Universal Serial Bus Specification Revision 2.0

Scope of this Revision

The 2.0 revision of the specification is intended for product design. Every attempt has been made to ensure a consistent and implementable specification. Implementations should ensure compliance with this revision.

Revision History

Revision	Issue Date	Comments
0.7	November 11, 1994	Supersedes 0.6e.
0.8	December 30, 1994	Revisions to Chapters 3-8, 10, and 11. Added appendixes.
0.9	April 13, 1995	Revisions to all the chapters.
0.99	August 25, 1995	Revisions to all the chapters.
1.0 FDR	November 13, 1995	Revisions to Chapters 1, 2, 5-11.
1.0	January 15, 1996	Edits to Chapters 5, 6, 7, 8, 9, 10, and 11 for consistency.
1.1	September 23, 1998	Updates to all chapters to fix problems identified.
2.0 (draft 0.79)	October 5, 1999	Revisions to chapters 5, 7, 8, 9, 11 to add high speed.
2.0 (draft 0.9)	December 21, 1999	Revisions to all chapters to add high speed.
2.0	April 27, 2000	Revisions for high-speed mode.

Acknowledgement of USB 2.0 Technical Contribution

The authors of this specification would like to recognize the following people who participated in the USB 2.0 Promoter Group technical working groups. We would also like to thank others in the USB 2.0 Promoter companies and throughout the industry who contributed to the development of this specification.

Contents

CHAPTER 1 INTRODUCTION

1.1	Motivation	1
1.2	Objective of the Specification	1
1.3	Scope of the Document	2
1.4	USB Product Compliance	2
1.5	Document Organization	2

CHAPTER 2 TERMS AND ABBREVIATIONS

CHAPTER 3 BACKGROUND

3.1	Goals for the Universal Serial Bus	11
3.2	Taxonomy of Application Space.....	12
3.3	Feature List	13

CHAPTER 4 ARCHITECTURAL OVERVIEW

4.1	USB System Description	15
4.1.1	Bus Topology	16
4.2	Physical Interface	17
4.2.1	Electrical.....	17
4.2.2	Mechanical	18
4.3	Power	18
4.3.1	Power Distribution	18
4.3.2	Power Management.....	18
4.4	Bus Protocol	18
4.5	Robustness.....	19
4.5.1	Error Detection.....	19
4.5.2	Error Handling.....	19
4.6	System Configuration.....	19
4.6.1	Attachment of USB Devices.....	20
4.6.2	Removal of USB Devices.....	20
4.6.3	Bus Enumeration	20

4.7	Data Flow Types	20
4.7.1	Control Transfers.....	21
4.7.2	Bulk Transfers.....	21
4.7.3	Interrupt Transfers.....	21
4.7.4	Isochronous Transfers	21
4.7.5	Allocating USB Bandwidth.....	21
4.8	USB Devices	22
4.8.1	Device Characterizations.....	22
4.8.2	Device Descriptions	22
4.9	USB Host: Hardware and Software.....	24
4.10	Architectural Extensions.....	24

CHAPTER 5 USB DATA FLOW MODEL

5.1	Implementer Viewpoints.....	25
5.2	Bus Topology	27
5.2.1	USB Host	27
5.2.2	USB Devices	28
5.2.3	Physical Bus Topology.....	29
5.2.4	Logical Bus Topology.....	30
5.2.5	Client Software-to-function Relationship.....	31
5.3	USB Communication Flow	31
5.3.1	Device Endpoints	33
5.3.2	Pipes	34
5.3.3	Frames and Microframes.....	36
5.4	Transfer Types.....	36
5.4.1	Table Calculation Examples.....	37
5.5	Control Transfers	38
5.5.1	Control Transfer Data Format	38
5.5.2	Control Transfer Direction	39
5.5.3	Control Transfer Packet Size Constraints.....	39
5.5.4	Control Transfer Bus Access Constraints.....	40
5.5.5	Control Transfer Data Sequences.....	43
5.6	Isochronous Transfers.....	44
5.6.1	Isochronous Transfer Data Format.....	44
5.6.2	Isochronous Transfer Direction.....	44
5.6.3	Isochronous Transfer Packet Size Constraints	44
5.6.4	Isochronous Transfer Bus Access Constraints	47
5.6.5	Isochronous Transfer Data Sequences.....	47
5.7	Interrupt Transfers	48
5.7.1	Interrupt Transfer Data Format	48
5.7.2	Interrupt Transfer Direction	48
5.7.3	Interrupt Transfer Packet Size Constraints.....	48
5.7.4	Interrupt Transfer Bus Access Constraints.....	49
5.7.5	Interrupt Transfer Data Sequences	52

- 5.8 Bulk Transfers 52**
 - 5.8.1 Bulk Transfer Data Format..... 52
 - 5.8.2 Bulk Transfer Direction..... 52
 - 5.8.3 Bulk Transfer Packet Size Constraints 53
 - 5.8.4 Bulk Transfer Bus Access Constraints 53
 - 5.8.5 Bulk Transfer Data Sequences 55

- 5.9 High-Speed, High Bandwidth Endpoints..... 56**
 - 5.9.1 High Bandwidth Interrupt Endpoints 56
 - 5.9.2 High Bandwidth Isochronous Endpoints 57

- 5.10 Split Transactions 58**

- 5.11 Bus Access for Transfers..... 58**
 - 5.11.1 Transfer Management..... 59
 - 5.11.2 Transaction Tracking..... 61
 - 5.11.3 Calculating Bus Transaction Times..... 63
 - 5.11.4 Calculating Buffer Sizes in Functions and Software 65
 - 5.11.5 Bus Bandwidth Reclamation 65

- 5.12 Special Considerations for Isochronous Transfers 65**
 - 5.12.1 Example Non-USB Isochronous Application..... 66
 - 5.12.2 USB Clock Model 69
 - 5.12.3 Clock Synchronization 71
 - 5.12.4 Isochronous Devices..... 71
 - 5.12.5 Data Prebuffering 80
 - 5.12.6 SOF Tracking 81
 - 5.12.7 Error Handling..... 81
 - 5.12.8 Buffering for Rate Matching 82

CHAPTER 6 MECHANICAL

- 6.1 Architectural Overview..... 85**

- 6.2 Keyed Connector Protocol..... 85**

- 6.3 Cable 86**

- 6.4 Cable Assembly..... 86**
 - 6.4.1 Standard Detachable Cable Assemblies 86
 - 6.4.2 High-/full-speed Captive Cable Assemblies..... 88
 - 6.4.3 Low-speed Captive Cable Assemblies 90
 - 6.4.4 Prohibited Cable Assemblies..... 92

- 6.5 Connector Mechanical Configuration and Material Requirements..... 93**
 - 6.5.1 USB Icon Location..... 93
 - 6.5.2 USB Connector Termination Data 94
 - 6.5.3 Series “A” and Series “B” Receptacles 94
 - 6.5.4 Series “A” and Series “B” Plugs 98

6.6 Cable Mechanical Configuration and Material Requirements102
6.6.1 Description102
6.6.2 Construction103
6.6.3 Electrical Characteristics105
6.1.4 Cable Environmental Characteristics106
6.1.5 Listing106

6.7 Electrical, Mechanical, and Environmental Compliance Standards106
6.7.1 Applicable Documents114

6.8 USB Grounding114

6.9 PCB Reference Drawings.....114

CHAPTER 7 ELECTRICAL

7.1 Signaling.....119
7.1.1 USB Driver Characteristics123
7.1.2 Data Signal Rise and Fall, Eye Patterns129
7.1.3 Cable Skew.....139
7.1.4 Receiver Characteristics139
7.1.5 Device Speed Identification141
7.1.6 Input Characteristics.....142
7.1.7 Signaling Levels144
7.1.8 Data Encoding/Decoding157
7.1.9 Bit Stuffing.....157
7.1.10 Sync Pattern159
7.1.11 Data Signaling Rate.....159
7.1.12 Frame Interval159
7.1.13 Data Source Signaling160
7.1.14 Hub Signaling Timings162
7.1.15 Receiver Data Jitter164
7.1.16 Cable Delay.....165
7.1.17 Cable Attenuation.....167
7.1.18 Bus Turn-around Time and Inter-packet Delay.....168
7.1.19 Maximum End-to-end Signal Delay.....168
7.1.20 Test Mode Support.....169

7.2 Power Distribution171
7.2.1 Classes of Devices.....171
7.2.2 Voltage Drop Budget175
7.2.3 Power Control During Suspend/Resume176
7.2.4 Dynamic Attach and Detach.....177

7.3 Physical Layer.....178
7.3.1 Regulatory Requirements178
7.3.2 Bus Timing/Electrical Characteristics178
7.3.3 Timing Waveforms191

CHAPTER 8 PROTOCOL LAYER

8.1 Byte/Bit Ordering 195

8.2 SYNC Field..... 195

8.3 Packet Field Formats..... 195

 8.3.1 Packet Identifier Field 195

 8.3.2 Address Fields 197

 8.3.3 Frame Number Field..... 197

 8.3.4 Data Field 197

 8.3.5 Cyclic Redundancy Checks..... 198

8.4 Packet Formats 199

 8.4.1 Token Packets..... 199

 8.4.2 Split Transaction Special Token Packets..... 199

 8.4.3 Start-of-Frame Packets 204

 8.4.4 Data Packets 206

 8.4.5 Handshake Packets 206

 8.4.6 Handshake Responses 207

8.5 Transaction Packet Sequences..... 209

 8.5.1 NAK Limiting via Ping Flow Control 217

 8.5.2 Bulk Transactions 221

 8.5.3 Control Transfers..... 225

 8.5.4 Interrupt Transactions..... 228

 8.5.5 Isochronous Transactions 229

8.6 Data Toggle Synchronization and Retry 232

 8.6.1 Initialization via SETUP Token 233

 8.6.2 Successful Data Transactions 233

 8.6.3 Data Corrupted or Not Accepted 233

 8.6.4 Corrupted ACK Handshake..... 234

 8.6.5 Low-speed Transactions 235

8.7 Error Detection and Recovery..... 236

 8.7.1 Packet Error Categories 236

 8.7.2 Bus Turn-around Timing 237

 8.7.3 False EOPs 237

 8.7.4 Babble and Loss of Activity Recovery..... 238

CHAPTER 9 USB DEVICE FRAMEWORK

9.1 USB Device States.....239

9.1.1 Visible Device States.....239

9.1.2 Bus Enumeration.....243

9.2 Generic USB Device Operations244

9.2.1 Dynamic Attachment and Removal.....244

9.2.2 Address Assignment.....244

9.2.3 Configuration244

9.2.4 Data Transfer.....245

9.2.5 Power Management.....245

9.2.6 Request Processing.....245

9.2.7 Request Error247

9.3 USB Device Requests.....248

9.3.1 bmRequestType.....248

9.3.2 bRequest.....249

9.3.3 wValue249

9.3.4 wIndex.....249

9.3.5 wLength.....249

9.4 Standard Device Requests250

9.4.1 Clear Feature252

9.4.2 Get Configuration.....253

9.4.3 Get Descriptor253

9.4.4 Get Interface.....254

9.4.5 Get Status254

9.4.6 Set Address.....256

9.4.7 Set Configuration257

9.4.8 Set Descriptor.....257

9.4.9 Set Feature.....258

9.4.10 Set Interface.....259

9.4.11 Synch Frame.....260

9.5 Descriptors260

9.6 Standard USB Descriptor Definitions.....261

9.6.1 Device261

9.6.2 Device_Qualifier264

9.6.3 Configuration264

9.6.4 Other_Speed_Configuration.....266

9.6.5 Interface.....267

9.6.6 Endpoint269

9.6.7 String.....273

9.7 Device Class Definitions274

9.7.1 Descriptors274

9.7.2 Interface(s) and Endpoint Usage274

9.7.3 Requests274

CHAPTER 10 USB HOST: HARDWARE AND SOFTWARE

10.1 Overview of the USB Host 275

 10.1.1 Overview 275

 10.1.2 Control Mechanisms 278

 10.1.3 Data Flow 278

 10.1.4 Collecting Status and Activity Statistics 279

 10.1.5 Electrical Interface Considerations 279

10.2 Host Controller Requirements 279

 10.2.1 State Handling 280

 10.2.2 Serializer/Deserializer 280

 10.2.3 Frame and Microframe Generation 280

 10.2.4 Data Processing 281

 10.2.5 Protocol Engine 281

 10.2.6 Transmission Error Handling 282

 10.2.7 Remote Wakeup 282

 10.2.8 Root Hub 282

 10.2.9 Host System Interface 283

10.3 Overview of Software Mechanisms 283

 10.3.1 Device Configuration 283

 10.3.2 Resource Management 285

 10.3.3 Data Transfers 286

 10.3.4 Common Data Definitions 286

10.4 Host Controller Driver 287

10.5 Universal Serial Bus Driver 287

 10.5.1 USB D Overview 288

 10.5.2 USB D Command Mechanism Requirements 289

 10.5.3 USB D Pipe Mechanisms 291

 10.5.4 Managing the USB via the USB D Mechanisms 293

 10.5.5 Passing USB Preboot Control to the Operating System 295

10.6 Operating System Environment Guides 296

CHAPTER 11 HUB SPECIFICATION

11.1 Overview 297

 11.1.1 Hub Architecture 297

 11.1.2 Hub Connectivity 298

11.2 Hub Frame/Microframe Timer 300

 11.2.1 High-speed Microframe Timer Range 300

 11.2.2 Full-speed Frame Timer Range 301

 11.2.3 Frame/Microframe Timer Synchronization 301

 11.2.4 Microframe Jitter Related to Frame Jitter 303

 11.2.5 EOF1 and EOF2 Timing Points 303

11.3	Host Behavior at End-of-Frame	306
11.3.1	Full-/low-speed Latest Host Packet.....	306
11.3.2	Full-/low-speed Packet Nullification.....	306
11.3.3	Full-/low-speed Transaction Completion Prediction.....	306
11.4	Internal Port	307
11.4.1	Inactive.....	308
11.4.2	Suspend Delay.....	308
11.4.3	Full Suspend (Fsus).....	308
11.4.4	Generate Resume (GResume)	308
11.5	Downstream Facing Ports	309
11.5.1	Downstream Facing Port State Descriptions	312
11.5.2	Disconnect Detect Timer.....	315
11.5.3	Port Indicator.....	316
11.6	Upstream Facing Port	318
11.6.1	Full-speed.....	318
11.6.2	High-speed	318
11.6.3	Receiver.....	318
11.6.4	Transmitter	322
11.7	Hub Repeater	324
11.7.1	High-speed Packet Connectivity	324
11.7.2	Hub Repeater State Machine.....	327
11.7.3	Wait for Start of Packet from Upstream Port (WFSOPFU)	329
11.7.4	Wait for End of Packet from Upstream Port (WFEOPFU).....	330
11.7.5	Wait for Start of Packet (WFSOP).....	330
11.7.6	Wait for End of Packet (WFEOP).....	330
11.8	Bus State Evaluation	330
11.8.1	Port Error.....	330
11.8.2	Speed Detection.....	331
11.8.3	Collision	331
11.8.4	Low-speed Port Behavior.....	331
11.9	Suspend and Resume	332
11.10	Hub Reset Behavior	334
11.11	Hub Port Power Control	335
11.11.1	Multiple Gangs.....	335
11.12	Hub Controller	336
11.12.1	Endpoint Organization	336
11.12.2	Hub Information Architecture and Operation	337
11.12.3	Port Change Information Processing.....	337
11.12.4	Hub and Port Status Change Bitmap	338
11.12.5	Over-current Reporting and Recovery	339
11.12.6	Enumeration Handling	340
11.13	Hub Configuration	340

11.14 Transaction Translator	342
11.14.1 Overview	342
11.14.2 Transaction Translator Scheduling.....	344
11.15 Split Transaction Notation Information	346
11.16 Common Split Transaction State Machines	349
11.16.1 Host Controller State Machine	350
11.16.2 Transaction Translator State Machine	354
11.17 Bulk/Control Transaction Translation Overview.....	360
11.17.1 Bulk/Control Split Transaction Sequences	360
11.17.2 Bulk/Control Split Transaction State Machines	366
11.17.3 Bulk/Control Sequencing	371
11.17.4 Bulk/Control Buffering Requirements	372
11.17.5 Other Bulk/Control Details.....	372
11.18 Periodic Split Transaction Pipelining and Buffer Management.....	372
11.18.1 Best Case Full-Speed Budget	373
11.18.2 TT Microframe Pipeline	373
11.18.3 Generation of Full-speed Frames	374
11.18.4 Host Split Transaction Scheduling Requirements	374
11.18.5 TT Response Generation	378
11.18.6 TT Periodic Transaction Handling Requirements	379
11.18.7 TT Transaction Tracking	380
11.18.8 TT Complete-split Transaction State Searching.....	381
11.19 Approximate TT Buffer Space Required	382
11.20 Interrupt Transaction Translation Overview	382
11.20.1 Interrupt Split Transaction Sequences	383
11.20.2 Interrupt Split Transaction State Machines	386
11.20.3 Interrupt OUT Sequencing	392
11.20.4 Interrupt IN Sequencing	393
11.21 Isochronous Transaction Translation Overview	394
11.21.1 Isochronous Split Transaction Sequences	395
11.21.2 Isochronous Split Transaction State Machines.....	398
11.21.3 Isochronous OUT Sequencing.....	403
11.21.4 Isochronous IN Sequencing.....	404
11.22 TT Error Handling.....	404
11.22.1 Loss of TT Synchronization With HS SOFs	404
11.22.2 TT Frame and Microframe Timer Synchronization Requirements	405
11.23 Descriptors	407
11.23.1 Standard Descriptors for Hub Class	407
11.23.2 Class-specific Descriptors	417
11.24 Requests.....	419
11.24.1 Standard Requests	419
11.24.2 Class-specific Requests	420

APPENDIX A TRANSACTION EXAMPLES

A.1 Bulk/Control OUT and SETUP Transaction Examples.....439
A.2 Bulk/Control IN Transaction Examples464
A.3 Interrupt OUT Transaction Examples489
A.4 Interrupt IN Transaction Examples509
A.5 Isochronous OUT SpAppendix A Transaction Examples

APPENDIX B EXAMPLE DECLARATIONS FOR STATE MACHINES

B.1 Global Declarations555
B.2 Host Controller Declarations.....558
B.3 Transaction Translator Declarations.....560

APPENDIX C RESET PROTOCOL STATE DIAGRAMS

C.1 Downstream Facing Port State Diagram.....565
C.2 Upstream Facing Port State Diagram.....567
 C.2.1 Reset From Suspended State567
 C.2.2 Reset From Full-speed Non-suspended State570
 C.2.3 Reset From High-speed Non-suspended State570
 C.2.4 Reset Handshake570

Chapter 1

Introduction

1.1 Motivation

The original motivation for the Universal Serial Bus (USB) came from three interrelated considerations:

- **Connection of the PC to the telephone**
It is well understood that the merge of computing and communication will be the basis for the next generation of productivity applications. The movement of machine-oriented and human-oriented data types from one location or environment to another depends on ubiquitous and cheap connectivity. Unfortunately, the computing and communication industries have evolved independently. The USB provides a ubiquitous link that can be used across a wide range of PC-to-telephone interconnects.
- **Ease-of-use**
The lack of flexibility in reconfiguring the PC has been acknowledged as the Achilles' heel to its further deployment. The combination of user-friendly graphical interfaces and the hardware and software mechanisms associated with new-generation bus architectures have made computers less confrontational and easier to reconfigure. However, from the end user's point of view, the PC's I/O interfaces, such as serial/parallel ports, keyboard/mouse/joystick interfaces, etc., do not have the attributes of plug-and-play.
- **Port expansion**
The addition of external peripherals continues to be constrained by port availability. The lack of a bi-directional, low-cost, low-to-mid speed peripheral bus has held back the creative proliferation of peripherals such as telephone/fax/modem adapters, answering machines, scanners, PDA's, keyboards, mice, etc. Existing interconnects are optimized for one or two point products. As each new function or capability is added to the PC, a new interface has been defined to address this need.

The more recent motivation for USB 2.0 stems from the fact that PCs have increasingly higher performance and are capable of processing vast amounts of data. At the same time, PC peripherals have added more performance and functionality. User applications such as digital imaging demand a high performance connection between the PC and these increasingly sophisticated peripherals. USB 2.0 addresses this need by adding a third transfer rate of 480 Mb/s to the 12 Mb/s and 1.5 Mb/s originally defined for USB. USB 2.0 is a natural evolution of USB, delivering the desired bandwidth increase while preserving the original motivations for USB and maintaining full compatibility with existing peripherals.

Thus, USB continues to be the answer to connectivity for the PC architecture. It is a fast, bi-directional, isochronous, low-cost, dynamically attachable serial interface that is consistent with the requirements of the PC platform of today and tomorrow.

1.2 Objective of the Specification

This document defines an industry-standard USB. The specification describes the bus attributes, the protocol definition, types of transactions, bus management, and the programming interface required to design and build systems and peripherals that are compliant with this standard.

The goal is to enable such devices from different vendors to interoperate in an open architecture. The specification is intended as an enhancement to the PC architecture, spanning portable, business desktop, and home environments. It is intended that the specification allow system OEMs and peripheral developers adequate room for product versatility and market differentiation without the burden of carrying obsolete interfaces or losing compatibility.

1.3 Scope of the Document

The specification is primarily targeted to peripheral developers and system OEMs, but provides valuable information for platform operating system/ BIOS/ device driver, adapter IHVs/ISVs, and platform/adaptor controller vendors. This specification can be used for developing new products and associated software.

1.4 USB Product Compliance

Adopters of the USB 2.0 specification have signed the USB 2.0 Adopters Agreement, which provides them access to a reciprocal royalty-free license from the Promoters and other Adopters to certain intellectual property contained in products that are compliant with the USB 2.0 specification. Adopters can demonstrate compliance with the specification through the testing program as defined by the USB Implementers Forum. Products that demonstrate compliance with the specification will be granted certain rights to use the USB Implementers Forum logo as defined in the logo license.

1.5 Document Organization

Chapters 1 through 5 provide an overview for all readers, while Chapters 6 through 11 contain detailed technical information defining the USB.

- Peripheral implementers should particularly read Chapters 5 through 11.
- USB Host Controller implementers should particularly read Chapters 5 through 8, 10, and 11.
- USB device driver implementers should particularly read Chapters 5, 9, and 10.

This document is complemented and referenced by the *Universal Serial Bus Device Class Specifications*. Device class specifications exist for a wide variety of devices. Please contact the USB Implementers Forum for further details.

Readers are also requested to contact operating system vendors for operating system bindings specific to the USB.

Chapter 2

Terms and Abbreviations

This chapter lists and defines terms and abbreviations used throughout this specification.

ACK	Handshake packet indicating a positive acknowledgment.
Active Device	A device that is powered and is not in the Suspend state.
Asynchronous Data	Data transferred at irregular intervals with relaxed latency requirements.
Asynchronous RA	The incoming data rate, F_{s_i} , and the outgoing data rate, F_{s_o} , of the RA process are independent (i.e., there is no shared master clock). See also rate adaptation.
Asynchronous SRC	The incoming sample rate, F_{s_i} , and outgoing sample rate, F_{s_o} , of the SRC process are independent (i.e., there is no shared master clock). See also sample rate conversion.
Audio Device	A device that sources or sinks sampled analog data.
AWG#	The measurement of a wire's cross section, as defined by the American Wire Gauge standard.
Babble	Unexpected bus activity that persists beyond a specified point in a (micro)frame.
Bandwidth	The amount of data transmitted per unit of time, typically bits per second (b/s) or bytes per second (B/s).
Big Endian	A method of storing data that places the most significant byte of multiple-byte values at a lower storage address. For example, a 16-bit integer stored in big endian format places the least significant byte at the higher address and the most significant byte at the lower address. See also little endian.
Bit	A unit of information used by digital computers. Represents the smallest piece of addressable memory within a computer. A bit expresses the choice between two possibilities and is typically represented by a logical one (1) or zero (0).
Bit Stuffing	Insertion of a "0" bit into a data stream to cause an electrical transition on the data wires, allowing a PLL to remain locked.
b/s	Transmission rate expressed in bits per second.
B/s	Transmission rate expressed in bytes per second.
Buffer	Storage used to compensate for a difference in data rates or time of occurrence of events, when transmitting data from one device to another.
Bulk Transfer	One of the four USB transfer types. Bulk transfers are non-periodic, large bursty communication typically used for a transfer that can use any available bandwidth and can also be delayed until bandwidth is available. See also transfer type.
Bus Enumeration	Detecting and identifying USB devices.

Universal Serial Bus Specification Revision 2.0

Byte	A data element that is eight bits in size.
Capabilities	Those attributes of a USB device that are administrated by the host.
Characteristics	Those qualities of a USB device that are unchangeable; for example, the device class is a device characteristic.
Client	Software resident on the host that interacts with the USB System Software to arrange data transfer between a function and the host. The client is often the data provider and consumer for transferred data.
Configuring Software	Software resident on the host software that is responsible for configuring a USB device. This may be a system configurator or software specific to the device.
Control Endpoint	A pair of device endpoints with the same endpoint number that are used by a control pipe. Control endpoints transfer data in both directions and, therefore, use both endpoint directions of a device address and endpoint number combination. Thus, each control endpoint consumes two endpoint addresses.
Control Pipe	Same as a message pipe.
Control Transfer	One of the four USB transfer types. Control transfers support configuration/command/status type communications between client and function. See also transfer type.
CRC	See Cyclic Redundancy Check.
CTI	Computer Telephony Integration.
Cyclic Redundancy Check (CRC)	A check performed on data to see if an error has occurred in transmitting, reading, or writing the data. The result of a CRC is typically stored or transmitted with the checked data. The stored or transmitted result is compared to a CRC calculated for the data to determine if an error has occurred.
Default Address	An address defined by the USB Specification and used by a USB device when it is first powered or reset. The default address is 00H.
Default Pipe	The message pipe created by the USB System Software to pass control and status information between the host and a USB device's endpoint zero.
Device	<p>A logical or physical entity that performs a function. The actual entity described depends on the context of the reference. At the lowest level, device may refer to a single hardware component, as in a memory device. At a higher level, it may refer to a collection of hardware components that perform a particular function, such as a USB interface device. At an even higher level, device may refer to the function performed by an entity attached to the USB; for example, a data/FAX modem device. Devices may be physical, electrical, addressable, and logical.</p> <p>When used as a non-specific reference, a USB device is either a hub or a function.</p>
Device Address	A seven-bit value representing the address of a device on the USB. The device address is the default address (00H) when the USB device is first powered or the device is reset. Devices are assigned a unique device address by the USB System Software.

Universal Serial Bus Specification Revision 2.0

Device Endpoint	A uniquely addressable portion of a USB device that is the source or sink of information in a communication flow between the host and device. See also endpoint address.
Device Resources	Resources provided by USB devices, such as buffer space and endpoints. See also Host Resources and Universal Serial Bus Resources.
Device Software	Software that is responsible for using a USB device. This software may or may not also be responsible for configuring the device for use.
Downstream	The direction of data flow from the host or away from the host. A downstream port is the port on a hub electrically farthest from the host that generates downstream data traffic from the hub. Downstream ports receive upstream data traffic.
Driver	When referring to hardware, an I/O pad that drives an external load. When referring to software, a program responsible for interfacing to a hardware device, that is, a device driver.
DWORD	Double word. A data element that is two words (i.e., four bytes or 32 bits) in size.
Dynamic Insertion and Removal	The ability to attach and remove devices while the host is in operation.
E²PROM	See Electrically Erasable Programmable Read Only Memory.
EEPROM	See Electrically Erasable Programmable Read Only Memory.
Electrically Erasable Programmable Read Only Memory (EEPROM)	Non-volatile rewritable memory storage technology.
End User	The user of a host.
Endpoint	See device endpoint.
Endpoint Address	The combination of an endpoint number and an endpoint direction on a USB device. Each endpoint address supports data transfer in one direction.
Endpoint Direction	The direction of data transfer on the USB. The direction can be either IN or OUT. IN refers to transfers to the host; OUT refers to transfers from the host.
Endpoint Number	A four-bit value between 0H and FH, inclusive, associated with an endpoint on a USB device.
Envelope detector	An electronic circuit inside a USB device that monitors the USB data lines and detects certain voltage related signal characteristics.
EOF	End-of-(micro)Frame.
EOP	End-of-Packet.
External Port	See port.
Eye pattern	A representation of USB signaling that provides minimum and maximum voltage levels as well as signal jitter.
False EOP	A spurious, usually noise-induced event that is interpreted by a packet receiver as an EOP.

Universal Serial Bus Specification Revision 2.0

Frame	A 1 millisecond time base established on full-/low-speed buses.
Frame Pattern	A sequence of frames that exhibit a repeating pattern in the number of samples transmitted per frame. For a 44.1 kHz audio transfer, the frame pattern could be nine frames containing 44 samples followed by one frame containing 45 samples.
F_s	See sample rate.
Full-duplex	Computer data transmission occurring in both directions simultaneously.
Full-speed	USB operation at 12 Mb/s. See also low-speed and high-speed.
Function	A USB device that provides a capability to the host, such as an ISDN connection, a digital microphone, or speakers.
Handshake Packet	A packet that acknowledges or rejects a specific condition. For examples, see ACK and NAK.
High-bandwidth endpoint	A high-speed device endpoint that transfers more than 1024 bytes and less than 3073 bytes per microframe.
High-speed	USB operation at 480 Mb/s. See also low-speed and full-speed.
Host	The host computer system where the USB Host Controller is installed. This includes the host hardware platform (CPU, bus, etc.) and the operating system in use.
Host Controller	The host's USB interface.
Host Controller Driver (HCD)	The USB software layer that abstracts the Host Controller hardware. The Host Controller Driver provides an SPI for interaction with a Host Controller. The Host Controller Driver hides the specifics of the Host Controller hardware implementation.
Host Resources	Resources provided by the host, such as buffer space and interrupts. See also Device Resources and Universal Serial Bus Resources.
Hub	A USB device that provides additional connections to the USB.
Hub Tier	One plus the number of USB links in a communication path between the host and a function. See Figure 4-1.
Interrupt Request (IRQ)	A hardware signal that allows a device to request attention from a host. The host typically invokes an interrupt service routine to handle the condition that caused the request.
Interrupt Transfer	One of the four USB transfer types. Interrupt transfer characteristics are small data, non-periodic, low-frequency, and bounded-latency. Interrupt transfers are typically used to handle service needs. See also transfer type.
I/O Request Packet	An identifiable request by a software client to move data between itself (on the host) and an endpoint of a device in an appropriate direction.
IRP	See I/O Request Packet.
IRQ	See Interrupt Request.
Isochronous Data	A stream of data whose timing is implied by its delivery rate.
Isochronous Device	An entity with isochronous endpoints, as defined in the USB Specification, that sources or sinks sampled analog streams or synchronous data streams.

Universal Serial Bus Specification Revision 2.0

Isochronous Sink Endpoint	An endpoint that is capable of consuming an isochronous data stream that is sent by the host.
Isochronous Source Endpoint	An endpoint that is capable of producing an isochronous data stream and sending it to the host.
Isochronous Transfer	One of the four USB transfer types. Isochronous transfers are used when working with isochronous data. Isochronous transfers provide periodic, continuous communication between host and device. See also transfer type.
Jitter	A tendency toward lack of synchronization caused by mechanical or electrical changes. More specifically, the phase shift of digital pulses over a transmission medium.
kb/s	Transmission rate expressed in kilobits per second.
kB/s	Transmission rate expressed in kilobytes per second.
Little Endian	Method of storing data that places the least significant byte of multiple-byte values at lower storage addresses. For example, a 16-bit integer stored in little endian format places the least significant byte at the lower address and the most significant byte at the next address. See also big endian.
LOA	Loss of bus activity characterized by an SOP without a corresponding EOP.
Low-speed	USB operation at 1.5 Mb/s. See also full-speed and high-speed.
LSb	Least significant bit.
LSB	Least significant byte.
Mb/s	Transmission rate expressed in megabits per second.
MB/s	Transmission rate expressed in megabytes per second.
Message Pipe	A bi-directional pipe that transfers data using a request/data/status paradigm. The data has an imposed structure that allows requests to be reliably identified and communicated.
Microframe	A 125 microsecond time base established on high-speed buses.
MSb	Most significant bit.
MSB	Most significant byte.
NAK	Handshake packet indicating a negative acknowledgment.
Non Return to Zero Invert (NRZI)	A method of encoding serial data in which ones and zeroes are represented by opposite and alternating high and low voltages where there is no return to zero (reference) voltage between encoded bits. Eliminates the need for clock pulses.
NRZI	See Non Return to Zero Invert.
Object	Host software or data structure representing a USB entity.
Packet	A bundle of data organized in a group for transmission. Packets typically contain three elements: control information (e.g., source, destination, and length), the data to be transferred, and error detection and correction bits.
Packet Buffer	The logical buffer used by a USB device for sending or receiving a single packet. This determines the maximum packet size the device can send or receive.

Universal Serial Bus Specification Revision 2.0

Packet ID (PID)	A field in a USB packet that indicates the type of packet, and by inference, the format of the packet and the type of error detection applied to the packet.
Phase	A token, data, or handshake packet. A transaction has three phases.
Phase Locked Loop (PLL)	A circuit that acts as a phase detector to keep an oscillator in phase with an incoming frequency.
Physical Device	A device that has a physical implementation; e.g., speakers, microphones, and CD players.
PID	See Packet ID.
Pipe	A logical abstraction representing the association between an endpoint on a device and software on the host. A pipe has several attributes; for example, a pipe may transfer data as streams (stream pipe) or messages (message pipe). See also stream pipe and message pipe.
PLL	See Phase Locked Loop.
Polling	Asking multiple devices, one at a time, if they have any data to transmit.
POR	See Power On Reset.
Port	Point of access to or from a system or circuit. For the USB, the point where a USB device is attached.
Power On Reset (POR)	Restoring a storage device, register, or memory to a predetermined state when power is applied.
Programmable Data Rate	Either a fixed data rate (single-frequency endpoints), a limited number of data rates (32 kHz, 44.1 kHz, 48 kHz, ...), or a continuously programmable data rate. The exact programming capabilities of an endpoint must be reported in the appropriate class-specific endpoint descriptors.
Protocol	A specific set of rules, procedures, or conventions relating to format and timing of data transmission between two devices.
RA	See rate adaptation.
Rate Adaptation	The process by which an incoming data stream, sampled at F_{s_i} , is converted to an outgoing data stream, sampled at F_{s_o} , with a certain loss of quality, determined by the rate adaptation algorithm. Error control mechanisms are required for the process. F_{s_i} and F_{s_o} can be different and asynchronous. F_{s_i} is the input data rate of the RA; F_{s_o} is the output data rate of the RA.
Request	A request made to a USB device contained within the data portion of a SETUP packet.
Retire	The action of completing service for a transfer and notifying the appropriate software client of the completion.
Root Hub	A USB hub directly attached to the Host Controller. This hub (tier 1) is attached to the host.
Root Port	The downstream port on a Root Hub.
Sample	The smallest unit of data on which an endpoint operates; a property of an endpoint.
Sample Rate (Fs)	The number of samples per second, expressed in Hertz (Hz).

Universal Serial Bus Specification Revision 2.0

Sample Rate Conversion (SRC)	A dedicated implementation of the RA process for use on sampled analog data streams. The error control mechanism is replaced by interpolating techniques.
Service	A procedure provided by a System Programming Interface (SPI).
Service Interval	The period between consecutive requests to a USB endpoint to send or receive data.
Service Jitter	The deviation of service delivery from its scheduled delivery time.
Service Rate	The number of services to a given endpoint per unit time.
SOF	See Start-of-Frame.
SOP	Start-of-Packet.
SPI	See System Programming Interface.
Split transaction	A transaction type supported by host controllers and hubs. This transaction type allows full- and low-speed devices to be attached to hubs operating at high-speed.
SRC	See Sample Rate Conversion.
Stage	One part of the sequence composing a control transfer; stages include the Setup stage, the Data stage, and the Status stage.
Start-of-Frame (SOF)	The first transaction in each (micro)frame. An SOF allows endpoints to identify the start of the (micro)frame and synchronize internal endpoint clocks to the host.
Stream Pipe	A pipe that transfers data as a stream of samples with no defined USB structure.
Synchronization Type	A classification that characterizes an isochronous endpoint's capability to connect to other isochronous endpoints.
Synchronous RA	The incoming data rate, F_{s_i} , and the outgoing data rate, F_{s_o} , of the RA process are derived from the same master clock. There is a fixed relation between F_{s_i} and F_{s_o} .
Synchronous SRC	The incoming sample rate, F_{s_i} , and outgoing sample rate, F_{s_o} , of the SRC process are derived from the same master clock. There is a fixed relation between F_{s_i} and F_{s_o} .
System Programming Interface (SPI)	A defined interface to services provided by system software.
TDM	See Time Division Multiplexing.
TDR	See Time Domain Reflectometer.
Termination	Passive components attached at the end of cables to prevent signals from being reflected or echoed.
Time Division Multiplexing (TDM)	A method of transmitting multiple signals (data, voice, and/or video) simultaneously over one communications medium by interleaving a piece of each signal one after another.
Time Domain Reflectometer (TDR)	An instrument capable of measuring impedance characteristics of the USB signal lines.

Universal Serial Bus Specification Revision 2.0

Timeout	The detection of a lack of bus activity for some predetermined interval.
Token Packet	A type of packet that identifies what transaction is to be performed on the bus.
Transaction	The delivery of service to an endpoint; consists of a token packet, optional data packet, and optional handshake packet. Specific packets are allowed/required based on the transaction type.
Transaction translator	A functional component of a USB hub. The Transaction Translator responds to special high-speed transactions and translates them to full/low-speed transactions with full/low-speed devices attached on downstream facing ports.
Transfer	One or more bus transactions to move information between a software client and its function.
Transfer Type	Determines the characteristics of the data flow between a software client and its function. Four standard transfer types are defined: control, interrupt, bulk, and isochronous.
Turn-around Time	The time a device needs to wait to begin transmitting a packet after a packet has been received to prevent collisions on the USB. This time is based on the length and propagation delay characteristics of the cable and the location of the transmitting device in relation to other devices on the USB.
Universal Serial Bus Driver (USBD)	The host resident software entity responsible for providing common services to clients that are manipulating one or more functions on one or more Host Controllers.
Universal Serial Bus Resources	Resources provided by the USB, such as bandwidth and power. See also Device Resources and Host Resources.
Upstream	The direction of data flow towards the host. An upstream port is the port on a device electrically closest to the host that generates upstream data traffic from the hub. Upstream ports receive downstream data traffic.
USBD	See Universal Serial Bus Driver.
USB-IF	USB Implementers Forum, Inc. is a nonprofit corporation formed to facilitate the development of USB compliant products and promote the technology.
Virtual Device	A device that is represented by a software interface layer. An example of a virtual device is a hard disk with its associated device driver and client software that makes it able to reproduce an audio .WAV file.
Word	A data element that is two bytes (16 bits) in size.

Chapter 3

Background

This chapter presents a brief description of the background of the Universal Serial Bus (USB), including design goals, features of the bus, and existing technologies.

3.1 Goals for the Universal Serial Bus

The USB is specified to be an industry-standard extension to the PC architecture with a focus on PC peripherals that enable consumer and business applications. The following criteria were applied in defining the architecture for the USB:

- Ease-of-use for PC peripheral expansion
- Low-cost solution that supports transfer rates up to 480 Mb/s
- Full support for real-time data for voice, audio, and video
- Protocol flexibility for mixed-mode isochronous data transfers and asynchronous messaging
- Integration in commodity device technology
- Comprehension of various PC configurations and form factors
- Provision of a standard interface capable of quick diffusion into product
- Enabling new classes of devices that augment the PC's capability
- Full backward compatibility of USB 2.0 for devices built to previous versions of the specification

3.2 Taxonomy of Application Space

Figure 3-1 describes a taxonomy for the range of data traffic workloads that can be serviced over a USB. As can be seen, a 480 Mb/s bus comprehends the high-speed, full-speed, and low-speed data ranges. Typically, high-speed and full-speed data types may be isochronous, while low-speed data comes from interactive devices. The USB is primarily a PC bus but can be readily applied to other host-centric computing devices. The software architecture allows for future extension of the USB by providing support for multiple USB Host Controllers.

<u>PERFORMANCE</u>	<u>APPLICATIONS</u>	<u>ATTRIBUTES</u>
LOW-SPEED <ul style="list-style-type: none"> • Interactive Devices • 10 – 100 kb/s 	Keyboard, Mouse Stylus Game Peripherals Virtual Reality Peripherals	Lowest Cost Ease-of-Use Dynamic Attach-Detach Multiple Peripherals
FULL-SPEED <ul style="list-style-type: none"> • Phone, Audio, Compressed Video • 500 kb/s – 10 Mb/s 	POTS Broadband Audio Microphone	Lower Cost Ease-of-Use Dynamic Attach-Detach Multiple Peripherals Guaranteed Bandwidth Guaranteed Latency
HIGH-SPEED <ul style="list-style-type: none"> • Video, Storage • 25 – 400 Mb/s 	Video Storage Imaging Broadband	Low Cost Ease-of-Use Dynamic Attach-Detach Multiple Peripherals Guaranteed Bandwidth Guaranteed Latency High Bandwidth

Figure 3-1. Application Space Taxonomy

3.3 Feature List

The USB Specification provides a selection of attributes that can achieve multiple price/performance integration points and can enable functions that allow differentiation at the system and component level. Features are categorized by the following benefits:

Easy to use for end user

- Single model for cabling and connectors
- Electrical details isolated from end user (e.g., bus terminations)
- Self-identifying peripherals, automatic mapping of function to driver and configuration
- Dynamically attachable and reconfigurable peripherals

Wide range of workloads and applications

- Suitable for device bandwidths ranging from a few kb/s to several hundred Mb/s
- Supports isochronous as well as asynchronous transfer types over the same set of wires
- Supports concurrent operation of many devices (multiple connections)
- Supports up to 127 physical devices
- Supports transfer of multiple data and message streams between the host and devices
- Allows compound devices (i.e., peripherals composed of many functions)
- Lower protocol overhead, resulting in high bus utilization

Isochronous bandwidth

- Guaranteed bandwidth and low latencies appropriate for telephony, audio, video, etc.

Flexibility

- Supports a wide range of packet sizes, which allows a range of device buffering options
- Allows a wide range of device data rates by accommodating packet buffer size and latencies
- Flow control for buffer handling is built into the protocol

Robustness

- Error handling/fault recovery mechanism is built into the protocol
- Dynamic insertion and removal of devices is identified in user-perceived real-time
- Supports identification of faulty devices

Synergy with PC industry

- Protocol is simple to implement and integrate
- Consistent with the PC plug-and-play architecture
- Leverages existing operating system interfaces

Low-cost implementation

- Low-cost subchannel at 1.5 Mb/s
- Optimized for integration in peripheral and host hardware
- Suitable for development of low-cost peripherals
- Low-cost cables and connectors
- Uses commodity technologies

Upgrade path

- Architecture upgradeable to support multiple USB Host Controllers in a system

Chapter 4

Architectural Overview

This chapter presents an overview of the Universal Serial Bus (USB) architecture and key concepts. The USB is a cable bus that supports data exchange between a host computer and a wide range of simultaneously accessible peripherals. The attached peripherals share USB bandwidth through a host-scheduled, token-based protocol. The bus allows peripherals to be attached, configured, used, and detached while the host and other peripherals are in operation.

Later chapters describe the various components of the USB in greater detail.

4.1 USB System Description

A USB system is described by three definitional areas:

- USB interconnect
- USB devices
- USB host

The USB interconnect is the manner in which USB devices are connected to and communicate with the host. This includes the following:

- **Bus Topology:** Connection model between USB devices and the host.
- **Inter-layer Relationships:** In terms of a capability stack, the USB tasks that are performed at each layer in the system.
- **Data Flow Models:** The manner in which data moves in the system over the USB between producers and consumers.
- **USB Schedule:** The USB provides a shared interconnect. Access to the interconnect is scheduled in order to support isochronous data transfers and to eliminate arbitration overhead.

USB devices and the USB host are described in detail in subsequent sections.

4.1.1 Bus Topology

The USB connects USB devices with the USB host. The USB physical interconnect is a tiered star topology. A hub is at the center of each star. Each wire segment is a point-to-point connection between the host and a hub or function, or a hub connected to another hub or function. Figure 4-1 illustrates the topology of the USB.

Due to timing constraints allowed for hub and cable propagation times, the maximum number of tiers allowed is seven (including the root tier). Note that in seven tiers, five non-root hubs maximum can be supported in a communication path between the host and any device. A compound device (see Figure 4-1) occupies two tiers; therefore, it cannot be enabled if attached at tier level seven. Only functions can be enabled in tier seven.

Figure 4-1. Bus Topology

4.1.1.1 USB Host

There is only one host in any USB system. The USB interface to the host computer system is referred to as the Host Controller. The Host Controller may be implemented in a combination of hardware, firmware, or software. A root hub is integrated within the host system to provide one or more attachment points.

Additional information concerning the host may be found in Section 4.9 and in Chapter 10.

4.1.1.2 USB Devices

USB devices are one of the following:

- Hubs, which provide additional attachment points to the USB
- Functions, which provide capabilities to the system, such as an ISDN connection, a digital joystick, or speakers

USB devices present a standard USB interface in terms of the following:

- Their comprehension of the USB protocol
- Their response to standard USB operations, such as configuration and reset
- Their standard capability descriptive information

Additional information concerning USB devices may be found in Section 4.8 and in Chapter 9.

4.2 Physical Interface

The physical interface of the USB is described in the electrical (Chapter 7) and mechanical (Chapter 6) specifications for the bus.

4.2.1 Electrical

The USB transfers signal and power over a four-wire cable, shown in Figure 4-2. The signaling occurs over two wires on each point-to-point segment.

There are three data rates:

- The USB high-speed signaling bit rate is 480 Mb/s.
- The USB full-speed signaling bit rate is 12 Mb/s.
- A limited capability low-speed signaling mode is also defined at 1.5 Mb/s.

USB 2.0 host controllers and hubs provide capabilities so that full-speed and low-speed data can be transmitted at high-speed between the host controller and the hub, but transmitted between the hub and the device at full-speed or low-speed. This capability minimizes the impact that full-speed and low-speed devices have upon the bandwidth available for high-speed devices.

The low-speed mode is defined to support a limited number of low-bandwidth devices, such as mice, because more general use would degrade bus utilization.

The clock is transmitted, encoded along with the differential data. The clock encoding scheme is NRZI with bit stuffing to ensure adequate transitions. A SYNC field precedes each packet to allow the receiver(s) to synchronize their bit recovery clocks.

Figure 4-2. USB Cable

The cable also carries VBUS and GND wires on each segment to deliver power to devices. VBUS is nominally +5 V at the source. The USB allows cable segments of variable lengths, up to several meters, by choosing the appropriate conductor gauge to match the specified IR drop and other attributes such as device power budget and cable flexibility. In order to provide guaranteed input voltage levels and proper termination impedance, biased terminations are used at each end of the cable. The terminations also permit the detection of attach and detach at each port and differentiate between high/full-speed and low-speed devices.

4.2.2 Mechanical

The mechanical specifications for cables and connectors are provided in Chapter 6. All devices have an upstream connection. Upstream and downstream connectors are not mechanically interchangeable, thus eliminating illegal loopback connections at hubs. The cable has four conductors: a twisted signal pair of standard gauge and a power pair in a range of permitted gauges. The connector is four-position, with shielded housing, specified robustness, and ease of attach-detach characteristics.

4.3 Power

The specification covers two aspects of power:

- Power distribution over the USB deals with the issues of how USB devices consume power provided by the host over the USB.
- Power management deals with how the USB System Software and devices fit into the host-based power management system.

4.3.1 Power Distribution

Each USB segment provides a limited amount of power over the cable. The host supplies power for use by USB devices that are directly connected. In addition, any USB device may have its own power supply. USB devices that rely totally on power from the cable are called bus-powered devices. In contrast, those that have an alternate source of power are called self-powered devices. A hub also supplies power for its connected USB devices. The architecture permits bus-powered hubs within certain constraints of topology that are discussed later in Chapter 11.

4.3.2 Power Management

A USB host may have a power management system that is independent of the USB. The USB System Software interacts with the host's power management system to handle system power events such as suspend or resume. Additionally, USB devices typically implement additional power management features that allow them to be power managed by system software.

The power distribution and power management features of the USB allow it to be designed into power-sensitive systems such as battery-based notebook computers.

4.4 Bus Protocol

The USB is a polled bus. The Host Controller initiates all data transfers.

Most bus transactions involve the transmission of up to three packets. Each transaction begins when the Host Controller, on a scheduled basis, sends a USB packet describing the type and direction of transaction, the USB device address, and endpoint number. This packet is referred to as the "token packet." The USB device that is addressed selects itself by decoding the appropriate address fields. In a given transaction, data is transferred either from the host to a device or from a device to the host. The direction of data transfer is specified in the token packet. The source of the transaction then sends a data packet or indicates it has no

data to transfer. The destination, in general, responds with a handshake packet indicating whether the transfer was successful.

Some bus transactions between host controllers and hubs involve the transmission of four packets. These types of transactions are used to manage the data transfers between the host and full-/low- speed devices.

The USB data transfer model between a source or destination on the host and an endpoint on a device is referred to as a pipe. There are two types of pipes: stream and message. Stream data has no USB-defined structure, while message data does. Additionally, pipes have associations of data bandwidth, transfer service type, and endpoint characteristics like directionality and buffer sizes. Most pipes come into existence when a USB device is configured. One message pipe, the Default Control Pipe, always exists once a device is powered, in order to provide access to the device's configuration, status, and control information.

The transaction schedule allows flow control for some stream pipes. At the hardware level, this prevents buffers from underrun or overrun situations by using a NAK handshake to throttle the data rate. When NAKed, a transaction is retried when bus time is available. The flow control mechanism permits the construction of flexible schedules that accommodate concurrent servicing of a heterogeneous mix of stream pipes. Thus, multiple stream pipes can be serviced at different intervals and with packets of different sizes.

4.5 Robustness

There are several attributes of the USB that contribute to its robustness:

- Signal integrity using differential drivers, receivers, and shielding
- CRC protection over control and data fields
- Detection of attach and detach and system-level configuration of resources
- Self-recovery in protocol, using timeouts for lost or corrupted packets
- Flow control for streaming data to ensure isochrony and hardware buffer management
- Data and control pipe constructs for ensuring independence from adverse interactions between functions

4.5.1 Error Detection

The core bit error rate of the USB medium is expected to be close to that of a backplane and any glitches will very likely be transient in nature. To provide protection against such transients, each packet includes error protection fields. When data integrity is required, such as with lossless data devices, an error recovery procedure may be invoked in hardware or software.

The protocol includes separate CRCs for control and data fields of each packet. A failed CRC is considered to indicate a corrupted packet. The CRC gives 100% coverage on single- and double-bit errors.

4.5.2 Error Handling

The protocol allows for error handling in hardware or software. Hardware error handling includes reporting and retry of failed transfers. A USB Host Controller will try a transmission that encounters errors up to three times before informing the client software of the failure. The client software can recover in an implementation-specific way.

4.6 System Configuration

The USB supports USB devices attaching to and detaching from the USB at any time. Consequently, system software must accommodate dynamic changes in the physical bus topology.

4.6.1 Attachment of USB Devices

All USB devices attach to the USB through ports on specialized USB devices known as hubs. Hubs have status bits that are used to report the attachment or removal of a USB device on one of its ports. The host queries the hub to retrieve these bits. In the case of an attachment, the host enables the port and addresses the USB device through the device's control pipe at the default address.

The host assigns a unique USB address to the device and then determines if the newly attached USB device is a hub or a function. The host establishes its end of the control pipe for the USB device using the assigned USB address and endpoint number zero.

If the attached USB device is a hub and USB devices are attached to its ports, then the above procedure is followed for each of the attached USB devices.

If the attached USB device is a function, then attachment notifications will be handled by host software that is appropriate for the function.

4.6.2 Removal of USB Devices

When a USB device has been removed from one of a hub's ports, the hub disables the port and provides an indication of device removal to the host. The removal indication is then handled by appropriate USB System Software. If the removed USB device is a hub, the USB System Software must handle the removal of both the hub and of all of the USB devices that were previously attached to the system through the hub.

4.6.3 Bus Enumeration

Bus enumeration is the activity that identifies and assigns unique addresses to devices attached to a bus. Because the USB allows USB devices to attach to or detach from the USB at any time, bus enumeration is an on-going activity for the USB System Software. Additionally, bus enumeration for the USB also includes the detection and processing of removals.

4.7 Data Flow Types

The USB supports functional data and control exchange between the USB host and a USB device as a set of either uni-directional or bi-directional pipes. USB data transfers take place between host software and a particular endpoint on a USB device. Such associations between the host software and a USB device endpoint are called pipes. In general, data movement through one pipe is independent from the data flow in any other pipe. A given USB device may have many pipes. As an example, a given USB device could have an endpoint that supports a pipe for transporting data to the USB device and another endpoint that supports a pipe for transporting data from the USB device.

The USB architecture comprehends four basic types of data transfers:

- Control Transfers: Used to configure a device at attach time and can be used for other device-specific purposes, including control of other pipes on the device.
- Bulk Data Transfers: Generated or consumed in relatively large and bursty quantities and have wide dynamic latitude in transmission constraints.
- Interrupt Data Transfers: Used for timely but reliable delivery of data, for example, characters or coordinates with human-perceptible echo or feedback response characteristics.
- Isochronous Data Transfers: Occupy a prenegotiated amount of USB bandwidth with a prenegotiated delivery latency. (Also called streaming real time transfers).

A pipe supports only one of the types of transfers described above for any given device configuration. The USB data flow model is described in more detail in Chapter 5.

4.7.1 Control Transfers

Control data is used by the USB System Software to configure devices when they are first attached. Other driver software can choose to use control transfers in implementation-specific ways. Data delivery is lossless.

4.7.2 Bulk Transfers

Bulk data typically consists of larger amounts of data, such as that used for printers or scanners. Bulk data is sequential. Reliable exchange of data is ensured at the hardware level by using error detection in hardware and invoking a limited number of retries in hardware. Also, the bandwidth taken up by bulk data can vary, depending on other bus activities.

4.7.3 Interrupt Transfers

A limited-latency transfer to or from a device is referred to as interrupt data. Such data may be presented for transfer by a device at any time and is delivered by the USB at a rate no slower than is specified by the device.

Interrupt data typically consists of event notification, characters, or coordinates that are organized as one or more bytes. An example of interrupt data is the coordinates from a pointing device. Although an explicit timing rate is not required, interactive data may have response time bounds that the USB must support.

4.7.4 Isochronous Transfers

Isochronous data is continuous and real-time in creation, delivery, and consumption. Timing-related information is implied by the steady rate at which isochronous data is received and transferred. Isochronous data must be delivered at the rate received to maintain its timing. In addition to delivery rate, isochronous data may also be sensitive to delivery delays. For isochronous pipes, the bandwidth required is typically based upon the sampling characteristics of the associated function. The latency required is related to the buffering available at each endpoint.

A typical example of isochronous data is voice. If the delivery rate of these data streams is not maintained, drop-outs in the data stream will occur due to buffer or frame underruns or overruns. Even if data is delivered at the appropriate rate by USB hardware, delivery delays introduced by software may degrade applications requiring real-time turn-around, such as telephony-based audio conferencing.

The timely delivery of isochronous data is ensured at the expense of potential transient losses in the data stream. In other words, any error in electrical transmission is not corrected by hardware mechanisms such as retries. In practice, the core bit error rate of the USB is expected to be small enough not to be an issue. USB isochronous data streams are allocated a dedicated portion of USB bandwidth to ensure that data can be delivered at the desired rate. The USB is also designed for minimal delay of isochronous data transfers.

4.7.5 Allocating USB Bandwidth

USB bandwidth is allocated among pipes. The USB allocates bandwidth for some pipes when a pipe is established. USB devices are required to provide some buffering of data. It is assumed that USB devices requiring more bandwidth are capable of providing larger buffers. The goal for the USB architecture is to ensure that buffering-induced hardware delay is bounded to within a few milliseconds.

The USB's bandwidth capacity can be allocated among many different data streams. This allows a wide range of devices to be attached to the USB. Further, different device bit rates, with a wide dynamic range, can be concurrently supported.

The USB Specification defines the rules for how each transfer type is allowed access to the bus.

4.8 USB Devices

USB devices are divided into device classes such as hub, human interface, printer, imaging, or mass storage device. The hub device class indicates a specially designated USB device that provides additional USB attachment points (refer to Chapter 11). USB devices are required to carry information for self-identification and generic configuration. They are also required at all times to display behavior consistent with defined USB device states.

4.8.1 Device Characterizations

All USB devices are accessed by a USB address that is assigned when the device is attached and enumerated. Each USB device additionally supports one or more pipes through which the host may communicate with the device. All USB devices must support a specially designated pipe at endpoint zero to which the USB device's USB control pipe will be attached. All USB devices support a common access mechanism for accessing information through this control pipe.

