Description

BACKGROUND OF THE INVENTION

[0001] The present invention relates to an apparatus for endovascularly replacing a heart valve comprising a seal as set forth in the claims

[0002] Heart valve surgery is used to repair or replace diseased heart valves. Valve surgery is an open-heart procedure conducted under general anesthesia. An incision is made through the patient's sternum (sternotomy), and the patient's heart is stopped while blood flow is rerouted through a heart-lung bypass machine.

[0003] Valve replacement may be indicated when there is a narrowing of the native heart valve, commonly referred to as stenosis, or when the native valve leaks or regurgitates.

When replacing the valve, the native valve is excised and replaced with either a biologic or a mechanical valve. Mechanical valves require lifelong anticoagulant medication to prevent blood clot formation, and clicking of the valve often may be heard through the chest. Biologic tissue valves typically do not require such medication. Tissue valves may be obtained from cadavers or may be porcine or bovine, and are commonly attached to synthetic rings that are secured to the patient's heart.

[0004] Valve replacement surgery is a highly invasive operation with significant concomitant risk. Risks include bleeding, infection, stroke, heart attack, arrhythmia, renal failure, adverse reactions to the anesthesia medications, as well as sudden death. 2-5% of patients die during surgery.

[0005] Post-surgery, patients temporarily may be confused due to emboli and other factors associated with the heart-lung machine. The first 2-3 days following surgery are spent in an intensive care unit where heart functions can be closely monitored. The average hospital stay is between 1 to 2 weeks, with several more weeks to months required for complete recovery.

[0006] In recent years, advancements in minimally invasive surgery and interventional cardiology have encouraged some investigators to pursue percutaneous replacement of the aortic heart valve. Percutaneous Valve Technologies ("PVT") of Fort Lee, New Jersey, has developed a balloon-expandable stent integrated with a bioprosthetic valve. The stent/valve device is deployed across the native diseased valve to permanently hold the valve open, thereby alleviating a need to excise the native valve and to position the bioprosthetic valve in place of the native valve. PVT's device is designed for delivery in a cardiac catheterization laboratory under local anesthesia using fluoroscopic guidance, thereby avoiding general anesthesia and open-heart surgery. The device was first implanted in a patient in April of 2002.

[0007] PVT's device suffers from several drawbacks. Deployment of PVT's stent is not reversible, and the stent is not retrievable. This is a critical drawback because improper positioning too far up towards the aorta risks blocking the coronary ostia of the patient. Furthermore, a misplaced stent/valve in the other direction (away from the aorta, closer to the ventricle) will impinge on the mitral apparatus and eventually wear through the leaflet as the leaflet continuously rubs against the edge of the stent/valve.

[0008] Another drawback of the PVT device is its relatively large cross-sectional delivery profile. The PVT system's stent/valve combination is mounted onto a delivery balloon, making retrograde delivery through the aorta challenging. An antegrade transseptal approach may therefore be needed, requiring puncture of the septum and routing through the mitral valve, which significantly increases complexity and risk of the procedure. Very few cardiologists are currently trained in performing a transseptal puncture, which is a challenging procedure by itself.

[0009] Other prior art replacement heart valves use self-expanding stents as anchors. In the endovascular aortic valve replacement procedure, accurate placement of aortic valves relative to coronary ostia and the mitral valve is critical. Standard self-expanding systems have very poor accuracy in deployment, however. Often the proximal end of the stent is not released from the delivery system until accurate placement is verified by fluoroscopy, and the stent typically jumps once released. It is therefore often impossible to know where the ends of the stent will be with respect to the native valve, the coronary ostia and the mitral valve.

[0010] Also, visualization of the way the new valve is functioning prior to final deployment is very desirable. Visualization prior to final and irreversible deployment cannot be done with standard self-expanding systems, however, and the replacement valve is often not fully functional before final deployment.

