let a highly-active interface lock out the others (which would happen with a single queue).

The transmit request may be a segment that is less than the MSS, or it may be as much as a full 64K SMB READ. Obviously the former request will go out as one segment, the latter as a number of MSS-sized segments. The transmitting TCB must hold on to the request until all data in it has been transmitted and acked. Appropriate pointers to do this will be kept in the TCB. A large buffer is acquired from the free buffer fifo, and the MAC and TCP/IP headers are created in it. It may be quicker/simpler to keep a basic frame header set up in the TCB and either dma directly this into the frame each time. Then data is dmad from host memory into the frame to create an MSS-sized segment. This dma also checksums the data. Then the checksum is adjusted for the pseudo-header and placed into the TCP header, and the frame is queued to the MAC transmit interface which may be controlled by the third sequencer. The final step is to update various window fields etc in the TCB. Eventually either the entire request will have been sent and acked, or a retransmission timer will expire in which case the context is flushed to the host. In either case, the INIC will place a command response in the Response queue containing the command buffer handle from the original transmit command and appropriate status. The above discussion has dealt how an actual transmit occurs. However the real challenge in the transmit processor is to determine whether it is appropriate to transmit at the time a transmit request arrives. There are many reasons not to transmit: the receiver's window size is <= 0, the Persist timer has expired, the amount to send is less than a full segment and an ACK is expected / outstanding, the receiver's window is not half-open etc. Much of the transmit processing will be in determining these conditions.

#### 5.3.4 Transmit Details - No Valid Context

The main difference between this and a context-based transmit is that the queued request here will already have the appropriate MAC and TCP/IP (or whatever) headers in the frame to be output. Also the request is guaranteed not to be greater than MSS-sized in length. So the processing is fairly simple. A large buffer is acquired and the frame is dmad into it, at which time the checksum is also calculated. If the frame is TCP/IP, the checksum will be appropriately adjusted if necessary (pseudo-header etc) and placed in the TCP header. The frame is then queued to the appropriate MAC transmit interface. Then the command is immediately responded to with appropriate status through the Response queue.

#### 5.3.5 Transmit Notes

- 1. Slow-start: the INIC will handle the slow-start algorithm that is now a part of the TCP standard. This obviates waiting until the connection is sending a full-rate before passing it to the INIC.
- Window Probe vs Window Update: an explanation for posterity....

A Window Probe is sent from the sending TCB to the receiving TCB, and it means the sender has the receiver in PERSIST state. Persist state is entered when the receiver advertises a zero window. It is thus the state of the transmitting TCB. In this state, he sends periodic window probes to the receiver in case an ACK from the receiver has been lost. The receiver will return his latest window size in the ACK.

> Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

A Window Update is sent from the receiving TCB to the sending TCB, usually to tell him that the receiving window has altered. It is mostly triggered by the upper layer when it accepts some data. This probably means the sending TCB is viewing the receiving TCB as being in PERSIST state.

- 3. Persist state: it is designed to handle Persist state on the INIC. It seems unreasonable to throw a TCB back to the host just because its receiver advertised a zero window. This would normally be a transient situation, and would tend to happen mostly with clients that do not support slow-start. Alternatively, the code can easily be changed to throw the TCB back to the host as soon as a receiver advertises a zero window.
- 4. MSS-sized frames: the INIC code will expect all transmit requests for which it has no TCB to not be greater than the MSS. If any request is, it will be dropped and an appropriate response status posted.
- 5. Silly Window avoidance: as a receiver, the INIC will do the right thing here and not advertise small windows - this is easy. However it is necessary to also do things to avoid this as a sender, for the cases where a stupid client does advertise small windows. Without getting into too much detail here, the mechanism requires the INIC code to calculate the largest window advertisement ever advertised by the other end. It is an attempt to guess the size of the other end's receive buffer and assumes the other end never reduces the size of its receive buffer. See Stevens Vol. 1 pp. 325-326.

# The Utility Processor

# Summary

The following is a summary of the main functions of the utility sequencer of the microprocessor:

- look at the event queues: Event13Type & Event23Type (we assume there will be an event status bit for this -USE EV13 and USE EV23) in the events register; these are events from sequencers 1 and 2; they will mainly be XMIT requests from the XMT sequencer. Dequeue request and place the frame on the appropriate interface.
- · RCV-frame support: in the model, RCV is done through VinicReceive() which is registered by the lower-edge driver, and is called at dispatch-level. This routine calls VinicTransferDataComplete() to check if the xfer (possibly DMA) of the frame into host buffers is complete. The latter rtne is also called at dispatch level on a DMA-completion interrupt. It queues complete buffers to the RCV sequencer via the normal queue mechanism.
- Other processes may also be employed here for supporting the RCV sequencer.
- service the following registers: (this will probably involve micro-interrupts) Header Buffer Address register:

buffers are 256 bytes long on 256-byte boundaries.

31-8 - physical addr in host of a set of contiguous hddr buffers

7-0 - number of hddr buffers passed.

Use contents to add to SmallHType queue

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

Data Buffer Handle & Data Buffer Address registers: buffers are 4K long aligned on 4K boundaries... Use contents to add to the FreeType queue.

Command Buffer Address register: buffers are multiple of 32 bytes up to 1K long (2\*\*5 \* 32) 31-5 - physical addr in host of cmd buffer 4-0 - length of cmd in bytes/32 (i.e. multiples of 32 bytes) Points to host cmd; get FreeSType buffer and move command into it; queue to Xmit0-Xmit3Type queues.

Response Buffer Address register: buffers are 32 bytes long on 32-byte boundaries 31-8 - physical addr in host of a set of contiguous resp buffers 7-0 - number of resp buffers passed. Use contents to add to the ResponseType queue.

low buffer threshold support: set approp bits in the ISR when the available-buffers count in the various queues filled by the host falls below a threshold.

#### Further Operations of the Utility Processor

The utility processor of the microprocessor housed on the INIC is responsible for setting up and implementing all configuration space and memory mapped operations, and also as described below, for managing the debug interface.

All data transfers, and other INIC initiated transfers will be done via DMA. Configuration space for both the network processor function and the utility processor function will define a single memory space for each. This memory space will define the basic communication structure for the host. In general, writing to one of these memory locations will perform a request for service from the INIC. This is detailed in the memory description for each function. This section defines much of the operation of the Host interface, but should be read in conjunction with the Host Interface Strategy for the Alacritech INIC to fully define the Host/INIC interface.

Two registers, DMA hardware and an interrupt function comprise the INIC interface to the Host through PCI. The interrupt function is implemented via a four bit register (PCI INT) tied to the PCI interrupt lines. This register is directly accessed by the microprocessor.

THE MICROPROCESSOR uses two registers, the PCI\_Data\_Reg and the PCI\_Address\_Reg, to enable the Host to access Configuration Space and the memory space allocated to the INIC. These registers are not available to the Host, but are used by THE MICROPROCESSOR to enable Host reads and writes. The function of these two registers is as follows.

> Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

# PCI Data Reg

This register can be both read and written by THE MICROPROCESSOR. On write operations from the host, this register contains the data being sent from the host. On read operations, this register contains the data to be sent to the host.

#### PCI Address Reg

This is the control register for memory reads and writes from the host. The structure of the register is as follows:

Bit 31 - 24 Byte enable 7 - 0. Only the low order four bits are valid for 32 bit addressing mode.

Bit 23 - 0 Memory access

1 Configuration access

Bit 22 - 0 Read (to Host) 1 Write (from Host)

Data Valid 1 Bit 21 -

Bit 20 - 16 Reserved Bit 15 - 0 Address

During a write operation from the Host the PCI\_Data\_Reg contains valid data after Data Valid is set in the PCI\_Address\_Reg. Both registers are locked until THE MICROPROCESSOR writes the PCI Data Reg, which resets Data Valid.

All read operations will be direct from SRAM. Memory space based reads will return 00. Configuration space reads will be mapped as follows:

Configuration Space 1	SRAM Address Offset		
00	00		
04	04		
08	08		
0C	0C		
10	10		
3C	14		
Configuration Space 2			
00	00		
04	18		
08	08		
OC	1C		
10	. 20		
3C	24		

All other reads to configuration space will return 00.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

#### 6.2.1 CONFIGURATION SPACE

The INIC is implemented as a multi-function device. The first device is the network controller, and the second device is the debug interface. An alternative production embodiment may implement only the network controller function. Both configuration space headers will be the same, except for the differences noted in the following description.

Vendor ID - This field will contain the Alacritech Vendor ID. One field will be used for both functions. The Alacritech Vendor ID is hex 139A.

Device ID - Chosen at Alacritech on a device specific basis. One field will be used for both functions.

Command - Initialized to 00. All bits defined below as not enabled (0) will remain 0. Those that are enabled will be set to 0 or 1 depending on the state of the system. Each function (network and debug) will have its own command field.

Bit 0-0I/O accesses are not enabled Bit 1 - 1Memory accesses are enabled Bit 2-1Bus master is enabled Special Cycle is not enabled Bit 3-0Bit 4-1Memory Write and Invalidate is enabled VGA palette snooping is not enabled Bit 5-0Bit 6-1Parity checking is enabled Address data stepping is not enabled Bit 7-0Bit 8 - SERR# is enabled Fast back to back is not enabled Bit 9-0

Status - This is not initialized to zero. Each function will have its own field. The configuration is as follows:

- 66 MHz capable is enabled. This bit will be set if the INIC Bit 5-1Detects the system running at 66 MHz on reset
- Bit 6-0User Definable Features is not enabled
- Fast Back-to-Back slave transfers enabled Bit 7-1
- Parity Error enabled This bit is initialized to 0 Bit 8 - 1
- Bit 9,10 00 Fast device select will be set if we are at 33 MHz
  - 01 Medium device select will be set if we are at
- Bit 11-1 Target Abort is implemented. Initialized to 0.
- Bit 12-1 Target Abort is implemented. Initialized to 0.
- Master Abort is implemented. Initialized to 0. Bit 13-1
- SERR# is implemented. Initialized to 0. Bit 14-1
- Parity error is implemented. Initialized to 0. Bit 15 – 1

Revision ID - The revision field will be shared by both functions.

Class Code - This is 02 00 00 for the network controller, and for the debug interface. The field will be shared.

> Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

Cache Line Size - This is initialized to zero. Supported sizes are 16, 32, 64 and 128 bytes. This hardware register is replicated in SRAM and supported separately for each function, but THE MICROPROCESSOR will implement the value set in Configuration Space 1 (the network processor).

Latency Timer - This is initialized to zero. The function is supported. This hardware register is replicated in SRAM. Each function is supported separately, but THE MICROPROCESSOR will implement the value set in Configuration Space 1 (the network processor).

Header Type – This is set to 80 for both functions, but will be supported separately.

BIST - Is implemented. In addition to responding to a request to run self test, if test after reset fails, a code will be set in the BIST register. This will be implemented separately for each function.

Base Address Register – A single base address register is implemented for each function. It is 64 bits in length, and the bottom four bits are configured as follows:

0 Indicates memory base address

Bit 1,2-00 Locate base address anywhere in 32 bit memory space

1 Memory is prefetchable Bit 3 -

CardBus CIS Pointer - Not implemented-initialized to 0.

Subsystem Vendor ID – Not implemented—initialized to 0.

Subsystem ID - Not implemented—initialized to 0.

Expansion ROM Base Address - Not implemented-initialized to 0.

Interrupt Line - Implemented-initialized to 0. This is implemented separately for each function.

Interrupt Pin - This is set to 01, corresponding to INTA# for the network controller, and 02, corresponding to INTB# for the debug interface. This is implemented separately for each function.

Min\_Gnt – This can be set at a value in the range of 10, to allow reasonably long bursts on the bus. This is implemented separately for each function.

Max Lat - This can be set to 0 to indicate no particular requirement for frequency of access to PCI. This is implemented separately for each function.

# 6.2.2 MEMORY SPACE

Because each of the following functions may or may not reside in a single location, and may or may not need to be in SRAM at all, the address for each is really only used as an identifier (label). There is, therefore, no control block anywhere in memory that represents this memory space. When the host writes one of these registers, the utility

> Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

processor will construct the data required and transfer it. Reads to this memory will generate 00 for data.

#### 6.2.2.1 Network Processor

The following four byte registers, beginning at location h00 of the network processor's allocated memory, are defined.