Associated with the control pipe at endpoint zero is the information required to completely describe the USB device. This information falls into the following categories:

- **Standard:** This is information whose definition is common to all USB devices and includes items such as vendor identification, device class, and power management capability. Device, configuration, interface, and endpoint descriptions carry configuration-related information about the device. Detailed information about these descriptors can be found in Chapter 9.
- **Class:** The definition of this information varies, depending on the device class of the USB device.
- **USB Vendor:** The vendor of the USB device is free to put any information desired here. The format, however, is not determined by this specification.

Additionally, each USB device carries USB control and status information.

4.8.2 Device Descriptions

Two major divisions of device classes exist: hubs and functions. Only hubs have the ability to provide additional USB attachment points. Functions provide additional capabilities to the host.

4.8.2.1 Hubs

Hubs are a key element in the plug-and-play architecture of the USB. Figure 4-3 shows a typical hub. Hubs serve to simplify USB connectivity from the user's perspective and provide robustness at relatively low cost and complexity.

Hubs are wiring concentrators and enable the multiple attachment characteristics of the USB. Attachment points are referred to as ports. Each hub converts a single attachment point into multiple attachment points. The architecture supports concatenation of multiple hubs.

The upstream port of a hub connects the hub towards the host. Each of the downstream ports of a hub allows connection to another hub or function. Hubs can detect attach and detach at each downstream port and enable the distribution of power to downstream devices. Each downstream port can be individually enabled and attached to either high-, full- or low-speed devices.

A USB 2.0 hub consists of three portions: the Hub Controller, the Hub Repeater, and the Transaction Translator. The Hub Repeater is a protocol-controlled switch between the upstream port and downstream ports. It also has hardware support for reset and suspend/resume signaling. The Host Controller provides the communication to/from the host. Hub-specific status and control commands permit the host to configure a hub and to monitor and control its ports. The Transaction Translator provides the mechanisms that support full-/low-speed devices behind the hub, while transmitting all device data between the host and the hub at high-speed.

Figure 4-3. A Typical Hub

Figure 4-4 illustrates how hubs provide connectivity in a typical desktop computer environment.

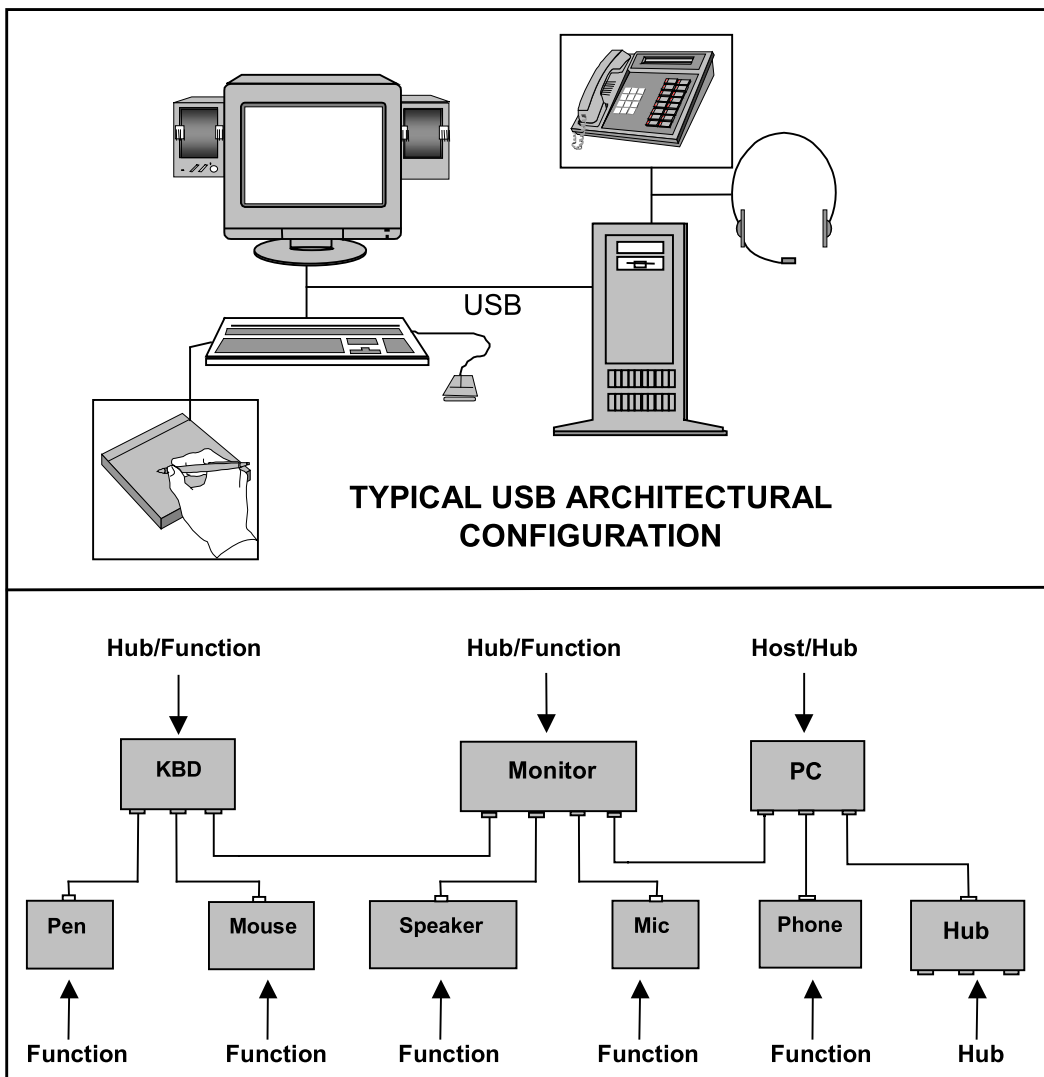

Figure 4-4. Hubs in a Desktop Computer Environment

4.8.2.2 Functions

A function is a USB device that is able to transmit or receive data or control information over the bus. A function is typically implemented as a separate peripheral device with a cable that plugs into a port on a hub. However, a physical package may implement multiple functions and an embedded hub with a single USB cable. This is known as a compound device. A compound device appears to the host as a hub with one or more non-removable USB devices.

Each function contains configuration information that describes its capabilities and resource requirements. Before a function can be used, it must be configured by the host. This configuration includes allocating USB bandwidth and selecting function-specific configuration options.

Examples of functions include the following:

- A human interface device such as a mouse, keyboard, tablet, or game controller
- An imaging device such as a scanner, printer, or camera
- A mass storage device such as a CD-ROM drive, floppy drive, or DVD drive

4.9 USB Host: Hardware and Software

The USB host interacts with USB devices through the Host Controller. The host is responsible for the following:

- Detecting the attachment and removal of USB devices
- Managing control flow between the host and USB devices
- Managing data flow between the host and USB devices
- Collecting status and activity statistics
- Providing power to attached USB devices

The USB System Software on the host manages interactions between USB devices and host-based device software. There are five areas of interactions between the USB System Software and device software:

- Device enumeration and configuration
- Isochronous data transfers
- Asynchronous data transfers
- Power management
- Device and bus management information

4.10 Architectural Extensions

The USB architecture comprehends extensibility at the interface between the Host Controller Driver and USB Driver. Implementations with multiple Host Controllers, and associated Host Controller Drivers, are possible.

Chapter 5

USB Data Flow Model

This chapter presents information about how data is moved across the USB. The information in this chapter affects all implementers. The information presented is at a level above the signaling and protocol definitions of the system. Consult Chapter 7 and Chapter 8 for more details about their respective parts of the USB system. This chapter provides framework information that is further expanded in Chapters 9 through 11. All implementers should read this chapter so they understand the key concepts of the USB.

5.1 Implementer Viewpoints

The USB provides communication services between a host and attached USB devices. However, the simple view an end user sees of attaching one or more USB devices to a host, as in Figure 5-1, is in fact a little more complicated to implement than is indicated by the figure. Different views of the system are required to explain specific USB requirements from the perspective of different implementers. Several important concepts and features must be supported to provide the end user with the reliable operation demanded from today's personal computers. The USB is presented in a layered fashion to ease explanation and allow implementers of particular USB products to focus on the details related to their product.

Figure 5-1. Simple USB Host/Device View

Figure 5-2 shows a deeper overview of the USB, identifying the different layers of the system that will be described in more detail in the remainder of the specification. In particular, there are four focus implementation areas:

- **USB Physical Device:** A piece of hardware on the end of a USB cable that performs some useful end user function.
- **Client Software:** Software that executes on the host, corresponding to a USB device. This client software is typically supplied with the operating system or provided along with the USB device.
- **USB System Software:** Software that supports the USB in a particular operating system. The USB System Software is typically supplied with the operating system, independently of particular USB devices or client software.
- **USB Host Controller (Host Side Bus Interface):** The hardware and software that allows USB devices to be attached to a host.

There are shared rights and responsibilities between the four USB system components. The remainder of this specification describes the details required to support robust, reliable communication flows between a function and its client.

Universal Serial Bus Specification Revision 2.0

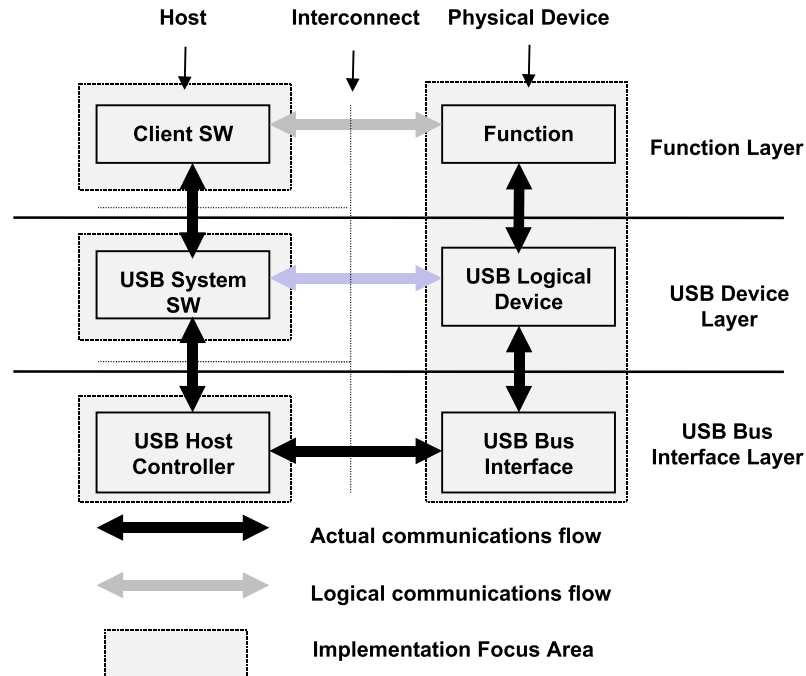

Figure 5-2. USB Implementation Areas

As shown in Figure 5-2, the simple connection of a host to a device requires interaction between a number of layers and entities. The USB Bus Interface layer provides physical/signaling/packet connectivity between the host and a device. The USB Device layer is the view the USB System Software has for performing generic USB operations with a device. The Function layer provides additional capabilities to the host via an appropriate matched client software layer. The USB Device and Function layers each have a view of logical communication within their layer that actually uses the USB Bus Interface layer to accomplish data transfer.

The physical view of USB communication as described in Chapters 6, 7, and 8 is related to the logical communication view presented in Chapters 9 and 10. This chapter describes those key concepts that affect USB implementers and should be read by all before proceeding to the remainder of the specification to find those details most relevant to their product.

To describe and manage USB communication, the following concepts are important:

- **Bus Topology:** Section 5.2 presents the primary physical and logical components of the USB and how they interrelate.
- **Communication Flow Models:** Sections 5.3 through 5.8 describe how communication flows between the host and devices through the USB and defines the four USB transfer types.
- **Bus Access Management:** Section 5.11 describes how bus access is managed within the host to support a broad range of communication flows by USB devices.
- **Special Consideration for Isochronous Transfers:** Section 5.12 presents features of the USB specific to devices requiring isochronous data transfers. Device implementers for non-isochronous devices do not need to read Section 5.12.

5.2 Bus Topology

There are four main parts to USB topology:

- Host and Devices: The primary components of a USB system
- Physical Topology: How USB elements are connected
- Logical Topology: The roles and responsibilities of the various USB elements and how the USB appears from the perspective of the host and a device
- Client Software-to-function Relationships: How client software and its related function interfaces on a USB device view each other

5.2.1 USB Host

The host's logical composition is shown in Figure 5-3 and includes the following:

- USB Host Controller
- Aggregate USB System Software (USB Driver, Host Controller Driver, and host software)
- Client

Figure 5-3. Host Composition

The USB host occupies a unique position as the coordinating entity for the USB. In addition to its special physical position, the host has specific responsibilities with regard to the USB and its attached devices. The host controls all access to the USB. A USB device gains access to the bus only by being granted access by the host. The host is also responsible for monitoring the topology of the USB.

For a complete discussion of the host and its duties, refer to Chapter 10.

5.2.2 USB Devices

A USB physical device's logical composition is shown in Figure 5-4 and includes the following:

- USB bus interface
- USB logical device
- Function

USB physical devices provide additional functionality to the host. The types of functionality provided by USB devices vary widely. However, all USB logical devices present the same basic interface to the host. This allows the host to manage the USB-relevant aspects of different USB devices in the same manner.

To assist the host in identifying and configuring USB devices, each device carries and reports configuration-related information. Some of the information reported is common among all logical devices. Other information is specific to the functionality provided by the device. The detailed format of this information varies, depending on the device class of the device.

For a complete discussion of USB devices, refer to Chapter 9.

Figure 5-4. Physical Device Composition

5.2.3 Physical Bus Topology

Devices on the USB are physically connected to the host via a tiered star topology, as illustrated in Figure 5-5. USB attachment points are provided by a special class of USB device known as a hub. The additional attachment points provided by a hub are called ports. A host includes an embedded hub called the root hub. The host provides one or more attachment points via the root hub. USB devices that provide additional functionality to the host are known as functions. To prevent circular attachments, a tiered ordering is imposed on the star topology of the USB. This results in the tree-like configuration illustrated in Figure 5-5.

Figure 5-5. USB Physical Bus Topology

Multiple functions may be packaged together in what appears to be a single physical device. For example, a keyboard and a trackball might be combined in a single package. Inside the package, the individual functions are permanently attached to a hub and it is the internal hub that is connected to the USB. When multiple functions are combined with a hub in a single package, they are referred to as a compound device. The hub and each function attached to the hub within the compound device is assigned its own device address. A device that has multiple interfaces controlled independently of each other is referred to as a composite device. A composite device has only a single device address. From the host's perspective, a compound device is the same as a separate hub with multiple functions attached. Figure 5-5 also illustrates a compound device.

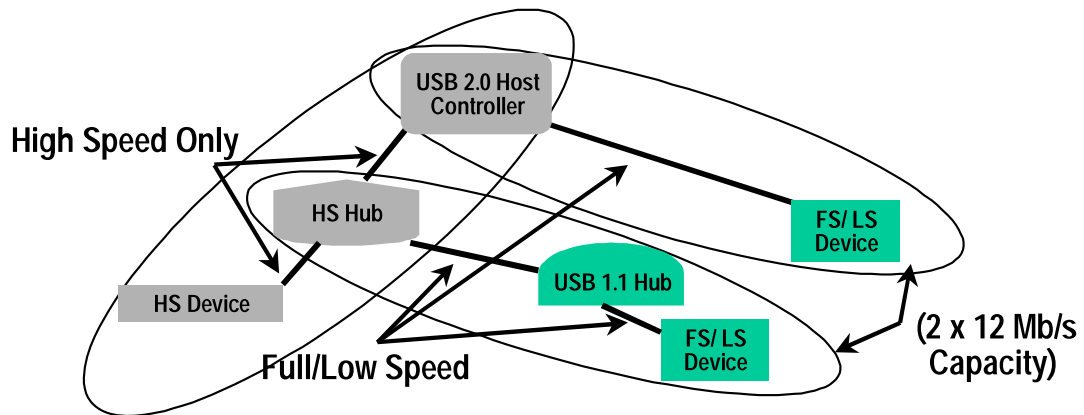

Figure 5-6. Multiple Full-speed Buses in a High-speed System

The hub plays a special role in a high-speed system. The hub isolates the full-/low-speed signaling environment from the high-speed signaling environment. Figure 5-6 shows a hub operating in high speed supporting a high-speed attached device. The hub also allows USB1.1 hubs to attach and operate at full-/low-speed along with other full-/low-speed only devices. The host controller also directly supports attaching full-/low-speed only devices. Chapter 11 describes the details of how the hub accomplishes the isolation of the two signaling environments.

Each high-speed operating hub essentially adds one (or more) additional full-/low-speed buses; i.e., each hub supports additional (optionally multiple) 12 Mb/s of USB full-/low-speed bandwidth. This allows more full-/low-speed buses to be attached without requiring additional host controllers in a system. Even though there can be several 12 Mb/s full-/low-speed buses, there are only at most 127 USB devices attached to any single host controller.

5.2.4 Logical Bus Topology

While devices physically attach to the USB in a tiered, star topology, the host communicates with each logical device as if it were directly connected to the root port. This creates the logical view illustrated in Figure 5-7 that corresponds to the physical topology shown in Figure 5-5. Hubs are logical devices also but are not shown in Figure 5-7 to simplify the picture. Even though most host/logical device activities use this logical perspective, the host maintains an awareness of the physical topology to support processing the removal of hubs. When a hub is removed, all of the devices attached to the hub must be removed from the host's view of the logical topology. A more complete discussion of hubs can be found in Chapter 11.

Figure 5-7. USB Logical Bus Topology

5.2.5 Client Software-to-function Relationship

Even though the physical and logical topology of the USB reflects the shared nature of the bus, client software (CSw) manipulating a USB function interface is presented with the view that it deals only with its interface(s) of interest. Client software for USB functions must use USB software programming interfaces to manipulate their functions as opposed to directly manipulating their functions via memory or I/O accesses as with other buses (e.g., PCI, EISA, PCMCIA, etc.). During operation, client software should be independent of other devices that may be connected to the USB. This allows the designer of the device and client software to focus on the hardware/software interaction design details. Figure 5-8 illustrates a device designer’s perspective of the relationships of client software and USB functions with respect to the USB logical topology of Figure 5-7.

Figure 5-8. Client Software-to-function Relationships

5.3 USB Communication Flow

The USB provides a communication service between software on the host and its USB function. Functions can have different communication flow requirements for different client-to-function interactions. The USB provides better overall bus utilization by allowing the separation of the different communication flows to a USB function. Each communication flow makes use of some bus access to accomplish communication between client and function. Each communication flow is terminated at an endpoint on a device. Device endpoints are used to identify aspects of each communication flow.

Figure 5-9 shows a more detailed view of Figure 5-2. The complete definition of the actual communication flows of Figure 5-2 supports the logical device and function layer communication flows. These actual communication flows cross several interface boundaries. Chapters 6 through 8 describe the mechanical, electrical, and protocol interface definitions of the USB “wire.” Chapter 9 describes the USB device programming interface that allows a USB device to be manipulated from the host side of the wire. Chapter 10 describes two host side software interfaces:

- Host Controller Driver (HCD): The software interface between the USB Host Controller and USB System Software. This interface allows a range of Host Controller implementations without requiring all host software to be dependent on any particular implementation. One USB Driver can support different Host Controllers without requiring specific knowledge of a Host Controller implementation. A Host Controller implementer provides an HCD implementation that supports the Host Controller.
- USB Driver (USBD): The interface between the USB System Software and the client software. This interface provides clients with convenient functions for manipulating USB devices.

Universal Serial Bus Specification Revision 2.0

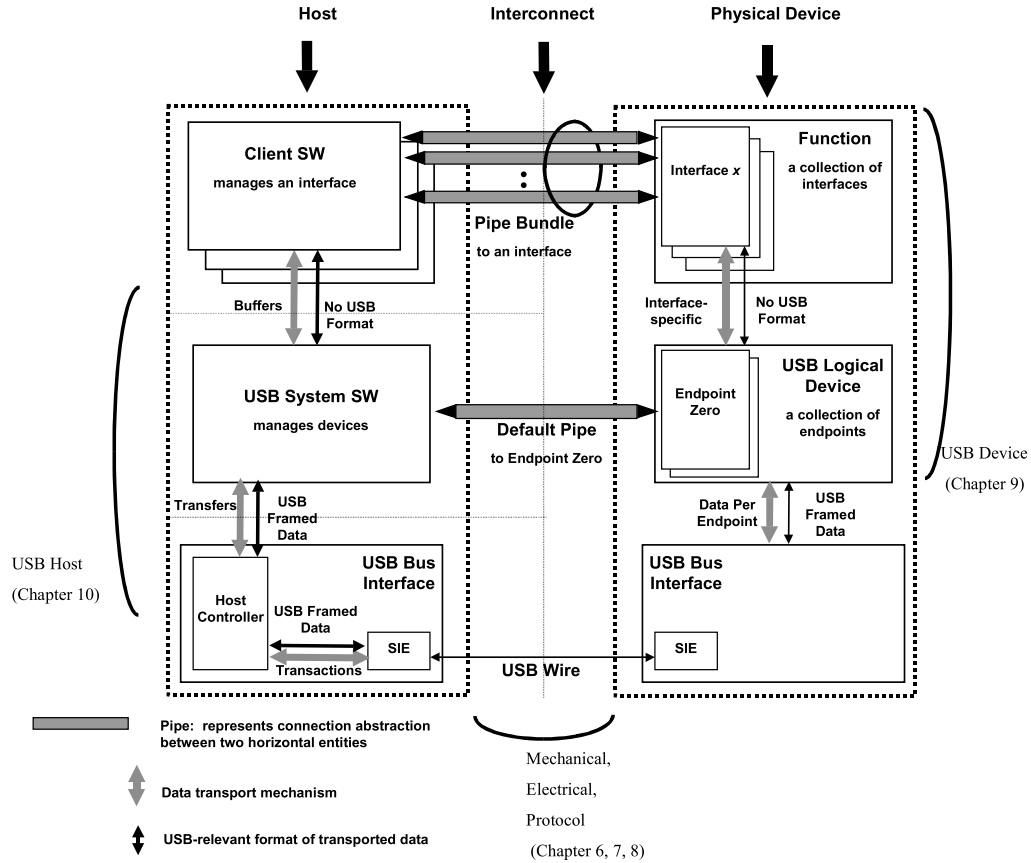

Figure 5-9. USB Host/Device Detailed View

A USB logical device appears to the USB system as a collection of endpoints. Endpoints are grouped into endpoint sets that implement an interface. Interfaces are views to the function. The USB System Software manages the device using the Default Control Pipe. Client software manages an interface using pipe bundles (associated with an endpoint set). Client software requests that data be moved across the USB between a buffer on the host and an endpoint on the USB device. The Host Controller (or USB device, depending on transfer direction) packetizes the data to move it over the USB. The Host Controller also coordinates when bus access is used to move the packet of data over the USB.

Figure 5-10 illustrates how communication flows are carried over pipes between endpoints and host side memory buffers. The following sections describe endpoints, pipes, and communication flows in more detail.

Figure 5-10. USB Communication Flow

Software on the host communicates with a logical device via a set of communication flows. The set of communication flows are selected by the device software/hardware designer(s) to efficiently match the communication requirements of the device to the transfer characteristics provided by the USB.

5.3.1 Device Endpoints

An endpoint is a uniquely identifiable portion of a USB device that is the terminus of a communication flow between the host and device. Each USB logical device is composed of a collection of independent endpoints. Each logical device has a unique address assigned by the system at device attachment time. Each endpoint on a device is given at design time a unique device-determined identifier called the endpoint number. Each endpoint has a device-determined direction of data flow. The combination of the device address, endpoint number, and direction allows each endpoint to be uniquely referenced. Each endpoint is a simplex connection that supports data flow in one direction: either input (from device to host) or output (from host to device).

An endpoint has characteristics that determine the type of transfer service required between the endpoint and the client software. An endpoint describes itself by:

- Bus access frequency/latency requirement
- Bandwidth requirement
- Endpoint number
- Error handling behavior requirements
- Maximum packet size that the endpoint is capable of sending or receiving
- The transfer type for the endpoint (refer to Section 5.4 for details)
- The direction in which data is transferred between the endpoint and the host

Endpoints other than those with endpoint number zero are in an unknown state before being configured and may not be accessed by the host before being configured.

5.3.1.1 Endpoint Zero Requirements

All USB devices are required to implement a default control method that uses both the input and output endpoints with endpoint number zero. The USB System Software uses this default control method to initialize and generically manipulate the logical device (e.g., to configure the logical device) as the Default Control Pipe (see Section 5.3.2). The Default Control Pipe provides access to the device's configuration information and allows generic USB status and control access. The Default Control Pipe supports control transfers as defined in Section 5.5. The endpoints with endpoint number zero are always accessible once a device is attached, powered, and has received a bus reset.

A USB device that is capable of operating at high-speed must have a minimum level of support for operating at full-speed. When the device is attached to a hub operating in full-speed, the device must:

- Be able to reset successfully at full-speed
- Respond successfully to standard requests: `set_address`, `set_configuration`, `get_descriptor` for device and configuration descriptors, and return appropriate information

The high-speed device may or may not be able to support its intended functionality when operating at full-speed.

5.3.1.2 Non-endpoint Zero Requirements

Functions can have additional endpoints as required for their implementation. Low-speed functions are limited to two optional endpoints beyond the two required to implement the Default Control Pipe. Full-speed devices can have additional endpoints only limited by the protocol definition (i.e., a maximum of 15 additional input endpoints and 15 additional output endpoints).

Endpoints other than those for the Default Control Pipe cannot be used until the device is configured as a normal part of the device configuration process (refer to Chapter 9).

5.3.2 Pipes

A USB pipe is an association between an endpoint on a device and software on the host. Pipes represent the ability to move data between software on the host via a memory buffer and an endpoint on a device. There are two mutually exclusive pipe communication modes:

- Stream: Data moving through a pipe has no USB-defined structure
- Message: Data moving through a pipe has some USB-defined structure

The USB does not interpret the content of data it delivers through a pipe. Even though a message pipe requires that data be structured according to USB definitions, the content of the data is not interpreted by the USB.

Additionally, pipes have the following associated with them:

- A claim on USB bus access and bandwidth usage.
- A transfer type.
- The associated endpoint's characteristics, such as directionality and maximum data payload sizes. The data payload is the data that is carried in the data field of a data packet within a bus transaction (as defined in Chapter 8).

The pipe that consists of the two endpoints with endpoint number zero is called the Default Control Pipe. This pipe is always available once a device is powered and has received a bus reset. Other pipes come into existence when a USB device is configured. The Default Control Pipe is used by the USB System Software to determine device identification and configuration requirements and to configure the device. The Default Control Pipe can also be used by device-specific software after the device is configured. The USB System

Software retains “ownership” of the Default Control Pipe and mediates use of the pipe by other client software.

A software client normally requests data transfers via I/O Request Packets (IRPs) to a pipe and then either waits or is notified when they are completed. Details about IRPs are defined in an operating system-specific manner. This specification uses the term to simply refer to an identifiable request by a software client to move data between itself (on the host) and an endpoint of a device in an appropriate direction. A software client can cause a pipe to return all outstanding IRPs if it desires. The software client is notified that an IRP has completed when the bus transactions associated with it have completed either successfully or due to errors.

If there are no IRPs pending or in progress for a pipe, the pipe is idle and the Host Controller will take no action with regard to the pipe; i.e., the endpoint for such a pipe will not see any bus transactions directed to it. The only time bus activity is present for a pipe is when IRPs are pending for that pipe.

If a non-isochronous pipe encounters a condition that causes it to send a STALL to the host (refer to Chapter 8) or three bus errors are encountered on any packet of an IRP, the IRP is aborted/retired, all outstanding IRPs are also retired, and no further IRPs are accepted until the software client recovers from the condition (in an implementation-dependent way) and acknowledges the halt or error condition via a USB_D call. An appropriate status informs the software client of the specific IRP result for error versus halt (refer to Chapter 10). Isochronous pipe behavior is described in Section 5.6.

An IRP may require multiple data payloads to move the client data over the bus. The data payloads for such a multiple data payload IRP are expected to be of the maximum packet size until the last data payload that contains the remainder of the overall IRP. See the description of each transfer type for more details. For such an IRP, short packets (i.e., less than maximum-sized data payloads) on input that do not completely fill an IRP data buffer can have one of two possible meanings, depending upon the expectations of a client:

- A client can expect a variable-sized amount of data in an IRP. In this case, a short packet that does not fill an IRP data buffer can be used simply as an in-band delimiter to indicate “end of unit of data.” The IRP should be retired without error and the Host Controller should advance to the next IRP.
- A client can expect a specific-sized amount of data. In this case, a short packet that does not fill an IRP data buffer is an indication of an error. The IRP should be retired, the pipe should be stalled, and any pending IRPs associated with the pipe should also be retired.

Because the Host Controller must behave differently in the two cases and cannot know on its own which way to behave for a given IRP; it is possible to indicate per IRP which behavior the client desires.

An endpoint can inform the host that it is busy by responding with NAK. NAKs are not used as a retire condition for returning an IRP to a software client. Any number of NAKs can be encountered during the processing of a given IRP. A NAK response to a transaction does not constitute an error and is not counted as one of the three errors described above.

5.3.2.1 Stream Pipes

Stream pipes deliver data in the data packet portion of bus transactions with no USB-required structure on the data content. Data flows in at one end of a stream pipe and out the other end in the same order. Stream pipes are always uni-directional in their communication flow.

Data flowing through a stream pipe is expected to interact with what the USB believes is a single client. The USB System Software is not required to provide synchronization between multiple clients that may be using the same stream pipe. Data presented to a stream pipe is moved through the pipe in sequential order: first-in, first-out.

A stream pipe to a device is bound to a single device endpoint number in the appropriate direction (i.e., corresponding to an IN or OUT token as defined by the protocol layer). The device endpoint number for the opposite direction can be used for some other stream pipe to the device.

Stream pipes support bulk, isochronous, and interrupt transfer types, which are explained in later sections.

5.3.2.2 Message Pipes

Message pipes interact with the endpoint in a different manner than stream pipes. First, a request is sent to the USB device from the host. This request is followed by data transfer(s) in the appropriate direction. Finally, a Status stage follows at some later time. In order to accommodate the request/data/status paradigm, message pipes impose a structure on the communication flow that allows commands to be reliably identified and communicated. Message pipes allow communication flow in both directions, although the communication flow may be predominately one way. The Default Control Pipe is always a message pipe.

The USB System Software ensures that multiple requests are not sent to a message pipe concurrently. A device is required to service only a single message request at a time per message pipe. Multiple software clients on the host can make requests via the Default Control Pipe, but they are sent to the device in a first-in, first-out order. A device can control the flow of information during the Data and Status stages based on its ability to respond to the host transactions (refer to Chapter 8 for more details).

A message pipe will not normally be sent the next message from the host until the current message's processing at the device has been completed. However, there are error conditions whereby a message transfer can be aborted by the host and the message pipe can be sent a new message transfer prematurely (from the device's perspective). From the perspective of the software manipulating a message pipe, an error on some part of an IRP retires the current IRP and all queued IRPs. The software client that requested the IRP is notified of the IRP completion with an appropriate error indication.

A message pipe to a device requires a single device endpoint number in both directions (IN and OUT tokens). The USB does not allow a message pipe to be associated with different endpoint numbers for each direction.

Message pipes support the control transfer type, which is explained in Section 5.5.

5.3.3 Frames and Microframes

USB establishes a 1 millisecond time base called a frame on a full-/low-speed bus and a 125 μ s time base called a microframe on a high-speed bus. A (micro)frame can contain several transactions. Each transfer type defines what transactions are allowed within a (micro)frame for an endpoint. Isochronous and interrupt endpoints are given opportunities to the bus every N (micro)frames. The values of N and other details about isochronous and interrupt transfers are described in Sections 5.6 and 5.7.

5.4 Transfer Types

The USB transports data through a pipe between a memory buffer associated with a software client on the host and an endpoint on the USB device. Data transported by message pipes is carried in a USB-defined structure, but the USB allows device-specific structured data to be transported within the USB-defined message data payload. The USB also defines that data moved over the bus is packetized for any pipe (stream or message), but ultimately the formatting and interpretation of the data transported in the data payload of a bus transaction is the responsibility of the client software and function using the pipe. However, the USB provides different transfer types that are optimized to more closely match the service requirements of the client software and function using the pipe. An IRP uses one or more bus transactions to move information between a software client and its function.

Each transfer type determines various characteristics of the communication flow including the following:

- Data format imposed by the USB
- Direction of communication flow
- Packet size constraints

- Bus access constraints
- Latency constraints
- Required data sequences
- Error handling

The designers of a USB device choose the capabilities for the device's endpoints. When a pipe is established for an endpoint, most of the pipe's transfer characteristics are determined and remain fixed for the lifetime of the pipe. Transfer characteristics that can be modified are described for each transfer type.

The USB defines four transfer types:

- Control Transfers: Bursty, non-periodic, host software-initiated request/response communication, typically used for command/status operations.
- Isochronous Transfers: Periodic, continuous communication between host and device, typically used for time-relevant information. This transfer type also preserves the concept of time encapsulated in the data. This does not imply, however, that the delivery needs of such data is always time-critical.
- Interrupt Transfers: Low-frequency, bounded-latency communication.
- Bulk Transfers: Non-periodic, large-packet bursty communication, typically used for data that can use any available bandwidth and can also be delayed until bandwidth is available.

Each transfer type is described in detail in the following four major sections. The data for any IRP is carried by the data field of the data packet as described in Section 8.3.4. Chapter 8 also describes details of the protocol that are affected by use of each particular transfer type.

5.4.1 Table Calculation Examples

The following sections describe each of the USB transfer types. In these sections, there are tables that illustrate the maximum number of transactions that can be expected to be contained in a (micro)frame. These tables can be used to determine the maximum performance behavior possible for a specific transfer type. Actual performance may vary with specific system implementation details.

Each table shows:

- The protocol overhead required for the specific transfer type (and speed)
- For some sample data payload sizes:
 - The maximum sustained bandwidth possible for this case
 - The percentage of a (micro)frame that each transaction requires
 - The maximum number of transactions in a (micro)frame for the specific case
 - The remaining bytes in a (micro)frame that would not be required for the specific case
 - The total number of data bytes transported in a single (micro)frame for the specific case

A transaction of a particular transfer type typically requires multiple packets. The protocol overhead for each transaction includes:

- A SYNC field for each packet: either 8 bits (full-/low-speed) or 32 bits (high-speed)
- A PID byte for each packet: includes PID and PID invert (check) bits
- An EOP for each packet: 3 bits (full-/low-speed) or 8 bits (high-speed)
- In a token packet, the endpoint number, device address, and CRC5 fields (16 bits total)

- In a data packet, CRC16 fields (16 bits total)
- In a data packet, any data field (8 bits per byte)
- For transaction with multiple packets, the inter packet gap or bus turnaround time required.

For these calculations, there is assumed to be no bit-stuffing required.

Using the low speed interrupt OUT as an example, there are 5 packets in the transaction:

- A PRE special packet
- A token packet
- A PRE special packet
- A data packet
- A handshake packet

There is one bus turnaround between the data and handshake packets. The protocol overhead is therefore:

5 SYNC, 5 PID, Endpoint + CRC5, CRC16, 5 EOPs and interpacket delay (one bus turnaround, 1 delay between packets, and 2 hub setup times).

5.5 Control Transfers

Control transfers allow access to different parts of a device. Control transfers are intended to support configuration/command/status type communication flows between client software and its function. A control transfer is composed of a Setup bus transaction moving request information from host to function, zero or more Data transactions sending data in the direction indicated by the Setup transaction, and a Status transaction returning status information from function to host. The Status transaction returns “success” when the endpoint has successfully completed processing the requested operation. Section 8.5.3 describes the details of what packets, bus transactions, and transaction sequences are used to accomplish a control transfer. Chapter 9 describes the details of the defined USB command codes.

Each USB device is required to implement the Default Control Pipe as a message pipe. This pipe is used by the USB System Software. The Default Control Pipe provides access to the USB device’s configuration, status, and control information. A function can, but is not required to, provide endpoints for additional control pipes for its own implementation needs.

The USB device framework (refer to Chapter 9) defines standard, device class, or vendor-specific requests that can be used to manipulate a device’s state. Descriptors are also defined that can be used to contain different information on the device. Control transfers provide the transport mechanism to access device descriptors and make requests of a device to manipulate its behavior.

Control transfers are carried only through message pipes. Consequently, data flows using control transfers must adhere to USB data structure definitions as described in Section 5.5.1.

The USB system will make a “best effort” to support delivery of control transfers between the host and devices. A function and its client software cannot request specific bus access frequency or bandwidth for control transfers. The USB System Software may restrict the bus access and bandwidth that a device may desire for control transfers. These restrictions are defined in Section 5.5.3 and Section 5.5.4.

5.5.1 Control Transfer Data Format

The Setup packet has a USB-defined structure that accommodates the minimum set of commands required to enable communication between the host and a device. The structure definition allows vendor-specific extensions for device specific commands. The Data transactions following Setup have a USB-defined structure except when carrying vendor-specific information. The Status transaction also has a USB-defined structure. Specific control transfer Setup/Data definitions are described in Section 8.5.3 and Chapter 9.

5.5.2 Control Transfer Direction

Control transfers are supported via bi-directional communication flow over message pipes. As a consequence, when a control pipe is configured, it uses both the input and output endpoint with the specified endpoint number.

5.5.3 Control Transfer Packet Size Constraints

An endpoint for control transfers specifies the maximum data payload size that the endpoint can accept from or transmit to the bus. The allowable maximum control transfer data payload sizes for full-speed devices is 8, 16, 32, or 64 bytes; for high-speed devices, it is 64 bytes and for low-speed devices, it is 8 bytes. This maximum applies to the data payloads of the Data packets following a Setup; i.e., the size specified is for the data field of the packet as defined in Chapter 8, not including other information that is required by the protocol. A Setup packet is always eight bytes. A control pipe (including the Default Control Pipe) always uses its *wMaxPacketSize* value for data payloads.

An endpoint reports in its configuration information the value for its maximum data payload size. The USB does not require that data payloads transmitted be exactly the maximum size; i.e., if a data payload is less than the maximum, it does not need to be padded to the maximum size.

All Host Controllers are required to have support for 8-, 16-, 32-, and 64-byte maximum data payload sizes for full-speed control endpoints, only 8-byte maximum data payload sizes for low-speed control endpoints, and only 64-byte maximum data payload size for high-speed control endpoints. No Host Controller is required to support larger or smaller maximum data payload sizes.

In order to determine the maximum packet size for the Default Control Pipe, the USB System Software reads the device descriptor. The host will read the first eight bytes of the device descriptor. The device always responds with at least these initial bytes in a single packet. After the host reads the initial part of the device descriptor, it is guaranteed to have read this default pipe's *wMaxPacketSize* field (byte 7 of the device descriptor). It will then allow the correct size for all subsequent transactions. For all other control endpoints, the maximum data payload size is known after configuration so that the USB System Software can ensure that no data payload will be sent to the endpoint that is larger than the supported size.

An endpoint must always transmit data payloads with a data field less than or equal to the endpoint's *wMaxPacketSize* (refer to Chapter 9). When a control transfer involves more data than can fit in one data payload of the currently established maximum size, all data payloads are required to be maximum-sized except for the last data payload, which will contain the remaining data.

The Data stage of a control transfer from an endpoint to the host is complete when the endpoint does one of the following:

- Has transferred exactly the amount of data specified during the Setup stage
- Transfers a packet with a payload size less than *wMaxPacketSize* or transfers a zero-length packet

When a Data stage is complete, the Host Controller advances to the Status stage instead of continuing on with another data transaction. If the Host Controller does not advance to the Status stage when the Data stage is complete, the endpoint halts the pipe as was outlined in Section 5.3.2. If a larger-than-expected data payload is received from the endpoint, the IRP for the control transfer will be aborted/retired.

The Data stage of a control transfer from the host to an endpoint is complete when all of the data has been transferred. If the endpoint receives a larger-than-expected data payload from the host, it halts the pipe.

5.5.4 Control Transfer Bus Access Constraints

Control transfers can be used by high-speed, full-speed, and low-speed USB devices.

An endpoint has no way to indicate a desired bus access frequency for a control pipe. The USB balances the bus access requirements of all control pipes and the specific IRPs that are pending to provide “best effort” delivery of data between client software and functions.

The USB requires that part of each (micro)frame be reserved to be available for use by control transfers as follows:

- If the control transfers that are attempted (in an implementation-dependent fashion) consume less than 10% of the frame time for full-/low-speed endpoints or less than 20% of a microframe for high-speed endpoints, the remaining time can be used to support bulk transfers (refer to Section 5.8).
- A control transfer that has been attempted and needs to be retried can be retried in the current or a future (micro)frame; i.e., it is not required to be retried in the same (micro)frame.
- If there are more control transfers than reserved time, but there is additional (micro)frame time that is not being used for isochronous or interrupt transfers, a Host Controller may move additional control transfers as they are available.
- If there are too many pending control transfers for the available (micro)frame time, control transfers are selected to be moved over the bus as appropriate.
- If there are control transfers pending for multiple endpoints, control transfers for the different endpoints are selected according to a fair access policy that is Host Controller implementation-dependent.
- A transaction of a control transfer that is frequently being retried should not be expected to consume an unfair share of the bus time.

High-speed control endpoints must support the PING flow control protocol for OUT transactions. The details of this protocol are described in Section 8.5.1.

These requirements allow control transfers between host and devices to be regularly moved over the bus with “best effort.”

The USB System Software can, at its discretion, vary the rate of control transfers to a particular endpoint. An endpoint and its client software cannot assume a specific rate of service for control transfers. A control endpoint may see zero or more transfers in a single (micro)frame. Bus time made available to a software client and its endpoint can be changed as other devices are inserted into and removed from the system or also as control transfers are requested for other device endpoints.

The bus frequency and (micro)frame timing limit the maximum number of successful control transfers within a (micro)frame for any USB system. For full-/low-speed buses, the number of successful control transfers per frame is limited to less than 29 full-speed eight-byte data payloads or less than four low-speed eight-byte data payloads. For high-speed buses, the number of control transfers is limited to less than 32 high-speed 64-byte data payloads per microframe.

Table 5-1 lists information about different-sized low-speed packets and the maximum number of packets possible in a frame. The table does not include the overhead associated with bit stuffing.

Table 5-1. Low-speed Control Transfer Limits

Protocol Overhead (63 bytes)		(15 SYNC bytes, 15 PID bytes, 6 Endpoint + CRC bytes, 6 CRC bytes, 8 Setup data bytes, and a 13-byte interpacket delay (EOP, etc.))				
Data Payload	Max Bandwidth (bytes/second)	Frame Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/Frame Useful Data	
1	3000	26%	3	40	3	
2	6000	27%	3	37	6	
4	12000	28%	3	31	12	
8	24000	30%	3	19	24	
Max	187500				187	

For all speeds, because a control transfer is composed of several packets, the packets can be spread over several (micro)frames to spread the bus time required across several (micro)frames.

The 10% frame reservation for full-/low-speed non-periodic transfers means that in a system with bus time fully allocated, all full-speed control transfers in the system contend for a nominal three control transfers per frame. Because the USB system uses control transfers for configuration purposes in addition to whatever other control transfers other client software may be requesting, a given software client and its function should not expect to be able to make use of this full bandwidth for its own control purposes. Host Controllers are also free to determine how the individual bus transactions for specific control transfers are moved over the bus within and across frames. An endpoint could see all bus transactions for a control transfer within the same frame or spread across several noncontiguous frames. A Host Controller, for various implementation reasons, may not be able to provide the theoretical maximum number of control transfers per frame.

For high-speed endpoints, the 20% microframe reservation for non-periodic transfers means that all high speed control transfers are contending for nominally six control transfers per microframe. High-speed control transfers contend for microframe time along with split-transactions (see Sections 11.15-11.21 for more information about split transactions) for full- and low-speed control transfers. Both full-speed and low-speed control transfers contend for the same available frame time. However, high-speed control transfers for some endpoints can occur simultaneously with full- and low-speed control transfers for other endpoints. Low-speed control transfers simply take longer to transfer.

Universal Serial Bus Specification Revision 2.0

Table 5-2 lists information about different-sized full-speed control transfers and the maximum number of transfers possible in a frame. This table was generated assuming that there is one Data stage transaction and that the Data stage has a zero-length status phase. The table illustrates the possible power of two data payloads less than or equal to the allowable maximum data payload sizes. The table does not include the overhead associated with bit stuffing.

Table 5-2. Full-speed Control Transfer Limits

Protocol Overhead (45 bytes)		(9 SYNC bytes, 9 PID bytes, 6 Endpoint + CRC bytes, 6 CRC bytes, 8 Setup data bytes, and a 7-byte interpacket delay (EOP, etc.))				
Data Payload	Max Bandwidth (bytes/second)	Frame Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/Frame Useful Data	
1	32000	3%	32	23	32	
2	62000	3%	31	43	62	
4	120000	3%	30	30	120	
8	224000	4%	28	16	224	
16	384000	4%	24	36	384	
32	608000	5%	19	37	608	
64	832000	7%	13	83	832	
Max	1500000				1500	

Universal Serial Bus Specification Revision 2.0

Table 5-3 lists information about different-sized high-speed control transfers and the maximum number of transfers possible in a microframe. This table was generated assuming that there is one Data stage transaction and that the Data stage has a zero-length status stage. The table illustrates the possible power of two data payloads less than or equal to the allowable maximum data payload size. The table does not include the overhead associated with bit stuffing.

Table 5-3. High-speed Control Transfer Limits

Protocol Overhead (173 bytes)		(Based on 480Mb/s and 8 bit interpacket gap, 88 bit min bus turnaround, 32 bit sync, 8 bit EOP: (9x4 SYNC bytes, 9 PID bytes, 6 EP/ADDR+CRC,6 CRC16, 8 Setup data, 9x(1+11) byte interpacket delay (EOP, etc.))				
Data Payload	Max Bandwidth (bytes/second)	Microframe Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/ Microframe Useful Data	
1	344000	2%	43	18	43	
2	672000	2%	42	150	84	
4	1344000	2%	42	66	168	
8	2624000	2%	41	79	328	
16	4992000	3%	39	129	624	
32	9216000	3%	36	120	1152	
64	15872000	3%	31	153	1984	
Max	60000000				7500	

5.5.5 Control Transfer Data Sequences

Control transfers require that a Setup bus transaction be sent from the host to a device to describe the type of control access that the device should perform. The Setup transaction is followed by zero or more control Data transactions that carry the specific information for the requested access. Finally, a Status transaction completes the control transfer and allows the endpoint to return the status of the control transfer to the client software. After the Status transaction for a control transfer is completed, the host can advance to the next control transfer for the endpoint. As described in Section 5.5.4, each control transaction and the next control transfer will be moved over the bus at some Host Controller implementation-defined time.

The endpoint can be busy for a device-specific time during the Data and Status transactions of the control transfer. During these times when the endpoint indicates it is busy (refer to Chapter 8 and Chapter 9 for details), the host will retry the transaction at a later time.

If a Setup transaction is received by an endpoint before a previously initiated control transfer is completed, the device must abort the current transfer/operation and handle the new control Setup transaction. A Setup transaction should not normally be sent before the completion of a previous control transfer. However, if a transfer is aborted, for example, due to errors on the bus, the host can send the next Setup transaction prematurely from the endpoint's perspective.

After a halt condition is encountered or an error is detected by the host, a control endpoint is allowed to recover by accepting the next Setup PID; i.e., recovery actions via some other pipe are not required for control endpoints. For the Default Control Pipe, a device reset will ultimately be required to clear the halt or error condition if the next Setup PID is not accepted.

The USB provides robust error detection and recovery/retransmission for errors that occur during control transfers. Transmitters and receivers can remain synchronized with regard to where they are in a control transfer and recover with minimum effort. Retransmission of Data and Status packets can be detected by a receiver via data retry indicators in the packet. A transmitter can reliably determine that its corresponding receiver has successfully accepted a transmitted packet by information returned in a handshake to the packet. The protocol allows for distinguishing a retransmitted packet from its original packet except for a control Setup packet. Setup packets may be retransmitted due to a transmission error; however, Setup packets cannot indicate that a packet is an original or a retried transmission.

5.6 Isochronous Transfers

In non-USB environments, isochronous transfers have the general implication of constant-rate, error-tolerant transfers. In the USB environment, requesting an isochronous transfer type provides the requester with the following:

- Guaranteed access to USB bandwidth with bounded latency
- Guaranteed constant data rate through the pipe as long as data is provided to the pipe
- In the case of a delivery failure due to error, no retrying of the attempt to deliver the data

While the USB isochronous transfer type is designed to support isochronous sources and destinations, it is not required that software using this transfer type actually be isochronous in order to use the transfer type. Section 5.12 presents more detail on special considerations for handling isochronous data on the USB.

5.6.1 Isochronous Transfer Data Format

The USB imposes no data content structure on communication flows for isochronous pipes.

5.6.2 Isochronous Transfer Direction

An isochronous pipe is a stream pipe and is, therefore, always uni-directional. An endpoint description identifies whether a given isochronous pipe's communication flow is into or out of the host. If a device requires bi-directional isochronous communication flow, two isochronous pipes must be used, one in each direction.

5.6.3 Isochronous Transfer Packet Size Constraints

An endpoint in a given configuration for an isochronous pipe specifies the maximum size data payload that it can transmit or receive. The USB System Software uses this information during configuration to ensure that there is sufficient bus time to accommodate this maximum data payload in each (micro)frame. If there is sufficient bus time for the maximum data payload, the configuration is established; if not, the configuration is not established.

The USB limits the maximum data payload size to 1,023 bytes for each full-speed isochronous endpoint. High-speed endpoints are allowed up to 1024-byte data payloads. A high speed, high bandwidth endpoint specifies whether it requires two or three transactions per microframe. Table 5-4 lists information about different-sized full-speed isochronous transactions and the maximum number of transactions possible in a frame. The table is shaded to indicate that a full-speed isochronous endpoint (with a non-zero *wMaxpacket* size) must not be part of a default interface setting. The table does not include the overhead associated with bit stuffing.

Universal Serial Bus Specification Revision 2.0

Table 5-4. Full-speed Isochronous Transaction Limits

Protocol Overhead (9 bytes)		(2 SYNC bytes, 2 PID bytes, 2 Endpoint + CRC bytes, 2 CRC bytes, and a 1-byte interpacket delay)			
Data Payload	Max Bandwidth(bytes/second)	Frame Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/Frame Useful Data
1	150000	1%	150	0	150
2	272000	1%	136	4	272
4	460000	1%	115	5	460
8	704000	1%	88	4	704
16	960000	2%	60	0	960
32	1152000	3%	36	24	1152
64	1280000	5%	20	40	1280
128	1280000	9%	10	130	1280
256	1280000	18%	5	175	1280
512	1024000	35%	2	458	1024
1023	1023000	69%	1	468	1023
Max	1500000				1500

Universal Serial Bus Specification Revision 2.0

Table 5-5 lists information about different-sized high-speed isochronous transactions and the maximum number of transactions possible in a microframe. The table is shaded to indicate that a high-speed isochronous endpoint must not be part of a default interface setting. The table does not include the overhead associated with bit stuffing.

Any given transaction for an isochronous pipe need not be exactly the maximum size specified for the endpoint. The size of a data payload is determined by the transmitter (client software or function) and can vary as required from transaction to transaction. The USB ensures that whatever size is presented to the Host Controller is delivered on the bus. The actual size of a data payload is determined by the data transmitter and may be less than the prenegotiated maximum size. Bus errors can change the actual packet size seen by the receiver. However, these errors can be detected by either CRC on the data or by knowledge the receiver has about the expected size for any transaction.

Table 5-5. High-speed Isochronous Transaction Limits

Protocol Overhead		(Based on 480Mb/s and 8 bit interpacket gap, 88 bit min bus turnaround, 32 bit sync, 8 bit EOP: (2x4 SYNC bytes, 2 PID bytes, 2 EP/ADDR+addr+CRC5, 2 CRC16, and a 2x(1+11)) byte interpacket delay (EOP, etc.))			
Data Payload	Max Bandwidth (bytes/second)	Microframe Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/ MicroFrame Useful Data
1	1536000	1%	192	12	192
2	2992000	1%	187	20	374
4	5696000	1%	178	24	712
8	10432000	1%	163	2	1304
16	17664000	1%	138	48	2208
32	27392000	1%	107	10	3424
64	37376000	1%	73	54	4672
128	46080000	2%	45	30	5760
256	51200000	4%	25	150	6400
512	53248000	7%	13	350	6656
1024	57344000	14%	7	66	7168
2048	49152000	28%	3	1242	6144
3072	49152000	41%	2	1280	6144
Max	60000000				7500

All device default interface settings must not include any isochronous endpoints with non-zero data payload sizes (specified via *wMaxPacketSize* in the endpoint descriptor). Alternate interface settings may specify non-zero data payload sizes for isochronous endpoints. If the isochronous endpoints have a large data payload size, it is recommended that additional alternate configurations or interface settings be used to specify a range of data payload sizes. This increases the chance that the device can be used successfully in combination with other USB devices.

5.6.4 Isochronous Transfer Bus Access Constraints

Isochronous transfers can only be used by full-speed and high-speed devices.

The USB requires that no more than 90% of any frame be allocated for periodic (isochronous and interrupt) transfers for full-speed endpoints. High-speed endpoints can allocate at most 80% of a microframe for periodic transfers.

An isochronous endpoint must specify its required bus access period. Full-/high-speed endpoints must specify a desired period as $(2^{bInterval-1}) \times F$, where *bInterval* is in the range one to (and including) 16 and *F* is 125 μ s for high-speed and 1ms for full-speed. This allows full-/high-speed isochronous transfers to have rates slower than one transaction per (micro)frame. However, an isochronous endpoint must be prepared to handle poll rates faster than the one specified. A host must not issue more than 1 transaction in a (micro)frame for an isochronous endpoint unless the endpoint is high-speed, high-bandwidth (see below). An isochronous IN endpoint must return a zero-length packet whenever data is requested at a faster interval than the specified interval and data is not available.

A high-speed endpoint can move up to 3072 bytes per microframe (or 192 Mb/s). A high-speed isochronous endpoint that requires more than 1024 bytes per period is called a high-bandwidth endpoint. A high-bandwidth endpoint uses multiple transactions per microframe. A high-bandwidth endpoint must specify a period of $1 \times 125 \mu$ s (i.e., a *bInterval* value of 1). See Section 5.9 for more information about the details of multiple transactions per microframe for high-bandwidth high-speed endpoints.

Errors on the bus or delays in operating system scheduling of client software can result in no packet being transferred for a (micro)frame. An error indication should be returned as status to the client software in such a case. A device can also detect this situation by tracking SOF tokens and noticing a disturbance in the specified bus access period pattern.

The bus frequency and (micro)frame timing limit the maximum number of successful isochronous transactions within a (micro)frame for any USB system to less than 151 full-speed one-byte data payloads and less than 193 high-speed one-byte data payloads. A Host Controller, for various implementation reasons, may not be able to provide the theoretical maximum number of isochronous transactions per (micro)frame.

5.6.5 Isochronous Transfer Data Sequences

Isochronous transfers do not support data retransmission in response to errors on the bus. A receiver can determine that a transmission error occurred. The low-level USB protocol does not allow handshakes to be returned to the transmitter of an isochronous pipe. Normally, handshakes would be returned to tell the transmitter whether a packet was successfully received or not. For isochronous transfers, timeliness is more important than correctness/retransmission, and, given the low error rates expected on the bus, the protocol is optimized by assuming transfers normally succeed. Isochronous receivers can determine whether they missed data during a (micro)frame. Also, a receiver can determine how much data was lost. Section 5.12 describes these USB mechanisms in more detail.

An endpoint for isochronous transfers never halts because there is no handshake to report a halt condition. Errors are reported as status associated with the IRP for an isochronous transfer, but the isochronous pipe is not halted in an error case. If an error is detected, the host continues to process the data associated with the next (micro)frame of the transfer. Only limited error detection is possible because the protocol for isochronous transactions does not allow per-transaction handshakes.

5.7 Interrupt Transfers

The interrupt transfer type is designed to support those devices that need to send or receive data infrequently but with bounded service periods. Requesting a pipe with an interrupt transfer type provides the requester with the following:

- Guaranteed maximum service period for the pipe
- Retry of transfer attempts at the next period, in the case of occasional delivery failure due to error on the bus

5.7.1 Interrupt Transfer Data Format

The USB imposes no data content structure on communication flows for interrupt pipes.

5.7.2 Interrupt Transfer Direction

An interrupt pipe is a stream pipe and is therefore always uni-directional. An endpoint description identifies whether a given interrupt pipe's communication flow is into or out of the host.

