</b> | <b>QUANT</b> |
|-------------|------------|--------------|---------------------------------|----------------------------------|--------------------------------|--------------|
| pred-i      | 10         |              |                                 |                                  |                                |              |
| pred-ic     |            |              |                                 |                                  |                                |              |
| pred-b      | 010        |              |                                 |                                  |                                |              |
| pred-bc     | 011        |              |                                 |                                  |                                |              |
| pred-f      | 0010       |              |                                 |                                  |                                |              |
| pred-tc     | 0011       |              |                                 |                                  |                                |              |
| intra-d     | 00011      |              |                                 |                                  |                                |              |
| pred-icq    | $00010 -$  |              |                                 |                                  |                                |              |
| pred-foq    | 0000 11    |              |                                 |                                  |                                |              |
| pred-baq    | 0000 10    |              |                                 |                                  |                                |              |
| intra-q     | 0000 OI    |              |                                 |                                  |                                |              |
| skipped     | N/A        |              |                                 |                                  |                                |              |

Compared with P-pictures, there are extra types due to the introduction of the backward motion vector. If only a forward motion vector is present, then the motion compensated—uncroblock is constructed from a previous picture, as in P-pictures. If only a backward motion vector is present, then the motionconnpensated macroblock is constructed from a future picture. Ifboth forward and backward motion vectors are present, then motion-compensated macroblocks are constructed from both previous and iuturepictunes, and the result is averaged to form the "interpolated' motion—compensated macrohlock.

#### 0.6.5.212 Quantizer scale

If the macroblock type is pred-icq, pred-fcq, pred-bcq, or intra-q. i.e. if the QUANT column in table D.21 base 1, then aquantizer scale is transmitted. For the remaining-macroblock types, the DCT correction is coded using the previously established value for the quantizer scale.

#### 0.6.5.2.3 Motion .vectors

If the MOTION FORWARD column in table  $D.21$  has a 1, then horizontal and vertical forward motion vectors are transmitted in succession. If the MOTION BACKWARD column in table DZ] has a 1, then horizontal and vertical backward motion vectors are transmitted in succession. If both types are present then four component vectors are transmitted in the following order:

> horizontal forward vertical forward horizontal backward vertical backward

#### 0.6.5.2.4 Coded block pattern

1f the CODED PA'ITERN column in table D21 has a 1, then acoded block pattern is transmitted. This informs the decoder which of die six blocks in the macroblock are coded, is. have transmitted DCT quantized coefficients, and which are not coded, i.e. have no additional correction after motion compensation.

#### D.6.5.3 Selection of macroblock type

The encoder has more types of macroblock to choose from in B-pictures, than in P-pictures, and consequently its job is a little harder.

For the simulation model used during development of this part of ISO/IEC 11172, the following sequential  $\frac{1}{2005}$ <br>decision algorithm was used: Apple v. PUMA, IPR2016-01135 Apple v. PUMA, IPR2016-01135

110 of 124 110 of 124

]: motion compensation mode, ie. is {onward or backward or mtezpolative motion compensation best? What of the vector values?

- 2: intra or non intra coding, i.e. is the macroblock type intra or is it motion compensated using mode and the vectors found in step 1'?
- if the macroblock type is non-intra, is it coded or not coded, i.e. is the residual error large enough to be coded using the DCT transform.  $3:$
- 4: decide if the quantizer scale is satisfactory or should be changed.

These decisions are summarized in the following diagram:

Figure D36 -- Selection of macroblock type in B-pictures

The four decision steps are discussed in the next four clauses.

#### D.6.5.3.t Selecting motion—compensation mode

An encoder should attempt to code E-pictures using skipped macroblocks if possible. This suggests that the encoder should first examine the case where the motion compensation is the same as for the previous macroblock. Ifthe previous macroblock was non-intra, and if the motion-compensated block is good enough, there will be no additional DCT correction required and the block can be coded as skipped.

Ifthe macroblock cannot be coded as skipped, then the following procedure may be followed.

For the simulation model, the selection of a motion compensation mode for a macroblock was based on the minimization of acost function. The costfuoction was the MSE of the luminance difference between the motion-compensated macroblock and the current macroblock. The encoder caICulated the best motioncornpensated macroblock for toward motion compensation. [t then caloilated the best motion-compensated mactohlock forbackwardmotion compensation by a similar method. Finally it averaged the two motioncompensated macrohlocks to produce the interpolated uncrohlock. It then selected the one that had the smallest mean square difference between it and the currentmacroblodc. In the event of a tie, interpolative mode was chosen.

> PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 111 of 124 111 of 124

> > Apple Exhibit 1009 Apple Exhibit 1009 Page 111 of 124 Page 111 of 124101

### D.6.5.3.2 Intra/non-intra coding decision

Based on the smallest MSE, a decision is made between the best of the three possible prediction modes and the Intra mode. The calculation is similar to that of P-pictures. The variances of the difference macroblock, vard, and of the current macroblock, varc, are calculated.

In the simulation model the final decision was based on simply the macroblock type with the smallest variance. Ifthe two variances were equal.non-intra coding was chosen.

#### 0.6.5.3.3 Codedlnot—coded decision

The choice of coded or not coded is a result of quantization, when all coefficients are zero then a block is not coded. A macroblock is not coded if no block in it is coded, else itis coded.

#### 0.6.5.4 DCT transform

Coefficients of blocks are transformed into quantized coefficients in the same way that they are for blocks in P-pictures.

#### 0.6.5.5 Quantization ol B-pictures

Blocks in B-pictures are quantized in the same way as for P-pictnrcs.

#### 0.6.5.6 Coding quantized coefficients

Blocks in B-pictures are coded the same way as blocks in P-pictures.

## 0.5.6 Coding D-plctures

D pictures contain only low frequency information They are intended to be used for fast visible search modes. It is intended that the low frequency information they contain is sufficient forthe user to locate the desired video.

D pictures are coded as the dc coefficients ofblocks. There is a bit umsmitted for the macroblock type, although only one marroblock type exists In addition there is a bit denoting end of macroblock.

## 9.5.7 Coding at lower picture rates

This part ofISO/IEC 11172 does not allow pictures to be dropped at the encoder. This differs from the case of CCITT Recommendation H261 [5] Where temporal sub-sampling may be done by omitting coded pictures from the sequence. This part of ISO/[EC 11172 requires that all source pictures must be encoded and that coded picturesmust be inserted into the bitstream nominally at the rate defined by the picture\_rate field in the sequence header.

Despite this requirement it is possible for encoders to operate at a lower effective picture rate than the one defined in the sequence header by using P-pictures or B-pictures that consist entirely of macroblocks that are copied from a neighbouring reference picture with no DCT information. This creates a flexible method of temporal sub—sampling and picture repetition that may be implemented in the encoder by inserting a defined block of data. For example, to encode at an effective rate of 12,5 Hz in a 25 Hz bitstrcam, alternate pictures can be copied from the preceding picture by inserting the block of data in table D.22.

> PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 112 of 124 112 of 124

# D.7 Decoding MPEG video

# D.7.1 Decoding a sequence

# D.7.1.1 Decoding for forward playback

At the beginning of a sequence, the decoder will decode the sequence header including the sequence parameters: If a parameter exceeds the capability of the decoder, then the decoder should report this. Ifthe decoder determines that it can decode the bitstream, then it will set up its parameters to match those defined in the sequence headcr. This will include the horizontal and vertical resolutions and aspect ratio, the bit rate, and the quantization matrices.

Next the decoder will decode the group of pictures header, including the closed\_gop and broken\_link infonnation,and take any appropriate action. It will decode the first picture header in the group of pictures and read the vbv\_delay field. If the decoder uses the vbv\_delay information to start-up decoding rather than the information in the system stream (ISO/IEC 11172-1) then it must delay displaying pictures until after a time determined by the vbv\_delay information and a knowledge of the decoder's architecture.

If the closed-gop flag is 0, indicating that the group is open, and the broken\_link flag is 1, then any Bpictures preceding (in display order) the first l-picture in the group cannot be decoded. The decoder may adopt one of several strategies. It may display the first l-picture during the time that the undecodable Bpictures would be displayed. This strategy maintains audio synchronization and buffer fullness. However it is likely that the broken link has occured because of post coding editing, in which case audio may be discontinuous. An alternative strategy might be to discard the B-pictures entirely, and delay decoding the Ipicture until the buffer fullness is within limits.

If playback begins from a random point in the bitstream, the decoder should discard all the bits until it finds<br>a sequence start code, a group of pictures start code, or a picture start code which introduces an Lphding Exh a sequence start code, a group of pictures start code, or a picture start code which introduces and phethod. XMDIT 2005<br>The slices and macroblocks in the picture are decoded and written into a display the start phethods in 113 of 124 If playback begins from a random point in the bitstream, the decoder should discard all the bits until it finds another buffer. The decoded pictures may be post processed and displayed in the order defined by the temporal reference at the picture rate defined in the sequence header.