- -00Interrupt Status Pointer -- Initialized by the host to point to a four byte area where status is stored
- 04 -Interrupt Status - Returned status from host. Sent after one or more status conditions have been reset. Also an interlock for storing any new status. Once status has been stored at the Interrupt Status Pointer location, no new status will be stored until the host writes the Interrupt Status Register. New status will be ored with any remaining uncleared status (as defined by the contents of the returned status) and stored again at the Interrupt Status Pointer location. Bits are as follows:

Bit 31 - ERR -- Error bits are set

Bit 30 - RCV - Receive has occurred

Bit 29 – XMT – Transmit command complete

Bit 25 – RMISS – Receive drop occurred due to no buffers

- Interrupt Mask Written by the host. Interrupts are masked for each of the bits in the interrupt status when the same bit in the mask register is set. When the Interrupt Mask register is written and as a result a status bit is unmasked, an interrupt is generated. Also, when the Interrupt Status Register is written, enabling new status to be stored, when it is stored if a bit is stored that is not masked by the Interrupt Mask, an interrupt is generated.
- OC Header Buffer Address Written by host to pass a set of header buffers to the
- 10 -Data Buffer Handle - First register to be written by the Host to transfer a receive data buffer to the INIC. This data is Host reference data. It is not used by the INIC, it is returned with the data buffer. However, to insure integrity of the buffer, this register must be interlocked with the Data Buffer Address register. Once the Data Buffer Address register has been written, neither register can be written until after the Data Buffer Handle register has been read by THE MICROPROCESSOR.
- Data Buffer Address Pointer to the data buffer being sent to the INIC by the Host. Must be interlocked with the Data Buffer Handle register.
- Command Buffer Address XMT0 Pointer to a set of command buffers sent by the Host. THE MICROPROCESSOR will DMA the buffers to local DRAM found on the FreeSType queue and queue the Command

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

Buffer Address XMT0 with the local address replacing the host

- Command Buffer Address SMT1
- Command Buffer Address SMT2
- Command Buffer Address SMT3
- Response Buffer Address -- Pointer to a set of response buffers sent by the Host. These will be treated in the same fashion as the Command Buffer Address registers.

#### 6.2.2.2 Utility Processor

Ending status will be handled by the utility processor in the same fashion as it is handled by the network processor. At present two ending status conditions are defined B31 – command complete, and B30 - error. When end status is stored an interrupt is generated.

Two additional registers are defined, Command Pointer and Data Pointer. The Host is responsible for insuring that the Data Pointer is valid and points to sufficient memory before storing a command pointer. Storing a command pointer initiates command decode and execution by the debug processor. The Host must not modify either command or Data Pointer until ending status has been received, at which point a new command may be initiated. Memory space is write only by the Host, reads will receive 00. The format is as follows:

- Interrupt Status Pointer -- Initialized by the host to point to a four byte area where status is stored
- Interrupt Status Returned status from host. Sent after one or more status conditions have been reset. Also an interlock for storing any new status. Once status has been stored at the Interrupt Status Pointer location, no new status will be stored until the host writes the Interrupt Status Register. New status will be ored with any remaining uncleared status (as defined by the contents of the returned status) and stored again at the Interrupt Status Pointer location. Bits are as follows:

Bit 31 – CC – Command Complete

Bit 30 - ERR -- Error

Bit29 - Transmit Processor Halted

Bit28 - Receive Processor Halted

Bit27 - Utility Processor Halted

08 - Interrupt Mask - Written by the host. Interrupts are masked for each of the bits in the interrupt status when the same bit in the mask register is set. When the Interrupt Mask register is written and as a result a status bit is unmasked, an interrupt is generated. Also,

> Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

when the Interrupt Status Register is written, enabling new status to be stored, when it is stored if a bit is stored that is not masked by the Interrupt Mask, an interrupt is generated.

- OC Command Pointer Points to command to be executed. Storing this pointer initiates command decode and execution.
- Data Pointer Points to the data buffer. This is used for both read and write data, determined by the command function.

# **Debug Interface**

In order to provide a mechanism to debug the microcode running on the microprocessor sequencers, a debug process has been defined which will run on the utility sequencer. This processor will interface with a control program on the host processor over PCI.

#### 7.1 PCI Interface

This interface is defined in the combination of the Utility Processor and the Host Interface Strategy sections, above.

#### **Command Format** 7.2

The first byte of the command, the command byte, defines the structure of the remainder of the command. The first five bits of the command byte are the command itself. The next bit is used to specify an alternate processor, and the last two bits specify which processors are intended for the command.

# 7.2.1 Command Byte

7 - 3Command

Alt. Proc.

1 - 0Processor

#### 7.2.2 Processor Bits

00 - Any Processor

01 - Transmit Processor

10 - Receive Processor

11 - Utility Processor

#### 7.2.3 Alternate Processor

This bit defines which processor should handle debug processing if the utility processor is defined as the processor in debug.

- 0 Transmit Processor
- 1 Receive Processor

### 7.2.4 Single Byte Commands

00 - Halt

This command asynchronously halts the processor.

08 - Run

This command starts the processor.

10 - Step

This command steps the processor.

### 7.2.5 Eight Byte Commands

18 - Break

 $\begin{array}{ccccc} 0 & & 1 & & 2-3 & & 4-7 \\ \text{Command} & \text{Reserved} & & \text{Count} & & \text{Address} \end{array}$ 

This command sets a stop at the specified address. A count of 1 causes the specified processor to halt the first time it executes the instruction. A count of 2 or more causes the processor to halt after that number of executions. The processor is halted just before executing the instruction. A count of 0 does not halt the processor, but causes a sync signal to be generated. If a second processor is set to the same break address, the count data from the first break request is used, and each time either processor executes the instruction the count is decremented.

20 - Reset Break

0 1 - 3 4 - 7 Command Reserved Address

> Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

This command resets a previously set break point at the specified address. Reset break fully resets that address. If multiple processors were set to that break point, all will be reset.

28 - Dump

0 Command

1 Descriptor 2 - 3 Count 4 – 7 Address

This command transfers to the host the contents of the descriptor. For descriptors larger than four bytes, a count, in four byte increments is specified. For descriptors utilizing an address the address field is specified.

7.2.6 Descriptor

00 - Register

This descriptor uses both count and address fields. Both fields are four byte based (a count of 1 transfers four bytes).

01 - Sram

This descriptor uses both count and address fields. Count is in four byte blocks. Address is in bytes, but if it is not four byte aligned, it is forced to the lower four byte aligned address.

02 - Dram

This descriptor uses both count and address fields. Count is in four byte blocks. Address is in bytes, but if it is not four byte aligned, it is forced to the lower four byte aligned address

03 - Cstore

This descriptor uses both count and address fields. Count is in four byte blocks. Address is in bytes, but if it is not four byte aligned, it is forced to the lower four byte aligned address

Stand-alone descriptors:

The following descriptors do not use either the count or address fields. They transfer the contents of the referenced register.

04 - CPU\_STATUS

05 - PC

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

06 - ADDR\_REGA

07 - ADDR\_REGB

08-RAM\_BASE

09-FILE\_BASE

0A-INSTR\_REG\_L

0B-INSTR\_REG\_H

OC-MAC\_DATA

0D-DMA\_EVENT

0E-MISC\_EVENT

0F-Q\_IN\_RDY

10 - Q\_OUT\_RDY

11 - LOCK STATUS

12 - STACK - This returns 12 bytes

13 - Sense Reg

This register contains four bytes of data. If error status is posted for a command, if the next command that is issued reads this register, a code describing the error in more detail may be obtained. If any command other than a dump of this register is issued after error status, sense information will be reset.

30 - Load

0 Command

1 Descriptor

2 - 3 Count

4 - 7Address

This command transfers from the host the contents of the descriptor. For descriptors larger than four bytes, a count, in four byte increments is specified. For descriptors utilizing an address the address field is specified.

7.2.7 Descriptor

00 - Register

This descriptor uses both count and address fields. Both fields are four byte based.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

01 - Sram

This descriptor uses both count and address fields. Count is in four byte blocks. Address is in bytes, but if it is not four byte aligned, it is forced to the lower four byte aligned address.

02 - Dram

This descriptor uses both count and address fields. Count is in four byte blocks. Address is in bytes, but if it is not four byte aligned, it is forced to the lower four byte aligned address

03 - Cstore

This descriptor uses both count and address fields. Count is in four byte blocks. Address is in bytes, but if it is not four byte aligned, it is forced to the lower four byte aligned address. This applies to WCS only.

Stand-alone descriptors:

The following descriptors do not use either the count or address fields. They transfer the contents of the referenced register.

04 - ADDR\_REGA

05 - ADDR\_REGB

06 - RAM\_BASE

07 - FILE BASE

08 - MAC\_DATA

09 - Q IN RDY

0A - Q\_OUT\_RDY

0B - DBG\_ADDR

38 - Map

This command allows an instruction in ROM to be replaced by an instruction in WCS. The new instruction will be located in the Host buffer. It will be stored in the first eight bytes of the buffer, with the high bits unused. To reset a mapped out instruction, map it to location 00.

Command

1 - 3Address to Map To

4 - 7Address to Map Out

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

# HARDWARE SPECIFICATION

#### **FEATURES**

# • Peripheral Component Interconnect (PCI) Interface

- Universal PCI interface supports both 5.0V and 3.3V signaling environments.
- Supports both 32-bit and 64 bit PCI interface.
- Supports PCI clock frequencies from 15MHz to 66MHz
- High performance bus mastering architecture.
- Host memory based communications reduce register accesses.
- Host memory based interrupt status word reduces register reads.
- Plug and Play compatible.
- PCI specification revision 2.1 compliant.
- PCI bursts up to 512 bytes.
- Supports cache line operations up to 128 bytes.
- Both big-endian and little-endian byte alignments supported.
- Supports Expansion ROM.

#### Network Interface

- Four internal 802.3 and ethernet compliant Macs.
- Media Independent Interface (MII) supports external PHYs.
- 10BASE-T, 100BASE-TX/FX and 100BASE-T4 supported.
- Full and half-duplex modes supported.
- Automatic PHY status polling notifies system of status change.
- Provides SNMP statistics counters.
- Supports broadcast and multicast packets.
- Provides promiscuous mode for network monitoring or multiple unicast address detection.
- Supports "huge packets" up to 32KB.
- Mac-layer loop-back test mode.
- Supports auto-negotiating Phys.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

### Memory Interface

- External Dram buffering of transmit and receive packets.
- Buffering configurable as 4MB, 8MB, 16MB or 32MB.
- 32-bit interface supports throughput of 224MB/s
- Supports external FLASH ROM up to 4 MB, for diskless boot applications.
- Supports external serial EEPROM for custom configuration and Mac addresses.

#### • Protocol Processor

- High speed, custom, 32-bit processor executes 66 million instructions per second.
- Processes IP, TCP and NETBIOS protocols.
- Supports up to 256 resident TCP/IP contexts.
- Writable control store (WCS) allows field updates for feature enhancements.

#### • Power

- 3.3V chip operation.
- PCI controlled 5.0V/3.3V I/O cell operation.

## Packaging

- 272-pin plastic ball grid array.
- 91 PCI signals.
- 68 MII signals.
- 58 external memory signals.
- 1 clock signal.
- 54 signals split between power and ground.
- 272 total pins.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

#### GENERAL DESCRIPTION

The microprocessor is a 32-bit, full-duplex, four channel, 10/100-Megabit per second (Mbps), Intelligent Network Interface Controller, designed to provide high-speed protocol processing for server applications. It combines the functions of a standard network interface controller and a protocol processor within a single chip. Although designed specifically for server applications, The microprocessor can be used by PCs, workstations and routers or anywhere that TCP/IP protocols are being utilized.

When combined with four 802.3/MII compliant Phys and Synchronous Dram (SDram), the INIC comprises four complete ethernet nodes. It contains four 802.3/ethernet compliant Macs, a PCI Bus Interface Unit (BIU), a memory controller, transmit fifos, receive fifos and a custom TCP/IP/NETBIOS protocol processor. The INIC supports 10Base-T, 100Base-TX, 100Base-FX and 100Base-T4 via the MII interface attachment of appropriate Phys.

The INIC Macs provide statistical information that may be used for SNMP. The Macs operate in promiscuous mode allowing the INIC to function as a network monitor, receive broadcast and multicast packets and implement multiple Mac addresses for each node.