5.7.3 Interrupt Transfer Packet Size Constraints

An endpoint for an interrupt pipe specifies the maximum size data payload that it will transmit or receive. The maximum allowable interrupt data payload size is 64 bytes or less for full-speed. High-speed endpoints are allowed maximum data payload sizes up to 1024 bytes. A high speed, high bandwidth endpoint specifies whether it requires two or three transactions per microframe. Low-speed devices are limited to eight bytes or less maximum data payload size. This maximum applies to the data payloads of the data packets; i.e., the size specified is for the data field of the packet as defined in Chapter 8, not including other protocol-required information. The USB does not require that data packets be exactly the maximum size; i.e., if a data packet is less than the maximum, it does not need to be padded to the maximum size.

All Host Controllers are required to support maximum data payload sizes from 0 to 64 bytes for full-speed interrupt endpoints, from 0 to 8 bytes for low-speed interrupt endpoints, and from 0 to 1024 bytes for high-speed interrupt endpoints. See Section 5.9 for more information about the details of multiple transactions per microframe for high bandwidth high-speed endpoints. No Host Controller is required to support larger maximum data payload sizes.

The USB System Software determines the maximum data payload size that will be used for an interrupt pipe during device configuration. This size remains constant for the lifetime of a device's configuration. The USB System Software uses the maximum data payload size determined during configuration to ensure that there is sufficient bus time to accommodate this maximum data payload in its assigned period. If there is sufficient bus time, the pipe is established; if not, the pipe is not established. However, the actual size of a data payload is still determined by the data transmitter and may be less than the maximum size.

An endpoint must always transmit data payloads with a data field less than or equal to the endpoint's *wMaxPacketSize* value. A device can move data via an interrupt pipe that is larger than *wMaxPacketSize*. A software client can accept this data via an IRP for the interrupt transfer that requires multiple bus transactions without requiring an IRP-complete notification per transaction. This can be achieved by specifying a buffer that can hold the desired data size. The size of the buffer is a multiple of *wMaxPacketSize* with some remainder. The endpoint must transfer each transaction except the last as *wMaxPacketSize* and the last transaction is the remainder. The multiple data transactions are moved over the bus at the period established for the pipe.

When an interrupt transfer involves more data than can fit in one data payload of the currently established maximum size, all data payloads are required to be maximum-sized except for the last data payload, which will contain the remaining data. An interrupt transfer is complete when the endpoint does one of the following:

Universal Serial Bus Specification Revision 2.0

- Has transferred exactly the amount of data expected
- Transfers a packet with a payload size less than *wMaxPacketSize* or transfers a zero-length packet

When an interrupt transfer is complete, the Host Controller retires the current IRP and advances to the next IRP. If a data payload is received that is larger than expected, the interrupt IRP will be aborted/retired and the pipe will stall future IRPs until the condition is corrected and acknowledged.

All high-speed device default interface settings must not include any interrupt endpoints with a data payload size (specified via *wMaxPacketSize* in the endpoint descriptor) greater than 64 bytes. Alternate interface settings may specify larger data payload sizes for interrupt endpoints. If the interrupt endpoints have a large data payload size, it is recommended that additional configurations or alternate interface settings be used to specify a range of data payload sizes. This increases the chances that the device can be used successfully in combination with other USB devices.

5.7.4 Interrupt Transfer Bus Access Constraints

Interrupt transfers can be used by low-speed, full-speed, and high-speed devices. High-speed endpoints can be allocated at most 80% of a microframe for periodic transfers. The USB requires that no more than 90% of any frame be allocated for periodic (isochronous and interrupt) full-/low-speed transfers.

The bus frequency and (micro)frame timing limit the maximum number of successful interrupt transactions within a (micro)frame for any USB system to less than 108 full-speed one-byte data payloads, or less than 10 low-speed one-byte data payloads, or to less than 134 high-speed one-byte data payloads. A Host Controller, for various implementation reasons, may not be able to provide the above maximum number of interrupt transactions per (micro)frame.

Table 5-6 lists information about different low-speed interrupt transactions and the maximum number of transactions possible in a frame. Table 5-7 lists similar information for full-speed interrupt transactions. Table 5-8 lists similar information for high-speed interrupt transactions. The shaded portion of Table 5-8 indicates the data payload sizes of a high-speed interrupt endpoint that must not be part of a default interface setting. The tables do not include the overhead associated with bit stuffing.

Table 5-6. Low-speed Interrupt Transaction Limits

Protocol Overhead (19 bytes)		(5 SYNC bytes, 5 PID bytes, 2 Endpoint + CRC bytes, 2 CRC bytes, and a 5-byte interpacket delay)				
Data Payload	Max Bandwidth (bytes/second)	Frame Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/Frame Useful Data	
1	9000	11%	9	7	9	
2	16000	11%	8	19	16	
4	32000	12%	8	3	32	
8	48000	14%	6	25	48	
Max	187500				187	

Universal Serial Bus Specification Revision 2.0

Table 5-7. Full-speed Interrupt Transaction Limits

Protocol Overhead (13 bytes)		(3 SYNC bytes, 3 PID bytes, 2 Endpoint + CRC bytes, 2 CRC bytes, and a 3-byte interpacket delay)			
Data Payload	Max Bandwidth (bytes/second)	Frame Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/Frame Useful Data

3072	49152000	42%	2	1246	6144
Max	60000000				7500

An endpoint for an interrupt pipe specifies its desired bus access period. A full-speed endpoint can specify a desired period from 1 ms to 255 ms. Low-speed endpoints are limited to specifying only 10 ms to 255 ms. High-speed endpoints can specify a desired period ($2^{bInterval-1}$)x125 μs, where *bInterval* is in the range 1 to (including) 16. The USB System Software will use this information during configuration to determine a period that can be sustained. The period provided by the system may be shorter than that desired by the device up to the shortest period defined by the USB (125 μs microframe or 1 ms frame). The client software and device can depend only on the fact that the host will ensure that the time duration between two transaction attempts with the endpoint will be no longer than the desired period. Note that errors on the bus can prevent an interrupt transaction from being successfully delivered over the bus and consequently exceed the desired period. Also, the endpoint is only polled when the software client has an IRP for an interrupt transfer pending. If the bus time for performing an interrupt transfer arrives and there is no IRP pending, the endpoint will not be given an opportunity to transfer data at that time. Once an IRP is available, its data will be transferred at the next allocated period.

A high-speed endpoint can move up to 3072 bytes per microframe (or 192 Mb/s). A high-speed interrupt endpoint that requires more than 1024 bytes per period is called a high-bandwidth endpoint. A high-bandwidth endpoint uses multiple transactions per microframe. A high-bandwidth endpoint must specify a period of $1 \times 125 \mu\text{s}$ (i.e., a *bInterval* value of 1). See Section 5.9 for more information about the details of multiple transactions per microframe for high-bandwidth high-speed endpoints.

Interrupt transfers are moved over the USB by accessing an interrupt endpoint every specified period. For input interrupt endpoints, the host has no way to determine whether an endpoint will source an interrupt without accessing the endpoint and requesting an interrupt transfer. If the endpoint has no interrupt data to transmit when accessed by the host, it responds with NAK. An endpoint should only provide interrupt data when it has an interrupt pending to avoid having a software client erroneously notified of IRP complete. A zero-length data payload is a valid transfer and may be useful for some implementations.

5.7.5 Interrupt Transfer Data Sequences

Interrupt transactions may use either alternating data toggle bits, such that the bits are toggled only upon successful transfer completion or a continuously toggling of data toggle bits. The host in any case must assume that the device is obeying full handshake/retry rules as defined in Chapter 8. A device may choose to always toggle DATA0/DATA1 PIDs so that it can ignore handshakes from the host. However, in this case, the client software can miss some data packets when an error occurs, because the Host Controller interprets the next packet as a retry of a missed packet.

If a halt condition is detected on an interrupt pipe due to transmission errors or a STALL handshake being returned from the endpoint, all pending IRPs are retired. Removal of the halt condition is achieved via software intervention through a separate control pipe. This recovery will reset the data toggle bit to DATA0 for the endpoint on both the host and the device. Interrupt transactions are retried due to errors detected on the bus that affect a given transfer.

5.8 Bulk Transfers

The bulk transfer type is designed to support devices that need to communicate relatively large amounts of data at highly variable times where the transfer can use any available bandwidth. Requesting a pipe with a bulk transfer type provides the requester with the following:

- Access to the USB on a bandwidth-available basis
- Retry of transfers, in the case of occasional delivery failure due to errors on the bus
- Guaranteed delivery of data but no guarantee of bandwidth or latency

Bulk transfers occur only on a bandwidth-available basis. For a USB with large amounts of free bandwidth, bulk transfers may happen relatively quickly; for a USB with little bandwidth available, bulk transfers may trickle out over a relatively long period of time.

5.8.1 Bulk Transfer Data Format

The USB imposes no data content structure on communication flows for bulk pipes.

5.8.2 Bulk Transfer Direction

A bulk pipe is a stream pipe and, therefore, always has communication flowing either into or out of the host for a given pipe. If a device requires bi-directional bulk communication flow, two bulk pipes must be used, one in each direction.

5.8.3 Bulk Transfer Packet Size Constraints

An endpoint for bulk transfers specifies the maximum data payload size that the endpoint can accept from or transmit to the bus. The USB defines the allowable maximum bulk data payload sizes to be only 8, 16, 32, or 64 bytes for full-speed endpoints and 512 bytes for high-speed endpoints. A low-speed device must not have bulk endpoints. This maximum applies to the data payloads of the data packets; i.e., the size specified is for the data field of the packet as defined in Chapter 8, not including other protocol-required information.

A bulk endpoint is designed to support a maximum data payload size. A bulk endpoint reports in its configuration information the value for its maximum data payload size. The USB does not require that data payloads transmitted be exactly the maximum size; i.e., if a data payload is less than the maximum, it does not need to be padded to the maximum size.

All Host Controllers are required to have support for 8-, 16-, 32-, and 64-byte maximum packet sizes for full-speed bulk endpoints and 512 bytes for high-speed bulk endpoints. No Host Controller is required to support larger or smaller maximum packet sizes.

During configuration, the USB System Software reads the endpoint's maximum data payload size and ensures that no data payload will be sent to the endpoint that is larger than the supported size.

An endpoint must always transmit data payloads with a data field less than or equal to the endpoint's reported *wMaxPacketSize* value. When a bulk IRP involves more data than can fit in one maximum-sized data payload, all data payloads are required to be maximum size except for the last data payload, which will contain the remaining data. A bulk transfer is complete when the endpoint does one of the following:

- Has transferred exactly the amount of data expected
- Transfers a packet with a payload size less than *wMaxPacketSize* or transfers a zero-length packet

When a bulk transfer is complete, the Host Controller retires the current IRP and advances to the next IRP. If a data payload is received that is larger than expected, all pending bulk IRPs for that endpoint will be aborted/retired.

5.8.4 Bulk Transfer Bus Access Constraints

Only full-speed and high-speed devices can use bulk transfers.

An endpoint has no way to indicate a desired bus access frequency for a bulk pipe. The USB balances the bus access requirements of all bulk pipes and the specific IRPs that are pending to provide "good effort" delivery of data between client software and functions. Moving control transfers over the bus has priority over moving bulk transfers.

There is no time guaranteed to be available for bulk transfers as there is for control transfers. Bulk transfers are moved over the bus only on a bandwidth-available basis. If there is bus time that is not being used for other purposes, bulk transfers will be moved over the bus. If there are bulk transfers pending for multiple endpoints, bulk transfers for the different endpoints are selected according to a fair access policy that is Host Controller implementation-dependent.

All bulk transfers pending in a system contend for the same available bus time. Because of this, the USB System Software at its discretion can vary the bus time made available for bulk transfers to a particular endpoint. An endpoint and its client software cannot assume a specific rate of service for bulk transfers. Bus time made available to a software client and its endpoint can be changed as other devices are inserted into and removed from the system or also as bulk transfers are requested for other device endpoints. Client software cannot assume ordering between bulk and control transfers; i.e., in some situations, bulk transfers can be delivered ahead of control transfers.

High-speed bulk OUT endpoints must support the PING flow control protocol. The details of this protocol are described in Section 8.5.1.

Universal Serial Bus Specification Revision 2.0

The bus frequency and (micro)frame timing limit the maximum number of successful bulk transactions within a (micro)frame for any USB system to less than 72 full-speed eight-byte data payloads or less than 14 high-speed 512-byte data payloads. Table 5-9 lists information about different-sized full-speed bulk transactions and the maximum number of transactions possible in a frame. The table does not include the overhead associated with bit stuffing. Table 5-10 lists similar information for high-speed bulk transactions.

Table 5-9. Full-speed Bulk Transaction Limits

Protocol Overhead (13 bytes)		(3 SYNC bytes, 3 PID bytes, 2 Endpoint + CRC bytes, 2 CRC bytes, and a 3-byte interpacket delay)				
Data Payload	Max Bandwidth (bytes/second)	Frame Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/Frame Useful Data	
1	107000	1%	107	2	107	
2	200000	1%	100	0	200	
4	352000	1%	88	4	352	
8	568000	1%	71	9	568	
16	816000	2%	51	21	816	
32	1056000	3%	33	15	1056	
64	1216000	5%	19	37	1216	
Max	1500000				1500	

Table 5-10. High-speed Bulk Transaction Limits

Protocol Overhead (55 bytes)		(3x4 SYNC bytes, 3 PID bytes, 2 EP/ADDR+CRC bytes, 2 CRC16, and a 3x(1+11) byte interpacket delay (EOP, etc.))			
Data Payload	Max Bandwidth (bytes/second)	Microframe Bandwidth per Transfer	Max Transfers	Bytes Remaining	Bytes/Microframe Useful Data
1	1064000	1%	133	52	133
2	2096000	1%	131	33	262
4	4064000	1%	127	7	508
8	7616000	1%	119	3	952
16	13440000	1%	105	45	1680
32	22016000	1%	86	18	2752
64	32256000	2%	63	3	4032
128	40960000	2%	40	180	5120
256	49152000	4%	24	36	6144
512	53248000	8%	13	129	6656
Max	60000000				7500

Host Controllers are free to determine how the individual bus transactions for specific bulk transfers are moved over the bus within and across (micro)frames. An endpoint could see all bus transactions for a bulk transfer within the same (micro)frame or spread across several (micro)frames. A Host Controller, for various implementation reasons, may not be able to provide the above maximum number of transactions per (micro)frame.

5.8.5 Bulk Transfer Data Sequences

Bulk transactions use data toggle bits that are toggled only upon successful transaction completion to preserve synchronization between transmitter and receiver when transactions are retried due to errors. Bulk transactions are initialized to DATA0 when the endpoint is configured by an appropriate control transfer. The host will also start the first bulk transaction with DATA0. If a halt condition is detected on a bulk pipe due to transmission errors or a STALL handshake being returned from the endpoint, all pending IRPs are retired. Removal of the halt condition is achieved via software intervention through a separate control pipe. This recovery will reset the data toggle bit to DATA0 for the endpoint on both the host and the device.

Bulk transactions are retried due to errors detected on the bus that affect a given transaction.

5.9 High-Speed, High Bandwidth Endpoints

USB supports individual high-speed interrupt or isochronous endpoints that require data rates up to 192 Mb/s (i.e., 3072 data bytes per microframe). One, two, or three high-speed transactions are allowed in a single microframe to support high-bandwidth endpoints.

A high-speed interrupt or isochronous endpoint indicates that it requires more than 1024 bytes per microframe when bits 12..11 of the *wMaxPacketSize* field of the endpoint descriptor (see Table 5-11) are non-zero. The lower 11 bits of *wMaxPacketSize* indicate the size of the data payload for each individual transaction while bits 12..11 indicate the maximum number of required transactions possible. See Section 9.6.6 for restrictions on the allowed combinations of values for bits 12..11 and bits 10..0.

Table 5-11. *wMaxPacketSize* Field of Endpoint Descriptor

Bits	15..13	12..11	10..0
Field	Reserved, must be set to zero	Number of transactions per microframe	Maximum size of data payload in bytes

Note: This representation means that endpoints requesting two transactions per microframe will specify a total data payload size in the microframe that is a multiple of two bytes. Also endpoints requesting three transactions per microframe will specify a total data payload size that is a multiple of three bytes. In any case, any number of bytes can actually be transferred in a microframe.

The host controller must issue an appropriate number of high-speed transactions per microframe. Errors in the host or on the bus can result in the host controller issuing fewer transactions than requested for the endpoint. The first transaction(s) must have a data payload(s) as specified by the lower 11 bits of *wMaxPacketSize* if enough data is available, while the last transaction has any remaining data less than or equal to the maximum size specified. The host controller may issue transactions for the same endpoint one immediately after the other (as required for the actual data provided) or may issue transactions for other endpoints in between the transactions for a high bandwidth endpoint.

5.9.1 High Bandwidth Interrupt Endpoints

For interrupt transactions, if the endpoint NAKs a transaction during a microframe, the host controller must not issue further transactions for that endpoint until the next period.

If the endpoint times-out a transaction, the host controller must retry the transaction. The endpoint specifies the maximum number of desired transactions per microframe. If the maximum number of transactions per microframe has not been reached, the host controller may immediately retry the transaction during the current microframe. Host controllers are recommended to do an immediate retry since this minimizes impact on devices that are bandwidth sensitive. If the maximum number of transactions per microframe has been reached, the host controller must retry the transaction at the next period for the endpoint.

A host controller is allowed to issue less than the maximum number of transactions to an endpoint per microframe only if more than a single memory buffer is required for the transactions within the microframe.

Normal DATA0/DATA1 data toggle sequencing is used for each interrupt transaction during a microframe.

5.9.2 High Bandwidth Isochronous Endpoints

For isochronous transactions, if an IN endpoint provides less than a maximum data payload as specified by its endpoint descriptor, the host must not issue further transactions for that endpoint for that microframe.

For an isochronous OUT endpoint, the host controller must issue the number of transactions as required for the actual data provided, not exceeding the maximum number specified by the endpoint descriptor. The transactions issued must adhere to the maximum payload sizes as specified in the endpoint descriptor.

No retries are ever done for isochronous endpoints.

High bandwidth isochronous endpoints (IN and OUT) must support data PID sequencing. Data PID sequencing provides the required support for the data receiver to detect one or more lost/damaged packets per microframe.

Data PID sequencing for a high-speed, high bandwidth isochronous IN endpoint uses a repeating sequence of DATA2, DATA1, DATA0 PIDs for the data packet of each transaction in a microframe. If there is only a single transaction in the microframe, only a DATA0 data packet PID is used. If there are two transactions per microframe, DATA1 is used for the first transaction data packet and DATA0 is used for the second transaction data packet. If there are three transactions per microframe, DATA2 is used for the first transaction data packet, DATA1 is used for the second, and DATA0 is used for the third. In all cases, the data PID sequence starts over again the next microframe. Figure 5-11 shows the order of data packet PIDs that are used in subsequent transactions within a microframe for high-bandwidth isochronous IN endpoints.

Figure 5-11. Data Phase PID Sequence for Isochronous IN High Bandwidth Endpoints

An endpoint must respond to an IN token for the first transaction with a DATA2 when it requires three transactions of data to be moved. It must respond with a DATA1 for the first transaction when it requires two transactions and with a DATA0 when it requires only a single transaction. After the first transaction, the endpoint follows the data PID sequence as described above.

The host knows the maximum number of allowed transactions per microframe for the IN endpoint. The host expects the response to the first transaction to encode (via the data packet PID) how many transactions are required by the endpoint for this microframe. If the host doesn't receive an error-free, appropriate response to any transaction, the host must not issue any further transactions to the endpoint for that microframe. When the host receives a DATA0 data packet from the endpoint, it must not issue any further transactions to the endpoint for that microframe.

Data PID sequencing for a high-speed, high bandwidth isochronous OUT endpoint uses a different sequence than that used for an IN endpoint. The host must issue a DATA0 data packet when there is a single transaction. The host must issue an MDATA for the first transaction and a DATA1 for the second transaction when there are two transactions per microframe. The host must issue two MDATA transactions and a DATA2 for the third transaction when there are three transactions per microframe. These sequences allow the endpoint to detect if there was a lost/damaged transaction during a microframe. Figure 5-12 shows the order of data packet PIDs that are used in subsequent transactions within a microframe for high-bandwidth isochronous OUT.

Figure 5-12. Data Phase PID Sequence for Isochronous OUT High Bandwidth Endpoints

If the wrong OUT transactions are detected by the endpoint, all of the data transferred during the microframe must be treated as if it had encountered an error. Note that for the three transactions per microframe case with a missing MDATA transaction, USB provides no way for the endpoint to determine which of the two MDATA transactions was lost. There may be application specific methods to more precisely determine which data was lost, but USB provides no method to do so at the bus level.

5.10 Split Transactions

Host controllers and hubs support one additional transaction type called split transactions. This transaction type allows full- and low-speed devices to be attached to hubs operating at high-speed. These transactions involve only host controllers and hubs and are not visible to devices. High-speed split transactions for interrupt and isochronous transfers must be allocated by the host from the 80% periodic portion of a microframe. More information on split transactions can be found in Chapter 8 and Chapter 11.

5.11 Bus Access for Transfers

Accomplishing any data transfer between the host and a USB device requires some use of the USB bandwidth. Supporting a wide variety of isochronous and asynchronous devices requires that each device's transfer requirements are accommodated. The process of assigning bus bandwidth to devices is called transfer management. There are several entities on the host that coordinate the information flowing over the USB: client software, the USB Driver (USBD), and the Host Controller Driver (HCD). Implementers of these entities need to know the key concepts related to bus access:

- Transfer Management: The entities and the objects that support communication flow over the USB
- Transaction Tracking: The USB mechanisms that are used to track transactions as they move through the USB system
- Bus Time: The time it takes to move a packet of information over the bus
- Device/Software Buffer Size: The space required to support a bus transaction
- Bus Bandwidth Reclamation: Conditions where bandwidth that was allocated to other transfers but was not used and can now be possibly reused by control and bulk transfers

The previous sections focused on how client software relates to a function and what the logical flows are over a pipe between the two entities. This section focuses on the different parts of the host and how they must interact to support moving data over the USB. This information may also be of interest to device implementers so they understand aspects of what the host is doing when a client requests a transfer and how that transfer is presented to the device.

5.11.1 Transfer Management

Transfer management involves several entities that operate on different objects in order to move transactions over the bus:

- Client Software: Consumes/generates function-specific data to/from a function endpoint via calls and callbacks requesting IRPs with the USBD interface.
- USB Driver (USB D): Converts data in client IRPs to/from device endpoint via calls/callbacks with the appropriate HCD. A single client IRP may involve one or more transfers.
- Host Controller Driver (HCD): Converts IRPs to/from transactions (as required by a Host Controller implementation) and organizes them for manipulation by the Host Controller. Interactions between the HCD and its hardware is implementation-dependent and is outside the scope of the USB Specification.
- Host Controller: Takes transactions and generates bus activity via packets to move function-specific data across the bus for each transaction.

Figure 5-13 shows how the entities are organized as information flows between client software and the USB. The objects of primary interest to each entity are shown at the interfaces between entities.

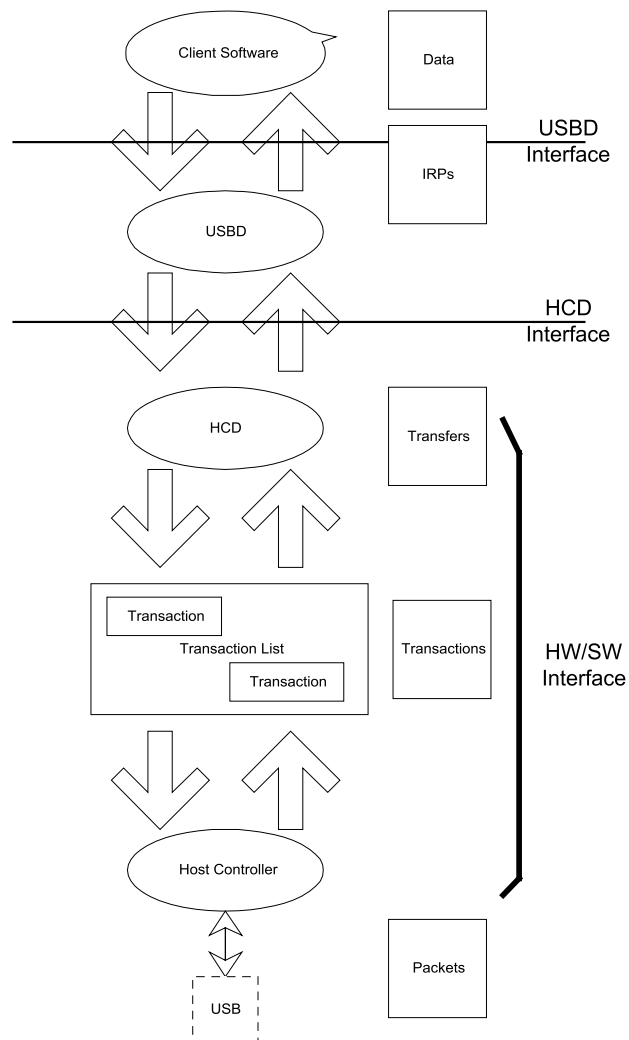

Figure 5-13. USB Information Conversion From Client Software to Bus

5.11.1.1 Client Software

Client software determines what transfers need to be made with a function. It uses appropriate operating system-specific interfaces to request IRPs. Client software is aware only of the set of pipes (i.e., the interface) it needs to manipulate its function. The client is aware of and adheres to all bus access and bandwidth constraints as described previously for each transfer type. The requests made by the client software are presented via the USBD interface.

Some clients may manipulate USB functions via other device class interfaces defined by the operating system and may themselves not make direct USBD calls. However, there is always some lowest level client that makes USBD calls to pass IRPs to the USBD. All IRPs presented are required to adhere to the prenegotiated bandwidth constraints set when the pipe was established. If a function is moved from a non-USB environment to the USB, the driver that would have directly manipulated the function hardware via memory or I/O accesses is the lowest client software in the USB environment that now interacts with the USBD to manipulate the driver's USB function.

After client software has requested a transfer of its function and the request has been serviced, the client software receives notification of the completion status of the IRP. If the transfer involved function-to-host data transfer, the client software can access the data in the data buffer associated with the completed IRP.

The USBD interface is defined in Chapter 10.

5.11.1.2 USB Driver

The Universal Serial Bus Driver (USB D) is involved in mediating bus access at two general times:

- While a device is attached to the bus during configuration
- During normal transfers

When a device is attached and configured, the USB D is involved to ensure that the desired device configuration can be accommodated on the bus. The USB D receives configuration requests from the configuring software that describe the desired device configuration: endpoint(s), transfer type(s), transfer period(s), data size(s), etc. The USB D either accepts or rejects a configuration request based on bandwidth availability and the ability to accommodate that request type on the bus. If it accepts the request, the USB D creates a pipe for the requester of the desired type and with appropriate constraints as defined for the transfer type. Bandwidth allocation for periodic endpoints does not have to be made when the device is configured and, once made, a bandwidth allocation can be released without changing the device configuration.

The configuration aspects of the USB D are typically operating system-specific and heavily leverage the configuration features of the operating system to avoid defining additional (redundant) interfaces.

Once a device is configured, the software client can request IRPs to move data between it and its function endpoints.

5.11.1.3 Host Controller Driver

The Host Controller Driver (HCD) is responsible for tracking the IRPs in progress and ensuring that USB bandwidth and (micro)frame time maximums are never exceeded. When IRPs are made for a pipe, the HCD adds them to the transaction list. When an IRP is complete, the HCD notifies the requesting software client of the completion status for the IRP. If the IRP involved data transfer from the function to the software client, the data was placed in the client-indicated data buffer.

IRPs are defined in an operating system-dependent manner.

5.11.1.4 Transaction List

The transaction list is a Host Controller implementation-dependent description of the current outstanding set of bus transactions that need to be run on the bus. Only the HCD and its Host Controller have access to the specific representation. Each description contains transaction descriptions in which parameters, such as data size in bytes, the device address and endpoint number, and the memory area to which data is to be sent or received, are identified.

A transaction list and the interface between the HCD and its Host Controller is typically represented in an implementation-dependent fashion and is not defined explicitly as part of the USB Specification.

5.11.1.5 Host Controller

The Host Controller has access to the transaction list and translates it into bus activity. In addition, the Host Controller provides a reporting mechanism whereby the status of a transaction (done, pending, halted, etc.) can be obtained. The Host Controller converts transactions into appropriate implementation-dependent activities that result in USB packets moving over the bus topology rooted in the root hub.

The Host Controller ensures that the bus access rules defined by the protocol are obeyed, such as inter-packet timings, timeouts, babble, etc. The HCD interface provides a way for the Host Controller to participate in deciding whether a new pipe is allowed access to the bus. This is done because Host Controller implementations can have restrictions/constraints on the minimum inter-transaction times they may support for combinations of bus transactions.

The interface between the transaction list and the Host Controller is hidden within an HCD and Host Controller implementation.

5.11.2 Transaction Tracking

A USB function sees data flowing across the bus in packets as described in Chapter 8. The Host Controller uses some implementation-dependent representation to track what packets to transfer to/from what endpoints at what time or in what order. Most client software does not want to deal with packetized communication flows because this involves a degree of complexity and interconnect dependency that limits the implementation. The USB System Software (USBD and HCD) provides support for matching data movement requirements of a client to packets on the bus. The Host Controller hardware and software uses IRPs to track information about one or more transactions that combine to deliver a transfer of information between the client software and the function. Figure 5-14 summarizes how transactions are organized into IRPs for the four transfer types. Detailed protocol information for each transfer type can be found in Chapter 8. More information about client software views of IRPs can be found in Chapter 10 and in the operating system specific-information for a particular operating system.

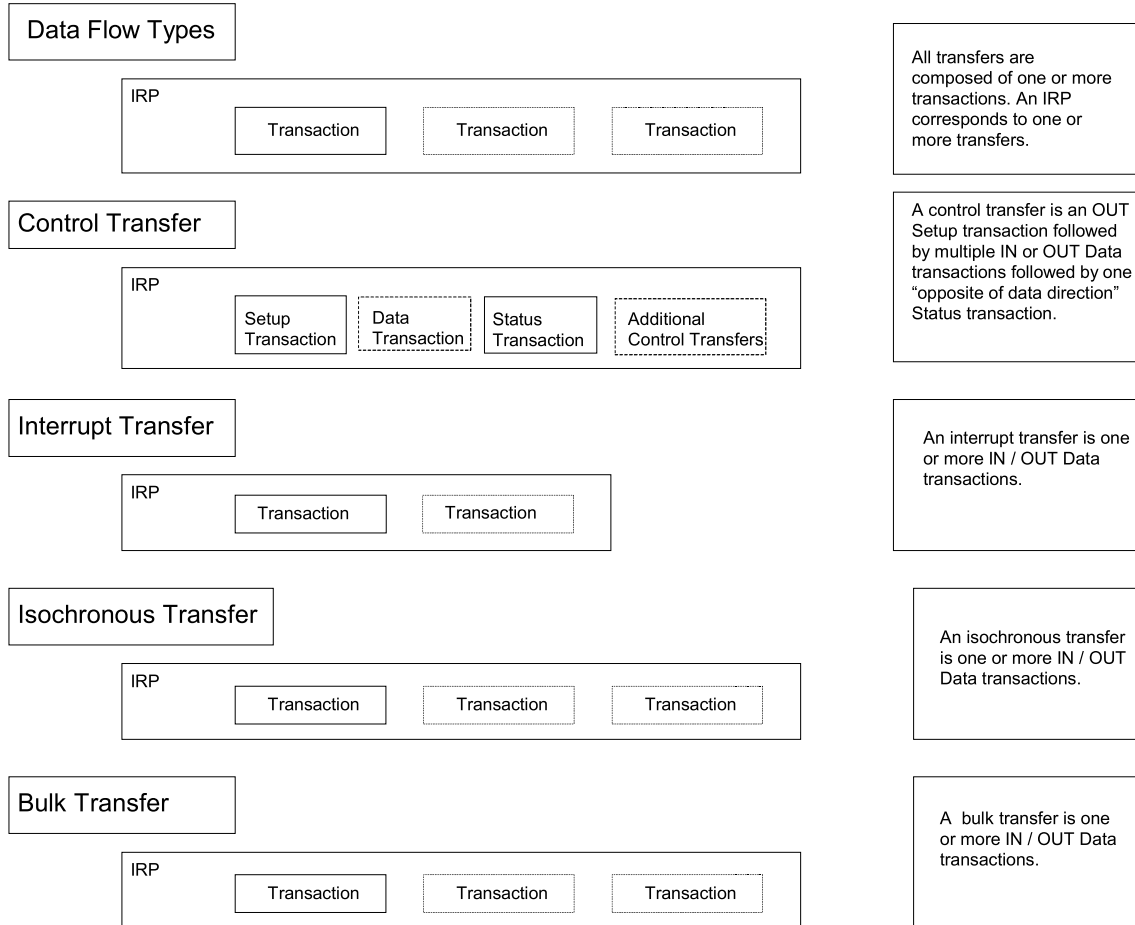

Figure 5-14. Transfers for Communication Flows

Even though IRPs track the bus transactions that need to occur to move a specific data flow over the USB, Host Controllers are free to choose how the particular bus transactions are moved over the bus subject to the USB-defined constraints (e.g., exactly one transaction per (micro)frame for isochronous transfers). In any case, an endpoint will see transactions in the order they appear within an IRP unless errors occur. For example, Figure 5-15 shows two IRPs, one each for two pipes where each IRP contains three transactions. For any transfer type, a Host Controller is free to move the first transaction of the first IRP followed by the first transaction of the second IRP somewhere in (micro)Frame 1, while moving the second transaction of each IRP in opposite order somewhere in (micro)Frame 2. If these are isochronous transfer types, that is the only degree of freedom a Host Controller has. If these are control or bulk transfers, a Host Controller could further move more or less transactions from either IRP within either (micro)frame. Functions cannot depend on seeing transactions within an IRP back-to-back within a (micro)frame nor should they depend on not seeing transactions back-to-back within a (micro)frame.

Figure 5-15. Arrangement of IRPs to Transactions/(Micro)frames

5.11.3 Calculating Bus Transaction Times

When the USB System Software allows a new pipe to be created for the bus, it must calculate how much bus time is required for a given transaction. That bus time is based on the maximum packet size information reported for an endpoint, the protocol overhead for the specific transaction type request, the overhead due to signaling imposed bit stuffing, inter-packet timings required by the protocol, inter-transaction timings, etc. These calculations are required to ensure that the time available in a (micro)frame is not exceeded. The equations used to determine transaction bus time are:

KEY:

Data_bc	The byte count of data payload
Host_Delay	The time required for the host or transaction translator to prepare for or recover from the transmission; Host Controller implementation-specific
Floor()	The integer portion of argument
Hub_LS_Setup	The time provided by the Host Controller for hubs to enable low-speed ports; measured as the delay from the end of the PRE PID to the start of the low-speed SYNC; minimum of four full-speed bit times
BitStuffTime	Function that calculates theoretical additional time required due to bit stuffing in signaling; worst case is $(1.1667 * 8 * \text{Data_bc})$

Universal Serial Bus Specification Revision 2.0

High-speed (Input)

Non-Isochronous Transfer (Handshake Included)
= $(55 * 8 * 2.083) + (2.083 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

Isochronous Transfer (No Handshake)
= $(38 * 8 * 2.083) + (2.083 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

High-speed (Output)

Non-Isochronous Transfer (Handshake Included)
= $(55 * 8 * 2.083) + (2.083 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

Isochronous Transfer (No Handshake)
= $(38 * 8 * 2.083) + (2.083 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

Full-speed (Input)

Non-Isochronous Transfer (Handshake Included)
= $9107 + (83.54 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

Isochronous Transfer (No Handshake)
= $7268 + (83.54 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

Full-speed (Output)

Non-Isochronous Transfer (Handshake Included)
= $9107 + (83.54 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

Isochronous Transfer (No Handshake)
= $6265 + (83.54 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

Low-speed (Input)

= $64060 + (2 * \text{Hub_LS_Setup}) + (676.67 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

Low-speed (Output)

= $64107 + (2 * \text{Hub_LS_Setup}) + (667.0 * \text{Floor}(3.167 + \text{BitStuffTime}(\text{Data_bc}))) + \text{Host_Delay}$

The bus times in the above equations are in nanoseconds and take into account propagation delays due to the distance the device is from the host. These are typical equations that can be used to calculate bus time; however, different implementations may choose to use coarser approximations of these times.

The actual bus time taken for a given transaction will almost always be less than that calculated because bit stuffing overhead is data-dependent. Worst case bit stuffing is calculated as 1.1667 (7/6) times the raw time (i.e., the BitStuffTime function multiplies the Data_bc by 8*1.1667 in the equations). This means that there will almost always be time unused on the bus (subject to data pattern specifics) after all regularly scheduled transactions have completed. The bus time made available due to less bit stuffing can be reused as discussed in Section 5.11.5.

The Host_Delay term in the equations is Host Controller-, Transaction Translator(TT)-, and system-dependent and allows for additional time a Host Controller (or TT) may require due to delays in gaining access to memory or other implementation dependencies. This term is incorporated into an implementation of these equations by using the transfer management functions provided by the HCD interface. These equations are typically implemented by a combination of USB and HCD software working in cooperation.

The results of these calculations are used to determine whether a transfer or pipe creation can be supported in a given USB configuration.

5.11.4 Calculating Buffer Sizes in Functions and Software

Client software and functions both need to provide buffer space for pending data transactions awaiting their turn on the bus. For non-isochronous pipes, this buffer space needs to be just large enough to hold the next data packet. If more than one transaction request is pending for a given endpoint, the buffering for each transaction must be supplied. Methods to calculate the precise absolute minimum buffering a function may require because of specific interactions defined between its client software and the function are outside the scope of this specification.

The Host Controller is expected to be able to support an unlimited number of transactions pending for the bus subject to available system memory for buffer and descriptor space, etc. Host Controllers are allowed to limit how many (micro)frames into the future they allow a transaction to be requested.

For isochronous pipes, Section 5.12.4 describes details affecting host side and device side buffering requirements. In general, buffers need to be provided to hold approximately twice the amount of data that can be transferred in 1ms for full-speed endpoints or 125 μ s for high-speed endpoints.

5.11.5 Bus Bandwidth Reclamation

The USB bandwidth and bus access are granted based on a calculation of worst-case bus transmission time and required latencies. However, due to the constraints placed on different transfer types and the fact that the bit stuffing bus time contribution is calculated as a constant but is data-dependent, there will frequently be bus time remaining in each (micro)frame time versus what the (micro)frame transmission time was calculated to be. In order to support the most efficient use of the bus bandwidth, control and bulk transfers are candidates to be moved over the bus as bus time becomes available. Exactly how a Host Controller supports this is implementation-dependent. A Host Controller can take into account the transfer types of pending IRPs and implementation-specific knowledge of remaining (micro)frame time to reuse reclaimed bandwidth.

5.12 Special Considerations for Isochronous Transfers

Support for isochronous data movement between the host and a device is one of the system capabilities supported by the USB. Delivering isochronous data reliably over the USB requires careful attention to detail. The responsibility for reliable delivery is shared by several USB entities:

- The device/function
- The bus
- The Host Controller
- One or more software agents

Because time is a key part of an isochronous transfer, it is important for USB designers to understand how time is dealt with within the USB by these different entities.

Note: The examples in this section describe USB for an example involving full-speed endpoints. The general example details are also appropriate for high-speed endpoints when corresponding changes are made; for example, frame replaced with microframe, 1 ms replaced with 125 μ s, rate adjustments made between full-speed and high-speed, etc.

All isochronous devices must report their capabilities in the form of device-specific descriptors. The capabilities should also be provided in a form that the potential customer can use to decide whether the device offers a solution to his problem(s). The specific capabilities of a device can justify price differences.

In any communication system, the transmitter and receiver must be synchronized enough to deliver data robustly. In an asynchronous communication system, data can be delivered robustly by allowing the transmitter to detect that the receiver has not received a data item correctly and simply retrying transmission of the data.

In an isochronous communication system, the transmitter and receiver must remain time- and data-synchronized to deliver data robustly. The USB does not support transmission retry of isochronous data so that minimal bandwidth can be allocated to isochronous transfers and time synchronization is not lost due to a retry delay. However, it is critical that a USB isochronous transmitter/receiver pair still remain synchronized both in normal data transmission cases and in cases where errors occur on the bus.

In many systems that deal with isochronous data, a single global clock is used to which all entities in the system synchronize. An example of such a system is the PSTN (Public Switched Telephone Network). Given that a broad variety of devices with different natural frequencies may be attached to the USB, no single clock can provide all the features required to satisfy the synchronization requirements of all devices and software while still supporting the cost targets of mass-market PC products. The USB defines a clock model that allows a broad range of devices to coexist on the bus and have reasonable cost implementations.

This section presents options or features that can be used by isochronous endpoints to minimize behavior differences between a non-USB implemented function and a USB version of the function. An example is included to illustrate the similarities and differences between the non-USB and USB versions of a function.

The remainder of the section presents the following key concepts:

- **USB Clock Model:** What clocks are present in a USB system that have impact on isochronous data transfers
- **USB (micro)frame Clock-to-function Clock Synchronization Options:** How the USB (micro)frame clock can relate to a function clock
- **SOF Tracking:** Responsibilities and opportunities of isochronous endpoints with respect to the SOF token and USB (micro)frames
- **Data Prebuffering:** Requirements for accumulating data before generation, transmission, and consumption
- **Error Handling:** Isochronous-specific details for error handling
- **Buffering for Rate Matching:** Equations that can be used to calculate buffer space required for isochronous endpoints

5.12.1 Example Non-USB Isochronous Application

The example used is a reasonably generalized example. Other simpler or more complex cases are possible and the relevant USB features identified can be used or not as appropriate.

The example consists of an 8 kHz mono microphone connected through a mixer driver that sends the input data stream to 44 kHz stereo speakers. The mixer expects the data to be received and transmitted at some sample rate and encoding. A rate matcher driver on input and output converts the sample rate and encoding from the natural rate and encoding of the device to the rate and encoding expected by the mixer.

Figure 5-16 illustrates this example.

Figure 5-16. Non-USB Isochronous Example

Universal Serial Bus Specification Revision 2.0

A master clock (which can be provided by software driven from the real time clock) in the PC is used to awaken the mixer to ask the input source for input data and to provide output data to the output sink. In this example, assume it awakens every 20 ms. The microphone and speakers each have their own sample clocks that are unsynchronized with respect to each other or the master mixer clock. The microphone produces data at its natural rate (one-byte samples, 8,000 times a second) and the speakers consume data at their natural rate (four-byte samples, 44,100 times a second). The three clocks in the system can drift and jitter with respect to each other. Each rate matcher may also be running at a different natural rate than either the mixer driver, the input source/driver, or output sink/driver.

The rate matchers also monitor the long-term data rate of their device compared to the master mixer clock and interpolate an additional sample or merge two samples to adjust the data rate of their device to the data rate of the mixer. This adjustment may be required every couple of seconds, but typically occurs infrequently. The rate matchers provide some additional buffering to carry through a rate match.

Note: Some other application might not be able to tolerate sample adjustment and would need some other means of accommodating master clock-to-device clock drift or else would require some means of synchronizing the clocks to ensure that no drift could occur.

The mixer always expects to receive exactly a service period of data (20 ms service period) from its input device and produce exactly a service period of data for its output device. The mixer can be delayed up to less than a service period if data or space is not available from its input/output device. The mixer assumes that such delays do not accumulate.

The input and output devices and their drivers expect to be able to put/get data in response to a hardware interrupt from the DMA controller when their transducer has processed one service period of data. They expect to get/put exactly one service period of data. The input device produces 160 bytes (ten samples) every service period of 20 ms. The output device consumes 3,528 bytes (882 samples) every 20 ms service period. The DMA controller can move a single sample between the device and the host buffer at a rate much faster than the sample rate of either device.

The input and output device drivers provide two service periods of system buffering. One buffer is always being processed by the DMA controller. The other buffer is guaranteed to be ready before the current buffer is exhausted. When the current buffer is emptied, the hardware interrupt awakens the device driver and it calls the rate matcher to give it the buffer. The device driver requests a new IRP with the buffer before the current buffer is exhausted.

The devices can provide two samples of data buffering to ensure that they always have a sample to process for the next sample period while the system is reacting to the previous/next sample.

The service periods of the drivers are chosen to survive interrupt latency variabilities that may be present in the operating system environment. Different operating system environments will require different service periods for reliable operation. The service periods are also selected to place a minimum interrupt load on the system, because there may be other software in the system that requires processing time.

5.12.2 USB Clock Model

Time is present in the USB system via clocks. In fact, there are multiple clocks in a USB system that must be understood:

- **Sample Clock:** This clock determines the natural data rate of samples moving between client software on the host and the function. This clock does not need to be different between non-USB and USB implementations.
- **Bus Clock:** This clock runs at a 1.000 ms period (1 kHz frequency) on full-speed segments and 125.000 μ s (8 kHz frequency) on high-speed segments of the bus and is indicated by the rate of SOF packets on the bus. This clock is somewhat equivalent to the 8 MHz clock in the non-USB example. In the USB case, the bus clock is often a lower-frequency clock than the sample clock, whereas the bus clock is almost always a higher-frequency clock than the sample clock in a non-USB case.
- **Service Clock:** This clock is determined by the rate at which client software runs to service IRPs that may have accumulated between executions. This clock also can be the same in the USB and non-USB cases.

In most existing operating systems, it is not possible to support a broad range of isochronous communication flows if each device driver must be interrupted for each sample for fast sample rates. Therefore, multiple samples, if not multiple packets, will be processed by client software and then given to the Host Controller to sequence over the bus according to the prenegotiated bus access requirements. Figure 5-17 presents an example for a reasonable USB clock environment equivalent to the non-USB example in Figure 5-16.

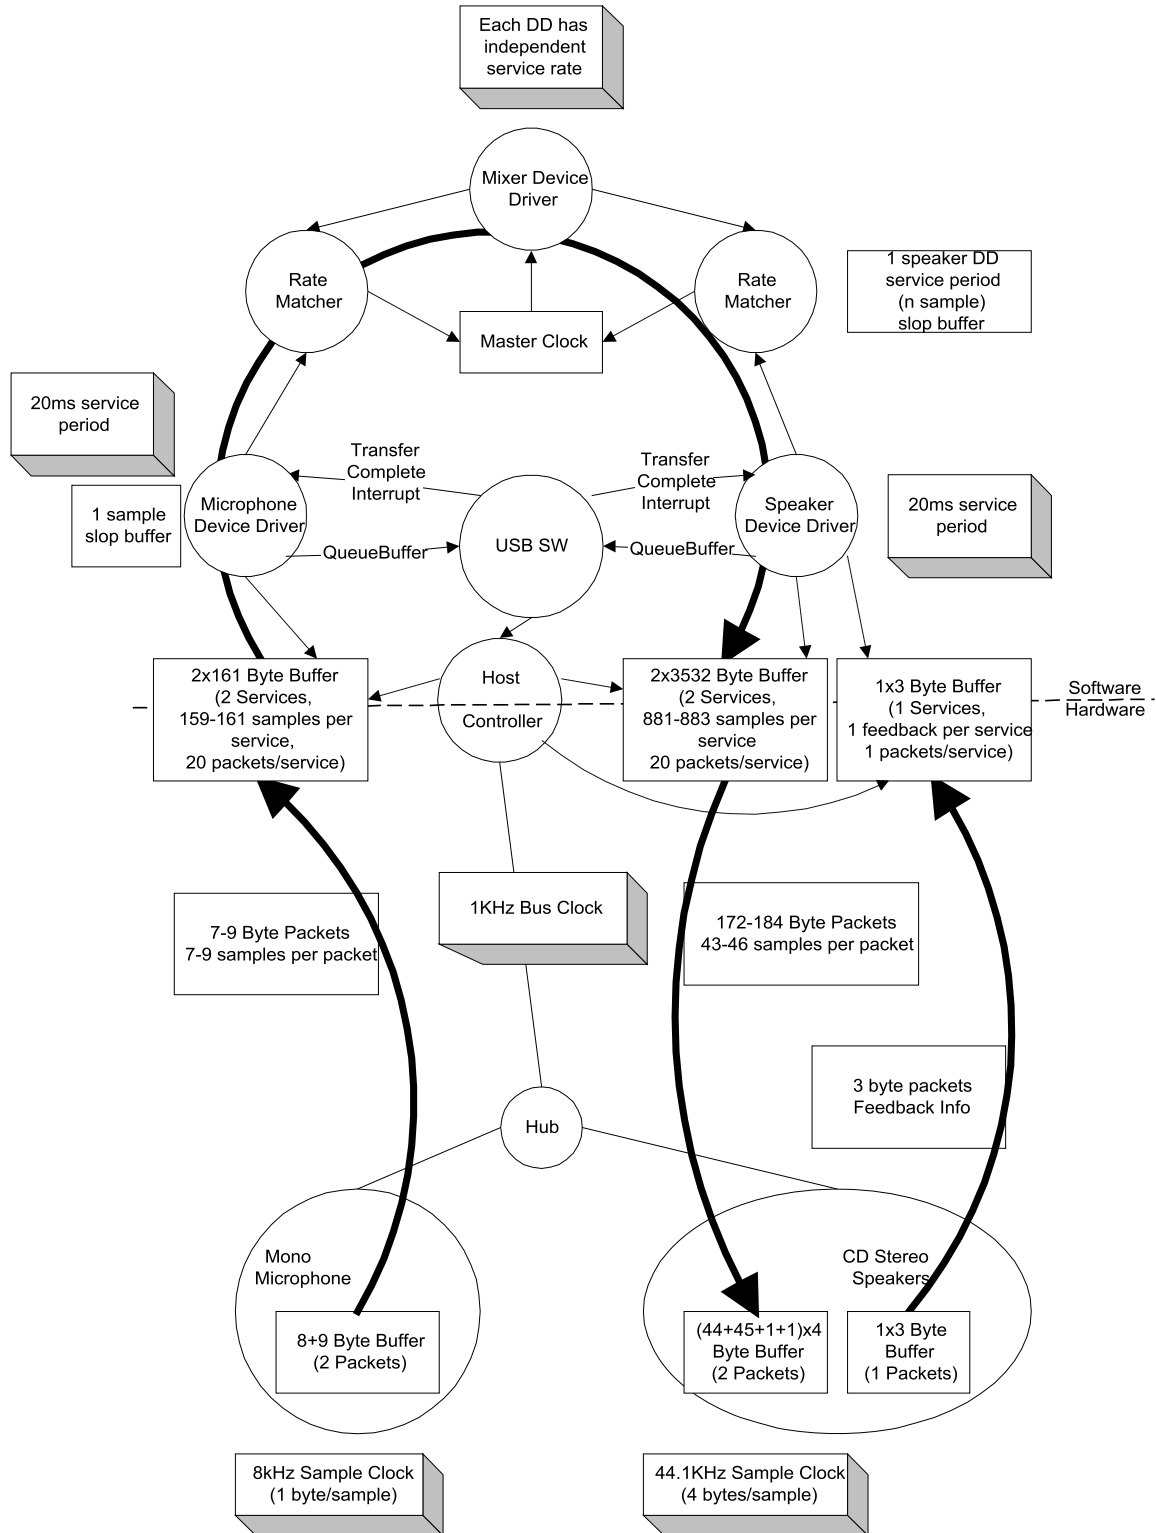

Figure 5-17. USB Full-speed Isochronous Application

Figure 5-17 shows a typical round trip path of information from a microphone as an input device to a speaker as an output device. The clocks, packets, and buffering involved are also shown. Figure 5-17 will be explored in more detail in the following sections.

The focus of this example is to identify the differences introduced by the USB compared to the previous non-USB example. The differences are in the areas of buffering, synchronization given the existence of a USB bus clock, and delay. The client software above the device drivers can be unaffected in most cases.

5.12.3 Clock Synchronization

In order for isochronous data to be manipulated reliably, the three clocks identified above must be synchronized in some fashion. If the clocks are not synchronized, several clock-to-clock attributes can be present that can be undesirable:

- **Clock Drift:** Two clocks that are nominally running at the same rate can, in fact, have implementation differences that result in one clock running faster or slower than the other over long periods of time. If uncorrected, this variation of one clock compared to the other can lead to having too much or too little data when data is expected to always be present at the time required.
- **Clock Jitter:** A clock may vary its frequency over time due to changes in temperature, etc. This may also alter when data is actually delivered compared to when it is expected to be delivered.
- **Clock-to-clock Phase Differences:** If two clocks are not phase locked, different amounts of data may be available at different points in time as the beat frequency of the clocks cycle out over time. This can lead to quantization/sampling related artifacts.

The bus clock provides a central clock with which USB hardware devices and software can synchronize to one degree or another. However, the software will, in general, not be able to phase- or frequency-lock precisely to the bus clock given the current support for “real time-like” operating system scheduling support in most PC operating systems. Software running in the host can, however, know that data moved over the USB is packetized. For isochronous transfer types, a unit of data is moved exactly once per (micro)frame and the (micro)frame clock is reasonably precise. Providing the software with this information allows it to adjust the amount of data it processes to the actual (micro)frame time that has passed.

Note: For high-speed high-bandwidth endpoints, the data exchanged in the two or three transactions per microframe is still considered to belong to the same “single packet.” The large amount of data per packet is split into two or three transactions only for bus efficiency reasons.

5.12.4 Isochronous Devices

The USB includes a framework for isochronous devices that defines synchronization types, how isochronous endpoints provide data rate feedback, and how they can be connected together. Isochronous devices include sampled analog devices (for example, audio and telephony devices) and synchronous data devices. Synchronization type classifies an endpoint according to its capability to synchronize its data rate to the data rate of the endpoint to which it is connected. Feedback is provided by indicating accurately what the required data rate is, relative to the SOF frequency. The ability to make connections depends on the quality of connection that is required, the endpoint synchronization type, and the capabilities of the host application that is making the connection. Additional device class-specific information may be required, depending on the application.

Note: The term “data” is used very generally, and may refer to data that represents sampled analog information (like audio), or it may be more abstract information. “Data rate” refers to the rate at which analog information is sampled, or the rate at which data is clocked.

The following information is required in order to determine how to connect isochronous endpoints:

- Synchronization type:
 - Asynchronous: Unsynchronized, although sinks provide data rate feedback
 - Synchronous: Synchronized to the USB's SOF
 - Adaptive: Synchronized using feedback or feedforward data rate information
- Available data rates
- Available data formats

Synchronization type and data rate information are needed to determine if an exact data rate match exists between source and sink, or if an acceptable conversion process exists that would allow the source to be connected to the sink. It is the responsibility of the application to determine whether the connection can be supported within available processing resources and other constraints (like delay). Specific USB device classes define how to describe synchronization type and data rate information.

Data format matching and conversion is also required for a connection, but it is not a unique requirement for isochronous connections. Details about format conversion can be found in other documents related to specific formats.

5.12.4.1 Synchronization Type

Three distinct synchronization types are defined. Table 5-12 presents an overview of endpoint synchronization characteristics for both source and sink endpoints. The types are presented in order of increasing capability.

Table 5-12. Synchronization Characteristics

	Source	Sink
Asynchronous	Free running F_s Provides implicit feedforward (data stream)	Free running F_s Provides explicit feedback (isochronous pipe)
Synchronous	F_s locked to SOF Uses implicit feedback (SOF)	F_s locked to SOF Uses implicit feedback (SOF)
Adaptive	F_s locked to sink Uses explicit feedback (isochronous pipe)	F_s locked to data flow Uses implicit feedforward (data stream)

5.12.4.1.1 Asynchronous

Asynchronous endpoints cannot synchronize to SOF or any other clock in the USB domain. They source or sink an isochronous data stream at either a fixed data rate (single-frequency endpoints), a limited number of data rates (32 kHz, 44.1 kHz, 48 kHz, ...), or a continuously programmable data rate. If the data rate is programmable, it is set during initialization of the isochronous endpoint. Asynchronous devices must report their programming capabilities in the class-specific endpoint descriptor as described in their device class specification. The data rate is locked to a clock external to the USB or to a free-running internal clock. These devices place the burden of data rate matching elsewhere in the USB environment. Asynchronous source endpoints carry their data rate information implicitly in the number of samples they produce per

(micro)frame. Asynchronous sink endpoints must provide explicit feedback information to an adaptive driver (refer to Section 5.12.4.2).

An example of an asynchronous source is a CD-audio player that provides its data based on an internal clock or resonator. Another example is a Digital Audio Broadcast (DAB) receiver or a Digital Satellite Receiver (DSR). Here, too, the sample rate is fixed at the broadcasting side and is beyond USB control.

Asynchronous sink endpoints could be low-cost speakers running off of their internal sample clock.

5.12.4.1.2 Synchronous

Synchronous endpoints can have their clock system (their notion of time) controlled externally through SOF synchronization. These endpoints must slave their sample clock to the 1 ms SOF tick (by means of a programmable PLL). For high-speed endpoints, the presence of the microframe SOF can be used for tighter frame clock tracking.

Synchronous endpoints may source or sink isochronous data streams at either a fixed data rate (single-frequency endpoints), a limited number of data rates (32 kHz, 44.1 kHz, 48 kHz, ...), or a continuously programmable data rate. If programmable, the operating data rate is set during initialization of the isochronous endpoint. The number of samples or data units generated in a series of USB (micro)frames is deterministic and periodic. Synchronous devices must report their programming capabilities in the class-specific endpoint descriptor as described in their device class specification.