[0011] Another drawback of prior art self-expanding replacement heart valve systems is their lack of radial strength. In order for self-expanding systems to be easily delivered through a delivery sheath, the metal needs to flex and bend inside the delivery catheter without being plastically deformed. In arterial stents, this is not a challenge, and there are many commercial arterial stent systems that apply adequate radial force against the vessel wall and yet can collapse to a small enough of a diameter to fit inside a delivery catheter without plastically deforming.

[0012] However when the stent has a valve fastened inside it, as is the case in aortic valve replacement, the anchoring of the stent to vessel walls is significantly challenged during diastole. The force to hold back arterial pressure and prevent blood from going back inside the ventricle during diastole will be directly transferred to the stent/vessel wall interface. Therefore the amount of radial force required to keep the self expanding stent/valve in contact with the vessel wall and not sliding will be much higher than in stents that do not have valves inside of them. Moreover, a self-expanding stent without sufficient radial force will end up dilating and contracting with each

heartbeat, thereby distorting the valve, affecting its function and possibly migrating and dislodging completely. Simply increasing strut thickness of the self-expanding stent is not a practical solution as it runs the risk of larger profile and/or plastic deformation of the self-expanding stent.

[0013] U.S. patent application Serial No. 2002/0151970 to Garrison et al. describes a two-piece device for replacement of the aortic valve that is adapted for delivery through a patient's aorta. A stent is percutaneously placed across the native valve, then a replacement valve is positioned within the lumen of the stent. By separating the stent and the valve during delivery, a profile of the device's delivery system may be sufficiently reduced to allow aortic delivery without requiring a transseptal approach. Both the stent and a frame of the replacement valve may be balloon-expandable or self-expanding.

[0014] While providing for an aortic approach, devices described in the Garrison patent application suffer from several drawbacks. First, the stent portion of the device is delivered across the native valve as a single piece in a single step, which precludes dynamic repositioning of the stent during delivery. Stent foreshortening or migration during expansion may lead to improper alignment.

[0015] Additionally, Garrison's stent simply crushes the native valve leaflets against the heart wall and does not engage the leaflets in a manner that would provide positive registration of the device relative to the native position of the valve. This increases an immediate risk of blocking the coronary ostia, as well as a longer-term risk of migration of the device post-implantation. Furthermore, the stent comprises openings or gaps in which the replacement valve is seated post-delivery. Tissue may protrude through these gaps, thereby increasing a risk of improper seating of the valve within the stent.

[0016] In view of drawbacks associated with previously known techniques for percutaneously replacing a heart valve, it would be desirable to provide methods and apparatus that overcome those drawbacks.

WO 00/47139 discloses a valve implantation sysetm having a valve displacer and a replacement valve attached to the valve displacer before or after introduction

SUMMARY OF THE INVENTION

[0017] The present invention relates to an apparatus for endovascularly replacing a heart valve comprising a seal as set forth in the claims.

The apparatus comprises an expandable anchor (30) supporting a replacement valve, the anchor (20) having a delivery configuration and a deployed configuration and has a fabric seal that extends from the distal end of the valve (20) proximally over the anchor in the delivery configuration. The seal is bunched up in the deployed configuration

The fabric seal can bunch up to create fabric flaps and pockets. The seal can bunch up and creates pleats. The seal can comprise a pleated seal. The pleating can create a seal around the replacement valve. The seal can bunch up in response to backflow blood pressure. The bunched up fabric or pleats can occur in particular when the pockets are filled with blood in response to backflow blood pressure. The expandable anchor can haves a delivery length in a delivery configuration that is substantially greater than a deployed length in a deployed configuration. The anchor can foreshorten during deployment. The delivery configuration can be a collapsed configuration and the deployed configuration can be an expanded configuration. The anchor can self-expand from the delivery configuration. The anchor can be balloon expandable. At least a portion of the seal can be adapted to be captured between native valve leaflets and a wall of the patient's heart when the anchor and replacement valve are fully deployed. The seal can be adapted to prevent blood flow around the replacement valve and the anchor when the anchor and the replacement valve are fully deployed.