Any 802.3/MII compliant PHY can be utilized, allowing the INIC to support 10BASE-T, 10BASE-T2, 100BASE-TX, 100Base-FX and 100BASE-T4 as well as future interface standards. PHY identification and initialization is accomplished through host driver initialization routines. PHY status registers can be polled continuously by the INIC and detected PHY status changes reported to the host driver. The Mac can be configured to support a maximum frame size of 1518 bytes or 32768 bytes.

The 64-bit, multiplexed BIU provides a direct interface to the PCI bus for both slave and master functions. The INIC is capable of operating in either a 64-bit or 32-bit PCI environment, while supporting 64-bit addressing in either configuration. PCI bus frequencies up to 66MHz are supported yielding instantaneous bus transfer rates of 533MB/s. Both 5.0V and 3.3V signaling environments can be utilized by the INIC. Configurable cache-line size up to 256B will accommodate future architectures, and Expansion ROM/Flash support allows for diskless system booting. Non-PC applications are supported via programmable big and little endian modes. Host based communication has been utilized to provide the best system performance possible.

The INIC supports Plug-N-Play auto-configuration through the PCI configuration space. External pull-up and pull-down resistors, on the memory I/O pins, allow selection of various features during chip reset. Support of an external eeprom allows for local storage of configuration information such as Mac addresses.

External SDram provides frame buffering, which is configurable as 4MB, 8MB, 16MB or 32MB using the appropriate SIMMs. Use of -10 speed grades yields an external buffer bandwidth of 224MB/s. The buffer provides temporary storage of both incoming and outgoing frames. The protocol processor accesses the frames within the buffer in order to implement TCP/IP and NETBIOS. Incoming frames are processed, assembled then transferred to host memory under the control of the protocol processor. For transmit, data is moved from host memory to buffers where various headers are created before being transmitted out via the Mac.

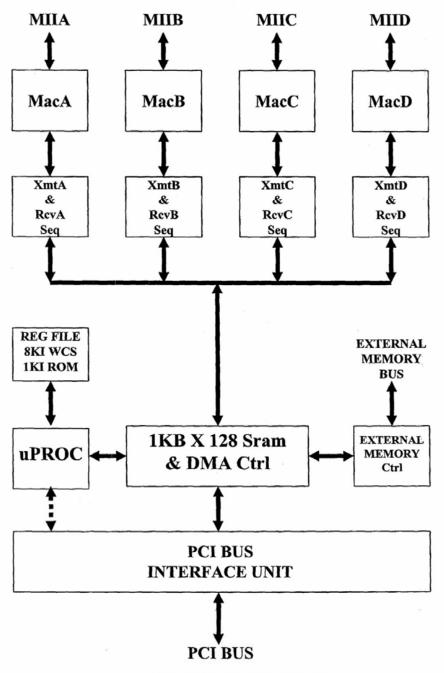

# OUTLINE

### • Cores/Cells

LSI Logic Ethernet-110 Core, 100Base & 10Base Mac with MII interface.

LSI Logic single port Sram, triple port Sram and ROM available.

LSI Logic PCI 66MHz, 5V compatible I/O cell.

LSI Logic PLL

# • Die Size / Pin Count

LSI Logic G10 process.

### • Performance Features

- 512 registers improve performance through reduced scratch ram accesses and reduced instructions.
- Register windowing eliminates context-switching overhead.
- Separate instruction and data paths eliminate memory contention.
- Totally resident control store eliminates stalling during instruction fetch.
- Multiple logical processors eliminate context switching and improve real-time response.
- Pipelined architecture increases operating frequency.
- Shared register and scratch ram improve inter-processor communication.
- Fly-by state-Machine assists address compare and checksum calculation.
- TCP/IP-context caching reduces latency.
- Hardware implemented queues reduce Cpu overhead and latency.
- Horizontal microcode greatly improves instruction efficiency.
- Automatic frame DMA and status between Mac and dram buffer.
- Deterministic architecture coupled with context switching eliminates processor stalls.

#### PROCESSOR

The processor is a convenient means to provide a programmable state-machine which is capable of processing incoming frames, processing host commands, directing network traffic and directing PCI bus traffic. Three processors are implemented using shared hardware in a three-level pipelined architecture which launches and completes a single instruction for every clock cycle. The instructions are executed in three distinct phases corresponding to each of the pipeline stages where each phase is responsible for a different function.

The first instruction phase writes the instruction results of the last instruction to the destination operand, modifies the program counter (Pc), selects the address source for the instruction to fetch, then fetches the instruction from the control store. The fetched instruction is then stored in the instruction register at the end of the clock cycle.

The processor instructions reside in the on-chip control-store, which is implemented as a mixture of ROM and Sram. The ROM contains 1K instructions starting at address 0x0000 and aliases each 0x0400 locations throughout the first 0x8000 of instruction space. The Sram (WCS) will hold up to 0x2000 instructions starting at address 0x8000 and aliasing each 0x2000 locations throughout the last 0x8000 of instruction space. The ROM and Sram are both 49-bits wide accounting for bits [48:0] of the instruction microword. A separate mapping ram provides bits [55:49] of the microword (MapAddr) to allow replacement of faulty ROM based instructions. The mapping ram has a configuration of 128x7 which is insufficient to allow a separate map address for each of the 1K ROM locations. To allow re-mapping of the entire 1K ROM space, the map ram address lines are connected to the address bits Fetch[9:3]. The result is that the ROM is re-mapped in blocks of 8 contiguous locations.

The second instruction phase decodes the instruction which was stored in the instruction register. It is at this point that the map address is checked for a non-zero value which will cause the decoder to force a Jmp instruction to the map address. If a non-zero value is detected then the decoder selects the source operands for the Alu operation based on the values of the OpdASel, OpdBSel and AluOp fields. These operands are then stored in the decode register at the end of the clock cycle. Operands may originate from File, Sram, or flipflop based registers. The second instruction phase is also where the results of the previous instruction are written to the Sram.

The third instruction phase is when the actual Alu operation is performed, the test condition is selected and the Stack push and pop are implemented. Results of the Alu operation are stored in the results register at the end of the clock cycle.

Following is a block diagram which shows the hardware functions associated with each of the instruction phases. Note that various functions have been distributed across the three phases of the instruction execution in order to minimize the combinatorial delays within any given phase.

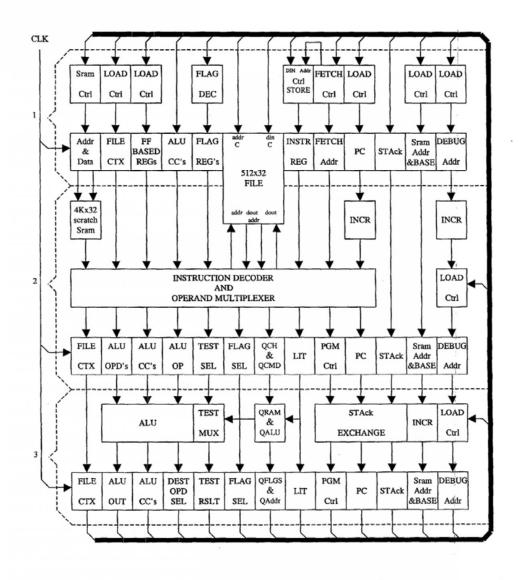

#### INSTRUCTION SET

The micro-instructions are divided into six types according to the program control directive. The microinstruction is further divided into sub-fields for which the definitions are dependent upon the instruction type. The six instruction types are listed below.

#### INSTRUCTION-WORD FORMAT

TYPE	_[55:49]_	[48:47]	[46:42]	[41:33]	[32:24]	[23:16]	[15:00]
Jcc	000000000	0b00,	AluOp,	OpdASel,	OpdBSel,	TstSel,	Literal
Jmp	0b0000000	0b01,	AluOp,	OpdASel,	OpdBSel,	FlgSel,	Literal
Jsr	000000000	0b10,	AluOp,	OpdASel,	OpdBSel,	FlgSel,	Literal
Rts	0b0000000	0b11,	AluOp,	OpdAsel,	OpdBSel,	Ohff,	Literal
Nxt	0р0000000	0b11,	AluOp,	OpdASel,	OpdBSel,	FlgSel,	Literal
Map	MapAddr	0bXX,	ObXXXXX,	0bXXXXXXXX,	ObXXXXXXXXX,	OhXX,	0hXXXX

All instructions include the Alu operation (AluOp), operand "A" select (OpdASel), operand "B" select (OpdBSel) and Literal fields. Other field usage depends upon the instruction type.

The "jump condition code" (Jcc) instruction causes the program counter to be altered if the condition selected by the "test select" (TstSel) field is asserted. The new program counter (Pc) value is loaded from either the Literal field or the AluOut as described in the following section and the Literal field may be used as a source for the Alu or the ram address if the new Pc value is sourced by the Alu.

The "jump" (Jmp) instruction causes the program counter to be altered unconditionally. The new program counter (Pc) value is loaded from either the Literal field or the AluOut as described in the following section. The format allows instruction bits 23:16 to be used to perform a flag operation and the Literal field may be used as a source for the Alu or the ram address if the new Pc value is sourced by the Alu.

The "jump subroutine" (Jsr) instruction causes the program counter to be altered unconditionally. The new program counter (Pc) value is loaded from either the Literal field or the AluOut as described in the following section. The old program counter value is stored on the top location of the Pc-Stack which is implemented as a LIFO memory. The format allows instruction bits 23:16 to be used to perform a flag operation and the Literal field may be used as a source for the Alu or the ram address if the new Pc value is sourced by the Alu.

The "Nxt" (Nxt) instruction causes the program counter to increment. The format allows instruction bits 23:16 to be used to perform a flag operation and the Literal field may be used as a source for the Alu or the ram address.

The "return from subroutine" (Rts) instruction is a special form of the Nxt instruction in which the "flag operation" (FlgSel) field is set to a value of 0hff. The current Pc value is replaced with the last value stored in the stack. The Literal field may be used as a source for the Alu or the ram address.

The Map instruction is provided to allow replacement of instructions which have been stored in ROM and is implemented any time the "map enable" (MapEn) bit has been set and the content of the "map address" (MapAddr) field is non-zero. The instruction decoder forces a jump instruction with the Alu operation and destination fields set to pass the MapAddr field to the program control block.

