

Great Circle

# Firewalls Mailing List

The *Firewalls* mailing list is for discussions of Internet firewall security systems and related issues. Relevant topics include the design, construction, operation, maintenance, and philosophy of Internet firewall security systems.

The *Firewalls* mailing list was created by [Great Circle Associates](#) in September 1992, and was hosted here until April 1998, when it was moved to a new home at [GNAC](#). In June 2002, the list was moved again, to its current home at the [Internet Software Consortium](#).

This web site provides access to the archives of the Firewalls mailing list from the period when it was hosted by [Great Circle Associates](#), from the list's creation in September 1992 until it moved to [GNAC](#) in April 1998. For archives after April 1998, see the [current Firewalls mailing list web page](#) hosted by the Internet Software Consortium.

## Subscription Information

To subscribe to or unsubscribe from the Firewalls mailing list, see the [current Firewalls mailing list web page](#) hosted by the Internet Software Consortium.

## Archives

All messages sent to the list while it was hosted by [Great Circle Associates](#) (from the list's creation in September 1992 until it moved to [GNAC](#) in April 1998) are publicly available in a [web-based archive](#), as well as searchable via Google and other search engines.

Messages sent to the list after it moved to [GNAC](#) in April 1998 (and, eventually, further moved to [ISC](#)) are available via the [current Firewalls mailing list web page](#) hosted by the Internet Software Consortium.

We strongly believe that searchable archives of past messages are one of the most important features of Internet mailing lists such as this one, and that it's critical that those archives be complete and accurate representations of the discussions on the list. Therefore, as a general rule we will not honor requests to edit the archives to remove or modify particular postings. So, subscribers were advised to be thoughtful before posting; as they were going to have to live with whatever they said being in the archives forever, searchable by employers, family members, etc.

The email address that messages were posted from will likely be harvested from the archives by spammers. We have carefully considered this problem, and concluded that there really isn't any way we can prevent that while still maintaining useful and searchable archives. Subscribers were advised to take whatever steps they felt were appropriate to protect themselves, such as using a strong spam-

Browsing the WWW from root is a bad idea. Doing anything from root that does not require root access is generally considered a bad habit to get into, because a typo can be more costly.

Independent Linux and BSD systems can be dangerous on your network, but that's a political problem. If the users want their own workstations, they should know that it could threaten the safety of the network. They should also know what the \*\*\*\* they're doing if they're running their own workstation; otherwise, they don't deserve one.

Windows NT and Windows 95 are multi-user operating systems; therefore, they have both global and user configs. Windows 3.1 systems have no user config, just a global. Overridability options can still be used in Windows 3.1.

Also, in a network I would not rely just upon the configuration of the browser, especially if there are Windows 3.1, Linux, BSD, or other user-administered systems on the network. On a network, users should go through a firewall proxy to access the internet. The firewall gives the network administrator an opportunity to centrally screen Java code (see below).

You could block URL's, but the http proxy could also scan for Java code. Java code could be removed, or a heuristic scan could be applied to the Java code that would check for things like editing of .rhosts, piping /etc/passwd into /bin/mail, or whatever. This may be too complex for a simple (and therefore secure) firewall.

Another option would be to scan for Java code and block all Java by default. When users clamor for a Java applet, the administrator could inspect the applet for safety. The administrator could use some sort of heuristic scanner. He could also simply decompile and read the code. Once the administrator is certain the code poses no threat, he could add the code's URL and checksum to a database of applets that are not filtered. If the applet changes, then the checksum verification would fail and the admin would have to re-verify the applet. Unfortunately, an annoyance would develop if an applet were being continuously revised and debugged "in public."

Some companies already forbid use of outside software not approved by MIS. Java, unfortunately, almost redefines "outside software."

I don't think the problem is insoluble. I just think that the solution will require technical insight, sophistication, and work.