An example of a synchronous source is a digital microphone that synthesizes its sample clock from SOF and produces a fixed number of audio samples every USB (micro)frame. Likewise, a synchronous sink derives its sample clock from SOF and consumes a fixed number of samples every USB (micro)frame.

5.12.4.1.3 Adaptive

Adaptive endpoints are the most capable endpoints possible. They are able to source or sink data at any rate within their operating range. Adaptive source endpoints produce data at a rate that is controlled by the data sink. The sink provides feedback (refer to Section 5.12.4.2) to the source, which allows the source to know the desired data rate of the sink. For adaptive sink endpoints, the data rate information is embedded in the data stream. The average number of samples received during a certain averaging time determines the instantaneous data rate. If this number changes during operation, the data rate is adjusted accordingly.

The data rate operating range may center around one rate (e.g., 8 kHz), select between several programmable or auto-detecting data rates (32 kHz, 44.1 kHz, 48 kHz, ...), or may be within one or more ranges (e.g., 5 kHz to 12 kHz or 44 kHz to 49 kHz). Adaptive devices must report their programming capabilities in the class-specific endpoint descriptor as described in their device class specification.

An example of an adaptive source is a CD player that contains a fully adaptive sample rate converter (SRC) so that the output sample frequency no longer needs to be 44.1 kHz but can be anything within the operating range of the SRC. Adaptive sinks include such endpoints as high-end digital speakers, headsets, etc.

5.12.4.2 Feedback

An asynchronous sink must provide explicit feedback to the host by indicating accurately what its desired data rate (F_f) is, relative to the USB (micro)frame frequency. This allows the host to continuously adjust the number of samples sent to the sink so that neither underflow or overflow of the data buffer occurs. Likewise, an adaptive source must receive explicit feedback from the host so that it can accurately generate the number of samples required by the host. Feedback endpoints can be specified as described in Section 9.6.6 for the *bmAttributes* field of the endpoint descriptor.

To generate the desired data rate F_f , the device must measure its actual sampling rate F_s , referenced to the USB notion of time, i.e., the USB (micro)frame frequency. This specification requires the data rate F_f to be

Universal Serial Bus Specification Revision 2.0

resolved to better than one sample per second (1Hz) in order to allow a high-quality source rate to be created and to tolerate delays and errors in the feedback loop. To achieve this accuracy, the measurement time T_{meas} must be at least 1 second. Therefore:

$$T_{meas} = 2^K$$

where T_{meas} is now expressed in USB (micro)frames and $K=10$ for full-speed devices (1 ms frames) and $K=13$ for high-speed devices (125 μ s microframes). However, in most devices, the actual sampling rate F_s is derived from a master clock F_m through a binary divider. Therefore:

$$F_m = F_s * 2^P$$

where P is a positive integer (including 0 if no higher-frequency master clock is available). The measurement time T_{meas} can now be decreased by measuring F_m instead of F_s and:

$$T_{meas} = \frac{2^K}{2^P} = 2^{(K-P)}$$

In this way, a new estimate for F_f becomes available every $2^{(K-P)}$ (micro)frames. P is practically bound to be in the range $[0, K]$ because there is no point in using a clock slower than F_s ($P=0$), and no point in trying to update F_f more than once per (micro)frame ($P=K$). A sink can determine F_f by counting cycles of the master clock F_m for a period of $2^{(K-P)}$ (micro)frames. The counter is read into F_f and reset every $2^{(K-P)}$ (micro)frames. As long as no clock cycles are skipped, the count will be accurate over the long term.

Each (micro)frame, an adaptive source adds F_f to any remaining fractional sample count from the previous (micro)frame, sources the number of samples in the integer part of the sum, and retains the fractional sample count for the next (micro)frame. The source can look at the behavior of F_f over many (micro)frames to determine an even more accurate rate, if it needs to.

F_f is expressed in number of samples per (micro)frame. The F_f value consists of an integer part that represents the (integer) number of samples per (micro)frame and a fractional part that represents the “fraction” of a sample that would be needed to match the sampling frequency F_s to a resolution of 1 Hz or better. The fractional part requires at least K bits to represent the “fraction” of a sample to a resolution of 1 Hz or better. The integer part must have enough bits to represent the maximum number of samples that can ever occur in a single (micro)frame. Assuming that the minimum sample size is one byte, then this number is limited to 1,023 for full-speed endpoints. Ten bits are therefore sufficient to encode this value. For high-speed endpoints, this number is limited to $3*1,024=3,072$ and twelve bits are needed.

In summary, for full-speed endpoints, the F_f value shall be encoded in an unsigned 10.10 ($K=10$) format which fits into three bytes. Because the maximum integer value is fixed to 1,023, the 10.10 number will be left-justified in the 24 bits, so that it has a 10.14 format. Only the first ten bits behind the binary point are required. The lower four bits may be optionally used to extend the precision of F_f , otherwise, they shall be reported as zero. For high-speed endpoints, the F_f value shall be encoded in an unsigned 12.13 ($K=13$) format which fits into four bytes. The value shall be aligned into these four bytes so that the binary point is located between the second and the third byte so that it has a 16.16 format. The most significant four bits shall be reported zero. Only the first 13 bits behind the binary point are required. The lower three bits may be optionally used to extend the precision of F_f , otherwise, they shall be reported as zero.

An endpoint needs to implement only the number of bits that it effectively requires for its maximum F_f .

The choice of P is endpoint-specific. Use the following guidelines when choosing P :

- P must be in the range $[0, K]$.
- Larger values of P are preferred, because they reduce the size of the frame counter and increase the rate at which F_f is updated. More frequent updates result in a tighter control of the source data rate, which reduces the buffer space required to handle F_f changes.
- P should be less than K so that F_f is averaged across at least two frames in order to reduce SOF jitter effects.
- P should not be zero in order to keep the deviation in the number of samples sourced to less than 1 in the event of a lost F_f value.

Isochronous transfers are used to read F_f from the feedback register. The desired reporting rate for the feedback should be $2^{(K-P)}$ frames. F_f will be reported at most once per update period. There is nothing to be gained by reporting the same F_f value more than once per update period. The endpoint may choose to report F_f only if the updated value has changed from the previous F_f value. If the value has not changed, the endpoint may report the current F_f value or a zero length data payload. It is strongly recommended that an endpoint always report the current F_f value any time it is polled.

It is possible that the source will deliver one too many or one too few samples over a long period due to errors or accumulated inaccuracies in measuring F_f . The sink must have sufficient buffer capability to accommodate this. When the sink recognizes this condition, it should adjust the reported F_f value to correct it. This may also be necessary to compensate for relative clock drifts. The implementation of this correction process is endpoint-specific and is not specified.

5.12.4.3 Implicit Feedback

In some cases, implementing a separate explicit feedback endpoint can be avoided. If a device implements a group of isochronous data endpoints that are closely related and if:

- All the endpoints in the group are synchronized (i.e. use sample clocks that are derived from a common master clock)
- The group contains one or more isochronous data endpoints in one direction that normally would need explicit feedback
- The group contains at least one isochronous data endpoint in the opposite direction

Under these circumstances, the device may elect not to implement a separate isochronous explicit feedback endpoint. Instead, feedback information can be derived from the data endpoint in the opposite direction by observing its data rate.

Two cases can arise:

- One or more asynchronous sink endpoints are accompanied by an asynchronous source endpoint. The data rate on the source endpoint can be used as implicit feedback information to adjust the data rate on the sink endpoint(s).
- One or more adaptive source endpoints are accompanied by an adaptive sink endpoint. The source endpoint can adjust its data rate based on the data rate received by the sink endpoint.

This specification provides the necessary framework to implement synchronization as described above (see Chapter 9). However, exactly how the desired data rate F_f is derived from the data rate of the implied feedback endpoint is implementation-dependent.

5.12.4.4 Connectivity

In order to fully describe the source-to-sink connectivity process, an interconnect model is presented. The model indicates the different components involved and how they interact to establish the connection.

The model provides for multi-source/multi-sink situations. Figure 5-18 illustrates a typical situation (highly condensed and incomplete). A physical device is connected to the host application software through different hardware and software layers as described in this specification. At the client interface level, a virtual device is presented to the application. From the application standpoint, only virtual devices exist. It is up to the device driver and client software to decide what the exact relation is between physical and virtual device.

Figure 5-18. Example Source/Sink Connectivity

Device manufacturers (or operating system vendors) must provide the necessary device driver software and client interface software to convert their device from the physical implementation to a USB-compliant software implementation (the virtual device). As stated before, depending on the capabilities built into this software, the virtual device can exhibit different synchronization behavior from the physical device. However, the synchronization classification applies equally to both physical and virtual devices. All physical devices belong to one of the three possible synchronization types. Therefore, the capabilities that have to be built into the device driver and/or client software are the same as the capabilities of a physical device. The word “application” must be replaced by “device driver/client software.” In the case of a physical source to virtual source connection, “virtual source device” must be replaced by “physical source device” and “virtual sink device” must be replaced by “virtual source device.” In the case of a virtual sink to physical sink connection, “virtual source device” must be replaced by “virtual sink device” and “virtual sink device” must be replaced by “physical sink device.”

Universal Serial Bus Specification Revision 2.0

Placing the rate adaptation (RA) functionality into the device driver/client software layer has the distinct advantage of isolating all applications, relieving the device from the specifics and problems associated with rate adaptation. Applications that would otherwise be multi-rate degenerate to simpler mono-rate systems.

Note: The model is not limited to only USB devices. For example, a CD-ROM drive containing 44.1 kHz audio can appear as either an asynchronous, synchronous, or adaptive source. Asynchronous operation means that the CD-ROM fills its buffer at the rate that it reads data from the disk, and the driver empties the buffer according to its USB service interval. Synchronous operation means that the driver uses the USB service interval (e.g., 10 ms) and nominal sample rate of the data (44.1 kHz) to determine to put out 441 samples every USB service interval. Adaptive operation would build in a sample rate converter to match the CD-ROM output rate to different sink sampling rates.

Using this reference model, it is possible to define what operations are necessary to establish connections between various sources and sinks. Furthermore, the model indicates at what level these operations must or can take place. First, there is the stage where physical devices are mapped onto virtual devices and vice versa. This is accomplished by the driver and/or client software. Depending on the capabilities included in this software, a physical device can be transformed into a virtual device of an entirely different synchronization type. The second stage is the application that uses the virtual devices. Placing rate matching capabilities at the driver/client level of the software stack relieves applications communicating with virtual devices from the burden of performing rate matching for every device that is attached to them. Once the virtual device characteristics are decided, the actual device characteristics are not any more interesting than the actual physical device characteristics of another driver.

As an example, consider a mixer application that connects at the source side to different sources, each running at their own frequencies and clocks. Before mixing can take place, all streams must be converted to a common frequency and locked to a common clock reference. This action can be performed in the physical-to-virtual mapping layer or it can be handled by the application itself for each source device independently. Similar actions must be performed at the sink side. If the application sends the mixed data stream out to different sink devices, it can either do the rate matching for each device itself or it can rely on the driver/client software to do that, if possible.

Table 5-13 indicates at the intersections what actions the application must perform to connect a source endpoint to a sink endpoint.

Table 5-13. Connection Requirements

Sink Endpoint	Source Endpoint		
	Asynchronous	Synchronous	Adaptive
Asynchronous	Async Source/Sink RA See Note 1.	Async SOF/Sink RA See Note 2.	Data + Feedback Feedthrough See Note 3.
Synchronous	Async Source/SOF RA See Note 4.	Sync RA See Note 5.	Data Feedthrough + Application Feedback See Note 6.
Adaptive	Data Feedthrough See Note 7.	Data Feedthrough See Note 8.	Data Feedthrough See Note 9.

Notes:

1. Asynchronous RA in the application. F_{sj} is determined by the source, using the feedforward information embedded in the data stream. F_{s0} is determined by the sink, based on feedback information from the sink. If nominally $F_{sj} = F_{s0}$, the process degenerates to a feedthrough connection if slips/stuffs due to lack of synchronization are tolerable. Such slips/stuffs will cause audible degradation in audio applications.
2. Asynchronous RA in the application. F_{sj} is determined by the source but locked to SOF. F_{s0} is determined by the sink, based on feedback information from the sink. If nominally $F_{sj} = F_{s0}$, the process degenerates to a feedthrough connection if slips/stuffs due to lack of synchronization are tolerable. Such slips/stuffs will cause audible degradation in audio applications.
3. If F_{s0} falls within the locking range of the adaptive source, a feedthrough connection can be established. $F_{sj} = F_{s0}$ and both are determined by the asynchronous sink, based on feedback information from the sink. If F_{s0} falls outside the locking range of the adaptive source, the adaptive source is switched to synchronous mode and Note 2 applies.
4. Asynchronous RA in the application. F_{sj} is determined by the source. F_{s0} is determined by the sink and locked to SOF. If nominally $F_{sj} = F_{s0}$, the process degenerates to a feedthrough connection if slips/stuffs due to lack of synchronization are tolerable. Such slips/stuffs will cause audible degradation in audio applications.
5. Synchronous RA in the application. F_{sj} is determined by the source and locked to SOF. F_{s0} is determined by the sink and locked to SOF. If $F_{sj} = F_{s0}$, the process degenerates to a loss-free feedthrough connection.
6. The application will provide feedback to synchronize the source to SOF. The adaptive source appears to be a synchronous endpoint and Note 5 applies.
7. If F_{sj} falls within the locking range of the adaptive sink, a feedthrough connection can be established. $F_{s0} = F_{sj}$ and both are determined by and locked to the source. If F_{sj} falls outside the locking range of the adaptive sink, synchronous RA is done in the host to provide an F_{s0} that is within the locking range of the adaptive sink.
8. If F_{sj} falls within the locking range of the adaptive sink, a feedthrough connection can be established. $F_{s0} = F_{sj}$ and both are determined by the source and locked to SOF. If F_{sj} falls outside the locking range of the adaptive sink, synchronous RA is done in the host to provide an F_{s0} that is within the locking range of the adaptive sink.
9. The application will use feedback control to set F_{s0} of the adaptive source when the connection is set up. The adaptive source operates as an asynchronous source in the absence of ongoing feedback information and Note 7 applies.

In cases where RA is needed but not available, the rate adaptation process could be mimicked by sample dropping/stuffing. The connection could then still be made, possibly with a warning about poor quality, otherwise, the connection cannot be made.

5.12.4.4.1 Audio Connectivity

When the above is applied to audio data streams, the RA process is replaced by sample rate conversion, which is a specialized form of rate adaptation. Instead of error control, some form of sample interpolation is used to match incoming and outgoing sample rates. Depending on the interpolation techniques used, the audio quality (distortion, signal to noise ratio, etc.) of the conversion can vary significantly. In general, higher quality requires more processing power.

5.12.4.4.2 Synchronous Data Connectivity

For the synchronous data case, RA is used. Occasional slips/stuffs may be acceptable to many applications that implement some form of error control. Error control includes error detection and discard, error detection and retransmit, or forward error correction. The rate of slips/stuffs will depend on the clock mismatch between the source and sink and may be the dominant error source of the channel. If the error control is sufficient, then the connection can still be made.

5.12.5 Data Prebuffering

The USB requires that devices prebuffer data before processing/transmission to allow the host more flexibility in managing when each pipe's transaction is moved over the bus from (micro)frame to (micro)frame.

For transfers from function to host, the endpoint must accumulate samples during (micro)frame X until it receives the SOF token for (micro)frame X+1. It "latches" the data from (micro)frame X into its packet buffer and is now ready to send the packet containing those samples during (micro)frame X+1. When it will send that data during the (micro)frame is determined solely by the Host Controller and can vary from (micro)frame to (micro)frame.

For transfers from host to function, the endpoint will accept a packet from the host sometime during (micro)frame Y. When it receives the SOF for (micro)frame Y+1, it can then start processing the data received in (micro)frame Y.

This approach allows an endpoint to use the SOF token as a stable clock with very little jitter and/or drift when the Host Controller moves the packet over the bus. This approach also allows the Host Controller to vary within a (micro)frame precisely when the packet is actually moved over the bus. This prebuffering introduces some additional delay between when a sample is available at an endpoint and when it moves over the bus compared to an environment where the bus access is at exactly the same time offset from SOF from (micro)frame to (micro)frame.

Figure 5-19 shows the time sequence for a function-to-host transfer (IN process). Data D_0 is accumulated during (micro)frame F_i at time T_i and transmitted to the host during (micro)frame F_{i+1} . Similarly, for a host-to-function transfer (OUT process), data D_0 is received by the endpoint during (micro)frame F_{i+1} and processed during (micro)frame F_{i+2} .

Figure 5-19. Data Prebuffering

5.12.6 SOF Tracking

Functions supporting isochronous pipes must receive and comprehend the SOF token to support prebuffering as previously described. Given that SOFs can be corrupted, a device must be prepared to recover from a corrupted SOF. These requirements limit isochronous transfers to full-speed and high-speed devices only, because low-speed devices do not see SOFs on the bus. Also, because SOF packets can be damaged in transmission, devices that support isochronous transfers need to be able to synthesize the existence of an SOF that they may not see due to a bus error.

Isochronous transfers require the appropriate data to be transmitted in the corresponding (micro)frame. The USB requires that when an isochronous transfer is presented to the Host Controller, it identifies the (micro)frame number for the first (micro)frame. The Host Controller must not transmit the first transaction before the indicated (micro)frame number. Each subsequent transaction in the IRP must be transmitted in succeeding (micro)frames (except for high-speed high-bandwidth transfers where up to three transactions may occur in the same microframe). If there are no transactions pending for the current (micro)frame, then the Host Controller must not transmit anything for an isochronous pipe. If the indicated (micro)frame number has passed, the Host Controller must skip (i.e., not transmit) all transactions until the one corresponding to the current (micro)frame is reached.

5.12.7 Error Handling

Isochronous transfers provide no data packet retries (i.e., no handshakes are returned to a transmitter by a receiver) so that timeliness of data delivery is not perturbed. However, it is still important for the agents responsible for data transport to know when an error occurs and how the error affects the communication flow. In particular, for a sequence of data packets (A, B, C, D), the USB allows sufficient information such that a missing packet (A, $_$, C, D) can be detected and will not unknowingly be turned into an incorrect data or time sequence (A, C, D or A, $_$, B, C, D). The protocol provides four mechanisms that support this: a strictly defined periodicity for the transmission of packets and data PID sequencing mechanisms for high-speed high-bandwidth endpoints, SOF, CRC, and bus transaction timeout.

- Isochronous transfers require periodic occurrence of data transactions for normal operation. The period must be an exact power of two (micro)frames. The USB does not dictate what data is transmitted in each frame. The data transmitter/source determines specifically what data to provide. This regular periodic data delivery provides a framework that is fundamental to detecting missing data errors. For high-speed high-bandwidth endpoints, data PID sequencing allows the detection of missing or damaged

transactions during a microframe. Any phase of a transaction can be damaged during transmission on the bus. Chapter 8 describes how each error case affects the protocol.

- Because every (micro)frame is preceded by an SOF and a receiver can see SOFs on the bus, a receiver can determine that its expected transaction for that (micro)frame did not occur between two SOFs. Additionally, because even an SOF can be damaged, a device must be able to reconstruct the existence of a missed SOF as described in Section 5.12.6.
- A data packet may be corrupted on the bus; therefore, CRC protection allows a receiver to determine that the data packet it received was corrupted.
- The protocol defines the details that allow a receiver to determine via bus transaction timeout that it is not going to receive its data packet after it has successfully seen its token packet.

Once a receiver has determined that a data packet was not received, it may need to know the size of the data that was missed in order to recover from the error with regard to its functional behavior. If the communication flow is always the same data size per (micro)frame, then the size is always a known constant. However, in some cases, the data size can vary from (micro)frame to (micro)frame. In this case, the receiver and transmitter have an implementation-dependent mechanism to determine the size of the lost packet.

In summary, whether a transaction is actually moved successfully over the bus or not, the transmitter and receiver always advance their data/buffer streams as indicated by the bus access period to keep data-per-time synchronization. The detailed mechanisms described above allow detection, tracking, and reporting of damaged transactions so that a function or its client software can react to the damage in a function-appropriate fashion. The details of that function- or application-specific reaction are outside the scope of the USB Specification.

5.12.8 Buffering for Rate Matching

Given that there are multiple clocks that affect isochronous communication flows in the USB, buffering is required to rate match the communication flow across the USB. There must be buffer space available both in the device per endpoint and on the host side on behalf of the client software. These buffers provide space for data to accumulate until it is time for a transfer to move over the USB. Given the natural data rates of the device, the maximum size of the data packets that move over the bus can also be calculated.

Figure 5-20 shows the equations used to determine buffer size on the device and host and maximum packet size that must be requested to support a desired data rate. These equations are a function of the service clock rate (F_X), bus clock rate (F_{SOF}), sample clock rate (F_S), bus access period (I), and sample size (S). These equations should provide design information for selecting the appropriate packet size that an endpoint will report in its characteristic information and the appropriate buffer requirements for the device/endpoint and its client software. Figure 5-17 shows actual buffer, packet, and clock values for a typical full-speed isochronous example.

Universal Serial Bus Specification Revision 2.0

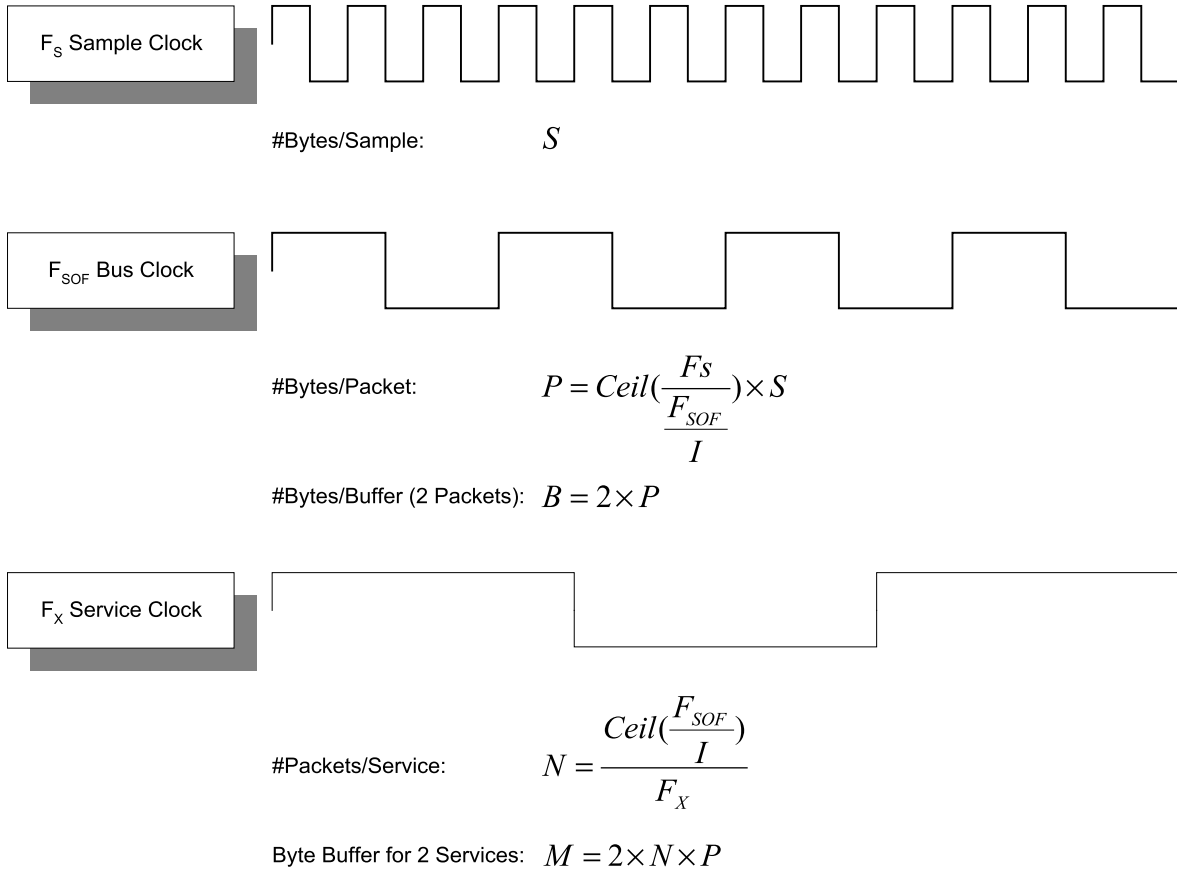

Figure 5-20. Packet and Buffer Size Formulas for Rate-matched Isochronous Transfers

The USB data model assumes that devices have some natural sample size and rate. The USB supports the transmission of packets that are multiples of sample size to make error recovery handling easier when isochronous transactions are damaged on the bus. If a device has no natural sample size or if its samples are larger than a packet, it should describe its sample size as being one byte. If a sample is split across a data packet, the error recovery can be harder when an arbitrary transaction is lost. In some cases, data synchronization can be lost unless the receiver knows in what (micro)frame number each partial sample is transmitted. Furthermore, if the number of samples can vary due to clock correction (e.g., for a non-derived device clock), it may be difficult or inefficient to know when a partial sample is transmitted. Therefore, the USB does not split samples across packets.

Chapter 6 Mechanical

This chapter provides the mechanical and electrical specifications for the cables, connectors, and cable assemblies used to interconnect USB devices. The specification includes the dimensions, materials, electrical, and reliability requirements. This chapter documents minimum requirements for the external USB interconnect. Substitute material may be used as long as it meets these minimums.

6.1 Architectural Overview

The USB physical topology consists of connecting the downstream hub port to the upstream port of another hub or to a device. The USB can operate at three speeds. High-speed (480 Mb/s) and full-speed (12 Mb/s) require the use of a shielded cable with two power conductors and twisted pair signal conductors. Low-speed (1.5 Mb/s) recommends, but does not require the use of a cable with twisted pair signal conductors.

The connectors are designed to be hot plugged. The USB Icon on the plugs provides tactile feedback making it easy to obtain proper orientation.

6.2 Keyed Connector Protocol

To minimize end user termination problems, USB uses a “keyed connector” protocol. The physical difference in the Series “A” and “B” connectors insures proper end user connectivity. The “A” connector is the principle means of connecting USB devices directly to a host or to the downstream port of a hub. All USB devices must have the standard Series “A” connector specified in this chapter. The “B” connector allows device vendors to provide a standard detachable cable. This facilitates end user cable replacement. Figure 6-1 illustrates the keyed connector protocol.

Figure 6-1. Keyed Connector Protocol

The following list explains how the plugs and receptacles can be mated:

- Series “A” receptacle mates with a Series “A” plug. Electrically, Series “A” receptacles function as outputs from host systems and/or hubs.
- Series “A” plug mates with a Series “A” receptacle. The Series “A” plug always is oriented towards the host system.
- Series “B” receptacle mates with a Series “B” plug (male). Electrically, Series “B” receptacles function as inputs to hubs or devices.
- Series “B” plug mates with a Series “B” receptacle. The Series “B” plug is always oriented towards the USB hub or device.

6.3 Cable

USB cable consists of four conductors, two power conductors, and two signal conductors.

High-/full-speed cable consists of a signaling twisted pair, VBUS, GND, and an overall shield. High-/full-speed cable must be marked to indicate suitability for USB usage (see Section 6.6.2). High-/full-speed cable may be used with either low-speed, full-speed, or high-speed devices. When high-/full-speed cable is used with low-speed devices, the cable must meet all low-speed requirements.

Low-speed recommends, but does not require the use of a cable with twisted signaling conductors.

6.4 Cable Assembly

This specification describes three USB cable assemblies: standard detachable cable, high-/full-speed captive cable, and low-speed captive cable.

A standard detachable cable is a high-/full-speed cable that is terminated on one end with a Series “A” plug and terminated on the opposite end with a series “B” plug. A high-/full-speed captive cable is terminated on one end with a Series “A” plug and has a vendor-specific connect means (hardwired or custom detachable) on the opposite end for the high-/full-speed peripheral. The low-speed captive cable is terminated on one end with a Series “A” plug and has a vendor-specific connect means (hardwired or custom detachable) on the opposite end for the low-speed peripheral. Any other cable assemblies are prohibited.

The color used for the cable assembly is vendor specific; recommended colors are white, grey, or black.

6.4.1 Standard Detachable Cable Assemblies

High-speed and full-speed devices can utilize the “B” connector. This allows the device to have a standard detachable USB cable. This eliminates the need to build the device with a hardwired cable and minimizes end user problems if cable replacement is necessary.

Devices utilizing the “B” connector must be designed to work with worst case maximum length detachable cable. Standard detachable cable assemblies may be used only on high-speed and full-speed devices. Using a high-/full-speed standard detachable cable on a low-speed device may exceed the maximum low-speed cable length.

Figure 6-2 illustrates a standard detachable cable assembly.

Figure 6-2. USB Standard Detachable Cable Assembly

Standard detachable cable assemblies must meet the following electrical requirements:

- The cable must be terminated on one end with an overmolded Series “A” plug and the opposite end is terminated with an overmolded Series “B” plug.
- The cable must be rated for high-speed and full-speed.
- The cable impedance must match the impedance of the high-speed and full-speed drivers. The drivers are characterized to drive specific cable impedance. Refer to Section 7.1.1 for details.
- The maximum allowable cable length is determined by signal pair attenuation and propagation delay. Refer to Sections 7.1.14 and 7.1.17 for details.
- Differences in propagation delay between the two signal conductors must be minimized. Refer to Section 7.1.3 for details.
- The GND lead provides a common ground reference between the upstream and downstream ports. The maximum cable length is limited by the voltage drop across the GND lead. Refer to Section 7.2.2 for details. The minimum acceptable wire gauge is calculated assuming the attached device is high power.
- The VBUS lead provides power to the connected device. For standard detachable cables, the VBUS requirement is the same as the GND lead.

6.4.2 High-/full-speed Captive Cable Assemblies

Assemblies are considered captive if they are provided with a vendor-specific connect means (hardwired or custom detachable) to the peripheral. High-/full-speed hardwired cable assemblies may be used with either high-speed, full-speed, or low-speed devices. When using a high-/full-speed hardwired cable on a low-speed device, the cable must meet all low-speed requirements.

Figure 6-3 illustrates a high-/full-speed hardwired cable assembly.

Universal Serial Bus Specification Revision 2.0

Figure 6-3. USB High-/full-speed Hardwired Cable Assembly

High-/full-speed captive cable assemblies must meet the following electrical requirements:

- The cable must be terminated on one end with an overmolded Series “A” plug and the opposite end is vendor specific. If the vendor specific interconnect is to be hot plugged, it must meet the same performance requirements as the USB “B” connector.
- The cable must be rated for high-speed and full-speed.
- The cable impedance must match the impedance of the high-speed and full-speed drivers. The drivers are characterized to drive specific cable impedance. Refer to Section 7.1.1 for details.
- The maximum allowable cable length is determined by signal pair attenuation and propagation delay. Refer to Sections 7.1.14 and 7.1.17 for details.
- Differences in propagation delay between the two signal conductors must be minimized. Refer to Section 7.1.3 for details.
- The GND lead provides a common reference between the upstream and downstream ports. The maximum cable length is determined by the voltage drop across the GND lead. Refer to Section 7.2.2 for details. The minimum wire gauge is calculated using the worst case current consumption.
- The VBUS lead provides power to the connected device. The minimum wire gauge is vendor specific.

6.4.3 Low-speed Captive Cable Assemblies

Assemblies are considered captive if they are provided with a vendor-specific connect means (hardwired or custom detachable) to the peripheral. Low-speed cables may only be used on low-speed devices.

Figure 6-4 illustrates a low-speed hardwired cable assembly.

Figure 6-4. USB Low-speed Hardwired Cable Assembly

Low-speed captive cable assemblies must meet the following electrical requirements:

- The cable must be terminated on one end with an overmolded Series “A” plug and the opposite end is vendor specific. If the vendor specific interconnect is to be hot plugged, it must meet the same performance requirements as the USB “B” connector.
- Low-speed drivers are characterized for operation over a range of capacitive loads. This value includes all sources of capacitance on the D+ and D-lines, not just the cable. Cable selection must insure that total load capacitance falls between specified minimum and maximum values. If the desired implementation does not meet the minimum requirement, additional capacitance needs to be added to the device. Refer to Section 7.1.1.2 for details.
- The maximum low-speed cable length is determined by the rise and fall times of low-speed signaling. This forces low-speed cable to be significantly shorter than high-/full-speed. Refer to Section 7.1.1.2 for details.
- Differences in propagation delay between the two signal conductors must be minimized. Refer to Section 7.1.3 for details.
- The GND lead provides a common reference between the upstream and downstream ports. The maximum cable length is determined by the voltage drop across the GND lead. Refer to Section 7.2.2 for details. The minimum wire gauge is calculated using the worst case current consumption.
- The VBUS lead provides power to the connected device. The minimum wire gauge is vendor specific.

6.4.4 Prohibited Cable Assemblies

USB is optimized for ease of use. The expectation is that if the device can be plugged in, it will work. By specification, the only conditions that prevent a USB device from being successfully utilized are lack of power, lack of bandwidth, and excessive topology depth. These conditions are well understood by the system software.

Prohibited cable assemblies may work in some situations, but they cannot be guaranteed to work in all instances.

- **Extension cable assembly**
A cable assembly that provides a Series “A” plug with a series “A” receptacle or a Series “B” plug with a Series “B” receptacle. This allows multiple cable segments to be connected together, possibly exceeding the maximum permissible cable length.
- **Cable assembly that violates USB topology rules**
A cable assembly with both ends terminated in either Series “A” plugs or Series “B” receptacles. This allows two downstream ports to be directly connected.

Note: This prohibition does not prevent using a USB device to provide a bridge between two USB buses.
- **Standard detachable cables for low-speed devices**
Low-speed devices are prohibited from using standard detachable cables. A standard detachable cable assembly must be high-/full-speed. Since a standard detachable cable assembly is high-/full-speed rated, using a long high-/full-speed cable exceeds the capacitive load of low-speed.

6.5 Connector Mechanical Configuration and Material Requirements

The USB Icon is used to identify USB plugs and the receptacles. Figure 6-5 illustrates the USB Icon.

Figure 6-5. USB Icon

6.5.1 USB Icon Location

The USB Icon is embossed, in a recessed area, on the topside of the USB plug. This provides easy user recognition and facilitates alignment during the mating process. The USB Icon and Manufacturer's logo should not project beyond the overmold surface. The USB Icon is required, while the Manufacturer's logo is recommended, for both Series "A" and "B" plug assemblies. The USB Icon is also located adjacent to each receptacle. Receptacles should be oriented to allow the Icon on the plug to be visible during the mating process. Figure 6-6 illustrates the typical plug orientation.

Figure 6-6. Typical USB Plug Orientation

6.5.2 USB Connector Termination Data

Table 6-1 provides the standardized contact terminating assignments by number and electrical value for Series “A” and Series “B” connectors.

Table 6-1. USB Connector Termination Assignment

Contact Number	Signal Name	Typical Wiring Assignment
1	VBUS	Red
2	D-	White
3	D+	Green
4	GND	Black
Shell	Shield	Drain Wire

6.5.3 Series “A” and Series “B” Receptacles

Electrical and mechanical interface configuration data for Series "A" and Series "B" receptacles are shown in Figure 6-7 and Figure 6-8. Also, refer to Figure 6-12, Figure 6-13, and Figure 6-14 at the end of this chapter for typical PCB receptacle layouts.

Figure 6-7. USB Series "A" Receptacle Interface and Mating Drawing

Figure 6-8. USB Series "B" Receptacle Interface and Mating Drawing

6.5.3.1 Receptacle Injection Molded Thermoplastic Insulator Material

Minimum UL 94-V0 rated, thirty percent (30%) glass-filled polybutylene terephthalate (PBT) or polyethylene terephthalate (PET) or better.

Typical Colors: Black, gray, and natural.

Flammability Characteristics: UL 94-V0 rated.

Flame Retardant Package must meet or exceed the requirements for UL, CSA, VDE, etc.

Oxygen Index (LOI): Greater than 21%. ASTM D 2863.

6.5.3.2 Receptacle Shell Materials

Substrate Material: $0.30 + 0.05$ mm phosphor bronze, nickel silver, or other copper based high strength materials.

Plating:

1. Underplate: Optional. Minimum 1.00 micrometers (40 microinches) nickel. In addition, manufacturer may use a copper underplate beneath the nickel.
2. Outside: Minimum 2.5 micrometers (100 microinches) bright tin or bright tin-lead.

6.5.3.3 Receptacle Contact Materials

Substrate Material: 0.30 ± 0.05 mm minimum half-hard phosphor bronze or other high strength copper based material.

Plating: Contacts are to be selectively plated.

A. Option I

1. Underplate: Minimum 1.25 micrometers (50 microinches) nickel. Copper over base material is optional.
2. Mating Area: Minimum 0.05 micrometers (2 microinches) gold over a minimum of 0.70 micrometers (28 microinches) palladium.
3. Solder Tails: Minimum 3.8 micrometers (150 microinches) bright tin-lead over the underplate.

B. Option II

1. Underplate: Minimum 1.25 micrometers (50 microinches) nickel. Copper over base material is optional.
2. Mating Area: Minimum 0.05 micrometers (2 microinches) gold over a minimum of 0.75 micrometers (30 microinches) palladium-nickel.
3. Solder Tails: Minimum 3.8 micrometers (150 microinches) bright tin-lead over the underplate.

C. Option III

1. Underplate: Minimum 1.25 micrometers (50 microinches) nickel. Copper over base material is optional.
2. Mating Area: Minimum 0.75 micrometers (30 microinches) gold.
3. Solder Tails: Minimum 3.8 micrometers (150 microinches) bright tin-lead over the underplate.

6.5.4 Series "A" and Series "B" Plugs

Electrical and mechanical interface configuration data for Series "A" and Series "B" plugs are shown in Figure 6-9 and Figure 6-10.

Figure 6-9. USB Series "A" Plug Interface Drawing

Figure 6-10. USB Series "B" Plug Interface Drawing

6.5.4.1 Plug Injection Molded Thermoplastic Insulator Material

Minimum UL 94-V0 rated, thirty percent (30%) glass-filled polybutylene terephthalate (PBT) or polyethylene terephthalate (PET) or better.

Typical Colors: Black, gray, and natural.

Flammability Characteristics: UL 94-V0 rated.

Flame Retardant Package must meet or exceed the requirements for UL, CSA, and VDE.

Oxygen Index (LOI): 21%. ASTM D 2863.

6.5.4.2 Plug Shell Materials

Substrate Material: 0.30 ± 0.05 mm phosphor bronze, nickel silver, or other suitable material.

Plating:

- A. Underplate: Optional. Minimum 1.00 micrometers (40 microinches) nickel. In addition, manufacturer may use a copper underplate beneath the nickel.
- B. Outside: Minimum 2.5 micrometers (100 microinches) bright tin or bright tin-lead.

6.5.4.3 Plug (Male) Contact Materials

Substrate Material: 0.30 ± 0.05 mm half-hard phosphor bronze.

Plating: Contacts are to be selectively plated.

A. Option I

- 1. Underplate: Minimum 1.25 micrometers (50 microinches) nickel. Copper over base material is optional.
- 2. Mating Area: Minimum 0.05 micrometers (2 microinches) gold over a minimum of 0.70 micrometers (28 microinches) palladium.
- 3. Solder Tails: Minimum 3.8 micrometers (150 microinches) bright tin-lead over the underplate.

B. Option II

- 1. Underplate: Minimum 1.25 micrometers (50 microinches) nickel. Copper over base material is optional.
- 2. Mating Area: Minimum 0.05 micrometers (2 microinches) gold over a minimum of 0.75 micrometers (30 microinches) palladium-nickel.
- 3. Wire Crimp/Solder Tails: Minimum 3.8 micrometers (150 microinches) bright tin-lead over the underplate.

C. Option III

- 1. Underplate: Minimum 1.25 micrometers (50 microinches) nickel. Copper over base material is optional.
- 2. Mating Area: Minimum 0.75 micrometers (30 microinches) gold.
- 3. Solder Tails: Minimum 3.8 micrometers (150 microinches) bright tin-lead over the underplate.

6.6 Cable Mechanical Configuration and Material Requirements

High-/full-speed and low-speed cables differ in data conductor arrangement and shielding. Low-speed recommends, but does not require, use of a cable with twisted data conductors. Low speed recommends, but does not require, use of a cable with a braided outer shield. Figure 6-11 shows the typical high-/full-speed cable construction.

Figure 6-11. Typical High-/full-speed Cable Construction

6.6.1 Description

High-/full-speed cable consists of one 28 to 20 AWG non-twisted power pair and one 28 AWG twisted data pair with an aluminum metallized polyester inner shield, 28 AWG stranded tinned copper drain wire, \geq 65% tinned copper wire interwoven (braided) outer shield, and PVC outer jacket.

Low-speed cable consists of one 28 to 20 AWG non-twisted power pair and one 28 AWG data pair (a twist is recommended) with an aluminum metallized polyester inner shield, 28 AWG stranded tinned copper drain wire and PVC outer jacket. A \geq 65% tinned copper wire interwoven (braided) outer shield is recommended.

6.6.2 Construction

Raw materials used in the fabrication of this cable must be of such quality that the fabricated cable is capable of meeting or exceeding the mechanical and electrical performance criteria of the most current USB Specification revision and all applicable domestic and international safety/testing agency requirements; e.g., UL, CSA, BSA, NEC, etc., for electronic signaling and power distribution cables in its category.

Table 6-2. Power Pair

American Wire Gauge (AWG)	Nominal Conductor Outer Diameter	Stranded Tinned Conductors
28	0.381 mm (0.015")	7 x 36
	0.406 mm (0.016")	19 x 40
26	0.483 mm (0.019")	7 x 34
	0.508 mm (0.020")	19 x 38
24	0.610 mm (0.024")	7 x 32
	0.610 mm (0.024")	19 x 36
22	0.762 mm (0.030")	7 x 30
	0.787 mm (0.031")	19 x 34
20	0.890 mm (0.035")	7 x 28
	0.931 mm (0.037")	19 x 32

Note: Minimum conductor construction must be stranded tinned copper.

Non-Twisted Power Pair:

- A. Wire Gauge: Minimum 28 AWG or as specified by the user contingent upon the specified cable length. Refer to Table 6-2.
- B. Wire Insulation: Semirigid polyvinyl chloride (PVC).
 - 1. Nominal Insulation Wall Thickness: 0.25 mm (0.010")
 - 2. Typical Power (V_{BUS}) Conductor: Red Insulation
 - 3. Typical Ground Conductor: Black Insulation

Signal Pair:

- A. Wire Gauge: 28 AWG minimum. Refer to Table 6-3.

Table 6-3. Signal Pair

American Wire Gauge (AWG)	Nominal Conductor Outer Diameter	Stranded Tinned Conductors
28	0.381 mm (0.015")	7 x 36
	0.406 mm (0.016")	19 x 40

Note: Minimum conductor construction must be stranded tinned copper.

- B. Wire Insulation: High-density polyethylene (HDPE), alternately foamed polyethylene or foamed polypropylene
 - 1. Nominal Insulation Wall Thickness: 0.31 mm (0.012")
 - 2. Typical Data Plus (+) Conductor: Green Insulation
 - 3. Typical Data Minus (-) Conductor: White Insulation
- C. Nominal Twist Ratio (not required for low-speed): One full twist every 60 mm (2.36") to 80 mm (3.15")

Aluminum Metallized Polyester Inner Shield (required for low-speed):

- A. Substrate Material: Polyethylene terephthalate (PET) or equivalent material
- B. Metallizing: Vacuum deposited aluminum
- C. Assembly:
 - 1. The aluminum metallized side of the inner shield must be positioned facing out to ensure direct contact with the drain wire.
 - 2. The aluminum metallized inner shield must overlap by approximately one-quarter turn.

Drain Wire (required for low-speed):

- A. Wire Gauge: Minimum 28 AWG stranded tinned copper (STC) non-insulated. Refer to Table 6-4.

Table 6-4. Drain Wire Signal Pair

American Wire Gauge (AWG)	Nominal Conductor Outer Diameter	Stranded Tinned Conductors
28	0.381 mm (0.015")	7 x 36
	0.406 mm (0.016")	19 x 40

Interwoven (Braided) Tinned Copper Wire (ITCW) Outer Shield (recommended but not required for low-speed):

- A. Coverage Area: Minimum 65%.
- B. Assembly: The interwoven (braided) tinned copper wire outer shield must encase the aluminum metallized PET shielded power and signal pairs and must be in direct contact with the drain wire.

Outer Polyvinyl Chloride (PVC) Jacket:

- A. Assembly: The outer PVC jacket must encase the fully shielded power and signal pairs and must be in direct contact with the tinned copper outer shield.

Universal Serial Bus Specification Revision 2.0

B. Nominal Wall Thickness: 0.64 mm (0.025”).

Marking: The cable must be legibly marked using contrasting color permanent ink.

- A. Minimum marking information for high-/full-speed cable must include:
USB SHIELDED <Gauge/2C + Gauge/2C> UL CM 75 °C — UL Vendor ID.
- B. Minimum marking information for low-speed cable shall include:
USB specific marking is not required for low-speed cable.

Nominal Fabricated Cable Outer Diameter:

This is a nominal value and may vary slightly from manufacturer to manufacturer as a function of the conductor insulating materials and conductor specified. Refer to Table 6-5.

Table 6-5. Nominal Cable Diameter

Shielded USB Cable Configuration	Nominal Outer Cable Diameter
28/28	4.06 mm (0.160")
28/26	4.32 mm (0.170")
28/24	4.57 mm (0.180")
28/22	4.83 mm (0.190")
28/20	5.21 mm (0.205")

6.6.3 Electrical Characteristics

All electrical characteristics must be measured at or referenced to +20 °C (68 °F).

Voltage Rating: 30 V rms maximum.

Conductor Resistance: Conductor resistance must be measured in accordance with ASTM-D-4566 Section 13. Refer to Table 6-6.

Conductor Resistance Unbalance (Pairs): Conductor resistance unbalance between two (2) conductors of any pair must not exceed five percent (5%) when measured in accordance with ASTM-D-4566 Section 15.

The DC resistance from plug shell to plug shell (or end of integrated cable) must be less than 0.6 ohms.

Table 6-6. Conductor Resistance

American Wire Gauge (AWG)	Ohms (Ω) / 100 Meters Maximum
28	23.20
26	14.60
24	9.09
22	5.74
20	3.58

6.6.4 Cable Environmental Characteristics

Temperature Range:

- A. Operating Temperature Range: 0 °C to +50 °C
- B. Storage Temperature Range: -20 °C to +60 °C
- C. Nominal Temperature Rating: +20 °C

Flammability: All plastic materials used in the fabrication of this product shall meet or exceed the requirements of NEC Article 800 for communications cables Type CM (Commercial).

6.6.5 Listing

The product shall be UL listed per UL Subject 444, Class 2, Type CM for Communications Cable Requirements.

6.7 Electrical, Mechanical, and Environmental Compliance Standards

Table 6-7 lists the minimum test criteria for all USB cable, cable assemblies, and connectors.

Table 6-7. USB Electrical, Mechanical, and Environmental Compliance Standards

Test Description	Test Procedure	Performance Requirement
Visual and Dimensional Inspection	EIA 364-18 Visual, dimensional, and functional inspection in accordance with the USB quality inspection plans.	Must meet or exceed the requirements specified by the most current version of Chapter 6 of the USB Specification.
Insulation Resistance	EIA 364-21 The object of this test procedure is to detail a standard method to assess the insulation resistance of USB connectors. This test procedure is used to determine the resistance offered by the insulation materials and the various seals of a connector to a DC potential tending to produce a leakage of current through or on the surface of these members.	1,000 MΩ minimum.
Dielectric Withstanding Voltage	EIA 364-20 The object of this test procedure is to detail a test method to prove that a USB connector can operate safely at its rated voltage and withstand momentary over-potentials due to switching, surges, and/or other similar phenomena.	The dielectric must withstand 500 V AC for one minute at sea level.

Table 6-7. USB Electrical, Mechanical, and Environmental Compliance Standards (Continued)

Test Description	Test Procedure	Performance Requirement
Low Level Contact Resistance	<p>EIA 364-23</p> <p>The object of this test is to detail a standard method to measure the electrical resistance across a pair of mated contacts such that the insulating films, if present, will not be broken or asperity melting will not occur.</p>	<p>30 mΩ maximum when measured at 20 mV maximum open circuit at 100 mA. Mated test contacts must be in a connector housing.</p>
Contact Current Rating	<p>EIA 364-70 — Method B</p> <p>The object of this test procedure is to detail a standard method to assess the current carrying capacity of mated USB connector contacts.</p>	<p>1.5 A at 250 V AC minimum when measured at an ambient temperature of 25 °C. With power applied to the contacts, the Δ T must not exceed +30 °C at any point in the USB connector under test.</p>
Contact Capacitance	<p>EIA 364-30</p> <p>The object of this test is to detail a standard method to determine the capacitance between conductive elements of a USB connector.</p>	<p>2 pF maximum unmated per contact.</p>
Insertion Force	<p>EIA 364-13</p> <p>The object of this test is to detail a standard method for determining the mechanical forces required for inserting a USB connector.</p>	<p>35 Newtons maximum at a maximum rate of 12.5 mm (0.492") per minute.</p>
Extraction Force	<p>EIA 364-13</p> <p>The object of this test is to detail a standard method for determining the mechanical forces required for extracting a USB connector.</p>	<p>10 Newtons minimum at a maximum rate of 12.5 mm (0.492") per minute.</p>

Table 6-7. USB Electrical, Mechanical, and Environmental Compliance Standards (Continued)

Test Description	Test Procedure	Performance Requirement
Durability	<p>EIA 364-09</p> <p>The object of this test procedure is to detail a uniform test method for determining the effects caused by subjecting a USB connector to the conditioning action of insertion and extraction, simulating the expected life of the connectors. Durability cycling with a gauge is intended only to produce mechanical stress. Durability performed with mating components is intended to produce both mechanical and wear stress.</p>	<p>1,500 insertion/extraction cycles at a maximum rate of 200 cycles per hour.</p>
Cable Pull-Out	<p>EIA 364-38</p> <p>Test Condition A</p> <p>The object of this test procedure is to detail a standard method for determining the holding effect of a USB plug cable clamp without causing any detrimental effects upon the cable or connector components when the cable is subjected to inadvertent axial tensile loads.</p>	<p>After the application of a steady state axial load of 40 Newtons for one minute.</p>
Physical Shock	<p>EIA 364-27</p> <p>Test Condition H</p> <p>The object of this test procedure is to detail a standard method to assess the ability of a USB connector to withstand specified severity of mechanical shock.</p>	<p>No discontinuities of 1 μs or longer duration when mated USB connectors are subjected to 11 ms duration 30 Gs half-sine shock pulses. Three shocks in each direction applied along three mutually perpendicular planes for a total of 18 shocks.</p>

Universal Serial Bus Specification Revision 2.0

Test Description	Test Procedure	Performance Requirement
Random Vibration	<p>EIA 364-28</p> <p>Test Condition V Test Letter A</p> <p>This test procedure is applicable to USB connectors that may, in service, be subjected to conditions involving vibration. Whether a USB connector has to function during vibration or merely to survive conditions of vibration should be clearly stated by the detailed product specification. In either case, the relevant specification should always prescribe the acceptable performance tolerances.</p>	<p>No discontinuities of 1 μs or longer duration when mated USB connectors are subjected to 5.35 Gs RMS. 15 minutes in each of three mutually perpendicular planes.</p>
Thermal Shock	<p>EIA 364-32</p> <p>Test Condition I</p> <p>The object of this test is to determine the resistance of a USB connector to exposure at extremes of high and low temperatures and to the shock of alternate exposures to these extremes, simulating the worst case conditions for storage, transportation, and application.</p>	<p>10 cycles -55°C and $+85^{\circ}\text{C}$. The USB connectors under test must be mated.</p>
Humidity Life	<p>EIA 364-31</p> <p>Test Condition A Method III</p> <p>The object of this test procedure is to detail a standard test method for the evaluation of the properties of materials used in USB connectors as they are influenced by the effects of high humidity and heat.</p>	<p>168 hours minimum (seven complete cycles). The USB connectors under test must be tested in accordance with EIA 364-31.</p>
Solderability	<p>EIA 364-52</p> <p>The object of this test procedure is to detail a uniform test method for determining USB connector solderability. The test procedure contained herein utilizes the solder dip technique. It is not intended to test or evaluate solder cup, solder eyelet, other hand-soldered type, or SMT type terminations.</p>	<p>USB contact solder tails must pass 95% coverage after one hour steam aging as specified in Category 2.</p>

Universal Serial Bus Specification Revision 2.0

Table 6-7. USB Electrical, Mechanical, and Environmental Compliance Standards (Continued)

Test Description	Test Procedure	Performance Requirement
Flammability	<p>UL 94 V-0</p> <p>This procedure is to ensure thermoplastic resin compliance to UL flammability standards.</p>	<p>The manufacturer will require its thermoplastic resin vendor to supply a detailed C of C with each resin shipment. The C of C shall clearly show the resin's UL listing number, lot number, date code, etc.</p>
Flammability	<p>UL 94 V-0</p> <p>This procedure is to ensure thermoplastic resin compliance to UL flammability standards.</p>	<p>The manufacturer will require its thermoplastic resin vendor to supply a detailed C of C with each resin shipment. The C of C shall clearly show the resin's UL listing number, lot number, date code, etc.</p>
Cable Impedance (Only required for high-/full-speed)	<p>The object of this test is to insure the signal conductors have the proper impedance.</p> <ol style="list-style-type: none"> 1. Connect the Time Domain Reflectometer (TDR) outputs to the impedance/delay/skew test fixture (Note 1). Use separate 50 Ω cables for the plus (or true) and minus (or complement) outputs. Set the TDR head to differential TDR mode. 2. Connect the Series "A" plug of the cable to be tested to the test fixture, leaving the other end open-circuited. 3. Define a waveform composed of the difference between the true and complement waveforms, to allow measurement of differential impedance. 4. Measure the minimum and maximum impedances found between the connector and the open circuited far end of the cable. 	<p>Impedance must be in the range specified in Table 7-9 (ZO).</p>

Table 6-7. USB Electrical, Mechanical, and Environmental Compliance Standards (Continued)

Test Description	Test Procedure	Performance Requirement
<p>Signal Pair Attenuation (Only required for high-/full-speed)</p>	<p>The object of this test is to insure that adequate signal strength is presented to the receiver to maintain a low error rate.</p> <ol style="list-style-type: none"> 1. Connect the Network Analyzer output port (port 1) to the input connector on the attenuation test fixture (Note 2). 2. Connect the Series "A" plug of the cable to be tested to the test fixture, leaving the other end open-circuited. 3. Calibrate the network analyzer and fixture using the appropriate calibration standards over the desired frequency range. 4. Follow the method listed in Hewlett Packard Application Note 380-2 to measure the open-ended response of the cable. 5. Short circuit the Series "B" end (or bare leads end, if a captive cable) and measure the short-circuit response. 6. Using the software in H-P App. Note 380-2 or equivalent, calculate the cable attenuation accounting for resonance effects in the cable as needed. 	<p>Refer to Section 7.1.17 for frequency range and allowable attenuation.</p>

Table 6-7. USB Electrical, Mechanical, and Environmental Compliance Standards (Continued)

Test Description	Test Procedure	Performance Requirement
Propagation Delay	<p>The purpose of the test is to verify the end to end propagation of the cable.</p> <ol style="list-style-type: none"> 1. Connect one output of the TDR sampling head to the D+ and D- inputs of the impedance/delay/skew test fixture (Note 1). Use one 50 Ω cable for each signal and set the TDR head to differential TDR mode. 2. Connect the cable to be tested to the test fixture. If detachable, plug both connectors in to the matching fixture connectors. If captive, plug the series "A" plug into the matching fixture connector and solder the stripped leads on the other end to the test fixture. 3. Measure the propagation delay of the test fixture by connecting a short piece of wire across the fixture from input to output and recording the delay. 4. Remove the short piece of wire and remeasure the propagation delay. Subtract from it the delay of the test fixture measured in the previous step. 	<p>High-/full-speed.</p> <p>See Section 7.1.1.1, Section 7.1.4, Section 7.1.16, and Table 7-9 (TFSCBL).</p> <p>Low-speed.</p> <p>See Section 7.1.1.2, Section 7.1.16, and Table 7-9 (TLSCBL).</p>

Table 6-7. USB Electrical, Mechanical, and Environmental Compliance Standards (Continued)

Test Description	Test Procedure	Performance Requirement
Propagation Delay Skew	<p>This test insures that the signal on both the D+ and D- lines arrive at the receiver at the same time.</p> <ol style="list-style-type: none"> 1. Connect the TDR to the fixture with test sample cable, as in the previous section. 2. Measure the difference in delay for the two conductors in the test cable. Use the TDR cursors to find the open-circuited end of each conductor (where the impedance goes infinite) and subtract the time difference between the two values. 	Propagation skew must meet the requirements as listed in Section 7.1.3.
<p>Capacitive Load</p> <p>Only required for low-speed</p>	<p>The purpose of this test is to insure the distributed inter-wire capacitance is less than the lumped capacitance specified by the low-speed transmit driver.</p> <ol style="list-style-type: none"> 1. Connect the one lead of the Impedance Analyzer to the D+ pin on the impedance/delay/skew fixture (Note 1) and the other lead to the D- pin. 2. Connect the series "A" plug to the fixture, with the series "B" end leads open-circuited. 3. Set the Impedance Analyzer to a frequency of 100 kHz, to measure the capacitance. 	See Section 7.1.1.2 and Table 7-7 (CLINUA).