The program control is determined by a combination of PgmCtrl, DstOpd, FlgSel and TstSel. The behavior of the program control is defined with the following "C-like" description.

```

OpdSel SELECTED OPERANDS

0b0000aaaaa File File@(OpdSel[4:0] | FileBase);

Allows paged access to any part of the register file.

0b000laaaaa File@{2'b11, CpuId, OpdSel[4:0]}; CpuReq

Allows direct access to Cpu specific registers.

0b001XXXXXX Reserved for future expansion. reserved

0b0100000XX CpuStatus 0b0000000000000BHD00000000000000CC

This is a read-only register providing information about the Cpu executing (OpdSel[1:0]) cycles after the current cycle. "CC" represents a value indicating the Cpu. Currently, only CpuId values of 0, 1 and 2 are returned. "H" represents the current state of Hlt, "D" indicates DbgMd and "B"

indicates BigMd. Writing this register has no effect.

0b0100001XX reserved Reserved for future expansion.

0b0100010XX Pc 0x0000AAAA

> Writing to this address causes the program control logic to use AluOut as the new Pc value in the event of a Jmp, Jcc or Jsr instruction for the Cpu executing during the current cycle. If the current instruction is Nxt, Map, or Rts, the register write has no effect. Reading this register returns the value in Pc for the Cpu executing (OpdSel[1:0]) cycles after the current cycle.

0b0100011XX DbgAddr 0xD000AAAA

> Writing to this register alters the contents of the debug address register (DbgAddr) for the Cpu executing (OpdSel[1:0]) cycles after the current cycle. DbgAddr provides the fetch address for the control-store when DbgMd has been selected and the Cpu is executing. DbgAddr is also used as the control-store address when performing a WrWcs@DbgAddr or RdWcs@DbgAddr operation. "D" represents bit 31 of the register. It is a general purpose flag that is used for event indication during simulation. Reading this

register returns a value of 0x00000000.

Reserved for future expansion. 0b01001XXXX reserved

0b010100000 RamAddr {0b1CCC, 0x000, 0b1, AAAA}

RamAddr = AluOut[15] ? AluOut : (AluOut | RamBase);

PrevCC = AluOut[31] ? CCC : AluCC;

A read/write register. When reading this register, the Alu condition codes from the previous instruction are returned together with RamAddr.

<u>bit</u>	name	description
31		Always 1.
30	PrevC	Previous Alu Carry.
29	PrevV	Previous Alu Overflow.
28	PrevZ	Previous Alu Zero.
27:16		Always 0.
15		Always 1.
14:0	RamAddr	Contents of last Sram address used.

When writing this register, if alu\_out[31] is set, the previous condition codes will be overwritten with bits 30:28 of AluOut. If AluOut[15] is set, bits 14:0 will be written to the RamAddr. If AluOut [15] is not set, bits 14:0 will be ored with the contents of the RamBase and written to the RamAddr.

> Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

SELECTED OPERANDS OpdSel

0b010100001 AddrRegA 0x0000AAAA AddrRegA = AluOut;

A read/write operand which loads AddrRegA used to provide the address for read and write

operations.

When AddrRegA[15] is set, the contents will be presented directly to the ram. When AddrRegA[15] is reset, the contents will first be ored with the contents of the RamBase register before presentation to

the

read

ram. Writing to this register takes priority over Literal loads using FlgOp. Reading this register returns the current value of the register.

0b010100010 AddrRegB 0x0000AAAA AddrRegB = AluOut;

> A read/write operand which loads AddrRegB used to provide the address for read and write operations.

When AddrRegB[15] is set, the contents will be presented directly to the ram. When AddrRegB[15] is reset, the contents will first be ored with the contents of the RamBase register before presentation to the

ram. Writing to this register takes priority over Literal loads using FlgOp. Reading this register returns the current value of the register.

0b010100011 AddrRegAb AAAA0000x0

AddrRegA = AluOut; AddrRegB = AluOut;

A destination only operand which loads AddrRegB and AddrRegA used to provide the address for

and write operations Writing to this register takes priority over Literal loads using FlgOp. Reading this register returns the value 0x00000000.

0b010100100 RamBase 0x0000AAAA

RamBase = AluOut;

A read/write register which provides the base address for ram read and write cycles. When RamAddr[15] is set, the contents will not be used. When RamAddr[15] is reset, the contents will first be ored with the contents of the RamBase register before presentation to the ram. Reading this register returns the value for the current Cpu.

0b010100101 FileBase 

FileBase = AluOut:

FileAddr = OpdSel[8] ? OpdSel:(OpdSel + FileBase);

A read/write register which provides the base address for file read and write cycles. When OpdSel[8]

set, the contents will not be used and OpdSel will be presented directly to the address lines of the file. When OpdSel[8] is reset, the contents will first be ored with the contents of the FileBase register before presentation to the file. Reading this register returns the value for the current Cpu.

0b010100110 InstrRegL IIIIIIIx0

> This is a read-only register which returns the contents of InstrReg[31:0]. Writing to this register has no effect.

InstrRegH 0b010100111 0x00IIIII

This is a read-only register which returns the contents of InstrReg[55:32]. Writing to this register has

no effect.

SELECTED OPERANDS OpdSel

0b010101100 MacData - Writing to this address loads the AluOut data into the MacData register for use during Mac operations. The Mac operation, resulting from writing to the MacOp register,

determines the definition of the MacData register contents as follows.

MacOp MacData definition

0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx Mstop

MacData is not used for the StopM operation.

WrMcfg hrstl, rsvd, rsvd, crcen, fulld, hrstl, hugen, nopre, paden, prtyl, xdl10, ipgr1[6:0],

ipgr2[6:0], ipgt[6:0].

Loads the MacCfg register with the contents of the MacData register. Refer to LSI Logic's

Ethernet-110 Core Technical Manual for detailed definitions of these bits.

WrMrng 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Loads seed[10:0] into the Mac's random number generator.

0bxxxxrrrrxxxxppppxxxxxxxxxxxxxxxxx RdPhy

Reads register[R] of phy[P].

WrPhy 0bXXXXRRRXXXXPPPPDDDDDDDDDDDDDDDDD

Writes register[R] of phy[P] with MacData[15:0].

Reading this register returns prsd[15:0] of Mac0 which contains phy status data returned to the Mac at the completion of a RdPhy command. This data is invalid while MacBsy is asserted as a result of a RdPhy command. Refer to the appropriate phy technical manual for a definition of the phy register contents.

#### SELECTED OPERANDS

AluOut

MacOp - A write only register. Writing to this address loads the MacSel register and staRts 0b010101101 execution of the specified operation as follows.

description

MX0XXXXxx0	Mstop - Halts execution of a MacOp for Mac[M]. The user must wait for MacBsy to be
	deasserted before issuing another command or changing the contents of MacData.
0xXXXXXXM	WrMcfg - Writes the contents of MacData to the MacCfg register of Mac[M]. The user
	must wait for MacBsy to be deasserted before issuing another command or changing the
	contents of MacData.
0xXXXXXXXXM	WrMrng - Writes the contents of MacData to the seed register of Mac[M]. The user must
	wait for MacBsy to be deasserted before issuing another command or changing the contents
	of MacData.
0xXXXXXXX	RdPhy - Reads the contents of reg[R] for phy[P] on the MII management bus of Mac[M].
	The contents may be read from MacData after MacBsy has been de-asserted.
0xXXXXXXXX	WrPhy - Writes the contents of MacData[15:0] to the reg[R] of phy[P] on the MII
	management bus of Mac[M]. The user must wait for MacBsy to be deasserted before issuing
	another command or changing the contents of MacData.
MX8XXXXxx	WrAddrAL - Writes the contents of MacData[15:0] to MacAddrA[15:0] for Mac[M].
0xXXXXX9XM	WrAddrAH - Writes the contents of MacData[11:0] to MacAddrA[47:16] for Mac[M].
0xxxxxxxx0	WrAddrBL - Writes the contents of MacData[15:0] to MacAddrB[15:0] for Mac[M].
0xXXXXXxx0	WrAddrBH - Writes the contents of MacData[11:0] to MacAddrB[47:16] for Mac[M].

0b010101110 ChCmd

A write-only register.

	DIL	name	description
	31:11	reserved	Data written to these bits is ignored.
	10:8	command	0 - Stops execution of the current operation and clears the corresponding event
flag.			
-			I - Transfer data from ExtMem to ExtMem.
			2 - Transfer data from Pci to ExtMem.
			3 - Transfer data from ExtMem to Pci.
			4 - Transfer data from Sram to ExtMem.
			5 - Transfer data from ExtMem to Sram.
			6 - Transfer data from Pci to Sram.
			7 - Transfer data from Sram to Pci.
	07:05	reserved	Data written to these bits is ignored.
	04:00	ChId	Provides the channel number for the channel command.

0b010101110 ChEvnt

A read-only register.

bit_	name	description
31:00	ChDn	Each bit represents the done flag for the respective dma channel. These
		bits are set by a dma sequencer upon completion of the channel
		command. Cleared when the processor writes 0 to the corresponding
		ChCmd register.

0b010101111 GenEvnt A read-only register.

bit_	name	description
31	PciRdEvnt	Indicates that a PCI initiator is attempting to read a uproc. register.
30	PciWrEvnt	Indicates that a PCI initiator has posted a write to a uproc. register.
29	TimeEvnt	An event which occurs once every 2.00 milliseconds.
28:00	reserved	Reserved for future use.