BRIEF DESCRIPTION OF THE DRAWINGS

[0018]

Figures 1A-B are elevational views of a replacement heart valve and anchor according to one embodiment of the invention.

Figures 2A-B are sectional views of the anchor and valve of Figures 1.

Figures 3A-B show delivery and deployment of a replacement heart valve and anchor, such as the anchor and valve of Figures 1 and 2.

Figures 4A-F also show delivery and deployment of a replacement heart valve and anchor, such as the anchor and valve of Figures 1 and 2.

Figures 5A-I show the use of a replacement heart valve and anchor to replace an aortic valve.

Figures 6A-F show the use of a replacement heart valve and anchor with a positive registration feature to replace an aortic valve.

Figure 7 shows the the use of a replacement heart valve and anchor with an alternative positive registration feature to replace an aortic valve.

Figures 8A-C show another embodiment of a replacement heart valve and anchor according to the invention.

Figures 9A-H show delivery and deployment of the replacement heart valve and anchor of Figures 8.

Figure 10 is a cross-sectional drawing of the delivery system used with the method and apparatus of Figures 8 and 9.

Figure 11 demonstrates paravalvular leaking around a replacement heart valve and anchor.

Figure 12 shows a seal for use with a replacement heart valve and anchor of this invention.

Figures 13A-E show alternative arrangements of seals on a replacement heart valve and anchor.

Figures 14A-C show alternative seal designs for use

with replacement heart valves and anchors.

Figure 15 shows yet another embodiment of the delivery and deployment apparatus of the invention in use with a replacement heart valve and anchor.

Figure 16 shows the delivery and deployment apparatus of Figure 15 in the process of deploying a replacement heart valve and anchor.

Figure 17 shows an embodiment of the invention employing seals at the interface of the replacement heart valve and anchor and the patient's tissue.

Figure 18 is a longitudinal cross-sectional view of the seal shown in Figure 17 in compressed form.

Figure 19 is a transverse cross-sectional view of the seal shown in Figure 18.

Figure 20 is a longitudinal cross-sectional view of the seal shown in Figure 17 in expanded form.

Figure 21 is a transverse cross-sectional view of the seal shown in Figure 20.

Figure 22 shows yet another embodiment of the replacement heart valve and anchor of this invention in an undeployed configuration.

Figure 23 shows the replacement heart valve and anchor of Figure 22 in a deployed configuration.

Figure 24 shows the replacement heart valve and anchor of Figures 22 and 23 deployed in a patient's heart valve.

Figures 25A and 25B show replacement valve apparatus in accordance with the present invention. Figure 25 illustrates the apparatus in a collapsed delivery configuration within a delivery system. Figure 25B illustrates the apparatus in an expanded configuration partially deployed from the delivery system.

Figures 26A-26F show an anchor of the apparatus of Figures 25 in the collapsed delivery configuration and the expanded deployed configuration, as well as the full apparatus in the deployed configuration, and optional locking mechanisms for use with the apparatus.

Figures 27A-27F illustrate deployment of an anchor with leaflet engagement elements on the deployment system.

Figure 28 illustrates a deployed anchor with leaflet engagement elements on the proximal end of the anchor.

Figures 29A-29C illustrate deployment of an anchor with anchor registration elements and a seal.

Figures 30A-30B illustrate an embodiment of the apparatus with a seal that does not reach the proximal end of the anchor during both systole and diastole.

Figures 31A-31B illustrate an embodiment of the apparatus with a seal that reaches the proximal end of the anchor during both systole and diastole.