Note1: Impedance, propagation delay, and skew test fixture
 This fixture will be used with the TDR for measuring the time domain performance of the cable under test. The fixture impedance should be matched to the equipment, typically 50 Ω. Coaxial connectors should be provided on the fixture for connection from the TDR.

Note 2: Attenuation test fixture
 This fixture provides a means of connection from the network analyzer to the Series "A" plug. Since USB signals are differential in nature and operate over balanced cable, a transformer or balun (North Hills NH13734 or equivalent) is ideally used. The transformer converts the unbalanced (also known as single-ended) signal from the signal generator which is typically a 50 Ω output to the balanced (also known as differential) and likely different impedance loaded presented by the cable. A second transformer or balun should be used on the other end of the cable under test to convert the signal back to unbalanced form of the correct impedance to match the network analyzer.

Chapter 7

Electrical

This chapter describes the electrical specification for the USB. It contains signaling, power distribution, and physical layer specifications. This specification does not address regulatory compliance. It is the responsibility of product designers to make sure that their designs comply with all applicable regulatory requirements.

The USB 2.0 specification requires hubs to support high-speed mode. USB 2.0 devices are not required to support high-speed mode. A high-speed capable upstream facing transceiver must not support low-speed signaling mode. A USB 2.0 downstream facing transceiver must support high-speed, full-speed, and low-speed modes.

To assure reliable operation at high-speed data rates, this specification requires the use of cables that conform to all current cable specifications.

In this chapter, there are numerous references to strings of J's and K's, or to strings of 1's and 0's. In each of these instances, the leftmost symbol is transmitted/received first, and the rightmost is transmitted/received last.

7.1 Signaling

The signaling specification for the USB is described in the following subsections.

Overview of High-speed Signaling

A high-speed USB connection is made through a shielded, twisted pair cable that conforms to all current USB cable specifications.

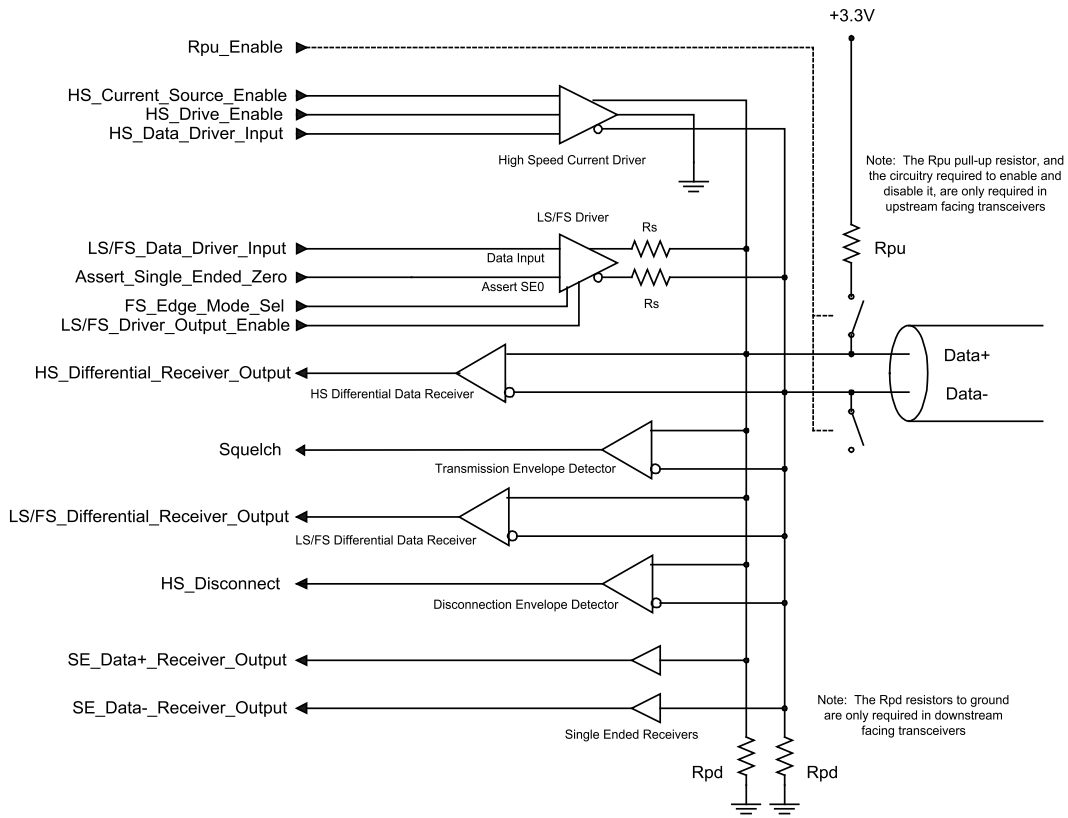

Figure 7-1. Example High-speed Capable Transceiver Circuit

Figure 7-1 depicts an example implementation which largely utilizes USB 1.1 transceiver elements and adds the new elements required for high-speed operation.

High-speed operation supports signaling at 480 Mb/s. To achieve reliable signaling at this rate, the cable is terminated at each end with a resistance from each wire to ground. The value of this resistance (on each wire) is nominally set to 1/2 the specified differential impedance of the cable, or 45 Ω. This presents a differential termination of 90 Ω.

For a link operating in high-speed mode, the high-speed idle state occurs when the transceivers at both ends of the cable present high-speed terminations to ground, and when neither transceiver drives signaling current into the D+ or D- lines. This state is achieved by using the low-/full-speed driver to assert a single ended zero, and to closely control the combined total of the intrinsic driver output impedance and the Rs resistance (to 45 Ω, nominal). The recommended practice is to make the intrinsic driver impedance as low as possible, and to let Rs contribute as much of the 45 Ω as possible. This will generally lead to the best termination accuracy with the least parasitic loading.

In order to transmit in high-speed mode, a transceiver activates an internal current source which is derived from its positive supply voltage and directs this current into one of the two data lines via a high speed current steering switch. In this way, the transceiver generates the high-speed J or K state on the cable.

The dynamic switching of this current into the D+ or D- line follows the same NRZI data encoding scheme used in low-speed or full-speed operation and also in the bit stuffing behavior. To signal a J, the current is directed into the D+ line, and to signal a K, the current is directed into the D- line. The SYNC field and the EOP delimiters have been modified for high-speed mode.

Universal Serial Bus Specification Revision 2.0

The magnitude of the current source and the value of the termination resistors are controlled to specified tolerances, and together they determine the actual voltage drive levels. The DC resistance from D+ or D- to the device ground is required to be $45\ \Omega \pm 10\%$ when measured without a load, and the differential output voltage measured across the lines (in either the J or K state) must be $\pm 400\ \text{mV} \pm 10\%$ when D+ and D- are terminated with precision $45\ \Omega$ resistors to ground.

The differential voltage developed across the lines is used for three purposes:

- A differential receiver at the receiving end of the cable receives the differential data signal.
- A differential envelope detector at the receiving end of the cable determines when the link is in the Squelch state. A receiver uses squelch detection as indication that the signal at its connector is not valid.
- In the case of a downstream facing hub transceiver, a differential envelope detector monitors whether the signal at its connector is in the high-speed state. A downstream facing transceiver operating in high-speed mode is required to test for this state at a particular point in time when it is transmitting a SOF packet, as described in Section 7.1.7.3. This is used to detect device disconnection. In the absence of the far end terminations, the differential voltage will nominally double (as compared to when a high-speed device is present) when a high-speed J or K are continuously driven for a period exceeding the round-trip delay for the cable and board-traces between the two transceivers.

USB 2.0 requires that a downstream facing transceiver must be able to operate in low-speed, full-speed, and high-speed signaling modes. An upstream facing high-speed capable transceiver must not operate in low-speed signaling mode, but must be able to operate in full-speed signaling mode. Therefore, a $1.5\ \text{k}\Omega$ pull-up on the D- line is not allowed for a high-speed capable device, since a high-speed capable transceiver must never signal low-speed operation to the hub port to which it is attached.

Table 7-1 describes the required functional elements of a high-speed capable transceiver, using the diagram shown in Figure 7-1 as an example.

Table 7-1. Description of Functional Elements in the Example Shown in Figure 7-1

Element	Description
Low-/full-speed Driver	<p>The low-/full-speed driver is used for low-speed and full-speed transmission. It is required to meet all specifications called out in USB 1.1 for low-speed and full-speed operation, with one exception. The exception is that in high-speed capable transceivers, the impedance of each output, including the contribution of R_s, must be $45\ \Omega \pm 10\%$.</p> <p>The line terminations for high-speed operation are created by having this driver drive D+ and D- to ground. (This is equivalent to driving SE0 in the full-speed or low-speed mode.) Because of the output impedance requirement described above, this provides a well-controlled high-speed termination on each data line to ground. This is equivalent to a $90\ \Omega$ differential termination.</p>
Low-/full-speed Differential Receiver	<p>The low-/full-speed differential receiver is used for receiving low-speed and full-speed data.</p>
Single Ended Receivers	<p>The single ended receivers are used for low-speed and full-speed signaling.</p>
High-speed Current Driver	<p>The high-speed current driver is used for high-speed data transmission. A current source derived from a positive supply is switched into either the D+ or D- lines to signal a J or a K, respectively. The nominal value of the current source is 17.78 mA. When this current is applied to a data line with a $45\ \Omega$ termination to ground at each end, the nominal high level voltage (V_{HSON}) is +400 mV. The nominal differential high-speed voltage (D+ - D-) is thus 400 mV for a J and -400 mV for a K.</p> <p>The current source must comply with the Transmit Eye Pattern Templates specified in Section 7.1.2.2, starting with the first symbol of a packet. One means of achieving this is to leave the current source on continuously when a transceiver is operating in high-speed mode. If this approach is used, the current can be directed to the port ground when the transceiver is not transmitting (the example design in Figure 7-1 shows a control line called HS_Current_Source_Enable to turn the current on, and another called HS_Drive_Enable to direct the current into the data lines.) The penalty of this approach is the 17.78 mA of standing current for every such enabled transceiver in the system.</p> <p>The preferred design is to fully turn the current source off when the transceiver is not transmitting.</p>
High-speed Differential Data Receiver	<p>The high-speed differential data receiver is used to receive high-speed data. It is left to transceiver designers to choose between incorporating separate high-speed and low-/full-speed receivers, as shown in Figure 7-1, or combining both functions into a single receiver.</p>

Table 7-1. Description of Functional Elements in the Example Shown in Figure 7-1 (Continued)

Transmission Envelope Detector	This envelope detector is used to indicate that data is invalid when the amplitude of the differential signal at a receiver's inputs falls below the squelch threshold (V_{HSSQ}). It must indicate Squelch when the signal drops below 100 mV differential amplitude, and it must indicate that the line is not in the Squelch state when the signal exceeds 150 mV differential amplitude. The response time of the detector must be fast enough to allow a receiver to detect data transmission, to achieve DLL lock, and to detect the end of the SYNC field within 12 bit times, the minimum number of SYNC bits that a receiver is guaranteed to see. This envelope detector must incorporate a filtering mechanism that prevents indication of squelch during the longest differential data transitions allowed by the receiver eye pattern specifications.
Disconnection Envelope Detector	This envelope detector is required in downstream facing ports to detect the high-speed Disconnect state on the line (V_{HSDSC}). Disconnection must be indicated when the amplitude of the differential signal at the downstream facing driver's connector ≥ 625 mV, and it must not be indicated when the signal amplitude is ≤ 525 mV. The output of this detector is sampled at a specific time during the transmission of the high-speed SOF EOP, as described in Section 7.1.7.3.
Pull-up Resistor (RPU)	This resistor is required only in upstream facing transceivers and is used to indicate signaling speed capability. A high-speed capable device is required to initially attach as a full-speed device and must transition to high-speed as described in this specification. Once operating in high-speed, the 1.5 k Ω resistor must be electrically removed from the circuit. In Figure 7-1, a control line called RPU_Enable is indicated for this purpose. The preferred embodiment is to attach matched switching devices to both the D+ and D- lines so as to keep the lines' parasitic loading balanced, even though a pull-up resistor must never be used on the D- line of an upstream facing high-speed capable transceiver. When connected, this pull-up must meet all the specifications called out for full-speed operation.
Pull-down Resistors (RPD)	These resistors are required only in downstream facing transceivers and must conform to the same specifications called out for low-speed and full-speed operation.

7.1.1 USB Driver Characteristics

The USB uses a differential output driver to drive the USB data signal onto the USB cable.

For low-speed and full-speed operation, the static output swing of the driver in its low state must be below V_{OL} (max) of 0.3 V with a 1.5 k Ω load to 3.6 V, and in its high state must be above the V_{OH} (min) of 2.8 V with a 15 k Ω load to ground as listed in Table 7-7. Full-speed drivers have more stringent requirements, as described in Section 7.1.1.1. The output swings between the differential high and low state must be well-balanced to minimize signal skew. Slew rate control on the driver is required to minimize the radiated noise and cross talk. The driver's outputs must support three-state operation to achieve bi-directional half-duplex operation.

Low-speed and full-speed USB drivers must never “intentionally” generate an SE1 on the bus. SE1 is a state in which both the D+ and D- lines are at a voltage above V_{OSE1} (min), which is 0.8 V.

High-speed drivers use substantially different signaling levels, as described in Section 7.1.1.3.

USB ports must be capable of withstanding continuous exposure to the waveforms shown in Figure 7-2 while in any drive state. These waveforms are applied directly into each USB data pin from a voltage source with an

output impedance of $39\ \Omega$. The open-circuit voltage of the source shown in Figure 7-2 is based on the expected worst-case overshoot and undershoot.

Figure 7-2. Maximum Input Waveforms for USB Signaling

Short Circuit Withstand

A USB transceiver is required to withstand a continuous short circuit of D+ and/or D- to V_{BUS} , GND, other data line, or the cable shield at the connector, for a minimum of 24 hours without degradation. It is recommended that transceivers be designed so as to withstand such short circuits indefinitely. The device must not be damaged under this short circuit condition when transmitting 50% of the time and receiving 50% of the time (in all supported speeds). The transmit phase consists of a symmetrical signal that toggles between drive high and drive low. This requirement must be met for max value of V_{BUS} (5.25 V).

It is recommended that these AC and short circuit stresses be used as qualification criteria against which the long-term reliability of each device is evaluated.

7.1.1.1 Full-speed (12 Mb/s) Driver Characteristics

A full-speed USB connection is made through a shielded, twisted pair cable with a differential characteristic impedance (Z_0) of $90\ \Omega \pm 15\%$, a common mode impedance (Z_{CM}) of $30\ \Omega \pm 30\%$, and a maximum one-way delay (T_{FSCBL}) of 26 ns. When the full-speed driver is not part of a high-speed capable transceiver, the impedance of each of the drivers (Z_{DRV}) must be between $28\ \Omega$ and $44\ \Omega$, i.e., within the gray area in Figure 7-4. When the full-speed driver is part of a high-speed capable transceiver, the impedance of each of the drivers (Z_{HSDRV}) must be between $40.5\ \Omega$ and $49.5\ \Omega$, i.e., within the gray area in Figure 7-5.

For a CMOS implementation, the driver impedance will typically be realized by a CMOS driver with an impedance significantly less than this resistance with a discrete series resistor making up the balance as shown in Figure 7-3. The series resistor R_S is included in the buffer impedance requirement shown in Figure 7-4 and Figure 7-5. In the rest of the chapter, references to the buffer assume a buffer with the series impedance unless stated otherwise.

Figure 7-3. Example Full-speed CMOS Driver Circuit (non High-speed capable)

Full-speed Buffers in Transceivers Which are Not High-speed Capable

The buffer impedance must be measured for driving high as well as driving low. Figure 7-4 shows the composite V/I characteristics for the full-speed drivers with included series damping resistor (RS). The characteristics are normalized to the steady-state, unloaded output swing of the driver. The normalized driver characteristics are found by dividing the measured voltages and currents by the actual swing of the driver under test. The normalized V/I curve for the driver must fall entirely inside the shaded region. The V/I region is bounded by the minimum driver impedance above and the maximum driver impedance below. The minimum drive region is intersected by a constant current region of $|6.1V_{OH}|$ mA when driving low and $-|6.1V_{OH}|$ mA when driving high. In the special case of a full-speed driver which is driving low, and which is part of a high-speed capable transceiver, the low drive region is intersected by a constant current region of 22.0 mA. This is the minimum current drive level necessary to ensure that the waveform at the receiver crosses the opposite single-ended switching level on the first reflection.

When testing, the current into or out of the device need not exceed $\pm 10.71 * V_{OH}$ mA and the voltage applied to D+/D- need not exceed $0.3 * V_{OH}$ for the drive low case and need not drop below $0.7 * V_{OH}$ for the drive high case.

Full-speed Buffers in High-speed Capable Transceivers

Figure 7-5 shows the V/I characteristics for a Full-speed buffer which is part of a high-speed capable transceiver. The output impedance, Z_{HSDRV} (including the contribution of RS), is required to be between 40.5Ω and 49.5Ω . Additionally, the output voltage must be within 10mV of ground when no current is flowing in or out of the pin (V_{HSTERM}).

Figure 7-4. Full-speed Buffer V/I Characteristics

Figure 7-5. Full-speed Buffer V/I Characteristics for High-speed Capable Transceiver

Figure 7-6 shows the full-speed driver signal waveforms.

Figure 7-6. Full-speed Signal Waveforms

7.1.1.2 Low-speed (1.5 Mb/s) Driver Characteristics

A low-speed device must have a captive cable with the Series A connector on the plug end. The combination of the cable and the device must have a single-ended capacitance of no less than 200 pF and no more than 450 pF on the D+ or D- lines.

The propagation delay (TLSCBL) of a low-speed cable must be less than 18 ns. This is to ensure that the reflection occurs during the first half of the signal rise/fall, which allows the cable to be approximated by a lumped capacitance.

Figure 7-7 shows the low-speed driver signal waveforms.

Figure 7-7. Low-speed Driver Signal Waveforms

7.1.1.3 High-speed (480 Mb/s) Driver Characteristics

A high-speed USB connection is made through a shielded, twisted pair cable with a differential characteristic impedance (Z_0) of $90\ \Omega \pm 15\%$, a common mode impedance (Z_{CM}) of $30\ \Omega \pm 30\%$, and a maximum one-way delay of 26 ns (T_{FSCBL}). The D+ and D- circuit board traces which run between a transceiver and its associated connector should also have a nominal differential impedance of $90\ \Omega$, and together they may add an additional 4 ns of delay between the transceivers. (See Section 7.1.6 for details on impedance specifications of boards and transceivers.) The differential output impedance of a high-speed capable driver is required to be $90\ \Omega \pm 10\%$. When either the D+ or D- lines are driven high, V_{HSOH} (the high-speed mode high-level output voltage driven on a data line with a precision $45\ \Omega$ load to GND) must be $400\ \text{mV} \pm 10\%$. On a line which is not driven, either because the transceiver is not transmitting or because the opposite line is being driven high, V_{HSOL} (the high-speed mode low-level output voltage driven on a data line with a $45\ \Omega$ load to GND) must be $0\ \text{V} \pm 10\ \text{mV}$.

Note: Unless indicated otherwise, all voltage measurements are to be made with respect to the local circuit ground.

Note: This specification requires that a high-speed capable transceiver operating in full-speed or low-speed mode must have a driver impedance (Z_{HSDRV}) of $45\ \Omega \pm 10\%$. It is recommended that the driver impedances be matched to within $5\ \Omega$ within a transceiver. For upstream facing transceivers which do not support high-speed mode, the driver output impedance (Z_{DRV}) must fall within the range of $28\ \Omega$ to $44\ \Omega$.

On downstream facing ports, RPD resistors ($15\ \text{k}\Omega \pm 5\%$) must be connected from D+ and D- to ground.

When a high-speed capable transceiver transitions to high-speed mode, the high-speed idle state is achieved by driving SE0 with the low-/full-speed drivers at each end of the link (so as to provide the required terminations), and by disconnecting the D+ pull-up resistor in the upstream facing transceiver.

In the preferred embodiment, a transceiver activates its high-speed current driver only when transmitting high-speed signals. This is a potential design challenge, however, since the signal amplitude and timing specifications must be met even on the first symbol within a packet. As a less efficient alternative, a transceiver may cause its high-speed current source to be continually active while in high-speed mode. When the transceiver is not transmitting, the current may be directed into the device ground rather than through the current steering switch which is used for data signaling. In the example circuit, steering the current to ground is accomplished by setting HS_Drive_Enable low.

In CMOS implementations, the driver impedance will typically be realized by the combination of the driver's intrinsic output impedance and R_s . To optimally control Z_{HSDRV} and to minimize parasitics, it is preferred the driver impedance be minimized (under $5\ \Omega$) and the balance of the $45\ \Omega$ should be contributed by the R_s component.

When a transceiver operating in high-speed mode transmits, the transmit current is directed into either the D+ or D- data line. A J is asserted by directing the current to the D+ line, a K by directing it to the D- line.

When each of the data lines is terminated with a $45\ \Omega$ resistor to the device ground, the effective load resistance on each side is $22.5\ \Omega$. Therefore, the line into which the drive current is being directed rises to $17.78\ \text{mA} * 22.5\ \Omega$ or $400\ \text{mV}$ (nominal). The other line remains at the device ground voltage. When the current is directed to the opposite line, these voltages are reversed.

7.1.2 Data Signal Rise and Fall, Eye Patterns

The following sections specify the data signal rise and fall times for full-speed and low-speed signaling, and the rise time and eye patterns for high-speed signaling.

7.1.2.1 Low-speed and Full-speed Data Signal Rise and Fall

For low-speed and full-speed, the output rise time and fall times are measured between 10% and 90% of the signal (Figure 7-8). Rise and fall time requirements apply to differential transitions as well as to transitions between differential and single-ended signaling.

The rise and fall times for full-speed buffers are measured with the load shown in Figure 7-9. The rise and fall times must be between 4 ns and 20 ns and matched to within $\pm 10\%$ to minimize RFI emissions and signal skew. The transitions must be monotonic.

The rise and fall times for low-speed buffers are measured with the load shown in Figure 7-10. The capacitive load shown in Figure 7-10 is representative of the worst-case load allowed by the specification. A downstream facing transceiver is allowed 150 pF of input/output capacitance (C_{IND}). A low-speed device (including cable) may have a capacitance of as little as 200 pF and as much as 450 pF. This gives a range of 200 pF to 600 pF as the capacitive load that a downstream facing low-speed buffer might encounter. Upstream facing buffers on low-speed devices must be designed to drive the capacitance of the attached cable plus an additional 150 pF. If a low-speed buffer is designed for an application where the load capacitance is known to fall in a different range, the test load can be adjusted to match the actual application. Low-speed buffers on hosts and hubs that are attached to USB receptacles must be designed for the 200 pF to 600 pF range. The rise and fall time must be between 75 ns and 300 ns for any balanced, capacitive test load. In all cases, the edges must be matched to within $\pm 20\%$ to minimize RFI emissions and signal skew. The transitions must be monotonic.

For both full-speed and low-speed signaling, the crossover voltage (V_{CRS}) must be between 1.3 V and 2.0 V.

For low-speed and full-speed, this specification does not require matching signal swing matching to any greater degree than described above. However, when signaling, it is preferred that the average voltage on the D+ and D- lines should be constant. This means that the amplitude of the signal swing on both D+ and D- should be the same; the low and high going transition should begin at the same time and change at the same rate; and the crossover voltage should be the same when switching to a J or K. Deviations from signal matching will result in common-mode noise that will radiate and affect the ability of devices and systems to pass tests that are mandated by government agencies.

Figure 7-8. Data Signal Rise and Fall Time

Figure 7-9. Full-speed Load

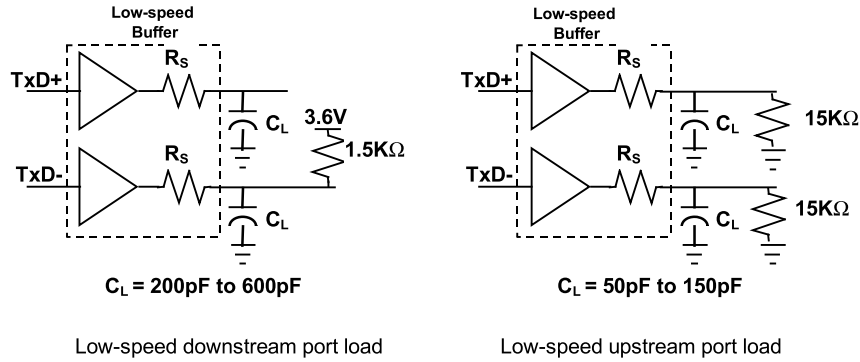

Figure 7-10. Low-speed Port Loads

Note: The CL for low-speed port load only represents the range of loading that might be added when the low-speed device is attached to a hub. The low-speed buffer must be designed to drive the load of its attached cable plus CL. A low-speed buffer design that can drive the downstream test load would be capable of driving any legitimate upstream load.

7.1.2.2 High-speed Signaling Eye Patterns and Rise and Fall Time

The following specifications apply to high-speed mode signaling. All bits, including the first and last bit of a packet, must meet the following eye pattern requirements for timing and amplitude.

Figure 7-11. Measurement Planes

Figure 7-11 defines four test planes which will be referenced in this section. TP1 and TP4 are the points where the transceiver IC pins are soldered to the hub and device circuit boards, respectively. TP2 is at the mated pins of the A connector, and TP3 is at the mated pins of the B connector (or, in the case of a captive cable, where the cable is attached to the circuit board). The following differential eye pattern templates specify transmit waveform and receive sensitivity requirements at various points and under various conditions.

When testing high-speed transmitters and receivers, measurements are made with the Transmitter/Receiver Test Fixture shown in Figure 7-12. In either case, the fixture is attached to the USB connector closest to the transceiver being tested.

Universal Serial Bus Specification Revision 2.0

Transmitter Test Attenuation: Voltage at Scope Inputs = 0.760 * Voltage at Transmitter Outputs
Receiver Test Attenuation: Voltage at Receiver Inputs = 0.684 * Voltage at Data Generator Outputs

Figure 7-12. Transmitter/Receiver Test Fixture

Note: When testing the upstream facing port of a device, VBUS must be provided from the time the device is placed in the appropriate test mode until the test is completed. This requirement will likely necessitate additional switching functionality in the test fixture (for example, to switch the D+ and D- lines between the host controller and the test instrument). Such additions must have minimal impact on the high frequency measurement results.

Transmit eye patterns specify the minimum and maximum limits, as well as limits on timing jitter, within which a driver must drive signals at each of the specified test planes. Receive eye patterns specify the minimum and maximum limits, as well as limits on timing jitter, within which a receiver must recover data.

Conformance to Templates 1, 2, 3, and 4 is required for USB 2.0 hubs and devices:

Template 1: Transmit waveform requirements for hub measured at TP2, and for device (without a captive cable) measured at TP3

Template 2: Transmit waveform requirements for device (with a captive cable) measured at TP2

Template 3: Receiver sensitivity requirements for device (with a captive cable) when signal is applied at TP2

Template 4: Receiver sensitivity requirements for device (without a captive cable) when signal is applied at TP3, and for hub when signal is applied at TP2

Templates 5 and 6 are recommended guidelines for designers:

Template 5: Transmit waveform requirements for hub transceiver measured at TP1, and for device transceiver measured at TP4

Template 6: Receiver sensitivity requirements for device transceiver when signal is applied at TP4, and for hub transceiver at when signal is applied at TP1

Template 1

Figure 7-13 shows the transmit waveform requirements for a hub measured at TP2, and for a device (without a captive cable) measured at TP3.

	Voltage Level (D+ - D-)	Time (% of Unit Interval)

High-speed Signaling Rise and Fall Times

The transition time of a high-speed driver must not be less than the specified minimum allowable differential rise and fall time (T_{HSR} and T_{HSF}). Transition times are measured when driving a reference load of $45\ \Omega$ to ground on D+ and D-. Figure 7-12 shows a recommended “Transmitter Test Fixture” for performing these measurements.

For a hub, or for a device with detachable cable, the 10% to 90% high-speed differential rise and fall times must be 500 ps or longer when measured at the A or B receptacles (respectively).

For a device with a captive cable assembly, it is a recommended design guideline that the 10% to 90% high-speed differential rise and fall times must be 500 ps or longer when measured at the point where the cable is attached to the device circuit board.

It is required that high-speed data transitions be monotonic over the minimum vertical openings specified in the preceding eye pattern templates.

7.1.2.3 Driver Usage

The upstream facing ports of functions must use one and only one of the following three driver configurations:

1. Low-speed – Low-speed drivers only
2. Full-speed – Full-speed drivers only
3. Full-/high-speed – Combination full-speed and high-speed drivers

Upstream facing USB 2.0 hub ports must use full-/high-speed drivers. Such ports must be capable of transmitting data at low-speed and full-speed rates with full-speed signaling, and at the high-speed rate using high-speed signaling. Downstream facing ports (including the host) must support low-speed, full-speed, and high-speed signaling, and must be able to transmit data at each of the three associated data rates.

In this section, there is reference to a situation in which high-speed operation is “disallowed.” This topic is discussed in depth in Chapter 11 of this specification. In brief, a high-speed capable hub's downstream facing ports are “high-speed disallowed” if the hub is unable to establish a high-speed connection on its upstream facing port. For example, this would be the case for the downstream facing ports of a high-speed capable hub when the hub is connected to a USB 1.1 host controller.

When a full-/high-speed device is attached to a pre-USB 2.0 hub, or to a hub port which is high-speed disallowed, it is required to behave as a full-speed only device. When a full-/high-speed device is attached to a USB 2.0 hub which is not high-speed disallowed, it must operate with high-speed signaling and data rate.

7.1.3 Cable Skew

The maximum skew introduced by the cable between the differential signaling pair (i.e., D+ and D- ($TSKEW$)) must be less than 100 ps and is measured as described in Section 6.7.

7.1.4 Receiver Characteristics

This section discusses the receiver characteristics for low-speed, full-speed, and full-/high-speed transceivers.

7.1.4.1 Low-speed and Full-speed Receiver Characteristics

A differential input receiver must be used to accept the USB data signal. The receiver must feature an input sensitivity (V_{DI}) of at least 200 mV when both differential data inputs are in the differential common mode range (V_{CM}) of 0.8 V to 2.5 V, as shown in Figure 7-19.

In addition to the differential receiver, there must be a single-ended receiver for each of the two data lines. The receivers must have a switching threshold between 0.8 V (V_{IL}) and 2.0 V (V_{IH}). It is recommended that the single-ended receivers incorporate hysteresis to reduce their sensitivity to noise.

Both D+ and D- may temporarily be less than V_{IH} (min) during differential signal transitions. This period can be up to 14 ns (TFST) for full-speed transitions and up to 210 ns (TLST) for low-speed transitions. Logic in the receiver must ensure that this is not interpreted as an SE0.

Figure 7-19. Differential Input Sensitivity Range for Low-/full-speed

7.1.4.2 High-speed Receiver Characteristics

A high-speed capable transceiver receiver must conform to the receiver characteristics specifications called out in Section 7.1.4.1 when receiving in low-speed or full-speed modes.

As shown in Figure 7-1, a high-speed capable transceiver which is operating in high-speed mode “listens” for an incoming serial data stream with the high-speed differential data receiver and the transmission envelope detector. Additionally, a downstream facing high-speed capable transceiver monitors the amplitude of the differential voltage on the lines with the disconnection envelope detector.

When receiving in high-speed mode, the differential receiver must be able to reliably receive signals that conform to the Receiver Eye Pattern templates shown in Section 7.1.2. Additionally, it is a strongly recommended guideline that a high-speed receiver should be able to reliably receive such signals in the presence of a common mode voltage component (V_{HSCM}) over the range of -50 mV to 500 mV (the nominal common mode component of high-speed signaling is 200 mV). Low frequency chirp J and K signaling, which occurs during the Reset handshake, should be reliably received with a common mode voltage range of -50 mV to 600 mV.

Reception of data is qualified by the output of the transmission envelope detector. The receiver must disable data recovery when the signal falls below the high-speed squelch level (V_{HSSQ}) defined in Table 7-3. (Detector must indicate squelch when the magnitude of the differential voltage envelope is ≤ 100 mV, and must not indicate squelch if the amplitude of differential voltage envelope is ≥ 150 mV.) Squelch detection must be done with a differential envelope detector, such as the one shown in Figure 7-1. The envelope detector used to detect the squelch state must incorporate a filtering mechanism that prevents indication of squelch during differential data crossovers.

The definition of a high-speed packet’s SYNC pattern, together with the requirements for high-speed hub repeaters, guarantee that a receiver will see at least 12 bits of SYNC (KJKJKJKJKKK) followed by the data portion of the packet. This means that the combination of squelch response time, DLL lock time, and end of SYNC detection must occur within 12 bit times. This is required to assure that the first bit of the packet payload will be received correctly.

In the case of a downstream facing port, a high-speed capable transceiver must include a differential envelope detector that indicates when the signal on the data exceeds the high-speed Disconnect level (V_{HSDSC}) as defined in Table 7-3. (The detector must not indicate that the disconnection threshold has been exceeded if the differential signal amplitude is ≤ 525 mV, and must indicate that the threshold has been exceeded if the differential signal amplitude is ≥ 625 mV.)

When sampled at the appropriate time, this detector provides indication that the device has been disconnected. The details of how the disconnection envelope detector is used are described in Section 7.1.7.3.

7.1.5 Device Speed Identification

The following sections specify the speed identification mechanisms for low-speed, full-speed, and high-speed.

7.1.5.1 Low-/Full-speed Device Speed Identification

The USB is terminated at the hub and function ends as shown in Figure 7-20 and Figure 7-21. Full-speed and low-speed devices are differentiated by the position of the pull-up resistor on the downstream end of the cable:

- Full-speed devices are terminated as shown in Figure 7-20 with the pull-up resistor on the D+ line.
- Low-speed devices are terminated as shown in Figure 7-21 with the pull-up resistor on the D- line.
- The pull-down terminators on downstream facing ports are resistors of $15\text{ k}\Omega \pm 5\%$ connected to ground.

The design of the pull-up resistor must ensure that the signal levels satisfy the requirements specified in Table 7-2. In order to facilitate bus state evaluation that may be performed at the end of a reset, the design must be able to pull-up D+ or D- from 0 V to $V_{IH}(\text{min})$ within the minimum reset relaxation time of $2.5\ \mu\text{s}$. A device that has a detachable cable must use a $1.5\text{ k}\Omega \pm 5\%$ resistor tied to a voltage source between 3.0 V and 3.6 V (V_{TERM}) to satisfy these requirements. Devices with captive cables may use alternative termination means. However, the Thevenin resistance of any termination must be no less than $900\ \Omega$.

Note: Thevenin resistance of termination does not include the $15\text{ k}\Omega \pm 5\%$ resistor on host/hub.

The voltage source on the pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when V_{BUS} is removed, the pull-up resistor does not supply current on the data line to which it is attached.

Figure 7-20. Full-speed Device Cable and Resistor Connections

Figure 7-21. Low-speed Device Cable and Resistor Connections

7.1.5.2 High-speed Device Speed Identification

The high-speed Reset and Detection mechanisms follow the behavioral model for low-/full-speed. When reset is complete, the link must be operating in its appropriate signaling mode (low-speed, full-speed, or high-speed as governed by the preceding usage rules), and the speed indication bits in the port status register will correctly report this mode. Software need only initiate the assertion of reset and read the port status register upon notification of reset completion.

High-speed capable devices initially attach as full-speed devices. This means that for high-speed capable upstream facing ports, R_{PU} ($1.5\text{ k}\Omega \pm 5\%$) must be connected from D+ to the 3.3 V supply (as shown in Figure 7-1) through a switch which can be opened under SW control.

After the initial attachment, high-speed capable transceivers engage in a low level protocol during reset to establish a high-speed link and to indicate high-speed operation in the appropriate port status register. This protocol is described in Section 7.1.7.5.

7.1.6 Input Characteristics

The following sections describe the input characteristics for transceivers operating in low-speed, full-speed, and high-speed modes.

7.1.6.1 Low-speed and Full-speed Input Characteristics

The input impedance of D+ or D- without termination should be $> 300\text{ k}\Omega$ (Z_{INP}). The input capacitance of a port is measured at the connector pins. Upstream facing and downstream facing ports are allowed different values of capacitance. The maximum capacitance (differential or single-ended) (C_{IND}) allowed on a downstream facing port of a hub or host is 150 pF on D+ or D- when operating in low-speed or full-speed. This is comprised of up to 75 pF of lumped capacitance to ground on each line at the transceiver and in the connector, and an additional 75 pF capacitance on each conductor in the transmission line between the receptacle and the transceiver. The transmission line between the receptacle and RS must be $90\ \Omega \pm 15\%$.

The maximum capacitance on an upstream facing port of a full-speed device with a detachable cable (C_{INUB}) is 100 pF on D+ or D-. This is comprised of up to 75 pF of lumped capacitance to ground on each line at the transceiver and in the connector and an additional 25 pF capacitance on each conductor in the transmission line between the receptacle and the transceiver. The difference in capacitance between D+ and D- must be less than 10%.

For full-speed devices with captive cables, the device itself may have up to 75 pF of lumped capacitance to ground on D+ and D-. The cable accounts for the remainder of the input capacitance.

A low-speed device is required to have a captive cable. The input capacitance of the low-speed device will include the cable. The maximum single-ended or differential input capacitance of a low-speed device is 450 pF (C_{LINUA}).

For devices with captive cables, the single-ended input capacitance must be consistent with the termination scheme used. The termination must be able to charge the D+ or D- line from 0 V to V_{IH} (min) within 2.5 μs . The capacitance on D+/D- includes the single-ended input-capacitance of the device (measured from the pins on the connector on the cable) and the 150 pF of input capacitance of the host/hub.

An implementation may use small capacitors at the transceiver for purposes of edge rate control. The sum of the capacitance of the added capacitor (C_{EDGE}), the transceiver, and the trace connecting capacitor and transceiver to Rs must not exceed 75 pF (either single-ended or differential) and the capacitance must be balanced to within 10%. The added capacitor, if present, must be placed between the transceiver pins and Rs (see Figure 7-22).

Use of ferrite beads on the D+ or D- lines of full-speed devices is discouraged.

Figure 7-22. Placement of Optional Edge Rate Control Capacitors for Low-/full-speed

7.1.6.2 High-speed Input Characteristics

Figure 7-23 shows the simple equivalent loading circuit of a USB device operating in high-speed receive mode.

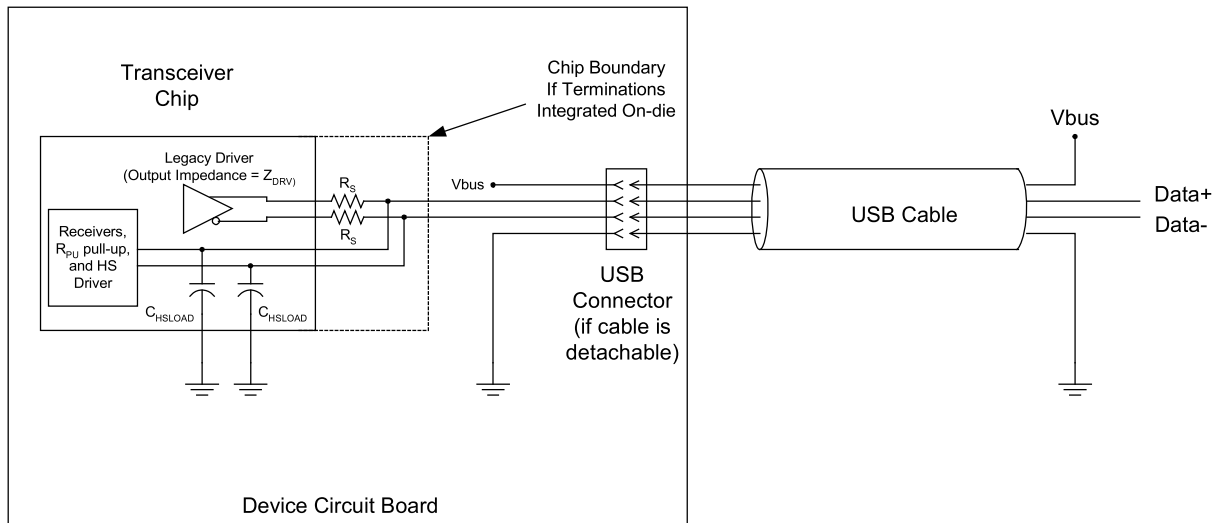

Figure 7-23. Diagram for High-speed Loading Equivalent Circuit

When operating in high-speed signaling mode, a transceiver must meet the following loading specifications:

1. DC output voltage and resistance specifications
2. TDR loading specification

Additionally, it is strongly recommended that a transceiver component operating in high-speed signaling mode should meet the following lumped capacitance guideline.

The use of ferrites on high-speed data lines is strongly discouraged.

DC output voltage and resistance specifications – A transceiver that is in high-speed mode must present a DC load on each of the data lines nominally equivalent to 45Ω to ground. The actual resistance, Z_{HSDRV} , must be $40.5 \Omega \leq Z_{HSDRV} \leq 49.5 \Omega$. The output voltage in the high-speed idle state (V_{HSTERM}) is specified in Table 7-3

TDR loading specification – The AC loading specifications of a transceiver in the high-speed idle state are specified in terms of differential TDR (Time Domain Reflectometer) measurements.

These measurements govern the maximum allowable transmission line discontinuities for the port connector, the interconnect leading from the connector to the transceiver, the transceiver package, and the transceiver IC itself. In the special case of a high-speed capable device with a captive cable, the transmission line discontinuities of the cable assembly are also governed.

Universal Serial Bus Specification Revision 2.0

The following specifications must be met with the incident rise time of the differential TDR set to 400 ps. It is important to note that all times are “as displayed” on the TDR and are hence “round trip times.”

Termination Impedance (Z_{HSTERM}) is measured on the TDR trace at a specific measurement time following the connector reference time. The connector reference time is determined by disconnecting the TDR connection from the port connector and noting the time of the open circuit step. For an A connector, the measurement time is 8 ns after the connector reference location. For a B connector, the measurement time is 4 ns after the connector reference location. The differential termination impedance must be:

$$80 \Omega \leq Z_{HSTERM} \leq 100 \Omega$$

Through Impedance (Z_{HSTHRU}) is the impedance measured from 500 ps before the connector reference location until the time governed by the Termination impedance specification.

$$70 \Omega \leq Z_{HSTHRU} \leq 110 \Omega$$

In the Exception Window (a sliding 1.4 ns window inside the Through Impedance time window), the differential impedance may exceed the Through limits. No single excursion, however, may exceed the Through limits for more than twice the TDR rise time (400 ps).

In the special case of a high-speed capable device with a captive cable, the same specifications must be met, but the TDR measurements must be made through the captive cable assembly. Determination of the connector reference time can be more difficult in this case, since the cable may not be readily removable from the port being tested. It is left to the tester of a specific device to determine the connector reference location by whatever means are available.

Lumped capacitance guideline for the transceiver component

When characterizing a transceiver chip as an isolated component, the measurement can be performed effectively at the chip boundary shown in Figure 7-23 without USB connectors or cables. Parasitic capacitance of the test fixture can be corrected by measuring the capacitance of the fixture itself and subtracting this reading from the reading taken with the transceiver inserted. If the terminations are off-chip, discrete R_s resistors should be in place during the measurements, and measurements should be taken on the “connector side” of the resistors. The transceiver should be in Test_SE0_NAK mode during testing.

Capacitance measurements are taken from each of the data lines to ground while the other line is left open. The instrument used to perform this measurement must be able to determine the effective capacitance to ground in the presence of the parallel effective resistance to ground.

Capacitance to Ground on each line: $C_{HLOAD} \leq 10$ pF

Matching of Capacitances to Ground: ≤ 1.0 pF

The guideline is to allow no more than 5.0 pF for the transceiver die itself and no more than an additional 5 pF for the package. The differential capacitance across the transceiver inputs should be no more than 5.0 pF

7.1.7 Signaling Levels

The following sections specify signaling levels for low-speed, full-speed, and high-speed operation.

7.1.7.1 Low-/Full-speed Signaling Levels

Table 7-2 summarizes the USB signaling levels. The source is required to drive the levels specified in the second column, and the target is required to identify the correct bus state when it sees the levels in the third column. (Target receivers can be more sensitive as long as they are within limits specified in the fourth column.)

Universal Serial Bus Specification Revision 2.0

Table 7-2. Low-/full-speed Signaling Levels

Bus State	Signaling Levels		
	At originating source connector (at end of bit time)	At final target connector	
		Required	Acceptable
Differential "1"	$D+ > V_{OH}(\text{min})$ and $D- < V_{OL}(\text{max})$	$(D+) - (D-) > 200 \text{ mV}$ and $D+ > V_{IH}(\text{min})$	$(D+) - (D-) > 200 \text{ mV}$
Differential "0"	$D- > V_{OH}(\text{min})$ and $D+ < V_{OL}(\text{max})$	$(D-) - (D+) > 200 \text{ mV}$ and $D- > V_{IH}(\text{min})$	$(D-) - (D+) > 200 \text{ mV}$
Single-ended 0 (SE0)	$D+$ and $D- < V_{OL}(\text{max})$	$D+$ and $D- < V_{IL}(\text{max})$	$D+$ and $D- < V_{IH}(\text{min})$
Single-ended 1 (SE1)	$D+$ and $D- > V_{OSE1}(\text{min})$	$D+$ and $D- > V_{IL}(\text{max})$	
Data J state: Low-speed Full-speed	Differential "0" Differential "1"	Differential "0" Differential "1"	
Data K state: Low-speed Full-speed	Differential "1" Differential "0"	Differential "1" Differential "0"	
Idle state: Low-speed Full-speed	NA	$D- > V_{IHZ}(\text{min})$ and $D+ < V_{IL}(\text{max})$ $D+ > V_{IHZ}(\text{min})$ and $D- < V_{IL}(\text{max})$	$D- > V_{IHZ}(\text{min})$ and $D+ < V_{IH}(\text{min})$ $D+ > V_{IHZ}(\text{min})$ and $D- < V_{IH}(\text{min})$
Resume state	Data K state	Data K state	
Start-of-Packet (SOP)	Data lines switch from Idle to K state		
End-of-Packet (EOP) ⁴	SE0 for approximately 2 bit times ¹ followed by a J for 1 bit time ³	SE0 for ≥ 1 bit time ² followed by a J state for 1 bit time	SE0 for ≥ 1 bit time ² followed by a J state
Disconnect (at downstream port)	NA	SE0 for $\geq 2.5 \mu\text{s}$	
Connect (at downstream port)	NA	Idle for $\geq 2 \text{ ms}$	Idle for $\geq 2.5 \mu\text{s}$
Reset	$D+$ and $D- < V_{OL}(\text{max})$ for $\geq 10\text{ms}$	$D+$ and $D- < V_{IL}(\text{max})$ for $\geq 10 \text{ ms}$	$D+$ and $D- < V_{IL}(\text{max})$ for $\geq 2.5 \mu\text{s}$

Note 1: The width of EOP is defined in bit times relative to the speed of transmission. (Specification EOP widths are given in Table 7-7 and Table 7-8.)

Note 2: The width of EOP is defined in bit times relative to the device type receiving the EOP. The bit time is approximate.

Note 3: The width of the J state following the EOP is defined in bit times relative to the buffer edge rate. The J state from a low-speed buffer must be a low-speed bit time wide and, from a full-speed buffer, a full-speed bit time wide.

Note 4: The keep-alive is a low-speed EOP.

Universal Serial Bus Specification Revision 2.0

The J and K data states are the two logical levels used to communicate differential data in the system. Differential signaling is measured from the point where the data line signals cross over. Differential data signaling is not concerned with the level at which the signals cross, as long as the crossover voltage meets the requirements in Section 7.1.2. Note that, at the receiver, the Idle and Resume states are logically equivalent to the J and K states respectively.

As shown in Table 7-2, the J and K states for full-speed signaling are inverted from those for low-speed signaling. The sense of data, idle, and resume signaling is set by the type of device that is being attached to a port. If a full-speed device is attached to a port, that segment of the USB uses full-speed signaling conventions (and fast rise and fall times), even if the data being sent across the data lines is at the low-speed data rate. The low-speed signaling conventions shown in Table 7-2 (plus slow rise and fall times) are used only between a low-speed device and the port to which it is attached.

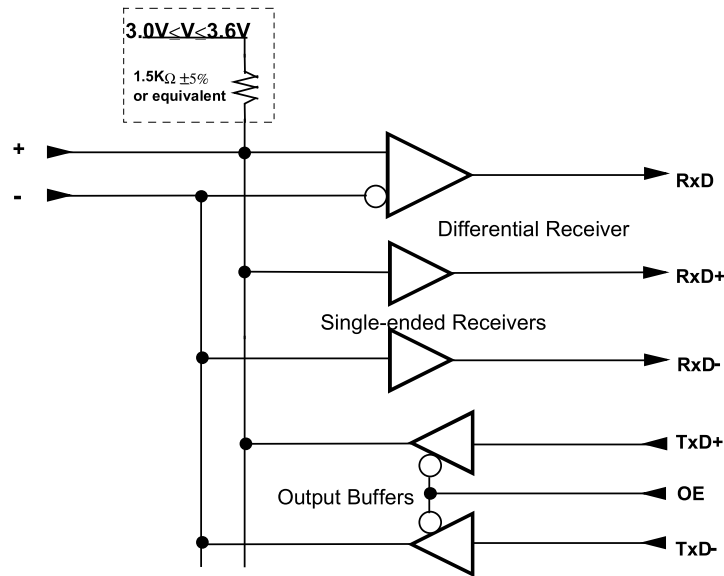

Figure 7-24. Upstream Facing Full-speed Port Transceiver

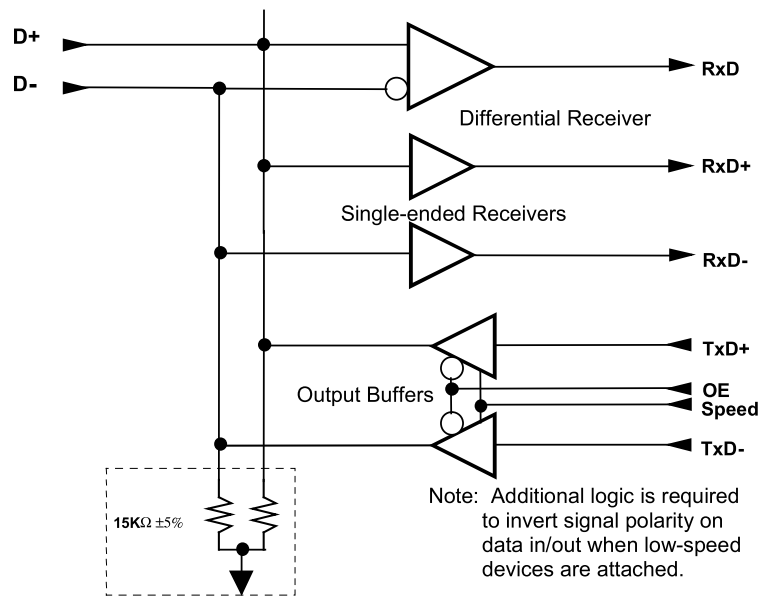

Figure 7-25. Downstream Facing Low-/full-speed Port Transceiver

7.1.7.2 Full-/High-speed Signaling Levels

The high-speed signaling voltage specifications in Table 7-3 must be met when measuring at the connector closest to the transceiver, using precision 45 Ω load resistors to the device ground as reference loads. All voltage measurements are taken with respect to the local device ground.

Table 7-3. High-speed Signaling Levels

Bus State	Required Signaling Level at Source Connector	Required Signaling Level at Target Connector
High-speed Differential "1"	<p>DC Levels:</p> <p>$V_{HSOH}(\min) \leq D+ \leq V_{HSOH}(\max)$</p> <p>$V_{HSOL}(\min) \leq D- \leq V_{HSOL}(\max)$</p> <p>See Note 1.</p> <p>AC Differential Levels:</p> <p>A transmitter must conform to the eye pattern templates called out in Section 7.1.2.</p> <p>See Note 2.</p>	<p>AC Differential Levels</p> <p>The signal at the target connector must be recoverable, as defined by the eye pattern templates called out in Section 7.1.2.</p> <p>See Note 2.</p>
High-speed Differential "0"	<p>DC Levels:</p> <p>$V_{HSOH}(\min) \leq D- \leq V_{HSOH}(\max)$</p> <p>$V_{HSOL}(\min) \leq D+ \leq V_{HSOL}(\max)$</p> <p>See Note 1.</p> <p>AC Differential Levels:</p> <p>A transmitter must conform to the eye pattern templates called out in Section 7.1.2.</p> <p>See Note 2.</p>	<p>AC Differential Levels:</p> <p>The signal at the target connector must be recoverable, as defined by the eye pattern templates called out in Section 7.1.2.</p> <p>See Note 2.</p>
High-speed J State	High-speed Differential "1"	High-speed Differential "1"
High-speed K State	High-speed Differential "0"	High-speed Differential "0"

Universal Serial Bus Specification Revision 2.0

Table 7-3. High-speed Signaling Levels (Continued)

Chirp J State (differential voltage; applies only during reset when both hub and device are high-speed capable)	DC Levels: $V_{CHIRPJ}(\min) \leq (D+ - D-) \leq V_{CHIRPJ}(\max)$	AC Differential Levels The differential signal at the target connector must be ≥ 300 mV
Chirp K State (differential voltage; applies only during reset when both hub and device are high-speed capable)	DC Levels: $V_{CHIRPK}(\min) \leq (D+ - D-) \leq V_{CHIRPK}(\max)$	AC Differential Levels The differential signal at the target connector must be ≤ -300 mV
High-speed Squelch State	NA	V_{HSSQ} - Receiver must indicate squelch when magnitude of differential voltage is ≤ 100 mV; receiver must not indicate squelch if magnitude of differential voltage is ≥ 150 mV. See Note 3.
High-speed Idle State	NA	DC Levels: $V_{HSOI} \min \leq (D+, D-) \leq V_{HSOI} \max$ See Note 1. AC Differential Levels: Magnitude of differential voltage is ≤ 100 mV See Note 3.
Start of High-speed Packet (HSSOP)	Data lines switch from high-speed Idle to high-speed J or high-speed K state.	
End of High-speed Packet (HSEOP)	Data lines switch from high-speed J or K to high-speed Idle state.	
High-speed Disconnect State (at downstream facing port)	NA	V_{HSDSC} - Downstream facing port must not indicate device disconnection if differential voltage is ≤ 525 mV, and must indicate device disconnection when magnitude of differential voltage is ≥ 625 mV, at the sample time discussed in Section 7.1.7.3.

Note 1: Measured with a 45 Ω resistor to ground at each data line, using test modes Test_J and Test_K

Note 2: Measured using test mode Test_Packet with fixture shown in Figure 7-12

Note 3: Measured with fixture shown in Figure 7-12, using test mode SE0_NACK

Note 4: A high-speed driver must never “intentionally” generate a signal in which both D+ and D- are driven to a level above 200 mV. The current-steering design of a high-speed driver should naturally preclude this possibility.

7.1.7.3 Connect and Disconnect Signaling

When no function is attached to the downstream facing port of a host or hub in low-/full-speed, the pull-down resistors present there will cause both D+ and D- to be pulled below the single-ended low threshold of the host or hub transceiver when that port is not being driven by the hub. This creates an SE0 state on the downstream facing port. A disconnect condition is indicated if the host or hub is not driving the data lines and an SE0 persists on a downstream facing port for more than T_{DDIS} (see Figure 7-26). The specifications for T_{DDIS} and T_{DCNN} are defined in Table 7-13.

A connect condition will be detected when the hub detects that one of the data lines is pulled above its V_{IH} threshold for more than T_{DCNN} (see Figure 7-27 and Figure 7-28).

Hubs must determine the speed of the attached device by sampling the state of the bus immediately before driving SE0 to indicate a reset condition to the device.

All signaling levels given in Table 7-2 are set for this bus segment (and this segment alone) once the speed of the attached device is determined. The mechanics of speed detection are described in Section 11.8.2.

Figure 7-26. Low-/full-speed Disconnect Detection

Figure 7-27. Full-/high-speed Device Connect Detection

Figure 7-28. Low-speed Device Connect Detection

Because USB components may be hot plugged, and hubs may implement power switching, it is necessary to comprehend the delays between power switching and/or device attach and when the device’s internal power has stabilized. Figure 7-29 shows all the events associated with both turning on port power with a device connected and hot-plugging a device. There are six delays and a sequence of events that are defined by this specification.