**QCtrl** 0b010110000 A write-only register used to select and manipulate a Q. bit name description 31:11 reserved Data written to these bits are ignored. Used only during InitQ operations to specify the size of the QBdy in Dram. 10:8 QSz 7 - Queue depth is 32K entries (128KB). 6 - Queue depth is 16K entries (64KB). 5 - Queue depth is 8K entries (32KB). 4 - Queue depth is 4K entries (16KB). 3 - Queue depth is 2K entries (8KB). 2 - Queue depth is 1K entries (4KB). 1 - Queue depth is 512 entries (2KB). 0 - Queue depth is 256 entries (1KB). 7:5 QOp Specifies the queue operation to perform. 7 - DblQ Disables all queues. 6 - EnQ Enables all queues 5 - RdBdy Increments the QBdyRdPtr and increments the QTIWrPtr. 4 - WrBdy Decrements the QBdyWrPtr and increments the QHdRdPtr. Returns a queue entry in register QData.. 3 - RdQ 2 - rsvd Reserved. Not to be used. Set the queue status to empty and initializes QSz. 1 - InitO Selects the QId to be utilized during writes to QData. 0 - SelQSpecifies the queue on which to perform all operations except DblQ or EnQ. 4:0 QId A read/write register. Writing this register will result in the data being pushed on to 0b010110001 OData the selected queue. Reading this register fetches queue data popped off during the previous RdQ operation. 0b010110010 reserved Reserved for future expansion. 0b010110011 XcvCtrl A write-only register used to enable and disable Mac transmit and receive sub-channels. bit name\_\_ description 31:09 reserved Data written to these bits are ignored. 8 When set, indicates to the Mac transmit or receive sequencer that the subchannel contains a transmit or receive descriptor. 07:05 reserved Data written to these bits is ignored. RevCh Selects a Mac receive subchannel when set. Selects a Mac transmit subchannel 04 when cleared. 03 reserved Data written to this bit are ignored. SubCh Selects subchannel B when set or A when reset. 02 01:00 MacId Provides the Mac number for the subchannel enable bit. 0b010110100 Lru 0x0000000A A read/write operand indicating which of the 16 entries is least recently used. When Reading This register the least recently used entry is returned, after which it is automatically made the most recently used entry. This register should only be read in conjunction with a 'Move' operation of the ALU, else the results are unpredictable. Writing to this register forces the addressed entry to become the least recently used entry. 0b010110101 Mru A0000000A A write only operand forcing the addressed entry to become the most recently used entry. ## SRAM CONTROL SEQUENCER (SramCtrl)

Sram is the nexus for data movement within the INIC. A hierarchy of sequencers, working in concert, accomplish the movement of data between dram, Sram, Cpu, ethernet and the Pci bus. Slave sequencers, provided with stimulus from master sequencers, request data movement operations by way of the Sram, Pci bus, Dram and Flash. The slave sequencers prioritize, service and acknowledge the requests

The preceding block diagram shows all of the master and slave sequencers of the INIC product, Request information such as r/w, address, size, endian and alignment are represented by each request line. Acknowledge information to master sequencers include only the size of the transfer being acknowledged.

The following block diagram illustrates how data movement is accomplished for a Pci slave write to Dram. Note that the Psi (Pci slave in) module functions as both a master sequencer. Psi sends a write request to the SramCtrl module. Psi requests Xwr to move data from Sram to dram. Xwr subsequently sends a read request to the SramCtrl module then writes the data to the dram via the Xctrl module. As each piece of data is moved from the Sram to Xwr, Xwr sends an acknowledge to the Psi module.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

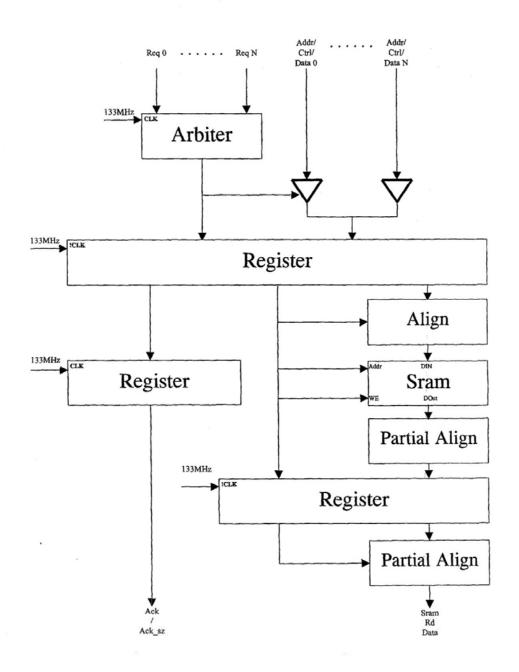

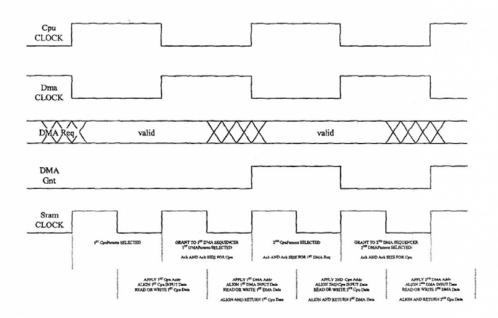

The Sram control sequencer services requests to store to, or retrieve data from an Sram organized as 1024 locations by 128 bits (16KB). The sequencer operates at a frequency of 133MHz, allowing both a Cpu access and a dma access to occur during a standard 66MHz Cpu cycle. One 133MHz cycle is reserved for Cpu accesses during each 66MHz cycle while the remaining 133MHz cycle is reserved for dma accesses on a prioritized basis.

The preceding block diagram shows the major functions of the Sram control sequencer. A slave sequencer begins by asserting a request along with r/w, ram address, endian, data path size, data path alignment and request size. SramCtrl prioritizes the requests. The request parameters are then selected by a multiplexer which feeds the parameters to the Sram via a register. The requestor provides the Sram address which when coupled with the other parameters controls the input and output alignment. Sram outputs are fed to the output aligner via a register. Requests are acknowledged in parallel with the returned data.

Following is a timing diagram depicting two ram accesses during a single 66MHz clock cycle.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

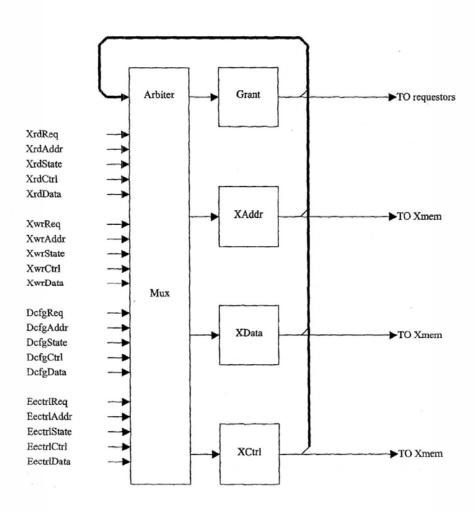

# **EXTERNAL MEMORY CONTROL (Xctrl)**

Xctrl provides the facility whereby Xwr, Xrd, Dcfg and Eectrl access external Flash and Dram. Xctrl includes an arbiter, i/o registers, data multiplexers, address multiplexers and control multiplexers. Ownership of the external memory interface is requested by each block and granted to each of the requesters by the arbiter function. Once ownership has been granted the multiplexers select the address, data and control signals from owner, allowing access to external memory.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

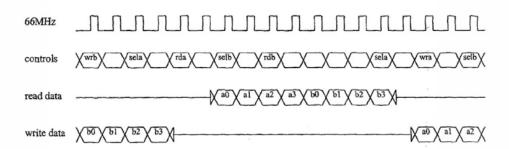

#### EXTERNAL MEMORY READ SEQUENCER (Xrd)

The Xrd sequencer acts only as a slave sequencer. Servicing requests issued by master sequencers, the Xrd sequencer moves data from external sdram or flash to the Sram, via the Xctrl module, in blocks of 32 bytes or less. The nature of the sdram requires fixed burst sizes for each of it's internal banks with ras precharge intervals between each access. By selecting a burst size of 32 bytes for sdram reads and interleaving bank accesses on a 16 byte boundary, we can ensure that the ras precharge interval for the first bank is satisfied before burst completion for the second bank, allowing us to re-instruct the first bank and continue with uninterrupted dram access. Sdrams require a consistent burst size be utilized each and every time the sdram is accessed. For this reason, if an sdram access does not begin or end on a 32 byte boundary, sdram bandwidth will be reduced due to less than 32 bytes of data being transferred during the burst cycle.

The following block diagram depicts the major functional blocks of the Xrd sequencer. The first step in servicing a request to move data from sdram to Sram is the prioritization of the master sequencer requests. Next the Xrd sequencer takes a snapshot of the dram read address and applies configuration information to determine the correct bank, row and column address to apply. Once sufficient data has been read, the Xrd sequencer issues a write request to the SramCtrl sequencer which in turn sends an acknowledge to the Xrd sequencer. The Xrd sequencer passes the acknowledge along to the level two master with a size code indicating how much data was written during the Sram cycle allowing the update of pointers and counters. The dram read and Sram write cycles repeat until the original burst request has been completed at which point the Xrd sequencer prioritizes any remaining requests in preparation for the next burst cycle.

Contiguous dram burst cycles are not guaranteed to the Xrd sequencer as an algorithm is implemented which ensures highest priority to refresh cycles followed by flash accesses, dram writes then dram reads.

Following is a timing diagram illustrating how data is read from sdram. The dram has been configured for a burst of four with a latency of two clock cycles. Bank A is first selected/activated followed by a read command two clock cycles later. The bank select/activate for bank B is next issued as read data begins returning two clocks after the read command was issued to bank A. Two clock cycles before we need to receive data from bank B we issue the read command. Once all 16 bytes have been received from bank A we begin receiving data from bank B.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

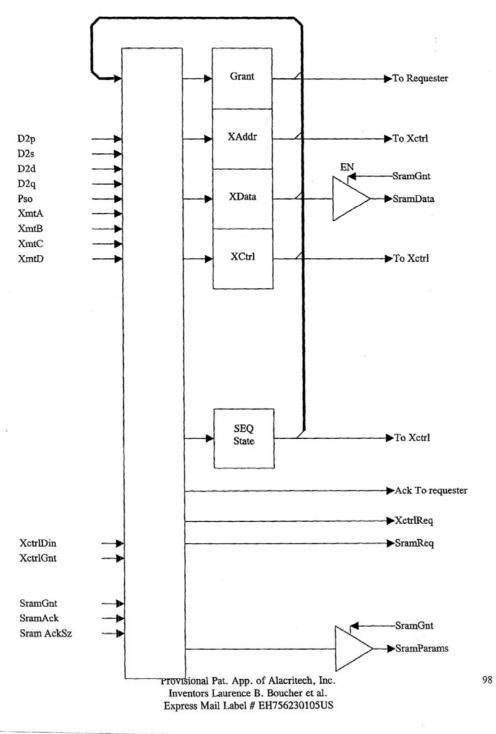

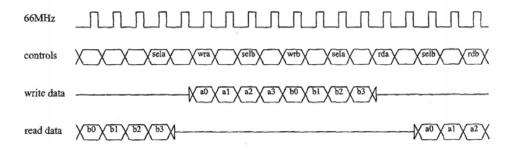

#### EXTERNAL MEMORY WRITE SEQUENCER (Xwr)

The Xwr sequencer is a slave sequencer. Servicing requests issued by master sequencers, the Xwr sequencer moves data from Sram to the external sdram or flash, via the Xctrl module, in blocks of 32 bytes or less while accumulating a checksum of the data moved. The nature of the sdram requires fixed burst sizes for each of it's internal banks with ras precharge intervals between each access. By selecting a burst size of 32 bytes for sdram writes and interleaving bank accesses on a 16 byte boundary, we can ensure that the ras prechage interval for the first bank is satisfied before burst completion for the second bank, allowing us to re-instruct the first bank and continue with uninterrupted dram access. Sdrams require a consistent burst size be utilized each and every time the sdram is accessed. For this reason, if an sdram access does not begin or end on a 32 byte boundary, sdram bandwidth will be reduced due to less than 32 bytes of data being transferred during the burst cycle.

The following block diagram depicts the major functional blocks of the Xwr sequencer. The first step in servicing a request to move data from Sram to sdram is the prioritization of the level two master requests. Next the Xwr sequencer takes a Snapshot of the dram write address and applies configuration information to determine the correct dram, bank, row and column address to apply. The Xwr sequencer immediately issues a read command to the Sram to which the Sram responds with both data and an acknowledge. The Xwr sequencer passes the acknowledge to the level two master along with a size code indicating how much data was read during the Sram cycle allowing the update of pointers and counters. Once sufficient data has been read from Sram, the Xwr sequencer issues a write command to the dram starting the burst cycle and computing a checksum as the data flies by. The Sram read cycle repeats until the original burst request has been completed at which point the Xwr sequencer prioritizes any remaining requests in preparation for the next burst cycle.

Contiguous dram burst cycles are not guaranteed to the Xwr sequencer as an algorithm is implemented which ensures highest priority to refresh cycles followed by flash accesses then dram writes.

Following is a timing diagram illustrating how data is written to sdram. The dram has been configured for a burst of four with a latency of two clock cycles. Bank A is first selected/activated followed by a write command two clock cycles later. The bank select/activate for bank B is next issued in preparation for issuing the second write command. As soon as the first 16 byte burst to bank A completes we issue the write command for bank B and begin supplying data.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

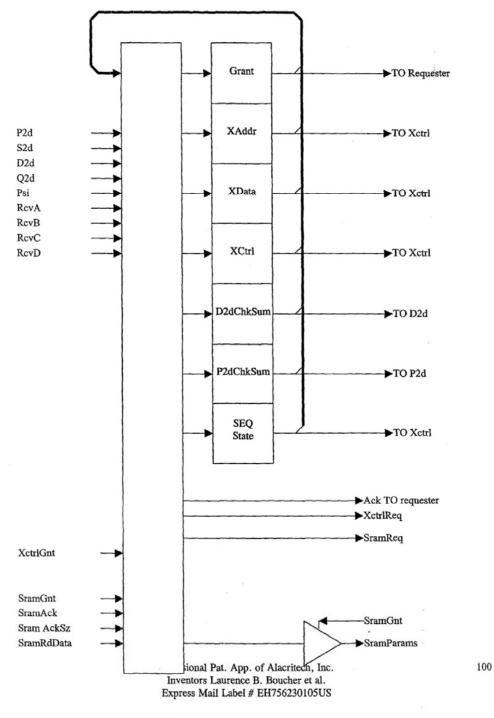