DETAILED DESCRIPTION

[0019] The present invention relates to apparatus and methods for endovascularly or percutaneously delivering and deploying a prosthesis, e.g., an aortic prosthesis, within and/or across a patient's native heart valve, referred to hereinafter as replacing the patient's heart valve. A delivery system and/or deployment tool is provided including a sheath assembly and a guidewire for placing the prosthetic apparatus endovascularly within the patient and a user control allowing manipulation of the prosthetic apparatus from external to the patient through the application of a non-hydraulically expanding or non-pneumatically expanding force on the anchor. A hydraulically or pneumatically expanding force would be, for example, a force applied to the anchor by a balloon expanded within the anchor. In certain embodiments, the application of a non-hydraulically expanding or non-pneumatically expanding force could include the use of a hydraulic component transmitting a proximally or distally directed force on an anchor.

[0020] The apparatus includes an anchor and a replacement valve. The anchor includes an expandable anchor such as a braid. In preferred embodiments, the expandable braid includes closed edges, but the edges may alternatively be open. The replacement valve is adapted to be secured within the anchor, and as such, be delivered endovascularly to the patient's heart to replace one of the patient's native heart valves. More preferably, the apparatus and methods of the present invention contemplate replacement of the patient's aortic valve.

[0021] With reference now to Figures 1-4, a first embodiment of replacement heart valve apparatus in accordance with the present invention is described, including a method of actively foreshortening and expanding the apparatus from a delivery configuration and to a deployed configuration. Apparatus 10 comprises replacement valve 20 disposed within and coupled to anchor 30. Figures 1 schematically illustrate individual cells of anchor 30 of apparatus 10, and should be viewed as if the cylindrical anchor has been cut open and laid flat. Figures 2 schematically illustrate a detail portion of apparatus 10 in side-section.

[0022] Anchor 30 has a lip region 32, a skirt region 34 and a body region 36. First, second and third posts 38a, 38b and 38c, respectively, are coupled to skirt region 34 and extend within lumen 31 of anchor 30. Posts 38 preferably are spaced 120° apart from one another about the circumference of anchor 30.

[0023] Anchor 30 preferably is fabricated by using self-expanding patterns (laser cut or chemically milled), braids, and materials, such as a stainless steel, nickel-titanium ("Nitinol") or cobalt chromium but alternatively may be fabricated using balloon-expandable patterns where the anchor is designed to plastically deform to it's final shape by means of balloon expansion. Replacement valve 20 is preferably from biologic tissues, e.g. porcine valve leaflets or bovine or equine pericardium tissues, alternatively it can be made from tissue engineered materials (such as extracellular matrix material from Small Intestinal Submucosa (SIS)) but alternatively may be prosthetic from an elastomeric polymer or silicone, Nitinol

or stainless steel mesh or pattern (sputtered, chemically milled or laser cut). The leaflet may also be made of a composite of the elastomeric or silicone materials and metal alloys or other fibers such Kevlar or carbon. Annular base 22 of replacement valve 20 preferably is coupled to skirt region 34 of anchor 30, while commissures 24 of replacement valve leaflets 26 are coupled to posts 38.

[0024] Anchor 30 may be actuated using external non-hydraulic or non-pneumatic force to actively foreshorten in order to increase its radial strength. As shown below, the proximal and distal end regions of anchor 30 may be actuated independently. The anchor and valve may be placed and expanded in order to visualize their location with respect to the native valve and other anatomical features and to visualize operation of the valve. The anchor and valve may thereafter be repositioned and even retrieved into the delivery sheath or catheter. The apparatus may be delivered to the vicinity of the patient's aortic valve in a retrograde approach in a catheter having a diameter no more than 23 french, preferably no more than 21 french, more preferably no more than 19 french, or more preferably no more than 17 french. Upon deployment the anchor and replacement valve capture the native valve leaflets and positively lock to maintain configuration and position.