Figure 7-29. Power-on and Connection Events Timing

- Δt1** This is the amount of time required for the hub port power switch to operate. This delay is a function of the type of hub port switch. Hubs report this time in the hub descriptor (see Section 11.15.2.1), which can be read via a request to the Hub Controller (see Section 11.16.2.4). If a device were plugged into a non-switched or already-switched on port, Δt1 is equal to zero.
- Δt2** (TSIGATT) This is the maximum time from when VBUS is up to valid level (4.01 V) to when a device has to signal attach. Δt2 represents the time required for the device’s internal power rail to stabilize and for D+ or D- to reach VIH (min) at the hub. Δt2 must be less than 100 ms for all hub and device implementations. (This requirement only applies if the device is drawing power from the bus.)
- Δt3** (TATTTDB) This is a debounce interval with a minimum duration of 100 ms that is provided by the USB System Software. It ensures that the electrical and mechanical connection is stable before software attempts to reset the attached device. The interval starts when the USB System Software is notified of a connection detection. The interval restarts if there is a disconnect. The debounce interval ensures that power is stable at the device for at least 100 ms before any requests will be sent to the device.
- Δt4** (T2SUSP) Anytime a device observes no bus activity, it must obey the rules of going into suspend (see Section 7.1.7.6).

Δt_5 (TDRST) This is the period of time hubs drive reset to a device. Refer to Section 7.1.7.5 and Section 11.5.1.5 for details.

Δt_6 (TRSTRCY) The USB System Software guarantees a minimum of 10 ms for reset recovery. Device response to any bus transactions addressed to the default device address during the reset recovery time is undefined.

High-speed capable devices must initially attach as full-speed devices and must comply with all full-speed connection requirements. A high-speed capable downstream facing port must correctly detect the attachment of low-speed and full-speed devices and must also comply with all low-speed and full-speed connection behaviors.

Transition to high-speed signaling is accomplished by means of a low level electrical protocol which occurs during Reset. This protocol is specified in Section 7.1.7.5.

A downstream facing transceiver operating in high-speed mode detects disconnection of a high-speed device by sensing the doubling in differential signal amplitude across the D+ and D- lines that can occur when the device terminations are removed. The Disconnection Envelope Detector output goes high when the downstream facing transceiver transmits and positive reflections from the open line return with a phase which is additive with the transceiver driver signal. Signals with differential amplitudes ≥ 625 mV must reliably activate the Disconnection Envelope Detector. Signals with differential amplitudes ≤ 525 mV must never activate the Disconnection Envelope Detector.

To assure that this additive effect occurs and is of sufficient duration to be detected, the EOP at the end of a high-speed SOF is lengthened to a continuous string of 40 bits without any transitions, as discussed in Section 7.1.13.2. This length is sufficient to guarantee that the voltage at the downstream facing port's connector will double, since the maximum allowable round trip signal delay is 30 bit times.

When a downstream facing port is transmitting in high-speed mode and detects that it has sent 32 bits without a transition, the disconnection envelope detector's output must be sampled once during transmission of the next 8 bits at the transceiver output. (In the absence of bus errors, the next 8 bits will not include a transition.) If the sample indicates that the disconnection detection threshold has been exceeded, the downstream facing port must indicate that the high-speed device has been disconnected. See Section 11.12.4.

7.1.7.4 Data Signaling

Data transmission within a packet is done with differential signals.

7.1.7.4.1 Low-/Full-Speed Signaling

The start of a packet (SOP) is signaled by the originating port by driving the D+ and D- lines from the Idle state to the opposite logic level (K state). This switch in levels represents the first bit of the SYNC field. Hubs must limit the change in the width of the first bit of SOP when it is retransmitted to less than ± 5 ns. Distortion can be minimized by matching the nominal data delay through the hub with the output enable delay of the hub.

The SE0 state is used to signal an end-of-packet (EOP). EOP will be signaled by driving D+ and D- to the SE0 state for two bit times followed by driving the lines to the J state for one bit time. The transition from the SE0 to the J state defines the end of the packet at the receiver. The J state is asserted for one bit time and then both the D+ and D- output drivers are placed in their high-impedance state. The bus termination resistors hold the bus in the Idle state. Figure 7-30 shows the signaling for start and end of a packet.

Figure 7-30. Low-/full-speed Packet Voltage Levels

7.1.7.4.2 High-speed Signaling

The high-speed Idle state is when both lines are nominally at GND.

The source of the packet signals the Start of Packet (SOP) in high-speed mode by driving the D+ and D- lines from the high-speed Idle state to the K state. This K is the first symbol of the SYNC pattern (NRZI sequence KJKJKJKJ KJKJKJKJ KJKJKJKJ KJKJKJKK) as described in Section 7.1.10.

The high-speed End of Packet (EOP) begins with a transition from the last symbol before the EOP to the opposite symbol. This opposite symbol is the first symbol in the EOP pattern (NRZ 01111111 with bit stuffing disabled) as described in Section 7.1.13.2. Upon completion of the EOP pattern, the driver ceases to inject current into the D+ or D- lines, and the lines return to the high-speed Idle state. The high-speed SOF EOP is a special case. This SOF EOP is 40 symbols without a transition (rather than 8 for a non-SOF packet).

The fact that the first symbol in the EOP pattern forces a transition simplifies the process of determining precisely which is the last bit in the packet prior to the EOP delimiter.

7.1.7.5 Reset Signaling

A hub signals reset to a downstream port by driving an extended SE0 at the port. After the reset is removed, the device will be in the Default state (refer to Section 9.1).

The reset signaling can be generated on any Hub or Host Controller port by request from the USB System Software. The reset signaling must be driven for a minimum of 10ms (TDRST). After the reset, the hub port will transition to the Enabled state (refer to Section 11.5).

As an additional requirement, Host Controllers and the USB System Software must ensure that resets issued to the root ports drive reset long enough to overwhelm any concurrent resume attempts by downstream devices. It is required that resets from root ports have a duration of at least 50 ms (TDRSTR). It is not required that this be 50 ms of continuous Reset signaling. However, if the reset is not continuous, the interval(s) between reset signaling must be less than 3 ms (TRHRSI), and the duration of each SE0 assertion must be at least 10 ms (TDRST).

A device operating in low-/full-speed mode that sees an SE0 on its upstream facing port for more than 2.5 μ s (TDETRST) may treat that signal as a reset. The reset must have taken effect before the reset signaling ends.

Hubs will propagate traffic to a newly reset port after the port is in the Enabled state. The device attached to this port must recognize this bus activity and keep from going into the Suspend state.

Hubs must be able to accept all hub requests and devices must be able to accept a SetAddress() request (refer to Section 11.24.2 and Section 9.4 respectively) after the reset recovery time 10 ms (TRSTRCY) after the reset is removed. Failure to accept this request may cause the device not to be recognized by the USB system software. Hubs and devices must complete commands within the times specified in Chapter 9 and Chapter 11.

Reset must wake a device from the Suspend state.

It is required that a high-speed capable device can be reset while in the Powered, Default, Address, Configured, or Suspended states shown in Figure 9-1. The reset signaling is compatible with low-/full-speed reset. This means that a hub must successfully reset any device (even USB 1.X devices), and a device must be successfully reset by any hub (even USB1.X hubs).

If, and only if, a high-speed capable device is reset by a high-speed capable hub which is not high-speed disallowed, both hub and device must be operating in the default state in high-speed signaling mode at the end of reset. The hub port status register must indicate that the port is in high-speed signaling mode. This requirement is met by having such a device and such a hub engage in a low level protocol during the reset signaling time. The protocol is defined in such a way that USB 1.X devices will not be disrupted from their normal reset behaviors.

Note: Because the downstream facing port will not be in Transmit state during the Reset Protocol, high-speed Chirp signaling levels will not provoke disconnect detection. (Refer to Section 7.1.7.3 and Section 11.5.1.7.)

Reset Protocol for high-speed capable hubs and devices

1. The hub checks to make sure the attached device is not low-speed. (A low-speed device is not allowed to support high-speed operation. If the hub determines that it is attached to a low-speed device, it does not conduct the following high-speed detection protocol during reset.)
2. The hub drives SE0. In this description of the Reset Protocol and High-speed Detection Handshake, the start of SE0 is referred to as time T0.

3. The device detects assertion of SE0.
 - a) If the device is being reset from suspend, then the device begins a high-speed detection handshake after the detection of SE0 for no less than $2.5 \mu\text{s}$ (T_{FILTSE0}). Since a suspended device will generally have its clock oscillator disabled, the detection of SE0 will cause the oscillator to be restarted. The clock must be useable (although not necessarily settled to 500 ppm accuracy) in time to detect the high-speed hub chirp as described in Step 8.
 - b) If the device is being reset from a non-suspended full-speed state, then the device begins a high-speed detection handshake after the detection of SE0 for no less than $2.5 \mu\text{s}$ and no more than 3.0 ms (T_{WTRSTFS}).
 - c) If the device is being reset from a non-suspended high-speed state, then the device must wait no less than 3.0 ms and no more than 3.125 ms (T_{WTREV}) before reverting to full-speed. Reversion to full-speed is accomplished by removing the high-speed termination and reconnecting the D+ pull-up resistor. The device samples the bus state, and checks for SE0 (reset as opposed to suspend), no less than $100 \mu\text{s}$ and no more than $875 \mu\text{s}$ (T_{WTRSTHS}) after starting reversion to full-speed. If SE0 (reset) is detected, then the device begins a high-speed detection handshake.

High-speed Detection Handshake (not performed if low-speed device detected by hub):

Note: In the following handshake, both the hub and device are required to detect Chirp J's and K's of specified minimum durations. It is strongly recommended that "gaps" in these Chirp signals as short as 16 high-speed bit times should restart the duration timers.

4. The high-speed device leaves the D+ pull-up resistor connected, leaves the high-speed terminations disabled, and drives the high-speed signaling current into the D- line. This creates a Chirp K on the bus. The device chirp must last no less than 1.0 ms (T_{UCH}) and must end no more than 7.0 ms (T_{UCHEND}) after high-speed Reset time T_0 .
5. The hub must detect the device chirp after it has seen assertion of the Chirp K for no less than $2.5 \mu\text{s}$ (T_{FILT}). If the hub does not detect a device chirp, it must continue the assertion of SE0 until the end of reset.
6. No more than $100 \mu\text{s}$ (T_{WTDCH}) after the bus leaves the Chirp K state, the hub must begin to send an alternating sequence of Chirp K's and Chirp J's. There must be no Idle states on the bus between the J's and K's. This sequence must continue until a time (T_{DCHSE0}) no more than $500 \mu\text{s}$ before and no less than $100 \mu\text{s}$ before the end of Reset. (This will guarantee that the bus remains active, preventing the device from entering the high-speed Suspend state.) Each individual Chirp K and Chirp J must last no less than $40 \mu\text{s}$ and no more than $60 \mu\text{s}$ (T_{DCHBIT}).
7. After completing the hub chirp sequence, the hub asserts SE0 until end of Reset. At the end of reset, the hub must transition to the high-speed Enabled state without causing any transitions on the data lines.
8. After the device completes its chirp, it looks for the high-speed hub chirp. At a minimum, the device is required to see the sequence Chirp K-J-K-J-K-J in order to detect a valid hub chirp. Each individual Chirp K and Chirp J must be detected for no less than $2.5 \mu\text{s}$ (T_{FILT}).
 - a) If the device detects the sequence Chirp K-J-K-J-K-J, then no more than $500 \mu\text{s}$ (T_{WTHS}) after detection, the device is required to disconnect the D+ pull-up resistor, enable the high-speed terminations, and enter the high-speed Default state.
 - b) If the device has not detected the sequence Chirp K-J-K-J-K-J by a time no less than 1.0 ms and no more than 2.5 ms (T_{WTFSS}) after completing its own chirp, then the device is required to revert to the full-speed Default state and wait for the end of Reset.

7.1.7.6 Suspending

All devices must support the Suspend state. Devices can go into the Suspend state from any powered state. They begin the transition to the Suspend state after they see a constant Idle state on their upstream facing bus lines for more than 3.0 ms . The device must actually be suspended, drawing only suspend current from the bus after no more than 10 ms of bus inactivity on all its ports. Any bus activity on the upstream facing port will keep

a device out of the Suspend state. In the absence of any other bus traffic, the SOF token (refer to Section 8.4.3) will occur once per (micro)frame to keep full-/high-speed devices from suspending. In the absence of any low-speed traffic, low-speed devices will see at least one keep-alive (defined in Table 7-2) in every frame in which an SOF occurs, which keeps them from suspending. Hubs generate this keep-alive as described in Section 11.8.4.1.

While in the Suspend state, a device must continue to provide power to its D+ (full-/high-speed) or D- (low-speed) pull-up resistor to maintain an idle so that the upstream hub can maintain the correct connectivity status for the device.

Additional Requirements for High-speed Capable Devices

From the perspective of a device operating in high-speed mode, a Reset and a Suspend are initially indistinguishable, so the first part of the device response is the same as for a Reset. When a device operating in high-speed mode detects that the data lines have been in the high-speed Idle state for at least 3.0 ms, it must revert to the full-speed configuration no later than 3.125 ms (T_{WTREV}) after the start of the idle state. Reversion to full-speed is accomplished by disconnecting its termination resistors and reconnecting its D+ pull-up resistor. No earlier than 100 μ s and no later than 875 μ s ($T_{WTRSTHS}$) after reverting to full-speed, the device must sample the state of the line. If the state is a full-speed J, the device continues with the Suspend process. (SE0 would have indicated that the downstream facing port was driving reset, and the device would have gone into the “High-speed Detection Handshake” as described in Section 7.1.7.5.)

A device or downstream facing port which is suspended from high-speed operation actually transitions to full-speed signaling during the suspend process, but is required to remember that it was operating in high-speed mode when suspended. When the resume occurs, the device or downstream facing transceiver must revert to high-speed as discussed in Section 7.1.7.7 without the need for a reset.

7.1.7.6.1 Global Suspend

Global suspend is used when no communication is desired anywhere on the bus and the entire bus is placed in the Suspend state. The host signals the start of global suspend by ceasing all its transmissions (including the SOF token). As each device on the bus recognizes that the bus is in the Idle state for the appropriate length of time, it goes into the Suspend state.

After 3.0 ms of continuous idle state, a downstream facing transceiver operating in high-speed must revert to the full-speed idle configuration (high-speed terminations disabled), but it does not enable full-speed disconnect detection until 1.0 ms later. This is to make sure that the device has returned to the full-speed Idle state prior to the enabling of full-speed disconnect detection, thereby preventing an unintended disconnect detection. After re-enabling the full-speed disconnect detection mechanism, the hub continues with the suspend process.

7.1.7.6.2 Selective Suspend

Segments of the bus can be selectively suspended by sending the command SetPortFeature(PORT_SUSPEND) to the hub port to which that segment is attached. The suspended port will block activity to the suspended bus segment, and devices on that segment will go into the Suspend state after the appropriate delay as described above.

When a downstream facing port operating in high-speed mode receives the SetPortFeature(PORT_SUSPEND) command, the port immediately reverts to the full-speed Idle state and blocks any activity to the suspend segment. Full-speed disconnect detection is disabled until the port has been in full-speed idle for 4.0 ms. This prevents an unintended disconnect detection. After re-enabling the full-speed disconnect detection mechanism, the hub continues with the suspend process.

Section 11.5 describes the port Suspend state and its interaction with the port state machine. Suspend is further described in Section 11.9.

7.1.7.7 Resume

If a device is in the Suspend state, its operation is resumed when any non-idle signaling is received on its upstream facing port. Additionally, the device can signal the system to resume operation if its remote wakeup capability has been enabled by the USB System Software. Resume signaling is used by the host or a device to bring a suspended bus segment back to the active condition. Hubs play an important role in the propagation and generation of resume signaling. The following description is an outline of a general global resume sequence. A complete description of the resume sequence, the special cases caused by selective suspend, and the role of the hub are given in Section 11.9.

The host may signal resume (TDRSMDN) at any time. It must send the resume signaling for at least 20 ms and then end the resume signaling in one of two ways, depending on the speed at which its port was operating when it was suspended. If the port was in low-/full-speed when suspended, the resume signaling must be ended with a standard, low-speed EOP (two low-speed bit times of SE0 followed by a J). If the port was operating in high-speed when it was suspended, the resume signaling must be ended with a transition to the high-speed idle state.

The 20 ms of resume signaling ensures that all devices in the network that are enabled to see the resume are awakened. The connectivity established by the resume signaling is torn down by the End of Resume, which prepares the hubs for normal operation. After resuming the bus, the host must begin sending bus traffic (at least the SOF token) within 3 ms of the start of the idle state to keep the system from going back into the Suspend state.

A device with remote wakeup capability may not generate resume signaling unless the bus has been continuously in the Idle state for 5 ms (TWTRSM). This allows the hubs to get into their Suspend state and prepare for propagating resume signaling. The remote wakeup device must hold the resume signaling for at least 1 ms but for no more than 15 ms (TDRSMUP). At the end of this period, the device stops driving the bus (puts its drivers into the high-impedance state and does not drive the bus to the J state).

If the hub upstream of a remote wakeup device is suspended, it will propagate the resume signaling to its upstream facing port and to all of its enabled downstream facing ports, including the port that originally signaled the resume. When a hub is propagating resume signaling from a downstream device, it may transition from the idle state to K with a risetime faster than is normally allowed. The hub must begin this rebroadcast (TURSM) of the resume signaling within 1 ms of receiving the original resume. The resume signal will propagate in this manner upstream until it reaches the host or a non-suspended hub (refer to Section 11.9), which will reflect the resume downstream and take control of resume timing. This hub is termed the controlling hub. Intermediate hubs (hubs between the resume initiator and the controlling hub) drive resume (TDRSMUP) on their upstream facing port for at least 1 ms during which time they also continue to drive resume on enabled downstream facing ports. An intermediate hub will stop driving resume on the upstream facing port and reverse the direction of connectivity from upstream to downstream within 15 ms after first asserting resume on its upstream facing port. When all intermediate hubs have reversed connectivity, resume is being driven from the controlling hub through all intermediate hubs and to all enabled ports. The controlling hub must rebroadcast the resume signaling within 1 ms (TURSM) and ensures that resume is signaled for at least 20 ms (TDRSMDN). The hub may then begin normal operation by terminating the resume process as described above.

The USB System Software must provide a 10 ms resume recovery time (TRSMRCY) during which it will not attempt to access any device connected to the affected (just-activated) bus segment.

Port connects and disconnects can also cause a hub to send a resume signal and awaken the system. These events will cause a hub to send a resume signal only if the hub has been enabled as a remote-wakeup source. Refer to Section 11.4.4 for more details.

Refer to Section 7.2.3 for a description of power control during suspend and resume.

If the hub port and device were operating in high-speed prior to suspend, they are required to "remember" that they were previously operating in high-speed, and they must transition back to high-speed operation, without arbitration, within two low-speed bit times of the K to SE0 transition. The inactivity timers must be started two low-speed bit times after the K to SE0 transition. Note that the transition from SE0 to J which would normally

occur at the end of full-speed resume signaling is omitted if the link was operating in high-speed at the time when it was suspended.

It is required that the host begin sending SOF's in time to prevent the high-speed tree from suspending.

7.1.8 Data Encoding/Decoding

The USB employs NRZI data encoding when transmitting packets. In NRZI encoding, a "1" is represented by no change in level and a "0" is represented by a change in level. Figure 7-31 shows a data stream and the NRZI equivalent. The high level represents the J state on the data lines in this and subsequent figures showing NRZI encoding. A string of zeros causes the NRZI data to toggle each bit time. A string of ones causes long periods with no transitions in the data.

Figure 7-31. NRZI Data Encoding

7.1.9 Bit Stuffing

In order to ensure adequate signal transitions, bit stuffing is employed by the transmitting device when sending a packet on USB (see Figure 7-32 and Figure 7-34). A zero is inserted after every six consecutive ones in the data stream before the data is NRZI encoded, to force a transition in the NRZI data stream. This gives the receiver logic a data transition at least once every seven bit times to guarantee the data and clock lock. Bit stuffing is enabled beginning with the Sync Pattern. The data "one" that ends the Sync Pattern is counted as the first one in a sequence. Bit stuffing by the transmitter is always enforced, except during high-speed EOP. If required by the bit stuffing rules, a zero bit will be inserted even if it is the last bit before the end-of-packet (EOP) signal.

The receiver must decode the NRZI data, recognize the stuffed bits, and discard them.

7.1.9.1 Full-/low-speed

Full-/low-speed signaling uses bit stuffing throughout the packet without exception. If the receiver sees seven consecutive ones anywhere in the packet, then a bit stuffing error has occurred and the packet should be ignored. The time interval just before an EOP is a special case. The last data bit before the EOP can become stretched by hub switching skews. This is known as dribble and can lead to the case illustrated in Figure 7-33, which shows where dribble introduces a sixth bit that does not require a bit stuff. Therefore, the receiver must accept a packet for which there are up to six full bit times at the port with no transitions prior to the EOP.

Data Encoding Sequence:

Figure 7-32. Bit Stuffing

Universal Serial Bus Specification Revision 2.0

Figure 7-33. Illustration of Extra Bit Preceding EOP (Full-/low-speed)

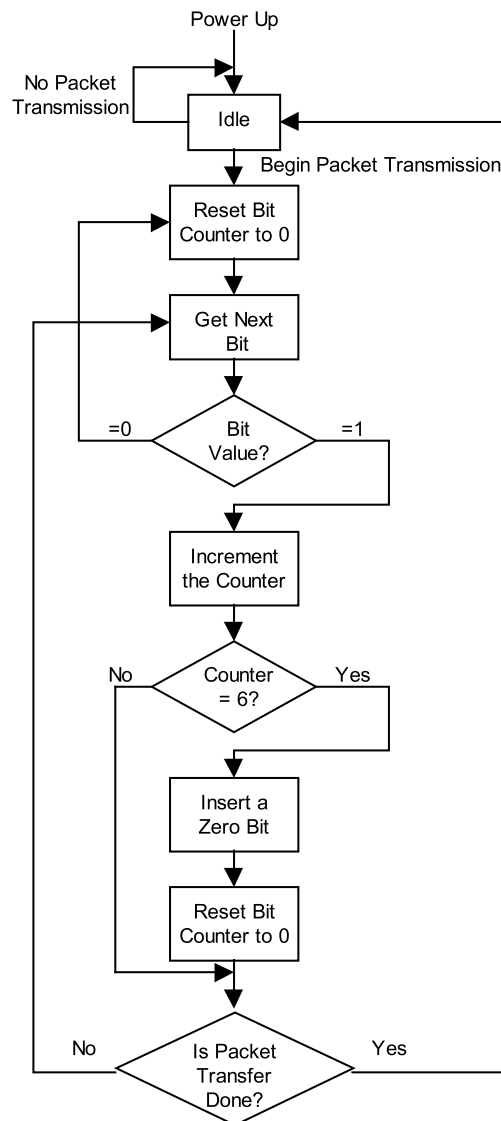

Figure 7-34. Flow Diagram for Bit Stuffing

7.1.9.2 High-Speed

High-speed signaling uses bit stuffing throughout the packet, with the exception of the intentional bit stuff errors used in the high-speed EOP as described in Section 7.1.13.2.

7.1.10 Sync Pattern

The SYNC pattern used for low-/full-speed transmission is required to be 3 KJ pairs followed by 2 K's for a total of eight symbols. Figure 7-35 shows the NRZI bit pattern, which is prefixed to each low-/full-speed packet.

Figure 7-35. Sync Pattern (Low-/full-speed)

The SYNC pattern used for high-speed transmission is required to be 15 KJ pairs followed by 2 K's, for a total of 32 symbols. Hubs are allowed to drop up to 4 bits from the start of the SYNC pattern when repeating packets. Hubs must not corrupt any repeated bits of the SYNC field, however. Thus, after being repeated by 5 hubs, a packet's SYNC field may be as short as 12 bits.

7.1.11 Data Signaling Rate

The high-speed data rate (T_{HSDRAT}) is nominally 480.00 Mb/s, with a required bit rate accuracy of ± 500 ppm. For hosts, hubs, and high-speed capable functions, the required data-rate accuracy when transmitting at any speed is $\pm 0.05\%$ (500 ppm). The full-speed rate for such hubs and functions is $T_{FDRATHS}$. The low-speed rate for such hubs is $T_{LDRATHS}$ (a low-speed function must not support high-speed).

The full-speed data rate is nominally 12.000 Mb/s. For full-speed only functions, the required data-rate when transmitting (T_{FDRATE}) is 12.000 Mb/s $\pm 0.25\%$ (2,500 ppm).

The low-speed data rate is nominally 1.50 Mb/s. For low-speed functions, the required data-rate when transmitting (T_{LDRATE}) is 1.50 Mb/s $\pm 1.5\%$ (15,000 ppm). This allows the use of resonators in low cost, low-speed devices.

Hosts and hubs must be able to receive data from any compliant low-speed, full-speed, or high-speed source. High-speed capable functions must be able to receive data from any compliant full-speed or high-speed source. Full-speed only functions must be able to receive data from any compliant full-speed source. Low-speed only functions must be able to receive data from any compliant low-speed source.

The above accuracy numbers include contributions from all sources:

- Initial frequency accuracy
- Crystal capacitive loading
- Supply voltage on the oscillator
- Temperature
- Aging

7.1.12 Frame Interval

The USB defines a frame interval (T_{FRAME}) to be 1.000 ms ± 500 ns long. The USB defines a microframe interval (T_{HFRAM}) to be 125.0 μ s ± 62.5 ns long. The (micro)frame interval is measured from any point in an SOF token in one (micro)frame to the same point in the SOF token of the next (micro)frame.

Since the Host Controller and hubs must meet clock accuracy specification of $\pm 0.05\%$, they will automatically meet the frame interval requirements without the need for adjustment.

The frame interval repeatability, TRFI (difference in frame interval between two successive frames), must be less than 0.5 full-speed bit times. The microframe interval repeatability, THSRFI (difference in the microframe interval between two successive microframes, measured at the host), must be less than 4 high-speed bit times. Each hub may introduce at most 4 additional high-speed bits of microframe jitter.

Hubs and certain full-/high-speed functions need to track the (micro)frame interval. They also are required to have sufficient frame timing adjustment to compensate for their own frequency inaccuracy.

7.1.13 Data Source Signaling

This section covers the timing characteristics of data produced and sent from a port (the data source).

Section 7.1.14 covers the timing characteristics of data that is transmitted through the Hub Repeater section of a hub. In this section, TPERIOD is defined as the actual period of the data rate that can have a range as defined in Section 7.1.11.

7.1.13.1 Data Source Jitter

This section describes the maximum allowable data source jitter for low-speed, full-speed, and high-speed signaling.

7.1.13.1.1 Low-/full-speed Data Source Jitter

The source of data can have some variation (jitter) in the timing of edges of the data transmitted. The time between any set of data transitions is $(N * T_{PERIOD}) \pm \text{jitter time}$, where 'N' is the number of bits between the transitions. The data jitter is measured with the same load used for maximum rise and fall times and is measured at the crossover points of the data lines, as shown in Figure 7-36.

Figure 7-36. Data Jitter Taxonomy

- For full-speed transmissions, the jitter time for any consecutive differential data transitions must be within ± 2.0 ns and within ± 1.0 ns for any set of paired (JK-to-next JK transition or KJ-to-next KJ transition) differential data transitions.
- For low-speed transmissions, the jitter time for any consecutive differential data transitions must be within ± 25 ns and within ± 10 ns for any set of paired differential data transitions.

These jitter numbers include timing variations due to differential buffer delay and rise and fall time mismatches, internal clock source jitter, and noise and other random effects.

7.1.13.1.2 High-speed Data Source Jitter

High-speed data within a single packet must be transmitted with no more jitter than is allowed by the eye patterns defined in Section 7.1.2 when measured over a sliding window of 480 high-speed bit times.

7.1.13.2 EOP Width

This section describes low-speed, full-speed, and high-speed EOP width.

7.1.13.2.1 Low-/full-speed EOP

The width of the SE0 in the EOP is approximately $2 * T_{PERIOD}$. The SE0 width is measured with the same load used for maximum rise and fall times and is measured at the same level as the differential signal crossover points of the data lines (see Figure 7-37).

Figure 7-37. SE0 for EOP Width Timing

- For full-speed transmissions, the SE0 for EOP width from the transmitter must be between 160 ns and 175 ns.
- For low-speed transmissions, the transmitter's SE0 for EOP width must be between 1.25 μ s and 1.50 μ s.

These ranges include timing variations due to differential buffer delay and rise and fall time mismatches and to noise and other random effects.

A receiver must accept any valid EOP. Receiver design should note that the single-ended input threshold voltage can be different from the differential crossover voltage and the SE0 transitions will in general be asynchronous to the clock encoded in the NRZI stream.

- A full-speed EOP may have the SE0 interval reduced to as little as 82 ns (T_{FEOPR}) and a low-speed SE0 interval may be as short as 670 ns (T_{LEOPR}).

A hub may tear down connectivity if it sees an SE0 of at least T_{FST} or T_{LST} followed by a transition to the J state. A hub must tear down connectivity on any valid EOP.

7.1.13.2.2 High-speed EOP

In high-speed signaling, a bit stuff error is intentionally generated to indicate EOP. A receiver is required to interpret any bit stuff error as an EOP.

For high-speed packets other than SOF's, the transmitted EOP delimiter is required to be an NRZ byte of 01111111 without bit stuffing. For example, if the last symbol prior to the EOP field is a J, this would lead to an EOP of KKKKKKKK.

For high-speed SOF's, the transmitted EOP delimiter is required to be 5 NRZ bytes without bit stuffing, consisting of 01111111 11111111 11111111 11111111 11111111. Thus if the last bit prior to the EOP field is a J, this would lead to 40 K's on the wire, at the end of which the lines must return to the high-speed Idle state. This extra EOP length is of no significance to a receiver; it is used for disconnect detection as discussed in Section 7.1.7.3.

A hub may add at most 4 random bits to the end of the EOP field when repeating a packet. Thus after 5 repeaters, a packet can have up to 20 random bits following the EOP field. A hub, however, must not corrupt any of the 8 (or 40 in the case of a SOF) required bits of the EOP field.

7.1.14 Hub Signaling Timings

This section describes low-speed, full-speed, and high-speed hub signaling timings.

7.1.14.1 Low-/full-speed Hub Signaling Timings

The propagation of a full-speed, differential data signal through a hub is shown in Figure 7-38. The downstream signaling is measured without a cable connected to the port and with the load used for measuring rise and fall times. The total delay through the upstream cable and hub electronics must be a maximum of 70 ns (THDD1). If the hub has a detachable USB cable, then the delay (THDD2) through hub electronics and the associated transmission line must be a maximum of 44 ns to allow for a maximum cable delay of 26 ns (TFSCBL). The delay through this hub is measured in both the upstream and downstream directions, as shown in Figure 7-38B, from data line crossover at the input port to data line crossover at the output port.

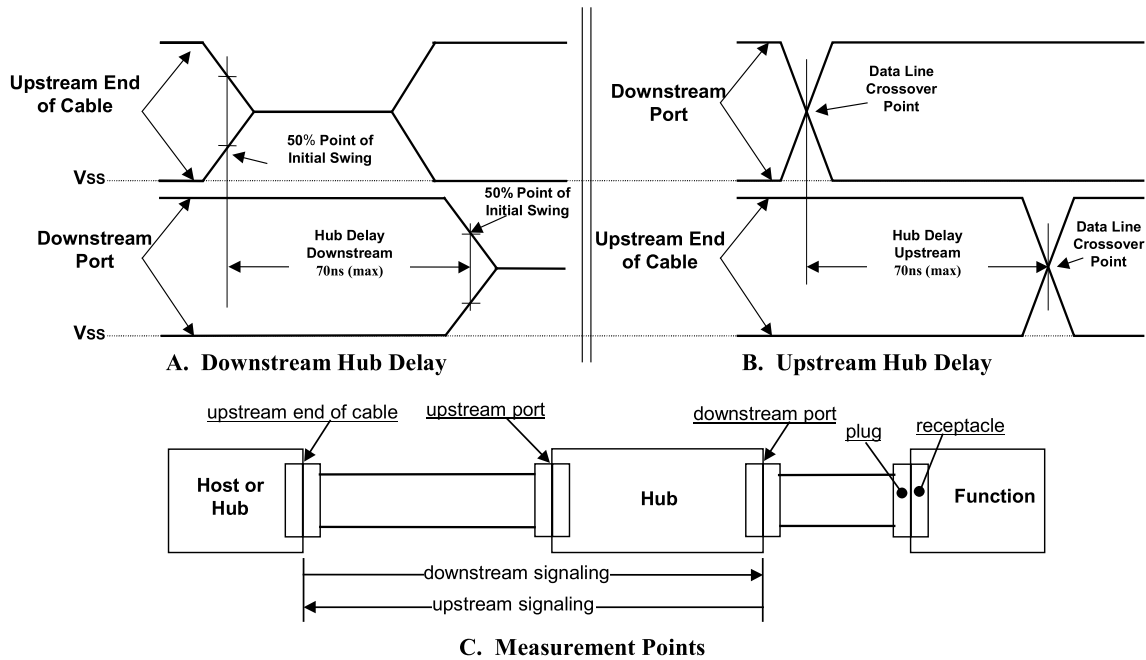

Figure 7-38. Hub Propagation Delay of Full-speed Differential Signals

Low-speed propagation delay for differential signals is measured in the same fashion as for full-speed signaling. The maximum low-speed hub delay is 300 ns (TLHDD). This allows for the slower low-speed buffer propagation delay and rise and fall times. It also provides time for the hub to re-clock the low-speed data in the upstream direction.

When the hub acts as a repeater, it must reproduce the received, full-speed signal accurately on its outputs. This means that for differential signals, the propagation delays of a J-to-K state transition must match closely to the delays of a K-to-J state transition. For full-speed propagation, the maximum difference allowed between these two delays (THDJ1) (see Figure 7-38 and Figure 7-52) for a hub plus cable is ± 3.0 ns. Similarly, the difference in delay between any two J-to-K or K-to-J transitions through a hub (THDJ2) must be less than ± 1.0 ns. For low-speed propagation in the downstream direction, the corresponding allowable jitter (TLDHJ1) is ± 45 ns and (TLDHJ2) ± 15 ns, respectively. For low-speed propagation in the upstream direction, the allowable jitter is ± 45 ns in both cases (TLUHJ1 and TLUHJ2).

An exception to this case is the skew that can be introduced in the Idle-to-K state transition at SOP (TFSOP and TLSOP) (refer to Section 7.1.7.4). In this case, the delay to the opposite port includes the time to enable the output buffer. However, the delays should be closely matched to the normal hub delay and the maximum

additional delay difference over a normal J-to-K transition is ± 5.0 ns. This limits the maximum distortion of the first bit in the packet.

Note: Because of this distortion of the SOP transition relative to the next K-to-J state transition, the first SYNC field bit should not be used to synchronize the receiver to the data stream.

The EOP must be propagated through a hub in the same way as the differential signaling. The propagation delay for sensing an SE0 must be no less than the greater of the J-to-K or K-to-J differential data delay (to avoid truncating the last data bit in a packet), but not more than 15 ns greater than the larger of these differential delays at full-speed and 200 ns at low-speed (to prevent creating a bit stuff error at the end of the packet). EOP delays are shown in Figure 7-53.

Because the sense levels for the SE0 state are not at the midpoint of the signal swing, the width of SE0 state will be changed as it passes through each hub. A hub may not change the width of the SE0 state in a full-speed EOP by more than ± 15 ns (TFHESK), as measured by the difference of the leading edge and trailing edge delays of the SE0 state (see Figure 7-53). An SE0 from a low-speed device has long rise and fall times and is subject to greater skew, but these conditions exist only on the cable from the low-speed device to the port to which it is connected. Thereafter, the signaling uses full-speed buffers and their faster rise and fall times. The SE0 from the low-speed device cannot be changed by more than ± 300 ns (TLHESK) as it passes through the hub to which the device is connected. This time allows for some signal conditioning in the low-speed transceiver to reduce its sensitivity to noise.

7.1.14.2 High-speed Hub Signaling Timings

When a hub acts as a repeater for high-speed data, the delay of the hub (T_{HSHDD}) must not exceed 36 high-speed bit times plus 4 ns (the trace delays allowed for the hub circuit board). This delay is measured from the last bit of the SYNC field at the input connector to the last bit of the SYNC field at the output connector.

A high-speed hub repeater must digitally resynchronize the buffered data, so there is no allowance for cumulative jitter (within a single packet) as a high-speed packet passes through multiple repeater stages. Within a single packet, the jitter must not exceed the eye pattern templates defined in Section 7.1.2 over a sliding window of 480 high-speed bit times.

Due to the data synchronization process, the propagation delay of a hub repeater is allowed to vary at most 5 high-speed bit times (T_{HSHDV}). The delay including this allowed variation must not exceed 36 high-speed bit times plus 4 ns. (This allows for some uncertainty as to when an incoming packet arrives at the hub with respect to the phase of the synchronization clock.)

7.1.15 Receiver Data Jitter

This section describes low-speed, full-speed, and high-speed receiver data jitter.

7.1.15.1 Low-/full-speed Receiver Data Jitter

The data receivers for all types of devices must be able to properly decode the differential data in the presence of jitter. The more of the bit cell that any data edge can occupy and still be decoded, the more reliable the data transfer will be. Data receivers are required to decode differential data transitions that occur in a window plus and minus a nominal quarter bit cell from the nominal (centered) data edge position. (A simple 4X over-sampling state machine DPLL can be built that satisfies these requirements.) This requirement is derived in Table 7-4 and Table 7-5. The tables assume a worst-case topology of five hubs between the host and device and the worst-case number of seven bits between transitions. The derived numbers are rounded up for ease of specification.

Jitter will be caused by the delay mismatches discussed above and by mismatches in the source and destination data rates (frequencies). The receive data jitter budgets for full- and low-speed are given in Table 7-4 and Table 7-5. These tables give the value and totals for each source of jitter for both consecutive (next) and paired transitions. Note that the jitter component related to the source or destination frequency tolerance has been allocated to the appropriate device (i.e., the source jitter includes bit shifts due to source frequency inaccuracy over the worst-case data transition interval). The output driver jitter can be traded off against the device clock accuracy in a particular implementation as long as the jitter specification is met.

The low-speed jitter budget table has an additional line in it because the jitter introduced by the hub to which the low-speed device is attached is different from all the other devices in the data path. The remaining devices operate with full-speed signaling conventions (though at low-speed data rate).

Table 7-4. Full-speed Jitter Budget

Jitter Source	Full-speed			
	Next Transition		Paired Transition	
	Each (ns)	Total (ns)	Each (ns)	Total (ns)
Source Driver Jitter	2.0	2.0	1.0	1.0
Source Frequency Tolerance (worst-case)	0.21/bit	1.5	0.21/bit	3.0
Source Jitter Total		3.5		4.0
Hub Jitter	3.0	15.0	1.0	5.0
Jitter Specification		18.5		9.0
Destination Frequency Tolerance	0.21/bit	1.5	0.21/bit	3.0
Receiver Jitter Budget		20.0		12.0

Table 7-5. Low-speed Jitter Budget

Jitter Source	Low-speed Upstream			
	Next Transition		Paired Transition	
	Each (ns)	Total (ns)	Each (ns)	Total (ns)
Function Driver Jitter	25.0	25.0	10.0	10.0
Function Frequency Tolerance (worst-case)	10.0/bit	70.0	10.0/bit	140.0
Source (Function) Jitter Total		95.0		150.0
Hub with Low-speed Device Jitter	45.0	45.0	45.0	45.0
Remaining (full-speed) Hubs' Jitter	3.0	12.0	1.0	4.0
Jitter Specification		152.0		199.0

Host Receiver Jitter Budget		164.0		223.0
	Low-speed Downstream			
	Next Transition		Paired Transition	
	Each (ns)	Total (ns)	Each (ns)	Total (ns)
Host Driver Jitter	2.0	2.0	1.0	1.0
Host Frequency Tolerance (worst-case)	1.7/bit	12.0	1.7/bit	24.0
Source (Host) Jitter Total		14.0		25.0
Hub with Low-speed Device Jitter	45.0	45.0	15.0	15.0
Remaining (full-speed) Hubs' Jitter	3.0	12.0	1.0	4.0
Jitter Spec		71.0		44.0
Function Frequency Tolerance	10.0/bit	70.0	10.0/bit	140.0
Function Receiver Jitter Budget		141.0		184.0

Note: This table describes the host transmitting at low-speed data rate using full-speed signaling to a low-speed device through the maximum number of hubs. When the host is directly connected to the low-speed device, it uses low-speed data rate and low-speed signaling, and the host has to meet the source jitter listed in the "Jitter Specification" row.

7.1.15.2 High-speed Receiver Data Jitter

A high-speed capable receiver must reliably recover high-speed data when the waveforms at its inputs conform to the receiver sensitivity eye pattern templates. The templates, which are called out in Section 7.1.2.2, specify the horizontal and vertical eye pattern opening over a 480 bit time sliding window over the duration of a packet. Thus, for example, a high-speed receiver within a function must reliably recover data with a peak to peak jitter of 30%, measured at its B receptacle (as described by Template 4).

Such conformance is tested using Test Mode Test_Packet, as defined in Section 7.1.20.

It is a recommended design guideline that a receiver's BER should be $\leq 10^{-12}$ when the receiver sensitivity requirement is met.

7.1.16 Cable Delay

The maximum total one-way signal propagation delay allowed is 30 ns. The allocation for cable delay is 26 ns. A maximum delay of 3 ns is allowed from a Host or Hub Controller downstream facing transceiver to its exterior downstream facing connector, while a maximum delay of 1 ns is allowed from the upstream facing connector to the upstream facing transceiver of any device. For a standard USB detachable cable, the cable

Universal Serial Bus Specification Revision 2.0

delay is measured from the Series A connector pins to the Series B connector pins and is no more than 26 ns. For other cables, the delay is measured from the series A connector to the point where the cable is connected to the device. The cable delay must also be less than 5.2 ns per meter.

The maximum one-way data delay on a full-speed cable is measured as shown in Figure 7-39.

One-way cable delay for low-speed cables must be less than 18 ns. It is measured as shown in Figure 7-40.

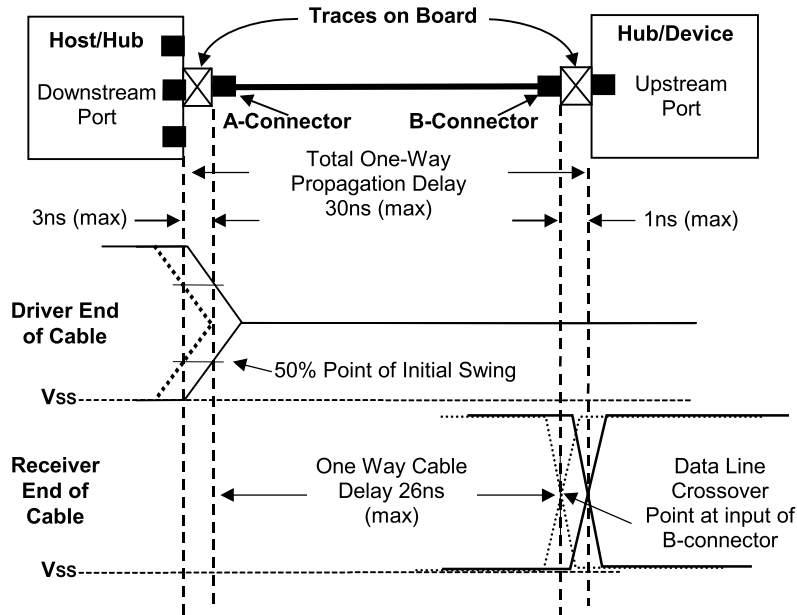

Figure 7-39. Full-speed Cable Delay

Figure 7-40. Low-speed Cable Delay

7.1.17 Cable Attenuation

USB cables must not exceed the loss figures shown in Table 7-6. Between the frequencies called out in the table, the cable loss should be no more than is shown in the accompanying graph.

Table 7-6. Maximum Allowable Cable Loss

Frequency (MHz)	Attenuation (maximum) dB/cable
0.064	0.08
0.256	0.11
0.512	0.13
0.772	0.15
1.000	0.20
4.000	0.39
8.000	0.57
12.000	0.67
24.000	0.95
48.000	1.35
96.000	1.9
200.00	3.2
400.00	5.8

7.1.18 Bus Turn-around Time and Inter-packet Delay

This section describes low-speed, full-speed, and high-speed bus turn-around time and inter-packet delay.

7.1.18.1 Low-/Full-Speed Bus Turn-around Time and Inter-packet Delay

Inter-packet delays are measured from the SE0-to-J transition at the end of the EOP to the J-to-K transition that starts the next packet.

A device must provide at least two bit times of inter-packet delay. The delay is measured at the responding device with a bit time defined in terms of the response. This provides adequate time for the device sending the EOP to drive J for one bit time and then turn off its output buffers.

The host must provide at least two bit times of J after the SE0 of an EOP and the start of a new packet (TIPD). If a function is expected to provide a response to a host transmission, the maximum inter-packet delay for a function or hub with a detachable (TRSP1PD1) cable is 6.5 bit times measured at the Series B receptacle. If the device has a captive cable, the inter-packet delay (TRSP1PD2) must be less than 7.5 bit times as measured at the Series A plug. These timings apply to both full-speed and low-speed devices and the bit times are referenced to the data rate of the packet.

The maximum inter-packet delay for a host response is 7.5 bit times measured at the host's port pins. There is no maximum inter-packet delay between packets in unrelated transactions.

7.1.18.2 High-Speed Bus Turn-around Time and Inter-packet Delay

High-speed inter-packet delays are measured from time when the line returns to a high-speed Idle State at the end of one packet to when the line leaves the high-speed Idle State at the start of the next packet.

When transmitting after receiving a packet, hosts and devices must provide an inter-packet delay of at least 8 bit times (THSP1DOD) measured at their A or B connectors (receptacles or plugs).

Additionally, if a host is transmitting two packets in a row, the inter-packet delay must be a minimum of 88 bit times (THSP1DSD), measured at the host's A receptacle. This will guarantee an inter-packet delay of at least 32 bit times at all devices (when receiving back to back packets). The maximum inter-packet delay provided by a host is 192 bit times within a transaction (THSRSP1PD1) measured at the A receptacle. When a host responds to a packet from a device, it will provide an inter-packet delay of at most 192 bit times measured at the A receptacle. There is no maximum inter-packet delay between packets in unrelated transactions.

When a device with a detachable cable responds to a packet from a host, it will provide an inter-packet delay of at most 192 bit times measured at the B receptacle. If the device has a captive cable, it will provide an inter-packet delay of at most 192 bit times plus 52 ns (2 times the max cable length) measured at the cable's A plug (THSRSP1PD2).

7.1.19 Maximum End-to-end Signal Delay

This section describes low-speed, full-speed, and high-speed end-to-end delay.

7.1.19.1 Low-/full-speed End-to-end Signal Delay

A device expecting a response to a transmission will invalidate the transaction if it does not see the start-of-packet (SOP) transition within the timeout period after the end of the transmission (after the SE0-to-J state transition in the EOP). This can occur between an IN token and the following data packet or between a data packet and the handshake packet (refer to Chapter 8). The device expecting the response will not time out before 16 bit times but will timeout before 18 bit times (measured at the data pins of the device from the SE0-to-J transition at the end of the EOP). The host will wait at least 18 bit times for a response to start before it will start a new transaction.

Figure 7-41 depicts the configuration of six signal hops (cables) that results in allowable worst-case signal delay. The maximum propagation delay from the upstream end of a hub's cable to any downstream facing connector on that hub is 70 ns.

Figure 7-41. Worst-case End-to-end Signal Delay Model for Low-/full-speed

7.1.19.2 High-Speed End-to-end Delay

A high-speed host or device expecting a response to a transmission must not timeout the transaction if the inter-packet delay is less than 736 bit times, and it must timeout the transaction if no signaling is seen within 816 bit times.

These timeout limits allow a response to be seen even for the worst-case round trip signal delay. In high-speed mode, the worst-case round trip signal delay model is the sum of the following components:

12 max length cable delays (6 cables)	= 312 ns
10 max delay hubs (5 hubs)	= 40 ns + 360 bit times
1 max device response time	= 192 bit times
<hr/>	
Worst-case round trip delay	= 352 ns + 552 bit times = 721 bit times

7.1.20 Test Mode Support

To facilitate compliance testing, host controllers, hubs, and high-speed capable functions must support the following test modes:

- Test mode Test_SE0_NAK: Upon command, a port's transceiver must enter the high-speed receive mode and remain in that mode until the exit action is taken. This enables the testing of output impedance, low level output voltage, and loading characteristics. In addition, while in this mode, upstream facing ports (and only upstream facing ports) must respond to any IN token packet with a NAK handshake (only if the packet CRC is determined to be correct) within the normal allowed device response time. This enables testing of the device squelch level circuitry and, additionally, provides a general purpose stimulus/response test for basic functional testing.
- Test mode Test_J: Upon command, a port's transceiver must enter the high-speed J state and remain in that state until the exit action is taken. This enables the testing of the high output drive level on the D+ line.
- Test mode Test_K: Upon command, a port's transceiver must enter the high-speed K state and remain in that state until the exit action is taken. This enables the testing of the high output drive level on the D- line.
- Test mode Test_Packet: Upon command, a port must repetitively transmit the following test packet until the exit action is taken. This enables the testing of rise and fall times, eye patterns, jitter, and any other dynamic waveform specifications.

The test packet is made up by concatenating the following strings. (Note: For J/K NRZI data, and for NRZ data, the bit on the left is the first one transmitted. "S" indicates that a bit stuff occurs, which inserts an "extra" NRZI data bit. "* N" is used to indicate N occurrences of a string of bits or symbols.)

Universal Serial Bus Specification Revision 2.0

NRZI Symbols (Fields)	NRZ Bit Strings	Number of NRZ Bits
{KJ * 15}, KK (SYNC)	{00000000 * 3}, 00000001	32
KKJKJJKK (DATA0 PID)	11000011	8
JKJKJKJK * 9	00000000 * 9	72
JJKKJJKK * 8	01010101 * 8	64
JJJJKKKK * 8	01110111 * 8	64
JJJJJJKKKKKKKK * 8	0, {111111S * 15}, 111111	97
JJJJJJK * 8	S, 111111S, {011111S * 7}	55
{JKKKKKKK * 10}, JK	00111111, {S0111111 * 9}, S0	72
JJKKKKJJKKKKJJKK (CRC16)	0110110101110011	16
JJJJJJJ (EOP)	01111111	8

A port in Test_Packet mode must send this packet repetitively. The inter-packet timing must be no less than the minimum allowable inter-packet gap as defined in Section 7.1.18 and no greater than 125 μ s.

- Test mode Test_Force_Enable: Upon command, downstream facing hub ports (and only downstream facing hub ports) must be enabled in high-speed mode, even if there is no device attached. Packets arriving at the hub's upstream facing port must be repeated on the port which is in this test mode. This enables testing of the hub's disconnect detection; the disconnect detect bit can be polled while varying the loading on the port, allowing the disconnect detection threshold voltage to be measured.

Test Mode Entry and Exit

Test mode of a port is entered by using a device specific standard request (for an upstream facing port) or a port specific hub class request (for a downstream facing port). The device standard request SetFeature(TEST_MODE) is defined in Section 9.4.9. The hub class request SetPortFeature(PORT_TEST) is defined in Section 11.24.2.13. All high-speed capable devices/hubs must support these requests. These requests are not supported for non-high-speed devices.

The transition to test mode must be complete no later than 3 ms after the completion of the status stage of the request.

For an upstream facing port, the exit action is to power cycle the device. For a downstream facing port, the exit action is to reset the hub, as defined in Section 11.24.2.13.

7.2 Power Distribution

This section describes the USB power distribution specification.

7.2.1 Classes of Devices

The power source and sink requirements of different device classes can be simplified with the introduction of the concept of a unit load. A unit load is defined to be 100 mA. The number of unit loads a device can draw is an absolute maximum, not an average over time. A device may be either low-power at one unit load or high-power, consuming up to five unit loads. All devices default to low-power. The transition to high-power is under software control. It is the responsibility of software to ensure adequate power is available before allowing devices to consume high-power.

The USB supports a range of power sourcing and power consuming agents; these include the following:

- **Root port hubs:** Are directly attached to the USB Host Controller. Hub power is derived from the same source as the Host Controller. Systems that obtain operating power externally, either AC or DC, must supply at least five unit loads to each port. Such ports are called high-power ports. Battery-powered systems may supply either one or five unit loads. Ports that can supply only one unit load are termed low-power ports.
- **Bus-powered hubs:** Draw all of their power for any internal functions and downstream facing ports from VBUS on the hub's upstream facing port. Bus-powered hubs may only draw up to one unit load upon power-up and five unit loads after configuration. The configuration power is split between allocations to the hub, any non-removable functions and the external ports. External ports in a bus-powered hub can supply only one unit load per port regardless of the current draw on the other ports of that hub. The hub must be able to supply this port current when the hub is in the Active or Suspend state.
- **Self-powered hubs:** Power for the internal functions and downstream facing ports does not come from VBUS. However, the USB interface of the hub may draw up to one unit load from VBUS on its upstream facing port to allow the interface to function when the remainder of the hub is powered down. Hubs that obtain operating power externally (from the USB) must supply five unit loads to each port. Battery-powered hubs may supply either one or five unit loads per port.
- **Low-power bus-powered functions:** All power to these devices comes from VBUS. They may draw no more than one unit load at any time.
- **High-power bus-powered functions:** All power to these devices comes from VBUS. They must draw no more than one unit load upon power-up and may draw up to five unit loads after being configured.
- **Self-powered functions:** May draw up to one unit load from VBUS to allow the USB interface to function when the remainder of the function is powered down. All other power comes from an external (to the USB) source.

No device shall supply (source) current on VBUS at its upstream facing port at any time. From VBUS on its upstream facing port, a device may only draw (sink) current. They may not provide power to the pull-up resistor on D+/D- unless VBUS is present (see Section 7.1.5). When VBUS is removed, the device must remove power from the D+/D- pull-up resistor within 10 seconds. On power-up, a device needs to ensure that its upstream facing port is not driving the bus, so that the device is able to receive the reset signaling. Devices must also ensure that the maximum operating current drawn by a device is one unit load, until configured. Any device that draws power from the bus must be able to detect lack of activity on the bus, enter the Suspend state, and reduce its current consumption from VBUS (refer to Section 7.2.3 and Section 9.2.5.1).

7.2.1.1 Bus-powered Hubs

Bus-powered hub power requirements can be met with a power control circuit such as the one shown in Figure 7-42. Bus-powered hubs often contain at least one non-removable function. Power is always available to the hub's controller, which permits host access to power management and other configuration registers during the enumeration process. A non-removable function(s) may require that its power be switched, so that upon power-up, the entire device (hub and non-removable functions) draws no more than one unit load. Power switching on any non-removable function may be implemented either by removing its power or by shutting off the clock. Switching on the non-removable function is not required if the aggregate power drawn by it and the Hub Controller is less than one unit load. However, as long as the hub port associated with the function is in the Power-off state, the function must be logically reset and the device must appear to be not connected. The total current drawn by a bus-powered device is the sum of the current to the Hub Controller, any non-removable function(s), and the downstream facing ports.

Figure 7-42 shows the partitioning of power based upon the maximum current draw (from upstream) of five unit loads: one unit load for the Hub Controller and the non-removable function and one unit load for each of the external downstream facing ports. If more than four external ports are required, then the hub will need to be self-powered. If the non-removable function(s) and Hub Controller draw more than one unit load, then the number of external ports must be appropriately reduced. Power control to a bus-powered hub may require a regulator. If present, the regulator is always enabled to supply the Hub Controller. The regulator can also power the non-removable function(s). Inrush current limiting must also be incorporated into the regulator subsystem.

Figure 7-42. Compound Bus-powered Hub

Power to external downstream facing ports of a bus-powered hub must be switched. The Hub Controller supplies a software controlled on/off signal from the host, which is in the “off” state when the device is powered up or after reset signaling. When switched to the “on” state, the switch implements a soft turn-on function that prevents excessive transient current from being drawn from upstream. The voltage drop across the upstream cable, connectors, and switch in a bus-powered hub must not exceed 350 mV at maximum rated current.

7.2.1.2 Self-powered Hubs

Self-powered hubs have a local power supply that furnishes power to any non-removable functions and to all downstream facing ports, as shown in Figure 7-43. Power for the Hub Controller, however, may be supplied from the upstream VBUS (a “hybrid” powered hub) or the local power supply. The advantage of supplying the Hub Controller from the upstream supply is that communication from the host is possible even if the device's power supply remains off. This makes it possible to differentiate between a disconnected and an unpowered device. If the hub draws power for its upstream facing port from VBUS, it may not draw more than one unit load.

Figure 7-43. Compound Self-powered Hub

The number of ports that can be supported is limited only by the address capability of the hub and the local supply.