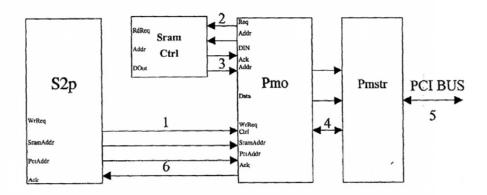

#### PCI MASTER-OUT SEQUENCER (Pmo)

The Pmo sequencer acts only as a slave sequencer. Servicing requests issued by master sequencers, the Pmo sequencer moves data from an Sram based fifo to a Pci target, via the PciMstrIO module, in bursts of up to 256 bytes. The nature of the PCI bus dictates the use of the write line command to ensure optimal system performance. The write line command requires that the Pmo sequencer be capable of transferring a whole multiple (1X, 2X, 3X, ...) of cache lines of which the size is set through the Pci configuration registers. To accomplish this end, Pmo will automatically perform partial bursts until it has aligned the transfers on a cache line boundary at which time it will begin usage of the write line command. The Sram fifo depth, of 256 bytes, has been chosen in order to allow Pmo to accommodate cache line sizes up to 128 bytes. Provided the cache line size is less than 128 bytes, Pmo will perform multiple, contiguous cache line bursts until it has exhausted the supply of data.

Pmo receives requests from two separate sources; the dram to Pci (D2p) module and the Sram to Pci (S2p) module. An operation first begins with prioritization of the requests where the S2p module is given highest priority. Next, the Pmo module takes a Snapshot of the Sram fifo address and uses this to generate read requests for the SramCtrl sequencer. The Pmo module then proceeds to arbitrate for ownership of the Pci bus via the PciMstrIO module. Once the Pmo holding registers have sufficient data and Pci bus mastership has been granted, the Pmo module begins transferring data to the Pci target. For each successful transfer, Pmo sends an acknowledge and encoded size to the master sequencer, allow it to update it's internal pointers, counters and status. Once the Pci burst transaction has terminated, Pmo parks on the Pci bus unless another initiator has requested ownership. Pmo again prioritizes the incoming requests and repeats the process.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

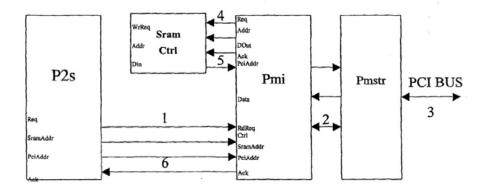

# PCI MASTER-IN SEQUENCER (Pmi)

The Pmi sequencer acts only as a slave sequencer. Servicing requests issued by master sequencers, the Pmi sequencer moves data from a Pci target to an Sram based fifo, via the PciMstrIO module, in bursts of up to 256 bytes. The nature of the PCI bus dictates the use of the read multiple command to ensure optimal system performance. The read multiple command requires that the Pmi sequencer be capable of transferring a cache line or more of data. To accomplish this end, Pmi will automatically perform partial cache line bursts until it has aligned the transfers on a cache line boundary at which time it will begin usage of the read multiple command. The Sram fifo depth, of 256 bytes, has been chosen in order to allow Pmi to accommodate cache line sizes up to 128 bytes. Provided the cache line size is less than 128 bytes, Pmi will perform multiple, contiguous cache line bursts until it has filled the fifo.

Pmi receive requests from two separate sources; the Pci to dram (P2d) module and the Pci to Sram (P2s) module. An operation first begins with prioritization of the requests where the P2s module is given highest priority. The Pmi module then proceeds to arbitrate for ownership of the Pci bus via the PciMstrIO module. Once the Pci bus mastership has been granted and the Pmi holding registers have sufficient data, the Pmi module begins transferring data to the Sram fifo. For each successful transfer, Pmi sends an acknowledge and encoded size to the master sequencer, allowing it to update it's internal pointers, counters and status. Once the Pci burst transaction has terminated, Pmi parks on the Pci bus unless another initiator has requested ownership. Pmi again prioritizes the incoming requests and repeats the process.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

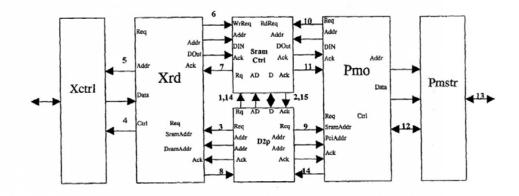

## Dram TO PCI SEQUENCER (D2p)

The D2p sequencer acts is a master sequencer. Servicing channel requests issued by the Cpu, the D2p sequencer manages movement of data from dram to the Pci bus by issuing requests to both the Xrd sequencer and the Pmo sequencer. Data transfer is accomplished using an Sram based fifo through which data is staged.

D2p can receive requests from any of the processor's thirty-two dma channels. Once a command request has been detected, D2p fetches a dma descriptor from an Sram location dedicated to the requesting channel which includes the dram address, Pci address, Pci endian and request size. D2p then issues a request to the D2s sequencer causing the Sram based fifo to fill with dram data. Once the fifo contains sufficient data for a Pci transaction, D2s issues a request to Pmo which in turn moves data from the fifo to a Pci target. The process repeats until the entire request has been satisfied at which time D2p writes ending status in to the Sram dma descriptor area and sets the channel done bit associated with that channel. D2p then monitors the dma channels for additional requests. Following is an illustration showing the major blocks involved in the movement of data from dram to Pci target.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

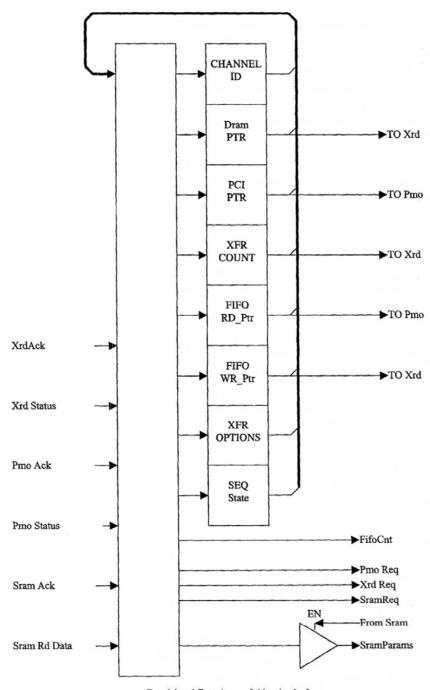

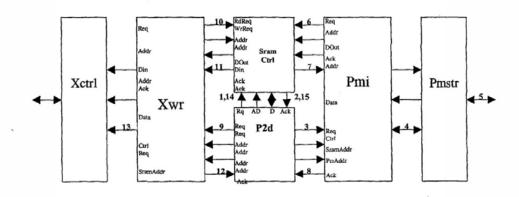

## PCI TO DRAM SEQUENCER (P2d)

The P2d sequencer acts as both a slave sequencer and a master sequencer. Servicing channel requests issued by the Cpu, the P2d sequencer manages movement of data from Pci bus to dram by issuing requests to both the Xwr sequencer and the Pmi sequencer. Data transfer is accomplished using an Sram based fifo through which data is staged.

P2d can receive requests from any of the processor's thirty-two dma channels. Once a command request has been detected, P2d, operating as a slave sequencer, fetches a dma descriptor from an Sram location dedicated to the requesting channel which includes the dram address, Pci address, Pci endian and request size. P2d then issues a request to Pmo which in turn moves data from the Pci target to the Sram fifo. Next, P2d issues a request to the Xwr sequencer causing the Sram based fifo contents to be written to the dram. The process repeats until the entire request has been satisfied at which time P2d writes ending status in to the Sram dma descriptor area and sets the channel done bit associated with that channel. P2d then monitors the dma channels for additional requests. Following is an illustration showing the major blocks involved in the movement of data from a Pci target to dram.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

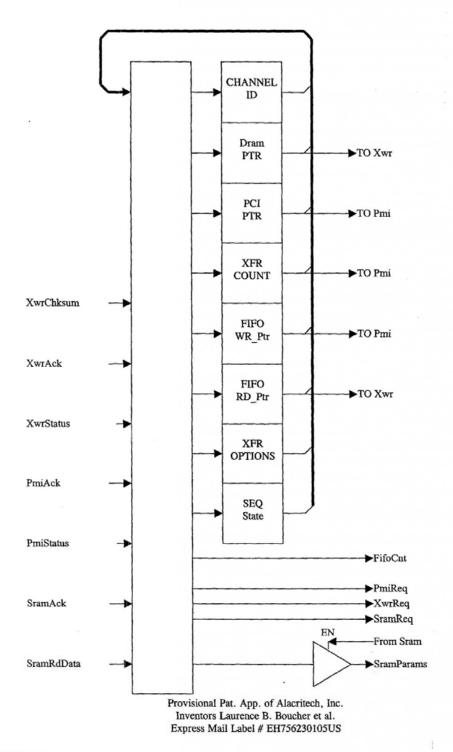

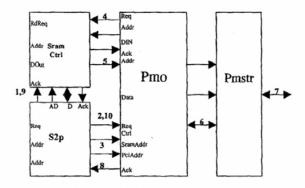

# SRAM TO PCI SEQUENCER (S2p)

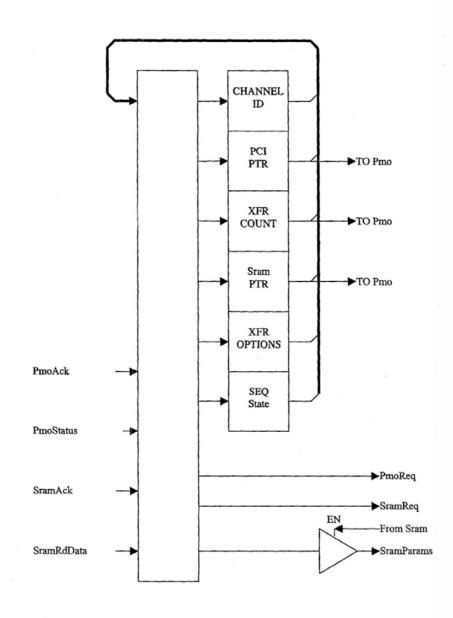

The S2p sequencer acts as both a slave sequencer and a master sequencer. Servicing channel requests issued by the Cpu, the S2p sequencer manages movement of data from Sram to the Pci bus by issuing requests to the Pmo sequencer

S2p can receive requests from any of the processor's thirty-two dma channels. Once a command request has been detected, S2p, operating as a slave sequencer, fetches a dma descriptor from an Sram location dedicated to the requesting channel which includes the Sram address, Pci address, Pci endian and request size. S2p then issues a request to Pmo which in turn moves data from the Sram to a Pci target. The process repeats until the entire request has been satisfied at which time S2p writes ending status in to the Sram dma descriptor area and sets the channel done bit associated with that channel. S2p then monitors the dma channels for additional requests. Following is an illustration showing the major blocks involved in the movement of data from Sram to Pci target.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

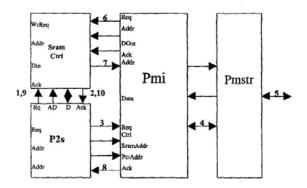

## PCI TO SRAM SEQUENCER (P2s)

The P2s sequencer acts as both a slave sequencer and a master sequencer. Servicing channel requests issued by the Cpu, the P2s sequencer manages movement of data from Pci bus to Sram by issuing requests to the Pmi sequencer.

P2s can receive requests from any of the processor's thirty-two dma channels. Once a command request has been detected, P2s, operating as a slave sequencer, fetches a dma descriptor from an Sram location dedicated to the requesting channel which includes the Sram address, Pci address, Pci endian and request size. P2s then issues a request to Pmo which in turn moves data from the Pci target to the Sram. The process repeats until the entire request has been satisfied at which time P2s writes ending status in to the dma descriptor area of Sram and sets the channel done bit associated with that channel. P2s then monitors the dma channels for additional requests. Following is an illustration showing the major blocks involved in the movement of data from a Pci target to dram.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

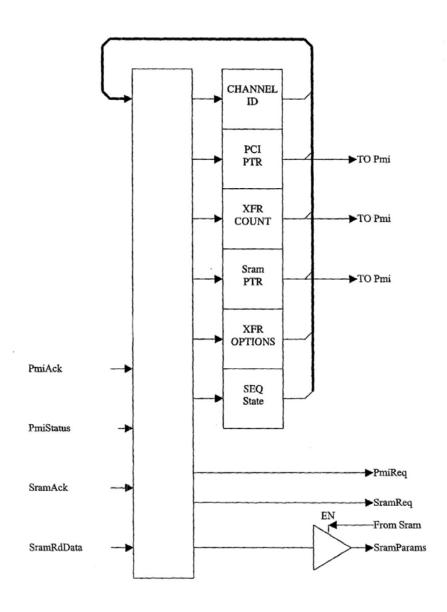

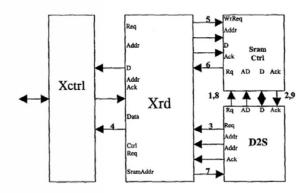

## DRAM TO SRAM SEQUENCER (D2s)

The D2s sequencer acts as both a slave sequencer and a master sequencer. Servicing channel requests issued by the Cpu, the D2s sequencer manages movement of data from dram to Sram by issuing requests to the Xrd sequencer.

D2s can receive requests from any of the processor's thirty-two dma channels. Once a command request has been detected, D2s, operating as a slave sequencer, fetches a dma descriptor from an Sram location dedicated to the requesting channel which includes the dram address, Sram address and request size. D2s then issues a request to the Xrd sequencer causing the transfer of data to the Sram. The process repeats until the entire request has been satisfied at which time D2s writes ending status in to the Sram dma descriptor area and sets the channel done bit associated with that channel. D2s then monitors the dma channels for additional requests. Following is an illustration showing the major blocks involved in the movement of data from dram to Sram.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

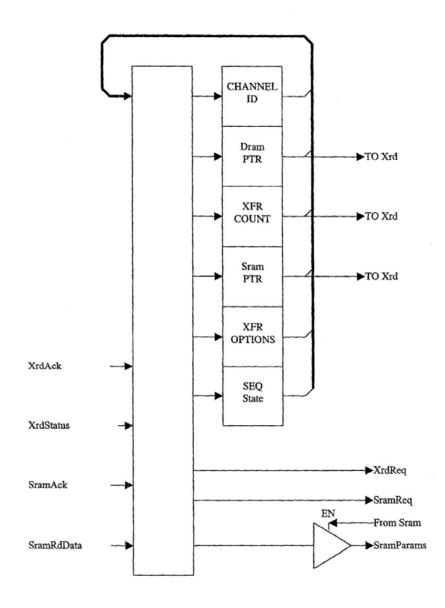

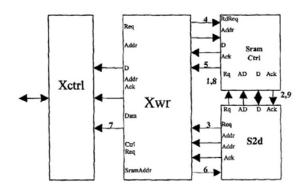

## SRAM TO DRAM SEQUENCER (S2d)

The S2d sequencer acts as both a slave sequencer and a master sequencer. Servicing channel requests issued by the Cpu, the S2d sequencer manages movement of data from Sram to dram by issuing requests to the Xwr sequencer.