Subsequent pictures are processed at the appropriate times to avoid buffer overflow and undertlow.

#### D.7.1.2 Decoding for fast playback

Fast forward can be supported by D pictures. It can also be supported by an appropriate spacing of Ipictures in a sequence. For example, if I-pictures were spaced regularly every 10 pictures, then a decoder mightbe able to playback the sequence at 10 times the normal speed by decoding and displaying only the 1 pictures. Thissimple concept places considerable burdens on the media and the decoder. The mediamust be capable of speeding up and delivering 10 times the data rate, the decoder must be capable of accepting this higher data rate and decoding the l-pictares. Since l—pictures typically require significantly more bits to code than F or B-pictures, the decoder will have to decode significantly more than 10% ofthe data, even if it can search for picture start codes and discard the data for P and B-pictures.

For example, a sequence might be coded as follows:

#### IBPBPBPBPBIBPBPBPBPBI...

Assume that the average code size per picture is C, that each B-picture requires 0,3C, that each P-picture requires 1,5C, and that each I-picture requires 2,5C, then the I-pictures require  $25\%$  of the code for their  $10\%$ of the display time.

Another way to achieve fast forward in a constant bit rate application, is for the media itself to sort out the l—pictures and transmit them. This would allow the data rate to remain connant. Since this selection process can be made to produce a valid ISO/IEC 11172-2 bitstream, the decoder should be able to decode it. If every [—pictnre of the preceding example were selected, then one I-picture would be transmitted every 2.5 picture periods, and the speed up rate would be  $10/2,5 = 4$  times. The decoder might be able to display the l-pictures at exactly 2,5 periods, or it might alternate displays at 2 and 3 periods.

If alternate I-pictures of the preceding example were selected, then one I-picture would again be transmitted every 2,5 picture periods, but the speed up rate would be  $20/2.5 = 8$  times.

If one in N I-pictures of the preceding example were selected, then the speed up rate would be  $10N/2.5 = 4N$ times.

#### D.7.1.3 Decoding for pause and step modes

Decoding for pause requires the demder to be able to control the incoming bitstream, and display adecoded picture without decoding any additional pictures. It the decoder has full control over the bitstream, then it can be stopped for pause and resumed when playback resumes. If the decoder has less control, as in the case of a CD ROM, then there may be adelay before playback can be resumed.

#### 0.7.1.4 Decoding for reverse playback

To decode a bitstream and playback in reverse, the decoder must decode each group of pictures in the forward direction, store the decoded pictures, then display them in reverse order. This places severe storage requirements on the decoder in addition to any problems in gaining access to the coded bitsttearn in the correct order.

To reduce decoder memory requirements, groups of pictures should be small. There is no mechanism in the syntax for the encoder to state whatthe decoder requirements are in order to playback in reverse.

The amount of display buffer storage may be reduced by reordering the pictures, either by having the storage unit read and transmittheminanother order. or by reordering the coded pictures in a decoder buffer. To illustrate the savings, consider the following typical group of pictures:

> PUMA Exhibit 2005 PUMA Exhibit 2005 Apple v. PUMA, IPR2016-01135 Apple V. PUMA, IPR2016-01135 114 of 124 114 of 124

#### Figure D.37 -- Example group of pictures

The decoder would decode the pictures in the new order, and display them in the reverse of the normal display order. Since the B-pictures are not decoded until they are ready to be displayed, the display buffer storage is minimized. The first two B—picrures, 0 and 1, would remain stored in the input buffer until the last P-picture in the previous group of pictures is decoded

## D.8 Fost processing

## 0-8.1 Editing

Editing of a video sequence is best performed before compression, but situations arise where only the coded bitstream is available. One possible method would be to decode the bitstream, perform the required editing, and recode the bitstream. This usually leads to a loss in video quality, and it is better, if pessible, to edit the coded bitstream itself.

Although editing may take several forms, the following discussion pertains only to editing at the picture level: deletion of coded video material from a hitsu'eam, insertion of coded video material into abitstream, orrearrangement of coded videomaterial within a bitstrearn.