Self-powered hubs may experience loss of power. This may be the result of disconnecting the power cord or exhausting the battery. Under these conditions, the hub may force a re-enumeration of itself as a bus-powered hub. This requires the hub to implement port power switching on all external ports. When power is lost, the hub must ensure that upstream current does not exceed low-power. All the rules of a bus-powered hub then apply.

7.2.1.2.1 Over-current Protection

The host and all self-powered hubs must implement over-current protection for safety reasons, and the hub must have a way to detect the over-current condition and report it to the USB software. Should the aggregate current drawn by a gang of downstream facing ports exceed a preset value, the over-current protection circuit removes or reduces power from all affected downstream facing ports. The over-current condition is reported through the hub to Host Controller, as described in Section 11.12.5. The preset value cannot exceed 5.0 A and must be sufficiently above the maximum allowable port current such that transient currents (e.g., during power up or dynamic attach or reconfiguration) do not trip the over-current protector. If an over-current condition occurs on any port, subsequent operation of the USB is not guaranteed, and once the condition is removed, it may be necessary to reinitialize the bus as would be done upon power-up. The over-current limiting mechanism must be resettable without user mechanical intervention. Polymeric PTCs and solid-state switches are examples of methods, which can be used for over-current limiting.

7.2.1.3 Low-power Bus-powered Functions

A low-power function is one that draws up to one unit load from the USB cable when operational. Figure 7-44 shows a typical bus-powered, low-power function, such as a mouse. Low-power regulation can be integrated into the function silicon. Low-power functions must be capable of operating with input VBUS voltages as low as 4.40 V, measured at the plug end of the cable.

Figure 7-44. Low-power Bus-powered Function

7.2.1.4 High-power Bus-powered Functions

A function is defined as being high-power if, when fully powered, it draws over one but no more than five unit loads from the USB cable. A high-power function requires staged switching of power. It must first come up in a reduced power state of less than one unit load. At bus enumeration time, its total power requirements are obtained and compared against the available power budget. If sufficient power exists, the remainder of the function may be powered on. A typical high-power function is shown in Figure 7-45. The function's electronics have been partitioned into two sections. The function controller contains the minimum amount of circuitry necessary to permit enumeration and power budgeting. The remainder of the function resides in the function block. High-power functions must be capable of operating in their low-power (one unit load) mode with an input voltage as low as 4.40 V, so that it may be detected and enumerated even when plugged into a bus-powered hub. They must also be capable of operating at full power (up to five unit loads) with a VBUS voltage of 4.75 V, measured at the upstream plug end of the cable.

Figure 7-45. High-power Bus-powered Function

7.2.1.5 Self-powered Functions

Figure 7-46 shows a typical self-powered function. The function controller is powered either from the upstream bus via a low-power regulator or from the local power supply. The advantage of the former scheme is that it permits detection and enumeration of a self-powered function whose local power supply is turned off. The maximum upstream power that the function controller can draw is one unit load, and the regulator block must implement inrush current limiting. The amount of power that the function block may draw is limited only by the local power supply. Because the local power supply is not required to power any downstream bus ports, it does not need to implement current limiting, soft start, or power switching.

Figure 7-46. Self-powered Function

7.2.2 Voltage Drop Budget

The voltage drop budget is determined from the following:

- The voltage supplied by high-powered hub ports is 4.75 V to 5.25 V.
- The voltage supplied by low-powered hub ports is 4.4 V to 5.25 V.
- Bus-powered hubs can have a maximum drop of 350 mV from their cable plug (where they attach to a source of power) to their output port connectors (where they supply power).
- The maximum voltage drop (for detachable cables) between the A-series plug and B-series plug on VBUS is 125 mV (VBUSD).
- The maximum voltage drop for all cables between upstream and downstream on GND is 125 mV (VGND).
- All hubs and functions must be able to provide configuration information with as little as 4.40 V at the connector end of their upstream cables. Only low-power functions need to be operational with this minimum voltage.
- Functions drawing more than one unit load must operate with a 4.75 V minimum input voltage at the connector end of their upstream cables.

Figure 7-47 shows the minimum allowable voltages in a worst-case topology consisting of a bus-powered hub driving a bus-powered function.

*Under transient conditions, supply at hub can drop from 4.400V to 4.070V

Figure 7-47. Worst-case Voltage Drop Topology (Steady State)

7.2.3 Power Control During Suspend/Resume

Suspend current is a function of unit load allocation. All USB devices initially default to low-power. Low-power devices or high-power devices operating at low-power are limited to 500 μA of suspend current. If the device is configured for high-power and enabled as a remote wakeup source, it may draw up to 2.5 mA during suspend. When computing suspend current, the current from VBUS through the bus pull-up and pull-down resistors must be included. Configured bus-powered hubs may also consume a maximum of 2.5 mA, with 500 μA allocated to each available external port and the remainder available to the hub and its internal functions. If a hub is not configured, it is operating as a low-power device and must limit its suspend current to 500 μA .

While in the Suspend state, a device may briefly draw more than the average current. The amplitude of the current spike cannot exceed the device power allocation 100 mA (or 500 mA). A maximum of 1.0 second is allowed for an averaging interval. The average current cannot exceed the average suspend current limit (ICCSH or ICCSL, see Table 7-7) during any 1.0-second interval (TSUSAVG1). The profile of the current spike is restricted so the transient response of the power supply (which may be an efficient, low-capacity, trickle power supply) is not overwhelmed. The rising edge of the current spike must be no more than 100 mA/ μs . Downstream facing ports must be able to absorb the 500 mA peak current spike and meet the voltage droop requirements defined for inrush current during dynamic attach (see Section 7.2.4.1). Figure 7-48 illustrates a typical example profile for an averaging interval. If the supply to the pull-up resistor on D+/D- is derived from VBUS, then the suspend current will never go to zero because the pull-up and pull-down resistors will always draw power.

Figure 7-48. Typical Suspend Current Averaging Profile

Devices are responsible for handling the bus voltage reduction due to the inductive and resistive effects of the cable. When a hub is in the Suspend state, it must still be able to provide the maximum current per port (one unit load of current per port for bus-powered hubs and five unit loads per port for self-powered hubs). This is necessary to support remote wakeup-capable devices that will power-up while the remainder of the system is still suspended. Such devices, when enabled to do remote wakeup, must drive resume signaling upstream within 10 ms of starting to draw the higher, non-suspend current. Devices not capable of remote wakeup must draw the higher current only when not suspended.

When devices wakeup, either by themselves (remote wakeup) or by seeing resume signaling, they must limit the inrush current on VBUS. The target maximum droop in the hub VBUS is 330 mV. The device must have sufficient on-board bypass capacitance or a controlled power-on sequence such that the current drawn from the hub does not exceed the maximum current capability of the port at any time while the device is waking up.

7.2.4 Dynamic Attach and Detach

The act of plugging or unplugging a hub or function must not affect the functionality of another device on other segments of the network. Unplugging a function will stop the transaction between that function and the host. However, the hub to which this function was attached will recover from this condition and will alert the host that the port has been disconnected.

7.2.4.1 Inrush Current Limiting

When a function or hub is plugged into the network, it has a certain amount of on-board capacitance between VBUS and ground. In addition, the regulator on the device may supply current to its output bypass capacitance and to the function as soon as power is applied. Consequently, if no measures are taken to prevent it, there could be a surge of current into the device which might pull the VBUS on the hub below its minimum operating level. Inrush currents can also occur when a high-power function is switched into its high-power mode. This problem must be solved by limiting the inrush current and by providing sufficient capacitance in each hub to prevent the power supplied to the other ports from going out of tolerance. An additional motivation for limiting inrush current is to minimize contact arcing, thereby prolonging connector contact life.

The maximum droop in the hub VBUS is 330 mV, or about 10% of the nominal signal swing from the function. In order to meet this requirement, the following conditions must be met:

- The maximum load (CRPB) that can be placed at the downstream end of a cable is 10 μF in parallel with 44 Ω . The 10 μF capacitance represents any bypass capacitor directly connected across the VBUS lines in the function plus any capacitive effects visible through the regulator in the device. The 44 Ω resistance represents one unit load of current drawn by the device during connect.
- If more bypass capacitance is required in the device, then the device must incorporate some form of VBUS surge current limiting, such that it matches the characteristics of the above load.
- The hub downstream facing port VBUS power lines must be bypassed (CHPB) with no less than 120 μF of low-ESR capacitance per hub. Standard bypass methods should be used to minimize inductance and resistance between the bypass capacitors and the connectors to reduce droop. The bypass capacitors themselves should have a low dissipation factor to allow decoupling at higher frequencies.

The upstream facing port of a hub is also required to meet the above requirements. Furthermore, a bus-powered hub must provide additional surge limiting in the form of a soft-start circuit when it enables power to its downstream facing ports.

A high-power bus-powered device that is switching from a lower power configuration to a higher power configuration must not cause droop > 330 mV on the VBUS at its upstream hub. The device can meet this by ensuring that changes in the capacitive load it presents do not exceed 10 μF .

Signal pins are protected from excessive currents during dynamic attach by being recessed in the connector such that the power pins make contact first. This guarantees that the power rails to the downstream device are referenced before the signal pins make contact. In addition, the signal lines are in a high-impedance state during connect, so that no current flows for standard signal levels.

7.2.4.2 Dynamic Detach

When a device is detached from the network with power flowing in the cable, the inductance of the cable will cause a large flyback voltage to occur on the open end of the device cable. This flyback voltage is not destructive. Proper bypass measures on the hub ports will suppress any coupled noise. The frequency range of this noise is inversely dependent on the length of the cable, to a maximum of 60 MHz for a one-meter cable. This will require some low capacitance, very low inductance bypass capacitors on each hub port connector. The flyback voltage and the noise it creates is also moderated by the bypass capacitance on the device end of the cable. Also, there must be some minimum capacitance on the device end of the cable to ensure that the

Universal Serial Bus Specification Revision 2.0

inductive flyback on the open end of the cable does not cause the voltage on the device end to reverse polarity. A minimum of 1.0 μF is recommended for bypass across V_{BUS} .

7.3 Physical Layer

The physical layer specifications are described in the following subsections.

7.3.1 Regulatory Requirements

All USB devices should be designed to meet the applicable regulatory requirements.

7.3.2 Bus Timing/Electrical Characteristics

Table 7-7. DC Electrical Characteristics

Parameter	Symbol	Conditions	Min.	Max.	Units
Supply Voltage:					
High-power Port	V_{BUS}	Note 2, Section 7.2.1	4.75	5.25	V
Low-power Port	V_{BUS}	Note 2, Section 7.2.1	4.40	5.25	V
Supply Current:					
High-power Hub Port (out)	I_{CCPRT}	Section 7.2.1	500		mA
Low-power Hub Port (out)	I_{CCUPT}	Section 7.2.1	100		mA
High-power Function (in)	I_{CCHPF}	Section 7.2.1		500	mA
Low-power Function (in)	I_{CCLPF}	Section 7.2.1		100	mA
Unconfigured Function/Hub (in)	I_{CCINIT}	Section 7.2.1.4		100	mA
Suspended High-power Device	I_{CCSH}	Section 7.2.3; Note 15		2.5	mA
Suspended Low-power Device	I_{CCSL}	Section 7.2.3		500	μA
Input Levels for Low-/full-speed:					
High (driven)	V_{IH}	Note 4, Section 7.1.4	2.0		V
High (floating)	V_{IHZ}	Note 4, Section 7.1.4	2.7	3.6	V
Low	V_{IL}	Note 4, Section 7.1.4		0.8	V
Differential Input Sensitivity	V_{DI}	$ (D^+)-(D^-) $; Figure 7-19; Note 4	0.2		V
Differential Common Mode Range	V_{CM}	Includes V_{DI} range; Figure 7-19; Note 4	0.8	2.5	V

Note 1: Measured at A plug.

Note 2: Measured at A receptacle.

Note 3: Measured at B receptacle.

Note 4: Measured at A or B connector.

Note 5: Measured with R_L of 1.425 kΩ to 3.6 V.

Note 6: Measured with R_L of 14.25 kΩ to GND.

Note 7: Timing difference between the differential data signals.

Note 8: Measured at crossover point of differential data signals.

Note 9: The maximum load specification is the maximum effective capacitive load allowed that meets the target V_{BUS} drop of 330 mV.

Note 10: Excluding the first transition from the Idle state.

Note 11: The two transitions should be a (nominal) bit time apart.

Note 12: For both transitions of differential signaling.

Note 13: Must accept as valid EOP.

Note 14: Single-ended capacitance of D+ or D- is the capacitance of D+/D- to all other conductors and, if present, shield in the cable. That is, to measure the single-ended capacitance of D+, short D-, V_{BUS}, GND, and the shield line together and measure the capacitance of D+ to the other conductors.

Note 15: For high power devices (non-hubs) when enabled for remote wakeup.

Table 7-13. Hub Event Timings

Event Description	Symbol	Conditions	Min	Max	Unit
Time to detect a downstream facing port connect event Awake Hub Suspended Hub	TDCNN	Section 11.5 and Section 7.1.7.3	2.5 2.5	2000 12000	μ s μ s
Time to detect a disconnect event at a hub's downstream facing port	TDDIS	Section 7.1.7.3	2	2.5	μ s
Duration of driving resume to a downstream port; only from a controlling hub	TDRSMDN	Nominal; Section 7.1.7.7 and Section 11.5	20		ms
Time from detecting downstream resume to rebroadcast	TURSM	Section 7.1.7.7		1.0	ms
Duration of driving reset to a downstream facing port	TDRST	Only for a SetPortFeature (PORT_RESET) request; Section 7.1.7.5 and Section 11.5	10	20	ms
Overall duration of driving reset to downstream facing port, root hub	TDRSTR	Only for root hubs; Section 7.1.7.5	50		ms
Maximum interval between reset segments used to create TDRSTR	TRHRSI	Only for root hubs; each reset pulse must be of length TDRST; Section 7.1.7.5		3	ms
Time to detect a long K from upstream	TURLK	Section 11.6	2.5	100	μ s
Time to detect a long SE0 from upstream	TURLSE0	Section 11.6	2.5	10000	μ s

Time for which a suspended high-speed capable device must see a continuous SE0 before beginning the high-speed detection handshake	TFILTSE0	Section 7.1.7.5	2.5		μs
Time a high-speed capable device operating in non-suspended full-speed must wait after start of SE0 before beginning the high-speed detection handshake	TWTRSTFS	Section 7.1.7.5	2.5	3000	μs
Time a high-speed capable device operating in high-speed must wait after start of SE0 before reverting to full-speed	TWTREV	Section 7.1.7.5	3.0	3.125	ms
Time a device must wait after reverting to full-speed before sampling the bus state for SE0 and beginning the high-speed detection handshake	TWTRSTHS	Section 7.1.7.5	100	875	μs

Table 7-14. Device Event Timings (Continued)

Parameter	Symbol	Conditions	Min	Max	Units
Minimum duration of a Chirp K from a high-speed capable device within the reset protocol	TUCH	Section 7.1.7.5	1.0		ms
Time after start of SE0 by which a high-speed capable device is required to have completed its Chirp K within the reset protocol	TUCHEND	Section 7.1.7.5		7.0	ms
Time between detection of downstream chirp and entering high-speed state	TWTHS	Section 7.1.7.5		500	μs
Time after end of upstream chirp at which device reverts to full-speed default state if no downstream chirp is detected	TWTFS	Section 7.1.7.5	1.0	2.5	ms

7.3.3 Timing Waveforms

Figure 7-49. Differential Data Jitter for Low-/full-speed

Figure 7-50. Differential-to-EOP Transition Skew and EOP Width for Low-/full-speed

Figure 7-51. Receiver Jitter Tolerance for Low-/full-speed

T_{PERIOD} is the data rate of the receiver that can have the range as defined in Section 7.1.11.

Hub Differential Jitter:

$$T_{HDJ1} = T_{HDDx}(J) - T_{HDDx}(K) \text{ or } T_{HDDx}(K) - T_{HDDx}(J) \text{ Consecutive Transitions}$$

$$T_{HDJ2} = T_{HDDx}(J) - T_{HDDx}(J) \text{ or } T_{HDDx}(K) - T_{HDDx}(K) \text{ Paired Transitions}$$

Bit after SOP Width Distortion (same as data jitter for SOP and next J transition):

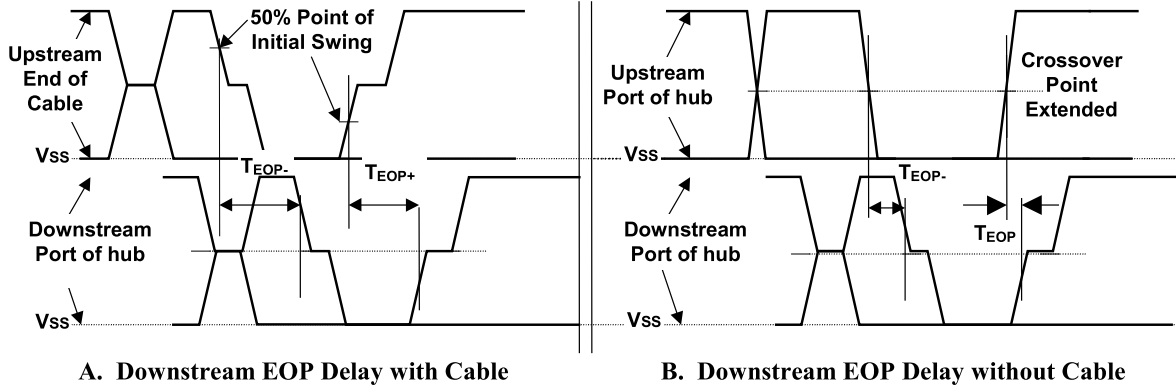

$$T_{FSOP} = T_{HDDx}(\text{next J}) - T_{HDDx}(\text{SOP})$$

Low-speed timings are determined in the same way for:

$$T_{LHDD}, T_{LDHJ1}, T_{LDJH2}, T_{LUHJ1}, T_{LUJH2}, \text{ and } T_{LSOP}$$

Figure 7-52. Hub Differential Delay, Differential Jitter, and SOP Distortion for Low-/full-speed

Measurement locations referenced in Figure 7-52 and Figure 7-53 are specified in Figure 7-38.

EOP Delay:
 $T_{FEOPD} = T_{EOPy} - T_{HDDx}$
 (T_{EOPy} means that this equation applies to T_{EOP-} and T_{EOP+})

EOP Skew:
 $T_{FHESK} = T_{EOP+} - T_{EOP-}$

Low-speed timings are determined in the same way for:
 T_{LEOPD} and T_{LHESK}

Figure 7-53. Hub EOP Delay and EOP Skew for Low-/full-speed

Chapter 8

Protocol Layer

This chapter presents a bottom-up view of the USB protocol, starting with field and packet definitions. This is followed by a description of packet transaction formats for different transaction types. Link layer flow control and transaction level fault recovery are then covered. The chapter finishes with a discussion of retry synchronization, babble, loss of bus activity recovery, and high-speed PING protocol.

8.1 Byte/Bit Ordering

Bits are sent out onto the bus least-significant bit (LSb) first, followed by the next LSb, through to the most-significant bit (MSb) last. In the following diagrams, packets are displayed such that both individual bits and fields are represented (in a left to right reading order) as they would move across the bus.

Multiple byte fields in standard descriptors, requests, and responses are interpreted as and moved over the bus in little-endian order, i.e., LSB to MSB.

8.2 SYNC Field

All packets begin with a synchronization (SYNC) field, which is a coded sequence that generates a maximum edge transition density. It is used by the input circuitry to align incoming data with the local clock. A SYNC from an initial transmitter is defined to be eight bits in length for full/low-speed and 32 bits for high-speed. Received SYNC fields may be shorter as described in Chapter 7. SYNC serves only as a synchronization mechanism and is not shown in the following packet diagrams (refer to Section 7.1.10). The last two bits in the SYNC field are a marker that is used to identify the end of the SYNC field and, by inference, the start of the PID.

8.3 Packet Field Formats

Field formats for the token, data, and handshake packets are described in the following section. Packet bit definitions are displayed in unencoded data format. The effects of NRZI coding and bit stuffing have been removed for the sake of clarity. All packets have distinct Start- and End-of-Packet delimiters. The Start-of-Packet (SOP) delimiter is part of the SYNC field, and the End-of-Packet (EOP) delimiter is described in Chapter 7.

8.3.1 Packet Identifier Field

A packet identifier (PID) immediately follows the SYNC field of every USB packet. A PID consists of a four-bit packet type field followed by a four-bit check field as shown in Figure 8-1. The PID indicates the type of packet and, by inference, the format of the packet and the type of error detection applied to the packet. The four-bit check field of the PID ensures reliable decoding of the PID so that the remainder of the packet is interpreted correctly. The PID check field is generated by performing a one's complement of the packet type field. A PID error exists if the four PID check bits are not complements of their respective packet identifier bits.

Figure 8-1. PID Format

The host and all functions must perform a complete decoding of all received PID fields. Any PID received with a failed check field or which decodes to a non-defined value is assumed to be corrupted and it, as well

Universal Serial Bus Specification Revision 2.0

as the remainder of the packet, is ignored by the packet receiver. If a function receives an otherwise valid PID for a transaction type or direction that it does not support, the function must not respond. For example, an IN-only endpoint must ignore an OUT token. PID types, codings, and descriptions are listed in Table 8-1.

Table 8-1. PID Types

PID Type	PID Name	PID<3:0>*	Description
Token	OUT	0001B	Address + endpoint number in host-to-function transaction
	IN	1001B	Address + endpoint number in function-to-host transaction
	SOF	0101B	Start-of-Frame marker and frame number
	SETUP	1101B	Address + endpoint number in host-to-function transaction for SETUP to a control pipe
Data	DATA0	0011B	Data packet PID even
	DATA1	1011B	Data packet PID odd
	DATA2	0111B	Data packet PID high-speed, high bandwidth isochronous transaction in a microframe (see Section 5.9.2 for more information)
	MDATA	1111B	Data packet PID high-speed for split and high bandwidth isochronous transactions (see Sections 5.9.2, 11.20, and 11.21 for more information)
Handshake	ACK	0010B	Receiver accepts error-free data packet
	NAK	1010B	Receiving device cannot accept data or transmitting device cannot send data
	STALL	1110B	Endpoint is halted or a control pipe request is not supported
	NYET	0110B	No response yet from receiver (see Sections 8.5.1 and 11.17-11.21)
Special	PRE	1100B	(Token) Host-issued preamble. Enables downstream bus traffic to low-speed devices.
	ERR	1100B	(Handshake) Split Transaction Error Handshake (reuses PRE value)
	SPLIT	1000B	(Token) High-speed Split Transaction Token (see Section 8.4.2)
	PING	0100B	(Token) High-speed flow control probe for a bulk/control endpoint (see Section 8.5.1)
	Reserved	0000B	Reserved PID

*Note: PID bits are shown in MSb order. When sent on the USB, the rightmost bit (bit 0) will be sent first.

PIDs are divided into four coding groups: token, data, handshake, and special, with the first two transmitted PID bits (PID<0:1>) indicating which group. This accounts for the distribution of PID codes.

8.3.2 Address Fields

Function endpoints are addressed using two fields: the function address field and the endpoint field. A function needs to fully decode both address and endpoint fields. Address or endpoint aliasing is not permitted, and a mismatch on either field must cause the token to be ignored. Accesses to non-initialized endpoints will also cause the token to be ignored.

8.3.2.1 Address Field

The function address (ADDR) field specifies the function, via its address, that is either the source or destination of a data packet, depending on the value of the token PID. As shown in Figure 8-2, a total of 128 addresses are specified as ADDR<6:0>. The ADDR field is specified for IN, SETUP, and OUT tokens and the PING and SPLIT special token. By definition, each ADDR value defines a single function. Upon reset and power-up, a function’s address defaults to a value of zero and must be programmed by the host during the enumeration process. Function address zero is reserved as the default address and may not be assigned to any other use.

Figure 8-2. ADDR Field

8.3.2.2 Endpoint Field

An additional four-bit endpoint (ENDP) field, shown in Figure 8-3, permits more flexible addressing of functions in which more than one endpoint is required. Except for endpoint address zero, endpoint numbers are function-specific. The endpoint field is defined for IN, SETUP, and OUT tokens and the PING special token. All functions must support a control pipe at endpoint number zero (the Default Control Pipe). Low-speed devices support a maximum of three pipes per function: a control pipe at endpoint number zero plus two additional pipes (either two control pipes, a control pipe and an interrupt endpoint, or two interrupt endpoints). Full-speed and high-speed functions may support up to a maximum of 16 IN and OUT endpoints.

Figure 8-3. Endpoint Field

8.3.3 Frame Number Field

The frame number field is an 11-bit field that is incremented by the host on a per-frame basis. The frame number field rolls over upon reaching its maximum value of 7FFH and is sent only in SOF tokens at the start of each (micro)frame.

8.3.4 Data Field

The data field may range from zero to 1,024 bytes and must be an integral number of bytes. Figure 8-4 shows the format for multiple bytes. Data bits within each byte are shifted out LSB first.

Figure 8-4. Data Field Format

Data packet size varies with the transfer type, as described in Chapter 5.

8.3.5 Cyclic Redundancy Checks

Cyclic redundancy checks (CRCs) are used to protect all non-PID fields in token and data packets. In this context, these fields are considered to be protected fields. The PID is not included in the CRC check of a packet containing a CRC. All CRCs are generated over their respective fields in the transmitter before bit stuffing is performed. Similarly, CRCs are decoded in the receiver after stuffed bits have been removed. Token and data packet CRCs provide 100% coverage for all single- and double-bit errors. A failed CRC is considered to indicate that one or more of the protected fields is corrupted and causes the receiver to ignore those fields and, in most cases, the entire packet.

For CRC generation and checking, the shift registers in the generator and checker are seeded with an all-ones pattern. For each data bit sent or received, the high order bit of the current remainder is XORed with the data bit and then the remainder is shifted left one bit and the low-order bit set to zero. If the result of that XOR is one, then the remainder is XORed with the generator polynomial.

When the last bit of the checked field is sent, the CRC in the generator is inverted and sent to the checker MSb first. When the last bit of the CRC is received by the checker and no errors have occurred, the remainder will be equal to the polynomial residual.

A CRC error exists if the computed checksum remainder at the end of a packet reception does not match the residual.

Bit stuffing requirements must be met for the CRC, and this includes the need to insert a zero at the end of a CRC if the preceding six bits were all ones.

8.3.5.1 Token CRCs

A five-bit CRC field is provided for tokens and covers the ADDR and ENDP fields of IN, SETUP, and OUT tokens or the time stamp field of an SOF token. The PING and SPLIT special tokens also include a five-bit CRC field. The generator polynomial is:

$$G(X) = X^5 + X^2 + 1$$

The binary bit pattern that represents this polynomial is 00101B. If all token bits are received without error, the five-bit residual at the receiver will be 01100B.

8.3.5.2 Data CRCs

The data CRC is a 16-bit polynomial applied over the data field of a data packet. The generating polynomial is:

$$G(X) = X^{16} + X^{15} + X^2 + 1$$

The binary bit pattern that represents this polynomial is 100000000000101B. If all data and CRC bits are received without error, the 16-bit residual will be 100000000000101B.

8.4 Packet Formats

This section shows packet formats for token, data, and handshake packets. Fields within a packet are displayed in these figures in the order in which bits are shifted out onto the bus.

8.4.1 Token Packets

Figure 8-5 shows the field formats for a token packet. A token consists of a PID, specifying either IN, OUT, or SETUP packet type and ADDR and ENDP fields. The PING special token packet also has the same fields as a token packet. For OUT and SETUP transactions, the address and endpoint fields uniquely identify the endpoint that will receive the subsequent Data packet. For IN transactions, these fields uniquely identify which endpoint should transmit a Data packet. For PING transactions, these fields uniquely identify which endpoint will respond with a handshake packet. Only the host can issue token packets. An IN PID defines a Data transaction from a function to the host. OUT and SETUP PIDs define Data transactions from the host to a function. A PING PID defines a handshake transaction from the function to the host.

Figure 8-5. Token Format

Token packets have a five-bit CRC that covers the address and endpoint fields as shown above. The CRC does not cover the PID, which has its own check field. Token and SOF packets are delimited by an EOP after three bytes of packet field data. If a packet decodes as an otherwise valid token or SOF but does not terminate with an EOP after three bytes, it must be considered invalid and ignored by the receiver.

8.4.2 Split Transaction Special Token Packets

USB defines a special token for split transactions: SPLIT. This is a 4 byte token packet compared to other normal 3 byte token packets. The split transaction token packet provides additional transaction types with additional transaction specific information. The split transaction token is used to support split transactions between the host controller communicating with a hub operating at high speed with full-/low-speed devices to some of its downstream facing ports. There are two split transactions defined that use the SPLIT special token: a start-split transaction (SSPLIT) and a complete-split transaction (CSPLIT). A field in the SPLIT special token, described in the following sections, indicates the specific split transaction.

8.4.2.1 Split Transactions

A high-speed split transaction is used only between the host controller and a hub when the hub has full-/low-speed devices attached to it. This high-speed split transaction is used to initiate a full-/low-speed transaction via the hub and some full-/low-speed device endpoint. The high-speed split transaction also allows the completion status of the full-/low-speed transaction to be retrieved from the hub. This approach allows the host controller to start a full-/low-speed transaction via a high-speed transaction and then continue with other high-speed transactions without having to wait for the full-/low-speed transaction to proceed/complete at the slower speed. See Chapter 11 for more details about the state machines and transaction definitions of split transactions.

A high-speed split transaction has two parts: a start-split and a complete-split. Split transactions are only defined to be used between the host controller and a hub. No other high-speed or full-/low-speed devices ever use split transactions.

Figure 8-6 shows the packets composing a generic start-split transaction. There are two packets in the token phase: the SPLIT special token and a full-/low-speed token. Depending on the direction of data transfer and whether a handshake is defined for the transaction type, the token phase is optionally followed by a data packet and a handshake packet. Start split transactions can consist of 2, 3, or 4 packets as determined by the specific transfer type and data direction.

Figure 8-6. Packets in a Start-split Transaction

Figure 8-7 shows the packets composing a generic complete-split transaction. There are two packets in the token phase: the SPLIT special token and a full-/low-speed token. A data or handshake packet follows the token phase packets in the complete-split depending on the data transfer direction and specific transaction type. Complete split transactions can consist of 2 or 3 packets as determined by the specific transfer type and data direction.

Figure 8-7. Packets in a Complete-split Transaction

The results of a split transaction are returned by a complete-split transaction. Figure 8-8 shows this conceptual “conversion” for an example interrupt IN transfer type. The host issues a start-split (indicated with 1) to the hub and then can proceed with other high-speed transactions. The start-split causes the hub to issue a full-/low-speed IN token sometime later (indicated by 2). The device responds to the IN token (in this example) with a data packet and the hub responds with a handshake to the device. Finally, the host sometime later issues a complete-split (indicated by 3) to retrieve the data provided by the device. Note that in the example, the hub provided the full-/low-speed handshake (ACK in this example) to the device endpoint before the complete-split, and the complete-split did not provide a high-speed handshake to the hub.

Figure 8-8. Relationship of Interrupt IN Transaction to High-speed Split Transaction

A normal full-/low-speed OUT transaction is similarly conceptually “converted” into start-split and complete-split transactions. Figure 8-9 shows this “conversion” for an example interrupt OUT transfer type. The host issues a start-split transaction consisting of a SSPLIT special token, an OUT token, and a DATA packet. The hub sometime later issues the OUT token and DATA packet on the full-/low-speed bus. The device responds with a handshake. Sometime later, the host issues the complete-split transaction and the hub responds with the results (either full-/low-speed data or handshake) provided by the device.

Figure 8-9. Relationship of Interrupt OUT Transaction to High-speed Split OUT Transaction

The next two sections describe the fields composing the detailed start- and complete-split token packets. Figure 8-10 and Figure 8-12 show the fields in the split-transaction token packet. The SPLIT special token follows the general token format and starts with a PID field (after a SYNC) and ends with a CRC5 field (and EOP). Start-split and complete-split token packets are both 4 bytes long. SPLIT transactions must only originate from the host. The start-split token is defined in Section 8.4.2.2 and the complete-split token is defined in Section 8.4.2.3.

8.4.2.2 Start-Split Transaction Token

	(lsb)							(msb)
Field	SPLIT PID	Hub Addr	SC	Port	S	E	ET	CRC5
Bits	8	7	1	7	1	1	2	5

Figure 8-10. Start-split (SSPLIT) Token

The Hub addr field contains the USB device address of the hub supporting the specified full-/low-speed device for this full-/low-speed transaction. This field has the same definition as the ADDR field definition in Section 8.3.2.1.

A SPLIT special token packet with the SC (Start/Complete) field set to zero indicates that this is a start-split transaction (SSPLIT).

The Port field contains the port number of the target hub for which this full-/low-speed transaction is destined. As shown in Figure 8-11, a total of 128 ports are specified as PORT<6:0>. The host must correctly set the port field for single and multiple TT hub implementations. A single TT hub implementation may ignore the port field.

Figure 8-11. Port Field

The S (Speed) field specifies the speed for this interrupt or control transaction as follows:

- 0 – Full speed
- 1 – Low speed

For bulk IN/OUT and isochronous IN start-splits, the S field must be set to zero. For bulk/control IN/OUT, interrupt IN/OUT, and isochronous IN start-splits, the E field must be set to zero.

For full-speed isochronous OUT start-splits, the S¹ (Start) and E (End) fields specify how the high-speed data payload corresponds to data for a full-speed data packet as shown in Table 8-2.

Table 8-2. Isochronous OUT Payload Continuation Encoding

S	E	High-speed to Full-speed Data Relation
0	0	High-speed data is the middle of the full-speed data payload
0	1	High-speed data is the end of the full-speed data payload
1	0	High-speed data is the beginning of the full-speed data payload
1	1	High-speed data is all of the full-speed data payload.

Isochronous OUT start-split transactions use these encodings to allow the hub to detect various error cases due to lack of receiving start-split transactions for an endpoint with a data payload that requires multiple start-splits. For example, a large full-speed data payload may require three start-split transactions: a start-split/beginning, a start-split/middle and a start-split/end. If any of these transactions is not received by the hub, it will either ignore the full-speed transaction (if the start-split/beginning is not received), or it will force an error for the corresponding full-speed transaction (if one of the other two transactions are not received). Other error conditions can be detected by not receiving a start-split during a microframe.

The ET (Endpoint Type) field specifies the endpoint type of the full-/low-speed transaction as shown in Table 8-3.

¹ The S bit can be reused for these encodings since isochronous transactions must not be low speed.

Table 8-3. Endpoint Type Values in Split Special Token

ET value (msb:lsb)	Endpoint Type
00	Control
01	Isochronous
10	Bulk
11	Interrupt

This field tells the hub which split transaction state machine to use for this full-/low-speed transaction. The full-/low-speed device address and endpoint number information is contained in the normal token packet that follows the SPLIT special token packet.

8.4.2.3 Complete-Split Transaction Token

		(lsb)							(msb)
Field	SPLIT PID	Hub Addr	SC	Port	S	U	ET	CRC5	
Bits	8	7	1	7	1	1	2	5	

Figure 8-12. Complete-split (CSPLIT) Transaction Token

A SPLIT special token packet with the SC field set to one indicates that this is a complete-split transaction (CSPLIT).

The U bit is reserved/unused and must be reset to zero(0B).

The other fields of the complete-split token packet have the same definitions as for the start-split token packet.

8.4.3 Start-of-Frame Packets

Start-of-Frame (SOF) packets are issued by the host at a nominal rate of once every 1.00 ms \pm 0.0005 ms for a full-speed bus and 125 μ s \pm 0.0625 μ s for a high-speed bus. SOF packets consist of a PID indicating packet type followed by an 11-bit frame number field as illustrated in Figure 8-13.

Figure 8-13. SOF Packet

The SOF token comprises the token-only transaction that distributes an SOF marker and accompanying frame number at precisely timed intervals corresponding to the start of each frame. All high-speed and full-speed functions, including hubs, receive the SOF packet. The SOF token does not cause any receiving function to generate a return packet; therefore, SOF delivery to any given function cannot be guaranteed.

The SOF packet delivers two pieces of timing information. A function is informed that an SOF has occurred when it detects the SOF PID. Frame timing sensitive functions, that do not need to keep track of frame number (e.g., a full-speed operating hub), need only decode the SOF PID; they can ignore the frame number and its CRC. If a function needs to track frame number, it must comprehend both the PID and the time stamp. Full-speed devices that have no particular need for bus timing information may ignore the SOF packet.

8.4.3.1 USB Frames and Microframes

USB defines a full-speed 1 ms frame time indicated by a Start Of Frame (SOF) packet each and every 1ms period with defined jitter tolerances. USB also defines a high-speed microframe with a 125 μ s frame time with related jitter tolerances (See Chapter 7). SOF packets are generated (by the host controller or hub transaction translator) every 1ms for full-speed links. SOF packets are also generated after the next seven 125 μ s periods for high-speed links.

Figure 8-14 shows the relationship between microframes and frames.

Figure 8-14. Relationship between Frames and Microframes

High-speed devices see an SOF packet with the same frame number eight times (every 125 μ s) during each 1 ms period. If desired, a high-speed device can locally determine a particular microframe “number” by detecting the SOF that had a different frame number than the previous SOF and treating that as the zeroth microframe. The next seven SOFs with the same frame number can be treated as microframes 1 through 7.

8.4.4 Data Packets

A data packet consists of a PID, a data field containing zero or more bytes of data, and a CRC as shown in Figure 8-15. There are four types of data packets, identified by differing PIDs: DATA0, DATA1, DATA2 and MDATA. Two data packet PIDs (DATA0 and DATA1) are defined to support data toggle synchronization (refer to Section 8.6). All four data PIDs are used in data PID sequencing for high bandwidth high-speed isochronous endpoints (refer to Section 5.9). Three data PIDs (MDATA, DATA0, DATA1) are used in split transactions (refer to Sections 11.17-11.21).

Figure 8-15. Data Packet Format

Data must always be sent in integral numbers of bytes. The data CRC is computed over only the data field in the packet and does not include the PID, which has its own check field.

The maximum data payload size allowed for low-speed devices is 8 bytes. The maximum data payload size for full-speed devices is 1023. The maximum data payload size for high-speed devices is 1024 bytes.

8.4.5 Handshake Packets

Handshake packets, as shown in Figure 8-16, consist of only a PID. Handshake packets are used to report the status of a data transaction and can return values indicating successful reception of data, command acceptance or rejection, flow control, and halt conditions. Only transaction types that support flow control can return handshakes. Handshakes are always returned in the handshake phase of a transaction and may be returned, instead of data, in the data phase. Handshake packets are delimited by an EOP after one byte of packet field. If a packet decodes as an otherwise valid handshake but does not terminate with an EOP after one byte, it must be considered invalid and ignored by the receiver.

Figure 8-16. Handshake Packet

There are four types of handshake packets and one special handshake packet:

- **ACK** indicates that the data packet was received without bit stuff or CRC errors over the data field and that the data PID was received correctly. ACK may be issued either when sequence bits match and the receiver can accept data or when sequence bits mismatch and the sender and receiver must resynchronize to each other (refer to Section 8.6 for details). An ACK handshake is applicable only in transactions in which data has been transmitted and where a handshake is expected. ACK can be returned by the host for IN transactions and by a function for OUT, SETUP, or PING transactions.
- **NAK** indicates that a function was unable to accept data from the host (OUT) or that a function has no data to transmit to the host (IN). NAK can only be returned by functions in the data phase of IN transactions or the handshake phase of OUT or PING transactions. The host can never issue NAK.

NAK is used for flow control purposes to indicate that a function is temporarily unable to transmit or receive data, but will eventually be able to do so without need of host intervention.

- **STALL** is returned by a function in response to an IN token or after the data phase of an OUT or in response to a PING transaction (see Figure 8-30 and Figure 8-38). STALL indicates that a function is unable to transmit or receive data, or that a control pipe request is not supported. The state of a function after returning a STALL (for any endpoint except the default endpoint) is undefined. The host is not permitted to return a STALL under any condition.

The STALL handshake is used by a device in one of two distinct occasions. The first case, known as “functional stall,” is when the *Halt* feature associated with the endpoint is set. (The *Halt* feature is specified in Chapter 9 of this document.) A special case of the functional stall is the “commanded stall.” Commanded stall occurs when the host explicitly sets the endpoint’s *Halt* feature, as detailed in Chapter 9. Once a function’s endpoint is halted, the function must continue returning STALL until the condition causing the halt has been cleared through host intervention.

The second case, known as “protocol stall,” is detailed in Section 8.5.3. Protocol stall is unique to control pipes. Protocol stall differs from functional stall in meaning and duration. A protocol STALL is returned during the Data or Status stage of a control transfer, and the STALL condition terminates at the beginning of the next control transfer (Setup). The remainder of this section refers to the general case of a functional stall.

- **NYET** is a high-speed only handshake that is returned in two circumstances. It is returned by a high-speed endpoint as part of the PING protocol described later in this chapter. NYET may also be returned by a hub in response to a split-transaction when the full-/low-speed transaction has not yet been completed or the hub is otherwise not able to handle the split-transaction. See Chapter 11 for more details.
- **ERR** is a high-speed only handshake that is returned to allow a high-speed hub to report an error on a full-/low-speed bus. It is only returned by a high-speed hub as part of the split transaction protocol. See Chapter 11 for more details.

8.4.6 Handshake Responses

Transmitting and receiving functions must return handshakes based upon an order of precedence detailed in Table 8-4 through Table 8-6. Not all handshakes are allowed, depending on the transaction type and whether the handshake is being issued by a function or the host. Note that if an error occurs during the transmission of the token to the function, the function will not respond with any packets until the next token is received and successfully decoded.

8.4.6.1 Function Response to IN Transactions

Table 8-4 shows the possible responses a function may make in response to an IN token. If the function is unable to send data, due to a halt or a flow control condition, it issues a STALL or NAK handshake, respectively. If the function is able to issue data, it does so. If the received token is corrupted, the function returns no response.

Table 8-4. Function Responses to IN Transactions

Token Received Corrupted	Function Tx Endpoint Halt Feature	Function Can Transmit Data	Action Taken
Yes	Don't care	Don't care	Return no response
No	Set	Don't care	Issue STALL handshake
No	Not set	No	Issue NAK handshake
No	Not set	Yes	Issue data packet

8.4.6.2 Host Response to IN Transactions

Table 8-5 shows the host response to an IN transaction. The host is able to return only one type of handshake: ACK. If the host receives a corrupted data packet, it discards the data and issues no response. If the host cannot accept data from a function, (due to problems such as internal buffer overrun) this condition is considered to be an error and the host returns no response. If the host is able to accept data and the data packet is received error-free, the host accepts the data and issues an ACK handshake.

Table 8-5. Host Responses to IN Transactions

Data Packet Corrupted	Host Can Accept Data	Handshake Returned by Host
Yes	N/A	Discard data, return no response
No	No	Discard data, return no response
No	Yes	Accept data, issue ACK

8.4.6.3 Function Response to an OUT Transaction

Handshake responses for an OUT transaction are shown in Table 8-6. Assuming successful token decode, a function, upon receiving a data packet, may return any one of the three handshake types. If the data packet was corrupted, the function returns no handshake. If the data packet was received error-free and the function's receiving endpoint is halted, the function returns STALL. If the transaction is maintaining sequence bit synchronization and a mismatch is detected (refer to Section 8.6 for details), then the function returns ACK and discards the data. If the function can accept the data and has received the data error-free, it returns ACK. If the function cannot accept the data packet due to flow control reasons, it returns NAK.

Table 8-6. Function Responses to OUT Transactions in Order of Precedence

Data Packet Corrupted	Receiver Halt Feature	Sequence Bits Match	Function Can Accept Data	Handshake Returned by Function
Yes	N/A	N/A	N/A	None
No	Set	N/A	N/A	STALL
No	Not set	No	N/A	ACK
No	Not set	Yes	Yes	ACK
No	Not set	Yes	No	NAK

8.4.6.4 Function Response to a SETUP Transaction

SETUP defines a special type of host-to-function data transaction that permits the host to initialize an endpoint’s synchronization bits to those of the host. Upon receiving a SETUP token, a function must accept the data. A function may not respond to a SETUP token with either STALL or NAK, and the receiving function must accept the data packet that follows the SETUP token. If a non-control endpoint receives a SETUP token, it must ignore the transaction and return no response.

8.5 Transaction Packet Sequences

The packets that comprise a transaction varies depending on the endpoint type. There are four endpoint types: bulk, control, interrupt, and isochronous.

A host controller and device each require different state machines to correctly sequence each type of transaction. Figures in the following sections show state machines that define the correct sequencing of packets within a transaction of each type. The diagrams should not be taken as a required implementation, but to specify the required behavior.

Figure 8-17 shows the legend for the state machine diagrams. A circle with a three-line border indicates a reference to another (hierarchical) state machine. A circle with a two-line border indicates an initial state. A circle with a single-line border represents a simple state.

Figure 8-17. Legend for State Machines

The “tab” shapes with arrows are the entry or exit (respectively in the legend) to/from the state machine. The entry/exit relates to another state in a state machine at a higher level in the state machine hierarchy.

A diamond (joint) is used to join several transitions to a common point. A joint allows a single input transition with multiple output transitions or multiple input transitions and a single output transition. All conditions on the transitions of a path involving a joint must be true for the path to be taken. A path is simply a sequence of transitions involving one or more joints.

A transition is labeled with a block with a line in the middle separating the (upper) condition and the (lower) actions. The condition is required to be true to take the transition. The syntax for actions and conditions is VHDL. The actions are performed if the transition is taken. A circle includes a name in bold and optionally one or more actions that are performed upon entry to the state.

The host controller and device state machines are in a context as shown in Figure 8-18. The host controller determines the next transaction to run for an endpoint and issues a command (HC_cmd) to the host controller state machines. This causes the host controller state machines to issue one or more packets to move over the downstream bus (HSD1).

The device receives these packets from the bus (HSD2), reacts to the received packet, and interacts with its function(s) via the state of the corresponding endpoint (in the EP_array). Then the device may respond with a packet on the upstream bus (HSU1). The host controller state machines can receive a packet from the bus (HSU2) and provide a result of the transaction back to the host controller (HC_resp). The details of what packets are sent on the bus is determined by the transfer type for the endpoint and what bus activity the state machines observe.

The state machines are presented in a hierarchical form. Figure 8-19 shows the top level state machines for the host controller. The non-split transactions are presented in the remainder of this chapter. The split transaction state machines (HC_Do_start and HC_Do_complete) are described and shown in Chapter 11.

Figure 8-18. State Machine Context Overview

Figure 8-19. Host Controller Top Level Transaction State Machine Hierarchy Overview

The host controller state machines are located in the host controller. The host controller causes packets to be issued downstream (labeled as HSD1) and it receives upstream packets (labeled as HSU2).

The device state machines are located in the device. The device causes packets to be issued upstream (labeled as HSU1) and it receives downstream packets (labeled as HSD2).

The host controller has commands that tell it what transaction to issue next for an endpoint. The host controller tracks transactions for several endpoints. The host controller state machines sequence to determine what the host controller needs to do next for the current endpoint. The device has a state for each of its endpoints. The device state machines sequence to determine what reaction the device has to a transaction.

The appendix includes some declarations that were used in constructing the state machines and may be useful in understanding additional details of the state machines. There are several pseudo-code procedures and functions for conditions and actions. Simple descriptions of them are also included in the appendix.

Figure 8-20 shows an overview of the overall state machine hierarchy for the host controller for the non-split transaction types. Figure 8-21 shows the hierarchy of the device state machines. The state machines

common to endpoint types are presented first. The lowest level endpoint type specific state machines are presented in each following endpoint type section.

8.5.1 NAK Limiting via Ping Flow Control

Full-/low-speed devices can have bulk/control endpoints that take time to process their data and, therefore, respond to OUT transactions with a NAK handshake. This handshake response indicates that the endpoint did not accept the data because it did not have space for the data. The host controller is expected to retry the transaction at some future time when the endpoint has space available. Unfortunately, by the time the endpoint NAKs, most of the full-/low-speed bus time for the transaction had been used. This means that the full-/low-speed bus has poor utilization when there is a high frequency of NAK'd OUT transactions.

High-speed devices must support an improved NAK mechanism for Bulk OUT and Control endpoints and transactions. Control endpoints must support this protocol for an OUT transaction in the data and status stages. The control Setup stage must not support the PING protocol.

This mechanism allows the device to tell the host controller whether it has sufficient endpoint space for the next OUT transaction. If the device endpoint does not have space, the host controller can choose to delay a transaction attempt for this endpoint and instead try some other transaction. This can lead to improved bus utilization. The mechanism avoids using bus time to send data until the host controller knows that the endpoint has space for the data.

The host controller queries the high-speed device endpoint with a PING special token. The PING special token packet is a normal token packet as shown in Figure 8-5. The endpoint either responds to the PING with a NAK or an ACK handshake.

A NAK handshake indicates that the endpoint does not have space for a *wMaxPacketSize* data payload. The host controller will retry the PING at some future time to query the endpoint again. A device can respond to a PING with a NAK for long periods of time. A NAK response is not a reason for the host controller to retire a transfer request. If a device responds with a NAK in a (micro)frame, the host controller may choose to issue the next transaction in the next *bInterval* specified for the endpoint. However, the device must be prepared to receive PINGs as sequential transactions, e.g., one immediately after the other.

An ACK handshake indicates the endpoint has space for a *wMaxPacketSize* data payload. The host controller must generate an OUT transaction with a DATA phase as the next transaction to the endpoint. The host controller may generate other transactions to other devices or endpoints before the OUT/DATA transaction for this endpoint.

If the endpoint responds to the OUT/DATA transaction with an ACK handshake, this means the endpoint accepted the data successfully and has room for another *wMaxPacketSize* data payload. The host controller continues with OUT/DATA transactions (which are not required to be the next transactions on the bus) as long as it has transactions to generate.

If the endpoint instead responds to the OUT/DATA transaction with a NYET handshake, this means that the endpoint accepted the data but does not have room for another *wMaxPacketSize* data payload. The host controller must return to using a PING token until the endpoint indicates it has space.

Figure 8-27. Host High-speed Bulk OUT/Control Ping State Machine

8.5.1.1 NAK Responses to OUT/DATA During PING Protocol

The endpoint may also respond to the OUT/DATA transaction with a NAK handshake. This means that the endpoint did not accept the data and does not have space for a *wMaxPacketSize* data payload at this time. The host controller must return to using a PING token until the endpoint indicates it has space.

A NAK response is expected to be an unusual occurrence. A high-speed bulk/control endpoint must specify its maximum NAK rate in its endpoint descriptor. The endpoint is allowed to NAK at most one time each *bInterval* period. A NAK suggests that the endpoint responded to a previous OUT or PING with an inappropriate handshake, or that the endpoint transitioned into a state where it (temporarily) could not

accept data. An endpoint can use a *bInterval* of zero to indicate that it never NAKs. An endpoint must always be able to accept a PING from the host, even if it never NAKs.

If a timeout occurs after the data phase, the host must return to using a PING token. Note that a transition back to the PING state does not affect the data toggle state of the transaction data phase.

Figure 8-27 shows the host controller state machine for the interactions and transitions between PING and OUT/DATA tokens and the allowed ACK, NAK, and NYET handshakes for the PING mechanism.

Figure 8-29 shows the device endpoint state machine for PING based on the buffer space the endpoint has available.

Figure 8-28. Dev_HS_ping State Machine

Figure 8-29. Device High-speed Bulk OUT /Control State Machine

Full-/low-speed devices/endpoints must not support the PING protocol. Host controllers must not support the PING protocol for full-/low-speed devices.

Note: The PING protocol is also not included as part of the split-transaction protocol definition. Some split-transactions have equivalent flow control without using PING. Other split-transactions will not benefit from PING as defined. In any case, split-transactions that can return a NAK handshake have small data payloads which should have minor high-speed bus impact. Hubs must support PING on their control endpoint, but PING is not defined for the split-transactions that are used to communicate with full-/low-speed devices supported by a hub.

8.5.2 Bulk Transactions

Bulk transaction types are characterized by the ability to guarantee error-free delivery of data between the host and a function by means of error detection and retry. Bulk transactions use a three-phase transaction consisting of token, data, and handshake packets as shown in Figure 8-30. Under certain flow control and halt conditions, the data phase may be replaced with a handshake resulting in a two-phase transaction in which no data is transmitted. The PING and NYET packets must only be used with devices operating at high-speed.

Figure 8-30. Bulk Transaction Format

When the host is ready to receive bulk data, it issues an IN token. The function endpoint responds by returning either a data packet or, should it be unable to return data, a NAK or STALL handshake. NAK indicates that the function is temporarily unable to return data, while STALL indicates that the endpoint is permanently halted and requires USB System Software intervention. If the host receives a valid data packet, it responds with an ACK handshake. If the host detects an error while receiving data, it returns no handshake packet to the function.

When the host is ready to transmit bulk data, it first issues an OUT token packet followed by a data packet (or PING special token packet, see Section 8.5.1). If the data is received without error by the function, it will return one of three (or four including NYET, for a device operating at high-speed) handshakes:

- ACK indicates that the data packet was received without errors and informs the host that it may send the next packet in the sequence.
- NAK indicates that the data was received without error but that the host should resend the data because the function was in a temporary condition preventing it from accepting the data (e.g., buffer full).
- If the endpoint was halted, STALL is returned to indicate that the host should not retry the transmission because there is an error condition on the function.

If the data packet was received with a CRC or bit stuff error, no handshake is returned.

Figure 8-31 and Figure 8-32 show the host and device state machines respectively for bulk, control, and interrupt OUT full/low-speed transactions. Figure 8-27, Figure 8-28, and Figure 8-29 show the state machines for high-speed transactions. Figure 8-33 and Figure 8-34 show the host and device state machines respectively for bulk, control, and interrupt IN transactions.

Figure 8-31. Bulk/Control/Interrupt OUT Transaction Host State Machine

Figure 8-32. Bulk/Control/Interrupt OUT Transaction Device State Machine

Figure 8-33. Bulk/Control/Interrupt IN Transaction Host State Machine

Figure 8-34. Bulk/Control/Interrupt IN Transaction Device State Machine

Figure 8-35 shows the sequence bit and data PID usage for bulk reads and writes. Data packet synchronization is achieved via use of the data sequence toggle bits and the DATA0/DATA1 PIDs. A bulk endpoint’s toggle sequence is initialized to DATA0 when the endpoint experiences any configuration event (configuration events are explained in Sections 9.1.1.5 and 9.4.5). Data toggle on an endpoint is NOT initialized as the direct result of a short packet transfer or the retirement of an IRP.

Figure 8-35. Bulk Reads and Writes

The host always initializes the first transaction of a bus transfer to the DATA0 PID with a configuration event. The second transaction uses a DATA1 PID, and successive data transfers alternate for the remainder of the bulk transfer. The data packet transmitter toggles upon receipt of ACK, and the receiver toggles upon receipt and acceptance of a valid data packet (refer to Section 8.6).

8.5.3 Control Transfers

Control transfers minimally have two transaction stages: Setup and Status. A control transfer may optionally contain a Data stage between the Setup and Status stages. During the Setup stage, a SETUP transaction is used to transmit information to the control endpoint of a function. SETUP transactions are similar in format to an OUT but use a SETUP rather than an OUT PID. Figure 8-36 shows the SETUP transaction format. A SETUP always uses a DATA0 PID for the data field of the SETUP transaction. The

function receiving a SETUP must accept the SETUP data and respond with ACK; if the data is corrupted, discard the data and return no handshake.

Figure 8-36. Control SETUP Transaction

The Data stage, if present, of a control transfer consists of one or more IN or OUT transactions and follows the same protocol rules as bulk transfers. All the transactions in the Data stage must be in the same direction (i.e., all INs or all OUTs). The amount of data to be sent during the data stage and its direction are specified during the Setup stage. If the amount of data exceeds the prenegotiated data packet size, the data is sent in multiple transactions (INs or OUTs) that carry the maximum packet size. Any remaining data is sent as a residual in the last transaction.

The Status stage of a control transfer is the last transaction in the sequence. The status stage transactions follow the same protocol sequence as bulk transactions. Status stage for devices operating at high-speed also includes the PING protocol. A Status stage is delineated by a change in direction of data flow from the previous stage and always uses a DATA1 PID. If, for example, the Data stage consists of OUTs, the status is a single IN transaction. If the control sequence has no Data stage, then it consists of a Setup stage followed by a Status stage consisting of an IN transaction.

Figure 8-37 shows the transaction order, the data sequence bit value, and the data PID types for control read and write sequences. The sequence bits are displayed in parentheses.

Figure 8-37. Control Read and Write Sequences

When a STALL handshake is sent by a control endpoint in either the Data or Status stages of a control transfer, a STALL handshake must be returned on all succeeding accesses to that endpoint until a SETUP PID is received. The endpoint is not required to return a STALL handshake after it receives a subsequent SETUP PID. For the default endpoint, if an ACK handshake is returned for the SETUP transaction, the host expects that the endpoint has automatically recovered from the condition that caused the STALL and the endpoint must operate normally.