S2d can receive requests from any of the processor's thirty-two dma channels. Once a command request has been detected, S2d, operating as a slave sequencer, fetches a dma descriptor from an Sram location dedicated to the requesting channel which includes the dram address, Sram address, checksum reset and request size. S2d then issues a request to the Xwr sequencer causing the transfer of data to the dram. The process repeats until the entire request has been satisfied at which time S2d writes ending status in to the Sram dma descriptor area and sets the channel done bit associated with that channel. S2d then monitors the dma channels for additional requests. Following is an illustration showing the major blocks involved in the movement of data from Sram to dram.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

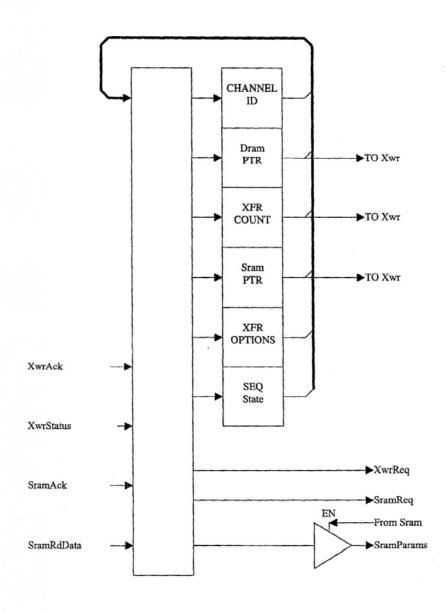

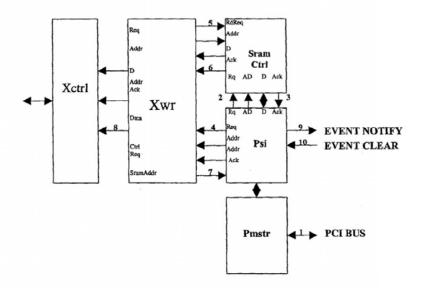

## PCI SLAVE INPUT SEQUENCER (Psi)

The Psi sequencer acts as both a slave sequencer and a master sequencer. Servicing requests issued by a Pci master, the Psi sequencer manages movement of data from Pci bus to Sram and Pci bus to dram via Sram by issuing requests to the SramCtrl and Xwr sequencers.

Psi manages write requests to configuration space, expansion rom, dram, Sram and memory mapped registers. Psi separates these Pci bus operations in to two categories with different action taken for each. Dram accesses result in Psi generating write request to an Sram buffer followed with a write request to the Xwr sequencer. Subsequent write or read dram operations are retry terminated until the buffer has been emptied. An event notification is set for the processor allowing message passing to occur through dram space.

All other Pci write transactions result in Psi posting the write information including Pci address, Pci byte marks and Pci data to a reserved location in Sram, then setting an event flag which the event processor monitors. Subsequent writes or reads of configuration, expansion rom, Sram or registers are terminated with retry until the processor clears the event flag. This allows the INIC to keep pipelining levels to a minimum for the posted write and give the processor ample time to modify data for subsequent Pci read operations.

The following diagram depicts the sequence of events when Psi is the target of a Pci write operation. Note that events 4 through 7 occur only when the write operation targets the dram.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

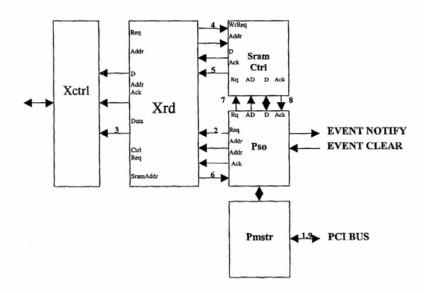

## PCI SLAVE OUTPUT SEQUENCER (Pso)

The Pso sequencer acts as both a slave sequencer and a master sequencer. Servicing requests issued by a Pci master, the Pso sequencer manages movement of data to Pci bus form Sram and to Pci bus from dram via Sram by issuing requests to the SramCtrl and Xrd sequencers.

Pso manages read requests to configuration space, expansion rom, dram, Sram and memory mapped registers. Pso separates these Pci bus operations in to two categories with different action taken for each. Dram accesses result in Pso generating read request to the Xrd sequencer followed with a read request to Sram buffer. Subsequent write or read dram operations are retry terminated until the buffer has been emptied.

All other Pci read transactions result in Pso posting the read request information including Pci address and Pci byte marks to a reserved location in Sram, then setting an event flag which the event processor monitors. Subsequent writes or reads of configuration, expansion rom, Sram or registers are terminated with retry until the processor clears the event flag. This allows the INIC to use a microcoded response mechanism to return data for the request. The processor decodes the request information, formulates or fetches the requested data and stores it in Sram then clears the event flag allowing Pso to fetch the data and return it on the Pci bus.

The following diagram depicts the sequence of events when Pso is the target of a Pci read operation.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

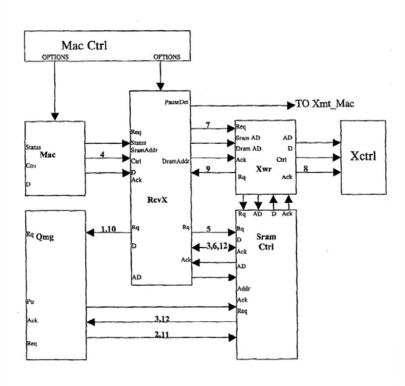

## FRAME RECEIVE SEQUENCER (RcvX)

The receive sequencer (RcvSeq) analyzes and manages incoming packets, stores the result in dram buffers, then notifies the processor through the receive queue (RcvQ) mechanism. The process begins when a buffer descriptor is available at the output of the FreeQ. RcvSeq issues a request to the Qmg which responds by supplying the buffer descriptor to RcvSeq. RcvSeq then waits for a receive packet. The Mac, network, transport and session information is analyzed as each byte is received and stored in the assembly register (AssyReg). When four bytes of information is available, RcvSeq requests a write of the data to the Sram. When sufficient data has been stored in the Sram based receive fifo, a dram write request is issued to Xwr. The process continues until the entire packet has been received at which point RcvSeq stores the results of the packet analysis in the beginning of the dram buffer. Once the buffer and status have both been stored, RcvSeq issues a write-queue request to Qmg. Qmg responds by storing a buffer descriptor provided by RcvSeq. The process then repeats. If RcvSeq detects the arrival of a packet before a free buffer is available, it ignores the packet and sets the FrameLost status bit for the next received buffer.

The following diagram depicts the sequence of events for successful reception of a packet followed by a definition of the receive buffer and the buffer descriptor as stored on the RcvQ.

## RECEIVE BUFFER DESCRIPTOR

bit31:30	name reserved	description
29:28	size	A copy of the bits in the FreeBufDscr.
27:00	address	Represents the last address +1 to which frame data was transferred. The address
		wraps around at the boundary dictated by the S bits. This can be used to determine
		the size of the frame received.

# RECEIVE BUFFER FORMAT

FRAME Status A		OFFSET 0x0000:0x0003		
bit	name	description		
31	attention	Indicates one or more of the following: CompositeErr, !IpDn, !MacADet &		
		!MacBDet, IpMcst, IpBcst, !ethernet & !802.3Snap, !Ip4, !Tcp .		
30	CompositeErr	Set when any of the error bits of ErrStatus are set or if frame processing stops		
		while receiving a Tcp or Udp header.		
29	CtrlFrame	A control frame was received at our unicast or special MltCst address.		
28	IpDn	Frame processing Hlted due to exhaustion of the IP4 length counter.		
27	802.3Dn	Frame processing Hlted due to exhaustion of the 802.3 length counter.		
26	MacADet	Frame's destination address matched the contents of MacAddrA.		
25	MacBDet	Frame's destination address matched the contents of MacAddrB.		
24	MacMcst	The Mac detected a MltCst address.		
23	MacBest	The Mac detected a BrdCst address.		
22	IpMcst	The frame processor detected an IP MltCst address.		
21	IpBcst	The frame processor detected an IP BrdCst address.		
20	Frag	The frame processor detected a Frag IP datagram.		
19	IpOffst	The frame processor detected a non-zero IP datagram offset.		
18	IpFlgs	The frame processor detected flags within the IP datagram.		
17	IpOpts	The frame processor detected a header length greater than 20 for the IP datagram.		
16	TcpFlgs	The frame processor detected an abnormal header flag for the TCP segment.		
15	TcpOpts	The frame processor detected a header length greater than 20 for the TCP segment.		
14	TcpUrg	The frame processor detected a non-zero urgent pointer for the TCP segment.		
13	Carrier Evnt	Refer to E110 Technical Manual.		
12	LongEvnt	Refer to E110 Technical Manual.		
11	FrameLost	Set when an incoming frame could not be processed as a result of an outstanding		
		frame completion event not yet serviced by the utility processor.		
10	reserved			
10	NoAck	The frame processor detected a

If an IP datagram was not detected, the checksum provides a total for the entire data portion of the received frame. The data area is defined as those bytes received after the type field of an ethernet frame, the LLC header of an 802.3 frame or the SNAP header of an 802.3-SNAP frame. TepChksum Reflects the value of the transport checksum at IP completion or frame completion. If IP was detected but session was unknown, the checksum will not include the psuedo-header. If IP was not detected, the checksum will be 0x0000. RESERVED OFFSET 0x0010:0x0011 **FRAME Data** OFFSET 0x0012:END OF BUFFER

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

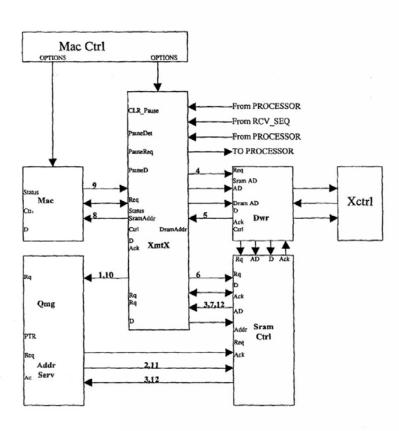

#### FRAME TRANSMIT SEQUENCER (XmtX)

The transmit sequencer (XmtSeq) analyzes and manages outgoing packets, using buffer descriptors retrieved from the transmit queue (XmtQ) then storing the descriptor for the freed buffer in the free buffer queue (FreeQ). The process begins when a buffer descriptor is available at the output of the XmtQ. XmtSeq issues a request to the Qmg which responds by supplying the buffer descriptor to XmtSeq. XmtSeq then issues a read request to the Xrd sequencer. Next, XmtSeq issues a read request to SramCtrl then instructs the Mac to begin frame transmission. The Mac accepts data from XmtSeq which analyzes the packet as it flys-by in order to generate checksums to insert in the data stream. Once the frame transmission has completed, XmtSeq stores the buffer descriptor on the FreeQ thereby recycling the buffer.

The following diagram depicts the sequence of events for successful transmission of a packet followed by a definition of the receive buffer and the buffer descriptor as stored on the XmtQ.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

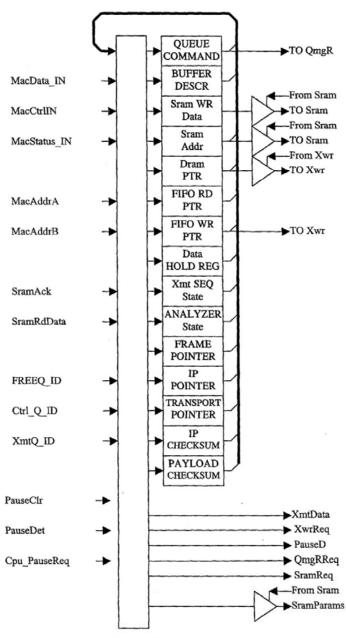

#### TRANSMIT BUFFER DESCRIPTOR

bit_	name	description
31	ChksumEn	When set, XmtSeq will insert a calculated checksum. When reset, XmtSeq will
		not alter the outgoing data stream.
30	reserved	
29:28	size	Represents the size of the buffer by indicating at what boundary the buffer should
		start and terminate. This is used in combination with EndAddr to determine the
		starting address of the buffer:
		S = 0 256B boundary, A[7:0] ignored.
		S = 1 2KB boundary. A[10:0] ignored.
		S = 2 4KB boundary. A[11:0] ignored.
		S = 3 32KB boundary. A[14:0] ignored.
27:00	EndAddr	The address of the last byte to transmit plus one.