[0025] A deployment tool is used to actuate, reposition, lock and/or retrieve anchor 30. In order to avoid delivery of anchor 30 on a balloon for balloon expansion, a non-hydraulic or non-pneumatic anchor actuator is used. In this embodiment, the actuator is a deployment tool that includes distal region control actuators 50, control actuators 60 (embodied here as rods or tubes) and proximal region control actuators 62. Locks 40 include posts or arms 38 preferably with male interlocking elements 44 extending from skirt region 34 and mating female interlocking elements 42 in lip region 32. Male interlocking elements 44 have eyelets 45. Control actuators 50 pass from a delivery system for apparatus 10 through female interlocking elements 42, through eyelets 45 of male interlocking elements 44, and back through female interlocking elements 42, such that a double strand of wire 50 passes through each female interlocking element 42 for manipulation by a medical practitioner external to the patient to actuate and control the anchor by changing the anchor's shape. Control actuators 50 may comprise, for example, strands of suture or wire.

[0026] Actuators 60 are reversibly coupled to apparatus 10 and may be used in conjunction with actuators 50 to actuate anchor 30, e.g., to foreshorten and lock apparatus 10 in the fully deployed configuration. Actuators 60 also facilitate repositioning and retrieval of apparatus 10, as described hereinafter. For example, anchor 30 may be foreshortened and radially expanded by applying a distally directed force on actuators 60 while proximally retracting actuators 50. As seen in Figures 3, control actuators 62 pass through interior lumens 61 of actuators 60. This ensures that actuators 60 are aligned properly with apparatus 10 during deployment and foreshortening. Control actuators 62 can also actuate anchor 60; proximally directed forces on control actuators 62 contacts the proximal lip region 32 of anchor 30. Actuators 62 also act to couple and decouple actuators 60 from apparatus 10. Actuators 62 may comprise, for example, strands of suture or wire.

[0027] Figures 1A and 2A illustrate anchor 30 in a delivery configuration or in a partially deployed configuration (e.g., after dynamic self-expansion expansion from a constrained delivery configuration within a delivery sheath). Anchor 30 has a relatively long length and a relatively small width in the delivery or partially deployed configuration, as compared to the foreshortened and fully deployed configuration of Figures 1B and 2B.

[0028] In Figures 1A and 2A, replacement valve 20 is collapsed within lumen 31 of anchor 30. Retraction of actuators 50 relative to actuators 60 foreshortens anchor 30, which increases the anchor's width while decreasing its length. Such foreshortening also properly seats replacement valve 20 within lumen 31 of anchor 30. Imposed foreshortening will enhance radial force applied by apparatus 10 to surrounding tissue over at least a portion of anchor 30. In some embodiments, the anchor exerts an outward force on surrounding tissue to engage the tissue in such way to prevent migration of anchor caused by force of blood against closed leaflet during diastole. This anchoring force is preferably 0,454 kg to 0,907 kg [1 to 2 lbs], more preferably 0,907 kg to 1,814 kg [2 to 4 lbs], or more preferably 1,814 kg to 4,536 kg [4 to 10 lbs]. In some embodiments, the anchoring force is preferably greater than 0,454 kg [1 pound], more preferably greater than 0,907 kg [2 pounds], or more preferably greater than 1,814 kg [4 pounds]. Enhanced radial force of the anchor is also important for enhanced crush resistance of the anchor against the surrounding tissue due to the healing response (fibrosis and contraction of annulus over a longer period of time) or to dynamic changes of pressure and flow at each heart beat. In an alternative embodiment, the anchor pattern or braid is designed to have gaps or areas where the native tissue is allowed to protrude through the anchor slightly (not shown) and as the foreshortening is applied, the tissue is trapped in the anchor. This feature would provide additional means to prevent anchor migration and enhance long term stability of the device.

[0029] Deployment of apparatus 10 is fully reversible until lock 40 has been locked via mating of male interlocking elements 44 with female interlocking elements 42. Deployment is then completed by decoupling actuators 60 from lip section 32 of anchor 30 by retracting one end of each actuator 62 relative to the other end of the actuator, and by retracting one end of each actuator 50 relative to the other end of the actuator until each actuator has been removed from eyelet 45 of its corresponding male interlocking element 44.

[0030] As best seen in Figure 2B, body region 36 of anchor 30 optionally may comprise barb elements 37 that protrude from anchor 30 in the fully deployed configura-