If editing is anticipated, cg. clip video is provided analogous to clipart for still pictures, then the video can be encoded with well defined cutting points. These cutting points are places at which the bitstrearn may be broken apart orjoined. Each cutting point should be followed bya closed group of pictures. This allows smooth playback after editing.

An editor must take care to ensure that the bitstreani it produces is a legal bitstream. In particular it must ensure that the new bitstream complies with the requirements of the video buffering verifier. This is a difficult disk and in general it will not be possible to edit together arbitrary sections of bitstreams that comply with this part of ISO/IEC 11172 to produce another bitstream that also complies with this part of ISO/EEC 11172(see for example figure D38).

Figure D.38 -- Sequences

It may however be possible to deliberately encode bitstreams in a manner that allows some editing to occur. For instance, if all Groups of Pictures had the same number of pictures and were encoded with the same number of bits, then many of the problems of complying with the video buffering verifier would be solved.

The easiest editing task is to cut at the beginning of groups of pictures. If the group of pictures following the cut is open, which can be detected by examining the closed\_gop flag in the group of pictures header, then the editor must set the broken\_1ink bit to <sup>1</sup> to indicate to the decoder that the previous group of pictures cannot be used for decoding any B-pidures.

# 0.8.2 Resampling

The decoded bitstrearn may not match the picture rate or the spatial resolution of the display device. In this quite frequent situation. the decoded videomustberesampled orsealed.

One example, considered under preprocessing, is the case where the decoded video has SIF resolution and<br>must be converted to CCIR 601 resolution

## D.8.2.1 Conversion of MPEG SIF to CCIR 601 format

A SIF is converted to its corresponding CCIR 601 format by spatial upsampling. A linear phase FIR filter is applied after the insertion of zeroes between samples. A filter that can be used for upsampling the luminance is shown in figure D39: (E)<br>
(E)<br> **mpling**<br>
by not match the picture rate or the spatial resolved decoded video must be resampled or scaled.<br>
Inder preprocessing, is the case where the decod<br>
R 601 resolution.<br>
of MPEG SIF to CCIR 601 format<br>
co

Figure  $D.39 - Upsampling$  filter for luminance

At the end of the lines some special technique, such as replicating the lastpel, must be adopted.

According to CCIR Rec. 601 the chrominance samples need to be co-sited with the luminance samples 1, 3, 5,... In order to achieve the proper location, the upsatnpiing filter should have an even number of laps,as shown in figure DAD.

The SIF may be reconstructed by adding four black pels to each end of the horizontal luminance lines in the decoded bitmap, and two gray pels to each end of the horizontal chrominance lines. The luminance SIF may then be upsampled horizontally and vertically. The chrominance SIF should be upsampled once horizontally and twice vertically. This process is illustrated by the following diagram:

### 0.8.2.2 Temporal resampling

since the picture rates are finited to those commonly used in the lettersten measury; the same teaming is smaller than  $\frac{1}{2005}$  may be applied. For example, conversion from 24 pictures/s to 60 fields/s may be achieved technique of 3.2 pulldown.<br>
Apple v. PUMA, IPR2016-01135 Since the picture rates are limited to those commonly used in the television industry, the same techniques

116 of 124 116 of 124

Video coded at 25 pictures/s can be converted to 50 fields/s by displaying the original decoded lines in the odd CCIR 601 fields, and the interpolated lines in the even fields. Video coded at 29,97 or 30 pictures/s maybe converted to a tieid rate twice as large using the same method.

Video coded at 23,976 or 24 pictures/s may be converted to 50 fieids/s by speeding it up by about 4% and deccding it as if it had been encoded at 25 pictures/8.. The decoded pictures could be displayed in the odd fields, and interpolated pictures in the even fields. The audio must he maintained in synchronization, either by increasing the pitch, or by speeding it up without a pitch change.

Video coded al 23,976 or 24 pictures/s may be converted to 59,94 or 6D fieldsls using the technique of 3:2 puli down.

## List of patent holders

The user's attention is called to the possibility that - forsome of the processes specified in this part of ISO/IEC 11172 - compliance with this international Standard may require use. of an invention covered by patent rights.

By publication of this part of ISO/IEC 11172, no position is taken with respect to the validity of this claim or of any patent rights in connection therewith. However, each company listed in this annex has filed with the Information Technology Task Force (ITTF) a statement of willingness to grant a license under such rights that they hold on reasonable and nondiscriminatory terms and conditions to applicants desiring to obtain such a license.

Information regarding such patents can be obtained from :