#### QUEUE MANAGER (Qmg)

The INIC includes special hardware assist for the implementation of message and pointer queues. The hardware assist is called the queue manager (Qmg) and manages the movement of queue entries between Cpu and Sram, between dma sequencers and Sram as well as between Sram and dram. Queues comprise three distinct entities; the queue head (QHd), the queue tail (QTI) and the queue body (QBdy). QHd resides in 64 bytes of scratch ram and provides the area to which entries will be written (pushed). QTI resides in 64 bytes of scratch ram and contains queue locations from which entries will be read (popped). QBdy resides in dram and contains locations for expansion of the queue in order to minimize the Sram space requirements. The QBdy size depends upon the queue being accessed and the initialization parameters presented during queue initialization.

Qmg accepts operations from both Cpu and dma sources. Executing these operations at a frequency of 133MHz, Qmg reserves even cycles for dma requests and reserves odd cycles for Cpu requests. Valid Cpu operations include initialize queue (InitQ), write queue (WrQ) and read queue (RdQ). Valid dma requests include read body (RdBdy) and write body (WrBdy). Qmg working in unison with Q2d and D2q generate requests to the Xwr and Xrd sequencers to control the movement of data between the QHd, QTl and QBdy.

The preceding block diagram shows the major functions of Qmg. The arbiter selects the next operation to be performed. The dual-ported Sram holds the queue variables HdWrAddr, HdRdAddr, TlWrAddr, TIRdAddr, BdyWrAddr, BdyRdAddr and QSz. Qmg accepts an operation request, fetches the queue variables from the queue ram (Qram), modifies the variables based on the current state and the requested operation then updates the variables and issues a read or write request to the Sram controller. The Sram controller services the requests by writing the tail or reading the head and returning an acknowledge.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

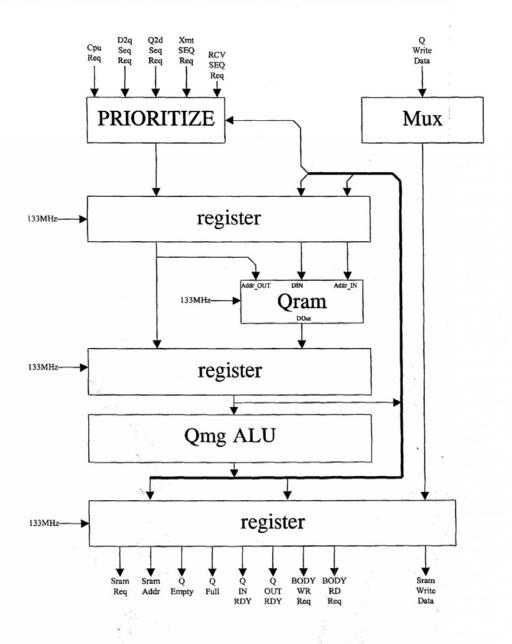

#### DMA OPERATIONS

DMA operations are accomplished through a combination of thirtytwo dma channels (DmaCh) and seven dma sequencers (DmaSeq). Each dma channel provides a mechanism whereby a Cpu can issue a command to any of the seven dma sequencers. Where as the dma channels are multi-purpose, the dma sequencers they command are single purpose as follows.

dma seq #	name	description	:
0	none	This is a no operation address.	
1	D2dSeq	Moves data from ExtMem to ExtMem.	
2	D2sSeq	Moves data from ExtMem bus to sram.	
3	D2pSeq	Moves data from ExtMem to Pci bus.	
4	S2dSeq	Moves data from sram to ExtMem.	
5	S2pSeq	Moves data from sram to Pci bus.	
6	P2dSeq	Moves data from Pci bus to ExtMem.	
7	P2sSeq	Moves data from Pci bus to sram.	

The processors manage dma in the following way. The processor writes a dma descriptor to an Sram location reserved for the dma channel. The format of the dma descriptor is dependent upon the targeted dma sequencer. The processor then writes the dma sequencer number to the channel command register.

Each of the dma sequencers polls all thirtytwo dma channels in search of commands to execute. Once a command request has been detected, the dma sequencer fetches a dma descriptor from a fixed location in Sram. The Sram location is fixed and is determined by the dma channel number. The dma sequencer loads the dma descriptor in to it's own registers, executes the command, then overwrites the dma descriptor with ending status. Once the command has halted, due to completion or error, and the ending status has been written, the dma sequencer sets the done bit for the current dma channel.

The done bit appears in a dma event register which the Cpu can examine. The Cpu fetches ending status from Sram, then clears the done bit by writing zeroes to the channel command (ChCmd) register. The channel is now ready to accept another command.

The format of all channel command registers is as follows.

bit_	name	description
31:11	reserved	Data written to these bits is ignored.
10:8	ChCmd	0 - Stops execution of the current operation and clears the corresponding event flag.
		1 - Transfer data from ExtMem to ExtMem.
		2 - Transfer data from ExtMem bus to sram.
		3 - Transfer data from ExtMem to Pci bus.
		4 - Transfer data from sram to ExtMem.
		5 - Transfer data from sram to Pci bus.
		6 - Transfer data from Pci bus to ExtMem.
		7 - Transfer data from Pci bus to Sram.
07:05	reserved	Data written to these bits is ignored.
04:00	ChId	Provides the channel number for the channel command.

Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

The format of the P2d or P2s descriptor is as follows.

bit	name	description
127:96	PciAddrH	Bits [63:32] of the Pci address.
95:64	<b>PciAddrL</b>	Bits [31:00] of the Pci address.
59:32	MemAddr	Bits [27:00] of the ExtMem address or bits [15:00] of the Sram address,
31	PciEndian	When set, selects big endian mode for Pci transfers.
30	WideDbl	When set, disables Pci 64-bit mode.
22	DstFlash	Selects Flash for the external memory destination of P2d.
15:00	XfrSz	Bits [15:00] of the requested dma size expressed in bytes.

The format of the S2p or D2p descriptor is as follows.

bit	name	description
123:96	MemAddr	Bits [27:00] of the ExtMem address or bits [15:00] of the Sram address.
95:64	PciAddrH	Bits [63:32] of the Pci address.
63:32	PciAddrL	Bits [31:00] of the Pci address.
30	SrcFlash	Selects Flash for the external memory source of D2p.
23	PciEndian	When set, selects big endian mode for Pci transfers.
22	WideDbl	When set, disables Pci 64-bit mode.
15:00	XfrSz	Bits [15:00] of the requested dma size expressed in bytes.

The format of the S2d, D2d or D2s descriptor is as follows.

bit	name	description
127:124	reserved	Reserved for future use.
123:96	SrcAddr	Bits [27:00] of the ExtMem address or bits [15:00] of the Sram address.
95:60	reserved	Reserved for future use,
59:32	DstAddr	Bits [27:00] of the ExtMem address or bits [15:00] of the Sram address.
30	FlashSel	Selects Flash for the external memory source of D2d or D2s.
22	FlashSel	Selects Flash for the external memory destination of S2p or D2d.
15:00	XfrSz	Bits [15:00] of the requested dma size expressed in bytes.

The format of the ending status or all channels is as follows.

bit_	name	description
127:64	reserved	Not used.
63:32	ChkSum	Represents the 1's compliment sum of all halfwords transferred during a P2d or D2d operation only.
31:24	reserved	Reserved for future use.
23:20	SrcStatus	TBD.
19:16	DstStatus	TBD.
15:00	XfrSz	Bits [15:00] of the residual dma size expressed in bytes. This value will be zero if the dma operation was successful

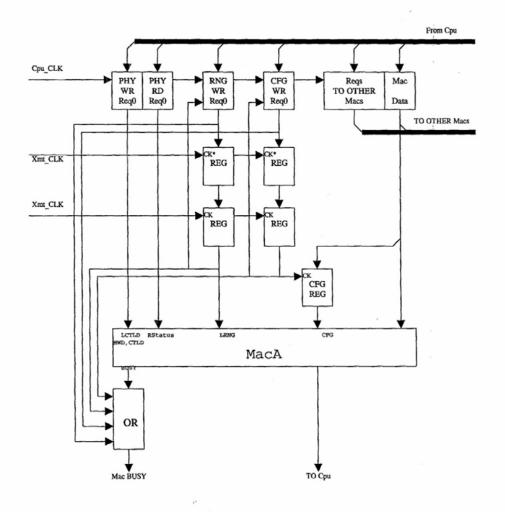

The format of the ChEvnt register is as follows.

bit_	name	description
31:00	ChDn	Each bit represents the done flag for the respective dma channel. These bits are set by a
		dma sequencer upon completion of the channel command. Cleared when the processor
		writes 0 to the corresponding ChCmd register ChCmdOp field.

# Appendix A

The following load calculations are based on the following basic formulae:

N = X \* R (Little's Law) where

N = number of jobs in the system (either in progress or in a queue),

X =system throughput,

R = response time (which includes time waiting in queues).

U = X \* S (from Little's Law) where

S = service time,

U = utilization.

R = S / (1-U) for exponential service times (which is the worst-case assumption).

A 256 byte frame at 100Mb/sec takes 20 µsec per frame.

4 \* 100 Mbit ethernets receiving at full frame rate is:

51200 (4 \* 12800) frames/sec @ 1024 bytes/frame

102000 frames/sec @ 512 bytes/frame

204000 frames/sec @ 256 bytes/frame.

The following calculations assume 250 instructions/frame, 45nsec clock. Thus  $S = 250 * 45 \text{ nsecs} = 11.2 \mu \text{secs}.$ 

Av. Frame Size	Thruput	Utilization	Response	Nbr. in system
	(X)	(U)	(R)	(N)
1024	51200	.57	26 usecs	1.3
512	102000	> 1		
256	204000	>1		

Lets look at it for varying instructions per frame assuming 512 bytes per frame average.

Instns Per Frame	Service Time (S)	Thruput (X)	Utilization (U)	Response (R)	Nbr. in system (N)
250	11.2 usec	102000	> 1		
250	11.2	85000 (*)	.95	224 usecs	19
250	11.2	80000 (*	*) .89	101	8
225	10	102000	1.0		
225	10	95000 (*)	.95	200	19
225	10	89000 (*	*) .89	90	8
200	9	102000	.9	90	9
150	6.7	102000	.68	20	2

(\*) shows what frame rate can be supported to get a utilization of less than 1.

(\*\*) shows what frame rate can be supported with 8 SRAM TCB buffers and at least 8 process contexts.

> Provisional Pat. App. of Alacritech, Inc. Inventors Laurence B. Boucher et al. Express Mail Label # EH756230105US

If 100 instructions / frame is used, S = 100 \* 45 nsecs = 4.5 usecs, and we can support 256 byte frames:

100

4.5

204000

.91

10

Firstly note that these calculations assume that response times increase exponentially as utilization increases. This is the worst-case assumption, and probably may not be true for

The figures show that to support a theoretical full 4 \* 100 Mbit receive load with an average frame size of 512 bytes, there will need to be 19 active "jobs" in the system, assuming 250 instructions per frame. Due to SRAM limitations, the current design specifies 8 SRAM buffers for active TCBs, and not to swap a TCB out of SRAM once it is active. So under these limitations, the INIC will not be able to keep up with the full frame rate. Note that the initial implementation is trying to use only 8KB of SRAM, although 16KB may be available, in which case 19 TCB SRAM buffers could be used. This is a cost trade-off.

The real point here is the effect of instructions/frame on the throughput that can be maintained. If the instructions/frame drops to 200, then the INIC is capable of handling the full theoretical load (102000 frames/second) with only 9 active TCBs. If it drops to 100 instructions per frame, then the INIC can handle full bandwidth at 256 byte frames (204000 frames/second) with 10 active TCBs. The bottom line is that ALL hardwareassist that reduces the instructions/frame is really worthwhile. If header-assist hardware can save us 50 instructions per frame then it goes straight to the throughput bottom line.

#### CERTIFICATE OF MAILING UNDER 37 CFR 1.10

I hereby certify that this Provisional Patent Application is being deposited with the United States Postal Service as "Express Mail Post Office to Addressee", label number EH756230105US, in an envelope addressed to: Assistant Commissioner for Patents, Washington, D.C. 20231, on October 14, 1997.

Date: October 14, 1997