8.5.3.1 Reporting Status Results

The Status stage reports to the host the outcome of the previous Setup and Data stages of the transfer. Three possible results may be returned:

- The command sequence completed successfully.
- The command sequence failed to complete.
- The function is still busy completing the command.

Status reporting is always in the function-to-host direction. Table 8-7 summarizes the type of responses required for each. Control write transfers return status information in the data phase of the Status stage transaction. Control read transfers return status information in the handshake phase of a Status stage transaction, after the host has issued a zero-length data packet during the previous data phase.

Table 8-7. Status Stage Responses

Status Response	Control Write Transfer (sent during data phase)	Control Read Transfer (sent during handshake phase)
Function completes	Zero-length data packet	ACK handshake
Function has an error	STALL handshake	STALL handshake
Function is busy	NAK handshake	NAK handshake

For control reads, the host must send either an OUT token or PING special token (for a device operating at high-speed) to the control pipe to initiate the Status stage. The host may only send a zero-length data packet in this phase but the function may accept any length packet as a valid status inquiry. The pipe’s handshake response to this data packet indicates the current status. NAK indicates that the function is still processing the command and that the host should continue the Status stage. ACK indicates that the function has completed the command and is ready to accept a new command. STALL indicates that the function has an error that prevents it from completing the command.

For control writes, the host sends an IN token to the control pipe to initiate the Status stage. The function responds with either a handshake or a zero-length data packet to indicate its current status. NAK indicates that the function is still processing the command and that the host should continue the Status stage; return of a zero-length packet indicates normal completion of the command; and STALL indicates that the function cannot complete the command. The function expects the host to respond to the data packet in the Status stage with ACK. If the function does not receive ACK, it remains in the Status stage of the command and will continue to return the zero-length data packet for as long as the host continues to send IN tokens.

If during a Data stage a command pipe is sent more data or is requested to return more data than was indicated in the Setup stage (see Section 8.5.3.2), it should return STALL. If a control pipe returns STALL during the Data stage, there will be no Status stage for that control transfer.

8.5.3.2 Variable-length Data Stage

A control pipe may have a variable-length data phase in which the host requests more data than is contained in the specified data structure. When all of the data structure is returned to the host, the function should indicate that the Data stage is ended by returning a packet that is shorter than the *MaxPacketSize* for the pipe. If the data structure is an exact multiple of *wMaxPacketSize* for the pipe, the function will return a zero-length packet to indicate the end of the Data stage.

8.5.3.3 Error Handling on the Last Data Transaction

If the ACK handshake on an IN transaction is corrupted, the function and the host will temporarily disagree on whether the transaction was successful. If the transaction is followed by another IN, the toggle retry mechanism will detect the mismatch and recover from the error. If the ACK was on the last IN of a Data stage, the toggle retry mechanism cannot be used and an alternative scheme must be used.

The host that successfully received the data of the last IN will send ACK. Later, the host will issue an OUT token to start the Status stage of the transfer. If the function did not receive the ACK that ended the Data stage, the function will interpret the start of the Status stage as verification that the host successfully received the data. Control writes do not have this ambiguity. If an ACK handshake on an OUT gets corrupted, the host does not advance to the Status stage and retries the last data instead. A detailed analysis of retry policy is presented in Section 8.6.4.

8.5.3.4 STALL Handshakes Returned by Control Pipes

Control pipes have the unique ability to return a STALL handshake due to function problems in control transfers. If the device is unable to complete a command, it returns a STALL in the Data and/or Status stages of the control transfer. Unlike the case of a functional stall, protocol stall does not indicate an error with the device. The protocol STALL condition lasts until the receipt of the next SETUP transaction, and the function will return STALL in response to any IN or OUT transaction on the pipe until the SETUP transaction is received. In general, protocol stall indicates that the request or its parameters are not understood by the device and thus provides a mechanism for extending USB requests.

A control pipe may also support functional stall as well, but this is not recommended. This is a degenerative case, because a functional stall on a control pipe indicates that it has lost the ability to communicate with the host. If the control pipe does support functional stall, then it must possess a *Halt* feature, which can be set or cleared by the host. Chapter 9 details how to treat the special case of a *Halt* feature on a control pipe. A well-designed device will associate all of its functions and *Halt* features with non-control endpoints. The control pipes should be reserved for servicing USB requests.

8.5.4 Interrupt Transactions

Interrupt transactions may consist of IN or OUT transfers. Upon receipt of an IN token, a function may return data, NAK, or STALL. If the endpoint has no new interrupt information to return (i.e., no interrupt is pending), the function returns a NAK handshake during the data phase. If the *Halt* feature is set for the interrupt endpoint, the function will return a STALL handshake. If an interrupt is pending, the function returns the interrupt information as a data packet. The host, in response to receipt of the data packet, issues either an ACK handshake if data was received error-free or returns no handshake if the data packet was received corrupted. Figure 8-38 shows the interrupt transaction format.

Section 5.9.1 contains additional information about high-speed, high-bandwidth interrupt endpoints. Such endpoints use multiple transactions in a microframe as defined in that section. Each transaction for a high-bandwidth endpoint follows the transaction format shown in Figure 8-38.

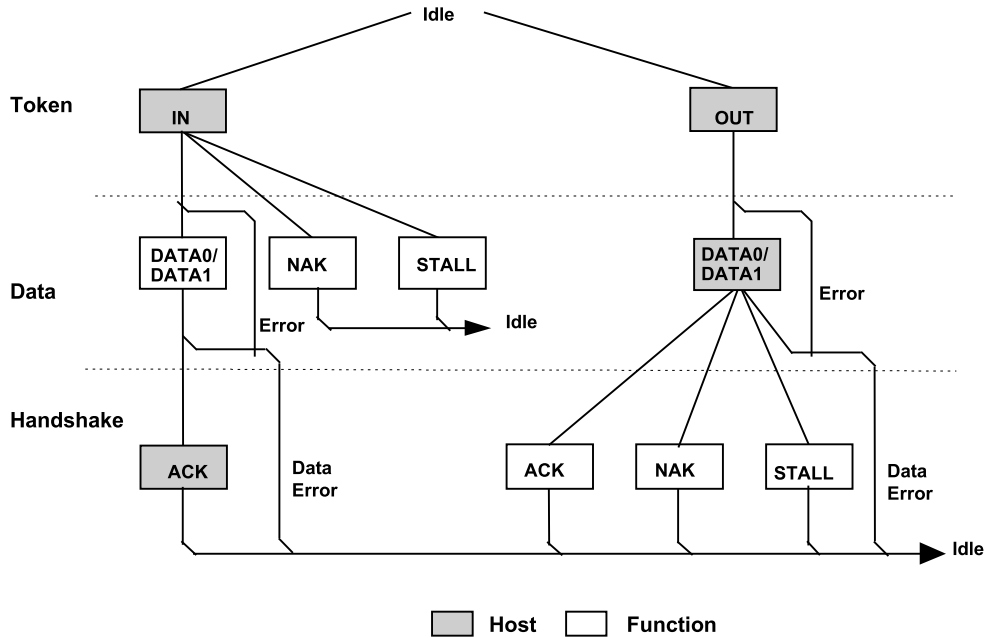

Figure 8-38. Interrupt Transaction Format

When an endpoint is using the interrupt transfer mechanism for actual interrupt data, the data toggle protocol must be followed. This allows the function to know that the data has been received by the host and the event condition may be cleared. This “guaranteed” delivery of events allows the function to only send the interrupt information until it has been received by the host rather than having to send the interrupt data every time the function is polled and until the USB System Software clears the interrupt condition. When used in the toggle mode, an interrupt endpoint is initialized to the DATA0 PID by any configuration event on the endpoint and behaves the same as the bulk transactions shown in Figure 8-35.

8.5.5 Isochronous Transactions

Isochronous transactions have a token and data phase, but no handshake phase, as shown in Figure 8-39. The host issues either an IN or an OUT token followed by the data phase in which the endpoint (for INs) or the host (for OUTs) transmits data. Isochronous transactions do not support a handshake phase or retry capability.

See Note Below

Figure 8-39. Isochronous Transaction Format

Note: A full-speed device or Host Controller should be able to accept either DATA0 or DATA1 PIDs in data packets. A full-speed device or Host Controller should only send DATA0 PIDs in data packets. A high-speed Host Controller must be able to accept and send DATA0, DATA1, DATA2, or MDATA PIDs in data packets. A high-speed device with at most 1 transaction per microframe must only send DATA0 PIDs in data packets. A high-speed device with high-bandwidth endpoints (e.g., one that has more than 1 transaction per microframe) must be able to accept and/or send DATA0, DATA1, DATA2, or MDATA PIDs in data packets.

Full-speed isochronous transactions do not support toggle sequencing. High-speed isochronous transactions with a single transaction per microframe do not support toggle sequencing. High bandwidth, high-speed isochronous transactions support data PID sequencing (see Section 5.9.1 for more details).

Figure 8-40 and Figure 8-41 show the host and device state machines respectively for isochronous OUT transactions. Figure 8-42 and Figure 8-43 show the host and device state machines respectively for isochronous IN transactions.

Figure 8-40. Isochronous OUT Transaction Host State Machine

Figure 8-41. Isochronous OUT Transaction Device State Machine

Figure 8-42. Isochronous IN Transaction Host State Machine

Figure 8-43. Isochronous IN Transaction Device State Machine

8.6 Data Toggle Synchronization and Retry

The USB provides a mechanism to guarantee data sequence synchronization between data transmitter and receiver across multiple transactions. This mechanism provides a means of guaranteeing that the handshake phase of a transaction was interpreted correctly by both the transmitter and receiver. Synchronization is achieved via use of the DATA0 and DATA1 PIDs and separate data toggle sequence bits for the data transmitter and receiver. Receiver sequence bits toggle only when the receiver is able to accept data and receives an error-free data packet with the correct data PID. Transmitter sequence bits toggle only when the data transmitter receives a valid ACK handshake. The data transmitter and receiver must have their sequence bits synchronized at the start of a transaction. The synchronization mechanism used varies with the transaction type. Data toggle synchronization is not supported for isochronous transfers.

The state machines contained in this chapter and in Chapter 11 describe data toggle synchronization in a more compact form. Instead of explicitly identifying DATA0 and DATA1, it uses a value “DATAx” to represent either/both DATA0/DATA1 PIDs. In some cases where the specific data PID is important, another variable labeled “x” is used that has the value 0 for DATA0 and 1 for DATA1.

High-speed, high-bandwidth isochronous and interrupt endpoints support a similar but different data synchronization technique called data PID sequencing. That technique is used instead of data toggle synchronization. Section 5.9.1 defines data PID sequencing.

8.6.1 Initialization via SETUP Token

Figure 8-44. SETUP Initialization

Control transfers use the SETUP token for initializing host and function sequence bits. Figure 8-44 shows the host issuing a SETUP packet to a function followed by an OUT transaction. The numbers in the circles represent the transmitter and receiver sequence bits. The function must accept the data and return ACK. When the function accepts the transaction, it must set its sequence bit so that both the host's and function's sequence bits are equal to one at the end of the SETUP transaction.

8.6.2 Successful Data Transactions

Figure 8-45 shows the case where two successful transactions have occurred. For the data transmitter, this means that it toggles its sequence bit upon receipt of ACK. The receiver toggles its sequence bit only if it receives a valid data packet and the packet's data PID matches the current value of its sequence bit. The transmitter only toggles its sequence bit after it receives an ACK to a data packet.

During each transaction, the receiver compares the transmitter sequence bit (encoded in the data packet PID as either DATA0 or DATA1) with its receiver sequence bit. If data cannot be accepted, the receiver must issue NAK and the sequence bits of both the transmitter and receiver remain unchanged. If data can be accepted and the receiver's sequence bit matches the PID sequence bit, then data is accepted and the sequence bit is toggled. Two-phase transactions in which there is no data packet leave the transmitter and receiver sequence bits unchanged.

Figure 8-45. Consecutive Transactions

8.6.3 Data Corrupted or Not Accepted

If data cannot be accepted or the received data packet is corrupted, the receiver will issue a NAK or STALL handshake, or timeout, depending on the circumstances, and the receiver will not toggle its sequence bit.

Figure 8-46 shows the case where a transaction is NAKed and then retried. Any non-ACK handshake or timeout will generate similar retry behavior. The transmitter, having not received an ACK handshake, will not toggle its sequence bit. As a result, a failed data packet transaction leaves the transmitter's and receiver's sequence bits synchronized and untoggled. The transaction will then be retried and, if successful, will cause both transmitter and receiver sequence bits to toggle.

Figure 8-46. NAKed Transaction with Retry

8.6.4 Corrupted ACK Handshake

The transmitter is the last and only agent to know for sure whether a transaction has been successful, due to its receiving an ACK handshake. A lost or corrupted ACK handshake can lead to a temporary loss of synchronization between transmitter and receiver as shown in Figure 8-47. Here the transmitter issues a valid data packet, which is successfully acquired by the receiver; however, the ACK handshake is corrupted.

Figure 8-47. Corrupted ACK Handshake with Retry

At the end of transaction *i*, there is a temporary loss of coherency between transmitter and receiver, as evidenced by the mismatch between their respective sequence bits. The receiver has received good data, but the transmitter does not know whether it has successfully sent data. On the next transaction, the transmitter will resend the previous data using the previous DATA0 PID. The receiver's sequence bit and the data PID will not match, so the receiver knows that it has previously accepted this data. Consequently, it discards the incoming data packet and does not toggle its sequence bit. The receiver then issues ACK, which causes the transmitter to regard the retried transaction as successful. Receipt of ACK causes the transmitter to toggle its sequence bit. At the beginning of transaction *i*+1, the sequence bits have toggled and are again synchronized.

The data transmitter must guarantee that any retried data packet is identical (same length and content) as that sent in the original transaction. If the data transmitter is unable, because of problems such as a buffer underrun condition, to transmit the identical amount of data as was in the original data packet, it must abort

the transaction by generating a bit stuffing violation for full-/low-speed. An error for high-speed must be forced by taking the currently calculated CRC and complementing it before transmitting it. This causes a detectable error at the receiver and guarantees that a partial packet will not be interpreted as a good packet. The transmitter should not try to force an error at the receiver by sending a constant known bad CRC. A combination of a bad packet with a “bad” CRC may be interpreted by the receiver as a good packet.

8.6.5 Low-speed Transactions

The USB supports signaling at three speeds: high-speed signaling at 480 Mb/s, full-speed signaling at 12.0 Mb/s, and low-speed signaling at 1.5 Mb/s. Hubs isolate high-speed signaling from full-/low-speed signaling environments.

Within a full-/low-speed signaling environment, hubs disable downstream bus traffic to all ports to which low-speed devices are attached during full-speed downstream signaling. This is required both for EMI reasons and to prevent any possibility that a low-speed device might misinterpret downstream a full-speed packet as being addressed to it.

Figure 8-48 shows an IN low-speed transaction in which the host (or TT) issues a token and handshake and receives a data packet.

Figure 8-48. Low-speed Transaction

All downstream packets transmitted to low-speed devices within a full-/low-speed signaling environment require a preamble. Preambles are never used in a high-speed signaling environment. The preamble consists of a SYNC followed by a PRE PID, both sent at full-speed. Hubs must comprehend the PRE PID; all other USB devices may ignore it and treat it as undefined. At the end of the preamble PID, the host (or TT) drives the bus to the Idle state for at least one full-speed bit time. This Idle period on the bus is termed the hub setup interval and lasts for at least four full-speed bit times. During this hub setup interval, hubs must drive their full-speed and low-speed ports to their respective Idle states. Hubs must be ready to repeat low-speed signaling on low-speed ports before the end of the hub setup interval. Low-speed connectivity rules are summarized below:

1. Low-speed devices are identified during the connection process, and the hub ports to which they are connected are identified as low-speed.
2. All downstream low-speed packets must be prefaced with a preamble (sent at full-speed), which turns on the output buffers on low-speed hub ports.

3. Low-speed hub port output buffers are turned off upon receipt of EOP and are not turned on again until a preamble PID is detected.
4. Upstream connectivity is not affected by whether a hub port is full- or low-speed.

Low-speed signaling begins with the host (or TT) issuing SYNC at low-speed, followed by the remainder of the packet. The end of the packet is identified by an End-of-Packet (EOP), at which time all hubs tear down connectivity and disable any ports to which low-speed devices are connected. Hubs do not switch ports for upstream signaling; low-speed ports remain enabled in the upstream direction for both low-speed and full-speed signaling.

Low-speed and full-speed transactions maintain a high degree of protocol commonality. However, low-speed signaling does have certain limitations which include:

- Data payload is limited to eight bytes, maximum.
- Only interrupt and control types of transfers are supported.
- The SOF packet is not received by low-speed devices.

8.7 Error Detection and Recovery

The USB permits reliable end-to-end communication in the presence of errors on the physical signaling layer. This includes the ability to reliably detect the vast majority of possible errors and to recover from errors on a transaction-type basis. Control transactions, for example, require a high degree of data reliability; they support end-to-end data integrity using error detection and retry. Isochronous transactions, by virtue of their bandwidth and latency requirements, do not permit retries and must tolerate a higher incidence of uncorrected errors.

8.7.1 Packet Error Categories

The USB employs three error detection mechanisms: bit stuff violations, PID check bits, and CRCs. Bit stuff violations are defined in Section 7.1.9. PID errors are defined in Section 8.3.1. CRC errors are defined in Section 8.3.5.

With the exception of the SOF token, any packet that is received corrupted causes the receiver to ignore it and discard any data or other field information that came with the packet. Table 8-8 lists error detection mechanisms, the types of packets to which they apply, and the appropriate packet receiver response.

Table 8-8. Packet Error Types

Field	Error	Action
PID	PID Check, Bit Stuff	Ignore packet
Address	Bit Stuff, Address CRC	Ignore token
Frame Number	Bit Stuff, Frame Number CRC	Ignore Frame Number field
Data	Bit Stuff, Data CRC	Discard data

8.7.2 Bus Turn-around Timing

Neither the device nor the host will send an indication that a received packet had an error. This absence of positive acknowledgement is considered to be the indication that there was an error. As a consequence of this method of error reporting, the host and USB function need to keep track of how much time has elapsed from when the transmitter completes sending a packet until it begins to receive a response packet. This time is referred to as the bus turn-around time. Devices and hosts require turn-around timers to measure this time.

For full-/low-speed transactions, the timer starts counting on the SE0-to-‘J’ transition of the EOP strobe and stops counting when the Idle-to-‘K’ SOP transition is detected. For high-speed transactions, the timer starts counting when the data lines return to the squelch level and stops counting when the data lines leave the squelch level.

The device bus turn-around time is defined by the worst case round trip delay plus the maximum device response delay (refer to Sections 7.1.18 and 7.1.19 for specific bus turn-around times). If a response is not received within this worst case timeout, then the transmitter considers that the packet transmission has failed.

Timeout is used and interpreted as a transaction error condition for many transfer types. If the host wishes to indicate an error condition for a transaction via a timeout, it must wait the full bus turn-around time before issuing the next token to ensure that all downstream devices have timed out.

As shown in Figure 8-49, the device uses its bus turn-around timer between token and data or data and handshake phases. The host uses its timer between data and handshake or token and data phases.

If the host receives a corrupted data packet, it may require additional wait time before sending out the next token. This additional wait interval guarantees that the host properly handles false EOPs.

Figure 8-49. Bus Turn-around Timer Usage

8.7.3 False EOPs

False EOPs must be handled in a manner which guarantees that the packet currently in progress completes before the host or any other device attempts to transmit a new packet. If such an event were to occur, it would constitute a bus collision and have the ability to corrupt up to two consecutive transactions. Detection of false EOP relies upon the fact that a packet into which a false EOP has been inserted will appear as a truncated packet with a CRC failure. (The last 16 bits of the data packet will have a very low probability of appearing to be a correct CRC.)

The host and devices handle false EOP situations differently. When a device receives a corrupted data packet, it issues no response and waits for the host to send the next token. This scheme guarantees that the device will not attempt to return a handshake while the host may still be transmitting a data packet. If a false EOP has occurred, the host data packet will eventually end, and the device will be able to detect the next token. If a device issues a data packet that gets corrupted with a false EOP, the host will ignore the

packet and not issue the handshake. The device, expecting to see a handshake from the host, will timeout the transaction.

If the host receives a corrupted full-/low-speed data packet, it assumes that a false EOP may have occurred and waits for 16 bit times to see if there is any subsequent upstream traffic. If no bus transitions are detected within the 16 bit interval and the bus remains in the Idle state, the host may issue the next token.

Otherwise, the host waits for the device to finish sending the remainder of its full-/low-speed packet. Waiting 16 bit times guarantees two conditions:

- The first condition is to make sure that the device has finished sending its packet. This is guaranteed by a timeout interval (with no bus transitions) greater than the worst case six-bit time bit stuff interval.
- The second condition is that the transmitting device's bus turn-around timer must be guaranteed to expire.

Note that the timeout interval is transaction speed sensitive. For full-speed transactions, the host must wait full-speed bit times; for low-speed transactions, it must wait low-speed bit times.

If the host receives a corrupted high-speed data packet, it ignores any data until the data lines return to the squelch level before issuing the next token. For high-speed transactions, the host does not need to wait additional time (beyond the normal inter-transaction gap time) after the data lines return to the squelch level.

If the host receives a data packet with a valid CRC, it assumes that the packet is complete and requires no additional delay (beyond normal inter-transaction gap time) in issuing the next token.

8.7.4 Babble and Loss of Activity Recovery

The USB must be able to detect and recover from conditions which leave it waiting indefinitely for a full-/low-speed EOP or which leave the bus in something other than the Idle state at the end of a (micro)frame.

- Full-/low-speed loss of activity (LOA) is characterized by an SOP followed by lack of bus activity (bus remains driven to a 'J' or 'K') and no EOP at the end of a frame.
- Full-/low-speed babble is characterized by an SOP followed by the presence of bus activity past the end of a frame.
- High-speed babble/LOA is characterized by the data lines being at an unsquelched level at the end of a microframe.

LOA and babble have the potential to either deadlock the bus or delay the beginning of the next (micro)frame. Neither condition is acceptable, and both must be prevented from occurring. As the USB component responsible for controlling connectivity, hubs are responsible for babble/LOA detection and recovery. All USB devices that fail to complete their transmission at the end of a (micro)frame are prevented from transmitting past a (micro)frame's end by having the nearest hub disable the port to which the offending device is attached. Details of the hub babble/LOA recovery mechanism appear in Section 11.2.5.

Chapter 9

USB Device Framework

A USB device may be divided into three layers:

- The bottom layer is a bus interface that transmits and receives packets.
- The middle layer handles routing data between the bus interface and various endpoints on the device. An endpoint is the ultimate consumer or provider of data. It may be thought of as a source or sink for data.
- The top layer is the functionality provided by the serial bus device, for instance, a mouse or ISDN interface.

This chapter describes the common attributes and operations of the middle layer of a USB device. These attributes and operations are used by the function-specific portions of the device to communicate through the bus interface and ultimately with the host.

9.1 USB Device States

A USB device has several possible states. Some of these states are visible to the USB and the host, while others are internal to the USB device. This section describes those states.

9.1.1 Visible Device States

This section describes USB device states that are externally visible (see Figure 9-1). Table 9-1 summarizes the visible device states.

Note: USB devices perform a reset operation in response to reset signaling on the upstream facing port. When reset signaling has completed, the USB device is reset.

Figure 9-1. Device State Diagram

Table 9-1. Visible Device States

Attached	Powered	Default	Address	Configured	Suspended	State
No	--	--	--	--	--	Device is not attached to the USB. Other attributes are not significant.
Yes	No	--	--	--	--	Device is attached to the USB, but is not powered. Other attributes are not significant.
Yes	Yes	No	--	--	--	Device is attached to the USB and powered, but has not been reset.
Yes	Yes	Yes	No	--	--	Device is attached to the USB and powered and has been reset, but has not been assigned a unique address. Device responds at the default address.
Yes	Yes	Yes	Yes	No	--	Device is attached to the USB, powered, has been reset, and a unique device address has been assigned. Device is not configured.
Yes	Yes	Yes	Yes	Yes	No	Device is attached to the USB, powered, has been reset, has a unique address, is configured, and is not suspended. The host may now use the function provided by the device.
Yes	Yes	--	--	--	Yes	Device is, at minimum, attached to the USB and is powered and has not seen bus activity for 3 ms. It may also have a unique address and be configured for use. However, because the device is suspended, the host may not use the device's function.

9.1.1.1 Attached

A USB device may be attached or detached from the USB. The state of a USB device when it is detached from the USB is not defined by this specification. This specification only addresses required operations and attributes once the device is attached.

9.1.1.2 Powered

USB devices may obtain power from an external source and/or from the USB through the hub to which they are attached. Externally powered USB devices are termed self-powered. Although self-powered devices may already be powered before they are attached to the USB, they are not considered to be in the Powered state until they are attached to the USB and VBUS is applied to the device.

A device may support both self-powered and bus-powered configurations. Some device configurations support either power source. Other device configurations may be available only if the device is self-powered. Devices report their power source capability through the configuration descriptor. The current power source is reported as part of a device's status. Devices may change their power source at any time, e.g., from self- to bus-powered. If a configuration is capable of supporting both power modes, the power maximum reported for that configuration is the maximum the device will draw from VBUS in either mode. The device must observe this maximum, regardless of its mode. If a configuration supports only one power mode and the power source of the device changes, the device will lose its current configuration and address and return to the Powered state. If a device is self-powered and its current configuration requires more than 100 mA, then if the device switches to being bus-powered, it must return to the Address state. Self-powered hubs that use VBUS to power the Hub Controller are allowed to remain in the Configured state if local power is lost. Refer to Section 11.13 for details.

A hub port must be powered in order to detect port status changes, including attach and detach. Bus-powered hubs do not provide any downstream power until they are configured, at which point they will provide power as allowed by their configuration and power source. A USB device must be able to be addressed within a specified time period from when power is initially applied (refer to Chapter 7). After an attachment to a port has been detected, the host may enable the port, which will also reset the device attached to the port.

9.1.1.3 Default

After the device has been powered, it must not respond to any bus transactions until it has received a reset from the bus. After receiving a reset, the device is then addressable at the default address.

When the reset process is complete, the USB device is operating at the correct speed (i.e., low-/full-/high-speed). The speed selection for low- and full-speed is determined by the device termination resistors. A device that is capable of high-speed operation determines whether it will operate at high-speed as a part of the reset process (see Chapter 7 for more details).

A device capable of high-speed operation must reset successfully at full-speed when in an electrical environment that is operating at full-speed. After the device is successfully reset, the device must also respond successfully to device and configuration descriptor requests and return appropriate information. The device may or may not be able to support its intended functionality when operating at full-speed.

9.1.1.4 Address

All USB devices use the default address when initially powered or after the device has been reset. Each USB device is assigned a unique address by the host after attachment or after reset. A USB device maintains its assigned address while suspended.

A USB device responds to requests on its default pipe whether the device is currently assigned a unique address or is using the default address.

9.1.1.5 Configured

Before a USB device's function may be used, the device must be configured. From the device's perspective, configuration involves correctly processing a SetConfiguration() request with a non-zero configuration value. Configuring a device or changing an alternate setting causes all of the status and configuration values associated with endpoints in the affected interfaces to be set to their default values. This includes setting the data toggle of any endpoint using data toggles to the value DATA0.

9.1.1.6 Suspended

In order to conserve power, USB devices automatically enter the Suspended state when the device has observed no bus traffic for a specified period (refer to Chapter 7). When suspended, the USB device maintains any internal status, including its address and configuration.

All devices must suspend if bus activity has not been observed for the length of time specified in Chapter 7. Attached devices must be prepared to suspend at any time they are powered, whether they have been assigned a non-default address or are configured. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the Suspended state when the hub port it is attached to is disabled. This is referred to as selective suspend.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If a USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

9.1.2 Bus Enumeration

When a USB device is attached to or removed from the USB, the host uses a process known as bus enumeration to identify and manage the device state changes necessary. When a USB device is attached to a powered port, the following actions are taken:

1. The hub to which the USB device is now attached informs the host of the event via a reply on its status change pipe (refer to Section 11.12.3 for more information). At this point, the USB device is in the Powered state and the port to which it is attached is disabled.
2. The host determines the exact nature of the change by querying the hub.
3. Now that the host knows the port to which the new device has been attached, the host then waits for at least 100 ms to allow completion of an insertion process and for power at the device to become stable. The host then issues a port enable and reset command to that port. Refer to Section 7.1.7.5 for sequence of events and timings of connection through device reset.
4. The hub performs the required reset processing for that port (see Section 11.5.1.5). When the reset signal is released, the port has been enabled. The USB device is now in the Default state and can draw no more than 100 mA from VBUS. All of its registers and state have been reset and it answers to the default address.
5. The host assigns a unique address to the USB device, moving the device to the Address state.
6. Before the USB device receives a unique address, its Default Control Pipe is still accessible via the default address. The host reads the device descriptor to determine what actual maximum data payload size this USB device's default pipe can use.
7. The host reads the configuration information from the device by reading each configuration zero to $n-1$, where n is the number of configurations. This process may take several milliseconds to complete.

8. Based on the configuration information and how the USB device will be used, the host assigns a configuration value to the device. The device is now in the Configured state and all of the endpoints in this configuration have taken on their described characteristics. The USB device may now draw the amount of VBUS power described in its descriptor for the selected configuration. From the device's point of view, it is now ready for use.

When the USB device is removed, the hub again sends a notification to the host. Detaching a device disables the port to which it had been attached. Upon receiving the detach notification, the host will update its local topological information.

9.2 Generic USB Device Operations

All USB devices support a common set of operations. This section describes those operations.

9.2.1 Dynamic Attachment and Removal

USB devices may be attached and removed at any time. The hub that provides the attachment point or port is responsible for reporting any change in the state of the port.

The host enables the hub port where the device is attached upon detection of an attachment, which also has the effect of resetting the device. A reset USB device has the following characteristics:

- Responds to the default USB address
- Is not configured
- Is not initially suspended

When a device is removed from a hub port, the hub disables the port where the device was attached and notifies the host of the removal.

9.2.2 Address Assignment

When a USB device is attached, the host is responsible for assigning a unique address to the device. This is done after the device has been reset by the host, and the hub port where the device is attached has been enabled.

9.2.3 Configuration

A USB device must be configured before its function(s) may be used. The host is responsible for configuring a USB device. The host typically requests configuration information from the USB device to determine the device's capabilities.

As part of the configuration process, the host sets the device configuration and, where necessary, selects the appropriate alternate settings for the interfaces.

Within a single configuration, a device may support multiple interfaces. An interface is a related set of endpoints that present a single feature or function of the device to the host. The protocol used to communicate with this related set of endpoints and the purpose of each endpoint within the interface may be specified as part of a device class or vendor-specific definition.

In addition, an interface within a configuration may have alternate settings that redefine the number or characteristics of the associated endpoints. If this is the case, the device must support the `GetInterface()` request to report the current alternate setting for the specified interface and `SetInterface()` request to select the alternate setting for the specified interface.

Within each configuration, each interface descriptor contains fields that identify the interface number and the alternate setting. Interfaces are numbered from zero to one less than the number of concurrent interfaces supported by the configuration. Alternate settings range from zero to one less than the number of alternate

settings for a specific interface. The default setting when a device is initially configured is alternate setting zero.

In support of adaptive device drivers that are capable of managing a related group of USB devices, the device and interface descriptors contain *Class*, *SubClass*, and *Protocol* fields. These fields are used to identify the function(s) provided by a USB device and the protocols used to communicate with the function(s) on the device. A class code is assigned to a group of related devices that has been characterized as a part of a USB Class Specification. A class of devices may be further subdivided into subclasses, and, within a class or subclass, a protocol code may define how the Host Software communicates with the device.

Note: The assignment of class, subclass, and protocol codes must be coordinated but is beyond the scope of this specification.

9.2.4 Data Transfer

Data may be transferred between a USB device endpoint and the host in one of four ways. Refer to Chapter 5 for the definition of the four types of transfers. An endpoint number may be used for different types of data transfers in different alternate settings. However, once an alternate setting is selected (including the default setting of an interface), a USB device endpoint uses only one data transfer method until a different alternate setting is selected.

9.2.5 Power Management

Power management on USB devices involves the issues described in the following sections.

9.2.5.1 Power Budgeting

USB bus power is a limited resource. During device enumeration, a host evaluates a device's power requirements. If the power requirements of a particular configuration exceed the power available to the device, Host Software shall not select that configuration.

USB devices shall limit the power they consume from VBUS to one unit load or less until configured. Suspended devices, whether configured or not, shall limit their bus power consumption as defined in Chapter 7. Depending on the power capabilities of the port to which the device is attached, a USB device may be able to draw up to five unit loads from VBUS after configuration.

9.2.5.2 Remote Wakeup

Remote wakeup allows a suspended USB device to signal a host that may also be suspended. This notifies the host that it should resume from its suspended mode, if necessary, and service the external event that triggered the suspended USB device to signal the host. A USB device reports its ability to support remote wakeup in a configuration descriptor. If a device supports remote wakeup, it must also allow the capability to be enabled and disabled using the standard USB requests.

Remote wakeup is accomplished using electrical signaling described in Section 7.1.7.7.

9.2.6 Request Processing

With the exception of `SetAddress()` requests (see Section 9.4.6), a device may begin processing of a request as soon as the device returns the ACK following the Setup. The device is expected to “complete” processing of the request before it allows the Status stage to complete successfully. Some requests initiate operations that take many milliseconds to complete. For requests such as this, the device class is required to define a method other than Status stage completion to indicate that the operation has completed. For example, a reset on a hub port takes at least 10 ms to complete. The `SetPortFeature(PORT_RESET)` (see Chapter 11) request “completes” when the reset on the port is initiated. Completion of the reset operation is

signaled when the port's status change is set to indicate that the port is now enabled. This technique prevents the host from having to constantly poll for a completion when it is known that the request will take a relatively long period of time.

9.2.6.1 Request Processing Timing

All devices are expected to handle requests in a timely manner. USB sets an upper limit of 5 seconds as the upper limit for any command to be processed. This limit is not applicable in all instances. The limitations are described in the following sections. It should be noted that the limitations given below are intended to encompass a wide range of implementations. If all devices in a USB system used the maximum allotted time for request processing, the user experience would suffer. For this reason, implementations should strive to complete requests in times that are as short as possible.

9.2.6.2 Reset/Resume Recovery Time

After a port is reset or resumed, the USB System Software is expected to provide a "recovery" interval of 10 ms before the device attached to the port is expected to respond to data transfers. The device may ignore any data transfers during the recovery interval.

After the end of the recovery interval (measured from the end of the reset or the end of the EOP at the end of the resume signaling), the device must accept data transfers at any time.

9.2.6.3 Set Address Processing

After the reset/resume recovery interval, if a device receives a SetAddress() request, the device must be able to complete processing of the request and be able to successfully complete the Status stage of the request within 50 ms. In the case of the SetAddress() request, the Status stage successfully completes when the device sends the zero-length Status packet or when the device sees the ACK in response to the Status stage data packet.

After successful completion of the Status stage, the device is allowed a SetAddress() recovery interval of 2 ms. At the end of this interval, the device must be able to accept Setup packets addressed to the new address. Also, at the end of the recovery interval, the device must not respond to tokens sent to the old address (unless, of course, the old and new address is the same).

9.2.6.4 Standard Device Requests

For standard device requests that require no Data stage, a device must be able to complete the request and be able to successfully complete the Status stage of the request within 50 ms of receipt of the request. This limitation applies to requests to the device, interface, or endpoint.

For standard device requests that require data stage transfer to the host, the device must be able to return the first data packet to the host within 500 ms of receipt of the request. For subsequent data packets, if any, the device must be able to return them within 500 ms of successful completion of the transmission of the previous packet. The device must then be able to successfully complete the status stage within 50 ms after returning the last data packet.

For standard device requests that require a data stage transfer to the device, the 5-second limit applies. This means that the device must be capable of accepting all data packets from the host and successfully completing the Status stage if the host provides the data at the maximum rate at which the device can accept it. Delays between packets introduced by the host add to the time allowed for the device to complete the request.

9.2.6.5 Class-specific Requests

Unless specifically exempted in the class document, all class-specific requests must meet the timing limitations for standard device requests. If a class document provides an exemption, the exemption may only be specified on a request-by-request basis.

A class document may require that a device respond more quickly than is specified in this section. Faster response may be required for standard and class-specific requests.

9.2.6.6 Speed Dependent Descriptors

A device capable of operation at high-speed can operate in either full- or high-speed. The device always knows its operational speed due to having to manage its transceivers correctly as part of reset processing (See Chapter 7 for more details on reset). A device also operates at a single speed after completing the reset sequence. In particular, there is no speed switch during normal operation. However, a high-speed capable device may have configurations that are speed dependent. That is, it may have some configurations that are only possible when operating at high-speed or some that are only possible when operating at full-speed. High-speed capable devices must support reporting their speed dependent configurations.

A high-speed capable device responds with descriptor information that is valid for the current operating speed. For example, when a device is asked for configuration descriptors, it only returns those for the current operating speed (e.g., full speed). However, there must be a way to determine the capabilities for both high- and full-speed operation.

Two descriptors allow a high-speed capable device to report configuration information about the other operating speed. The two descriptors are: the (`other_speed`) `device_qualifier` descriptor and the `other_speed_configuration` descriptor. These two descriptors are retrieved by the host by using the `GetDescriptor` request with the corresponding descriptor type values.

Note: These descriptors are not retrieved unless the host explicitly issues the corresponding `GetDescriptor` requests. If these two requests are not issued, the device would simply appear to be a single speed device.

Devices that are high-speed capable must set the version number in the `bcdUSB` field of their descriptors to 0200H. This indicates that such devices support the `other_speed` requests defined by USB 2.0. A device with descriptor version numbers less than 0200H should cause a Request Error response (see next section) if it receives these `other_speed` requests. A USB 1.x device (i.e., one with a device descriptor version less than 0200H) should not be issued the `other_speed` requests.

9.2.7 Request Error

When a request is received by a device that is not defined for the device, is inappropriate for the current setting of the device, or has values that are not compatible with the request, then a Request Error exists. The device deals with the Request Error by returning a STALL PID in response to the next Data stage transaction or in the Status stage of the message. It is preferred that the STALL PID be returned at the next Data stage transaction, as this avoids unnecessary bus activity.

9.3 USB Device Requests

All USB devices respond to requests from the host on the device’s Default Control Pipe. These requests are made using control transfers. The request and the request’s parameters are sent to the device in the Setup packet. The host is responsible for establishing the values passed in the fields listed in Table 9-2. Every Setup packet has eight bytes.

Table 9-2. Format of Setup Data

Offset	Field	Size	Value	Description
0	<i>bmRequestType</i>	1	Bitmap	Characteristics of request: D7: Data transfer direction 0 = Host-to-device 1 = Device-to-host D6...5: Type 0 = Standard 1 = Class 2 = Vendor 3 = Reserved D4...0: Recipient 0 = Device 1 = Interface 2 = Endpoint 3 = Other 4...31 = Reserved
1	<i>bRequest</i>	1	Value	Specific request (refer to Table 9-3)
2	<i>wValue</i>	2	Value	Word-sized field that varies according to request
4	<i>wIndex</i>	2	Index or Offset	Word-sized field that varies according to request; typically used to pass an index or offset
6	<i>wLength</i>	2	Count	Number of bytes to transfer if there is a Data stage

9.3.1 *bmRequestType*

This bitmapped field identifies the characteristics of the specific request. In particular, this field identifies the direction of data transfer in the second phase of the control transfer. The state of the *Direction* bit is ignored if the *wLength* field is zero, signifying there is no Data stage.

The USB Specification defines a series of standard requests that all devices must support. These are enumerated in Table 9-3. In addition, a device class may define additional requests. A device vendor may also define requests supported by the device.

Requests may be directed to the device, an interface on the device, or a specific endpoint on a device. This field also specifies the intended recipient of the request. When an interface or endpoint is specified, the *wIndex* field identifies the interface or endpoint.

9.3.2 bRequest

This field specifies the particular request. The *Type* bits in the *bmRequestType* field modify the meaning of this field. This specification defines values for the *bRequest* field only when the bits are reset to zero, indicating a standard request (refer to Table 9-3).

9.3.3 wValue

The contents of this field vary according to the request. It is used to pass a parameter to the device, specific to the request.

9.3.4 wIndex

The contents of this field vary according to the request. It is used to pass a parameter to the device, specific to the request.

The *wIndex* field is often used in requests to specify an endpoint or an interface. Figure 9-2 shows the format of *wIndex* when it is used to specify an endpoint.

D7	D6	D5	D4	D3	D2	D1	D0
Direction	Reserved (Reset to zero)			Endpoint Number			
D15	D14	D13	D12	D11	D10	D9	D8
Reserved (Reset to zero)							

Figure 9-2. wIndex Format when Specifying an Endpoint

The *Direction* bit is set to zero to indicate the OUT endpoint with the specified *Endpoint Number* and to one to indicate the IN endpoint. In the case of a control pipe, the request should have the *Direction* bit set to zero but the device may accept either value of the *Direction* bit.

Figure 9-3 shows the format of *wIndex* when it is used to specify an interface.

D7	D6	D5	D4	D3	D2	D1	D0
Interface Number							
D15	D14	D13	D12	D11	D10	D9	D8
Reserved (Reset to zero)							

Figure 9-3. wIndex Format when Specifying an Interface

9.3.5 wLength

This field specifies the length of the data transferred during the second phase of the control transfer. The direction of data transfer (host-to-device or device-to-host) is indicated by the *Direction* bit of the *bmRequestType* field. If this field is zero, there is no data transfer phase.

On an input request, a device must never return more data than is indicated by the *wLength* value; it may return less. On an output request, *wLength* will always indicate the exact amount of data to be sent by the host. Device behavior is undefined if the host should send more data than is specified in *wLength*.

9.4 Standard Device Requests

This section describes the standard device requests defined for all USB devices. Table 9-3 outlines the standard device requests, while Table 9-4 and Table 9-5 give the standard request codes and descriptor types, respectively.

USB devices must respond to standard device requests, even if the device has not yet been assigned an address or has not been configured.

Table 9-3. Standard Device Requests

bmRequestType	bRequest	wValue	wIndex	wLength	Data
00000000B 00000001B 00000010B	CLEAR_FEATURE	Feature Selector	Zero Interface Endpoint	Zero	None
10000000B	GET_CONFIGURATION	Zero	Zero	One	Configuration Value
10000000B	GET_DESCRIPTOR	Descriptor Type and Descriptor Index	Zero or Language ID	Descriptor Length	Descriptor
10000001B	GET_INTERFACE	Zero	Interface	One	Alternate Interface
10000000B 10000001B 10000010B	GET_STATUS	Zero	Zero Interface Endpoint	Two	Device, Interface, or Endpoint Status
00000000B	SET_ADDRESS	Device Address	Zero	Zero	None
00000000B	SET_CONFIGURATION	Configuration Value	Zero	Zero	None
00000000B	SET_DESCRIPTOR	Descriptor Type and Descriptor Index	Zero or Language ID	Descriptor Length	Descriptor
00000000B 00000001B 00000010B	SET_FEATURE	Feature Selector	Zero Interface Endpoint	Zero	None
00000001B	SET_INTERFACE	Alternate Setting	Interface	Zero	None
10000010B	SYNCH_FRAME	Zero	Endpoint	Two	Frame Number

Table 9-4. Standard Request Codes

bRequest	Value
GET_STATUS	0
CLEAR_FEATURE	1
Reserved for future use	2
SET_FEATURE	3
Reserved for future use	4
SET_ADDRESS	5
GET_DESCRIPTOR	6
SET_DESCRIPTOR	7
GET_CONFIGURATION	8
SET_CONFIGURATION	9
GET_INTERFACE	10
SET_INTERFACE	11
SYNCH_FRAME	12

Table 9-5. Descriptor Types

Descriptor Types	Value
DEVICE	1
CONFIGURATION	2
STRING	3
INTERFACE	4
ENDPOINT	5
DEVICE_QUALIFIER	6
OTHER_SPEED_CONFIGURATION	7
INTERFACE_POWER ¹	8

¹ The INTERFACE_POWER descriptor is defined in the current revision of the *USB Interface Power Management Specification*.

Feature selectors are used when enabling or setting features, such as remote wakeup, specific to a device, interface, or endpoint. The values for the feature selectors are given in Table 9-6.

Table 9-6. Standard Feature Selectors

Feature Selector	Recipient	Value
DEVICE_REMOTE_WAKEUP	Device	1
ENDPOINT_HALT	Endpoint	0
TEST_MODE	Device	2

If an unsupported or invalid request is made to a USB device, the device responds by returning STALL in the Data or Status stage of the request. If the device detects the error in the Setup stage, it is preferred that the device returns STALL at the earlier of the Data or Status stage. Receipt of an unsupported or invalid request does NOT cause the optional *Halt* feature on the control pipe to be set. If for any reason, the device becomes unable to communicate via its Default Control Pipe due to an error condition, the device must be reset to clear the condition and restart the Default Control Pipe.

9.4.1 Clear Feature

This request is used to clear or disable a specific feature.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0000000B 0000001B 0000010B	CLEAR_FEATURE	Feature Selector	Zero Interface Endpoint	Zero	None

Feature selector values in *wValue* must be appropriate to the recipient. Only device feature selector values may be used when the recipient is a device, only interface feature selector values may be used when the recipient is an interface, and only endpoint feature selector values may be used when the recipient is an endpoint.

Refer to Table 9-6 for a definition of which feature selector values are defined for which recipients.

A ClearFeature() request that references a feature that cannot be cleared, that does not exist, or that references an interface or endpoint that does not exist, will cause the device to respond with a Request Error.

If *wLength* is non-zero, then the device behavior is not specified.

Default state: Device behavior when this request is received while the device is in the Default state is not specified.

Address state: This request is valid when the device is in the Address state; references to interfaces or to endpoints other than endpoint zero shall cause the device to respond with a Request Error.

Configured state: This request is valid when the device is in the Configured state.

Note: The Test_Mode feature cannot be cleared by the ClearFeature() request.

9.4.2 Get Configuration

This request returns the current device configuration value.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1000000B	GET_CONFIGURATION	Zero	Zero	One	Configuration Value

If the returned value is zero, the device is not configured.

If *wValue*, *wIndex*, or *wLength* are not as specified above, then the device behavior is not specified.

Default state: Device behavior when this request is received while the device is in the Default state is not specified.

Address state: The value zero must be returned.

Configured state: The non-zero *bConfigurationValue* of the current configuration must be returned.

9.4.3 Get Descriptor

This request returns the specified descriptor if the descriptor exists.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1000000B	GET_DESCRIPTOR	Descriptor Type and Descriptor Index	Zero or Language ID (refer to Section 9.6.7)	Descriptor Length	Descriptor

The *wValue* field specifies the descriptor type in the high byte (refer to Table 9-5) and the descriptor index in the low byte. The descriptor index is used to select a specific descriptor (only for configuration and string descriptors) when several descriptors of the same type are implemented in a device. For example, a device can implement several configuration descriptors. For other standard descriptors that can be retrieved via a GetDescriptor() request, a descriptor index of zero must be used. The range of values used for a descriptor index is from 0 to one less than the number of descriptors of that type implemented by the device.

The *wIndex* field specifies the Language ID for string descriptors or is reset to zero for other descriptors. The *wLength* field specifies the number of bytes to return. If the descriptor is longer than the *wLength* field, only the initial bytes of the descriptor are returned. If the descriptor is shorter than the *wLength* field, the device indicates the end of the control transfer by sending a short packet when further data is requested. A short packet is defined as a packet shorter than the maximum payload size or a zero length data packet (refer to Chapter 5).

The standard request to a device supports three types of descriptors: device (also *device_qualifier*), configuration (also *other_speed_configuration*), and string. A high-speed capable device supports the *device_qualifier* descriptor to return information about the device for the speed at which it is not operating (including *wMaxPacketSize* for the default endpoint and the number of configurations for the other speed). The *other_speed_configuration* returns information in the same structure as a configuration descriptor, but for a configuration if the device were operating at the other speed. A request for a configuration descriptor returns the configuration descriptor, all interface descriptors, and endpoint descriptors for all of the

interfaces in a single request. The first interface descriptor follows the configuration descriptor. The endpoint descriptors for the first interface follow the first interface descriptor. If there are additional interfaces, their interface descriptor and endpoint descriptors follow the first interface's endpoint descriptors. Class-specific and/or vendor-specific descriptors follow the standard descriptors they extend or modify.

All devices must provide a device descriptor and at least one configuration descriptor. If a device does not support a requested descriptor, it responds with a Request Error.

Default state: This is a valid request when the device is in the Default state.

Address state: This is a valid request when the device is in the Address state.

Configured state: This is a valid request when the device is in the Configured state.

9.4.4 Get Interface

This request returns the selected alternate setting for the specified interface.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1000001B	GET_INTERFACE	Zero	Interface	One	Alternate Setting

Some USB devices have configurations with interfaces that have mutually exclusive settings. This request allows the host to determine the currently selected alternate setting.

If *wValue* or *wLength* are not as specified above, then the device behavior is not specified.

If the interface specified does not exist, then the device responds with a Request Error.

Default state: Device behavior when this request is received while the device is in the Default state is not specified.

Address state: A Request Error response is given by the device.

Configured state: This is a valid request when the device is in the Configured state.

9.4.5 Get Status

This request returns status for the specified recipient.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1000000B 1000001B 1000010B	GET_STATUS	Zero	Zero Interface Endpoint	Two	Device, Interface, or Endpoint Status

The *Recipient* bits of the *bmRequestType* field specify the desired recipient. The data returned is the current status of the specified recipient.

Universal Serial Bus Specification Revision 2.0

If *wValue* or *wLength* are not as specified above, or if *wIndex* is non-zero for a device status request, then the behavior of the device is not specified.

If an interface or an endpoint is specified that does not exist, then the device responds with a Request Error.

Default state: Device behavior when this request is received while the device is in the Default state is not specified.

Address state: If an interface or an endpoint other than endpoint zero is specified, then the device responds with a Request Error.

Configured state: If an interface or endpoint that does not exist is specified, then the device responds with a Request Error.

A `GetStatus()` request to a device returns the information shown in Figure 9-4.

D7	D6	D5	D4	D3	D2	D1	D0
Reserved (Reset to zero)						Remote Wakeup	Self Powered
D15	D14	D13	D12	D11	D10	D9	D8
Reserved (Reset to zero)							

Figure 9-4. Information Returned by a `GetStatus()` Request to a Device

The *Self Powered* field indicates whether the device is currently self-powered. If D0 is reset to zero, the device is bus-powered. If D0 is set to one, the device is self-powered. The *Self Powered* field may not be changed by the `SetFeature()` or `ClearFeature()` requests.

The *Remote Wakeup* field indicates whether the device is currently enabled to request remote wakeup. The default mode for devices that support remote wakeup is disabled. If D1 is reset to zero, the ability of the device to signal remote wakeup is disabled. If D1 is set to one, the ability of the device to signal remote wakeup is enabled. The *Remote Wakeup* field can be modified by the `SetFeature()` and `ClearFeature()` requests using the `DEVICE_REMOTE_WAKEUP` feature selector. This field is reset to zero when the device is reset.

A `GetStatus()` request to an interface returns the information shown in Figure 9-5.

D7	D6	D5	D4	D3	D2	D1	D0
Reserved (Reset to zero)							
D15	D14	D13	D12	D11	D10	D9	D8
Reserved (Reset to zero)							

Figure 9-5. Information Returned by a `GetStatus()` Request to an Interface

A GetStatus() request to an endpoint returns the information shown in Figure 9-6.

D7	D6	D5	D4	D3	D2	D1	D0
Reserved (Reset to zero)							Halt
D15	D14	D13	D12	D11	D10	D9	D8
Reserved (Reset to zero)							

Figure 9-6. Information Returned by a GetStatus() Request to an Endpoint

The *Halt* feature is required to be implemented for all interrupt and bulk endpoint types. If the endpoint is currently halted, then the *Halt* feature is set to one. Otherwise, the *Halt* feature is reset to zero. The *Halt* feature may optionally be set with the SetFeature(ENDPOINT_HALT) request. When set by the SetFeature() request, the endpoint exhibits the same stall behavior as if the field had been set by a hardware condition. If the condition causing a halt has been removed, clearing the *Halt* feature via a ClearFeature(ENDPOINT_HALT) request results in the endpoint no longer returning a STALL. For endpoints using data toggle, regardless of whether an endpoint has the *Halt* feature set, a ClearFeature(ENDPOINT_HALT) request always results in the data toggle being reinitialized to DATA0. The *Halt* feature is reset to zero after either a SetConfiguration() or SetInterface() request even if the requested configuration or interface is the same as the current configuration or interface.

It is neither required nor recommended that the *Halt* feature be implemented for the Default Control Pipe. However, devices may set the *Halt* feature of the Default Control Pipe in order to reflect a functional error condition. If the feature is set to one, the device will return STALL in the Data and Status stages of each standard request to the pipe except GetStatus(), SetFeature(), and ClearFeature() requests. The device need not return STALL for class-specific and vendor-specific requests.

9.4.6 Set Address

This request sets the device address for all future device accesses.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0000000B	SET_ADDRESS	Device Address	Zero	Zero	None

The *wValue* field specifies the device address to use for all subsequent accesses.

As noted elsewhere, requests actually may result in up to three stages. In the first stage, the Setup packet is sent to the device. In the optional second stage, data is transferred between the host and the device. In the final stage, status is transferred between the host and the device. The direction of data and status transfer depends on whether the host is sending data to the device or the device is sending data to the host. The Status stage transfer is always in the opposite direction of the Data stage. If there is no Data stage, the Status stage is from the device to the host.

Stages after the initial Setup packet assume the same device address as the Setup packet. The USB device does not change its device address until after the Status stage of this request is completed successfully. Note that this is a difference between this request and all other requests. For all other requests, the operation indicated must be completed before the Status stage.

If the specified device address is greater than 127, or if *wIndex* or *wLength* are non-zero, then the behavior of the device is not specified.

Universal Serial Bus Specification Revision 2.0

Device response to SetAddress() with a value of 0 is undefined.

Default state: If the address specified is non-zero, then the device shall enter the Address state; otherwise, the device remains in the Default state (this is not an error condition).

Address state: If the address specified is zero, then the device shall enter the Default state; otherwise, the device remains in the Address state but uses the newly-specified address.

Configured state: Device behavior when this request is received while the device is in the Configured state is not specified.

9.4.7 Set Configuration

This request sets the device configuration.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0000000B	SET_CONFIGURATION	Configuration Value	Zero	Zero	None

The lower byte of the *wValue* field specifies the desired configuration. This configuration value must be zero or match a configuration value from a configuration descriptor. If the configuration value is zero, the device is placed in its Address state. The upper byte of the *wValue* field is reserved.

If *wIndex*, *wLength*, or the upper byte of *wValue* is non-zero, then the behavior of this request is not specified.

Default state: Device behavior when this request is received while the device is in the Default state is not specified.

Address state: If the specified configuration value is zero, then the device remains in the Address state. If the specified configuration value matches the configuration value from a configuration descriptor, then that configuration is selected and the device enters the Configured state. Otherwise, the device responds with a Request Error.

Configured state: If the specified configuration value is zero, then the device enters the Address state. If the specified configuration value matches the configuration value from a configuration descriptor, then that configuration is selected and the device remains in the Configured state. Otherwise, the device responds with a Request Error.

9.4.8 Set Descriptor

This request is optional and may be used to update existing descriptors or new descriptors may be added.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0000000B	SET_DESCRIPTOR	Descriptor Type and Descriptor Index	Language ID (refer to Section 9.6.7) or zero	Descriptor Length	Descriptor

Universal Serial Bus Specification Revision 2.0

The *wValue* field specifies the descriptor type in the high byte (refer to Table 9-5) and the descriptor index in the low byte. The descriptor index is used to select a specific descriptor (only for configuration and string descriptors) when several descriptors of the same type are implemented in a device. For example, a device can implement several configuration descriptors. For other standard descriptors that can be set via a SetDescriptor() request, a descriptor index of zero must be used. The range of values used for a descriptor index is from 0 to one less than the number of descriptors of that type implemented by the device.

The *wIndex* field specifies the Language ID for string descriptors or is reset to zero for other descriptors. The *wLength* field specifies the number of bytes to transfer from the host to the device.

The only allowed values for descriptor type are device, configuration, and string descriptor types.

If this request is not supported, the device will respond with a Request Error.

Default state: Device behavior when this request is received while the device is in the Default state is not specified.

Address state: If supported, this is a valid request when the device is in the Address state.

Configured state: If supported, this is a valid request when the device is in the Configured state.

9.4.9 Set Feature

This request is used to set or enable a specific feature.

bmRequestType	bRequest	wValue	wIndex		wLength	Data
00000000B 00000001B 00000010B	SET_FEATURE	Feature Selector	Test Selector	Zero Interface Endpoint	Zero	None

Feature selector values in *wValue* must be appropriate to the recipient. Only device feature selector values may be used when the recipient is a device; only interface feature selector values may be used when the recipient is an interface, and only endpoint feature selector values may be used when the recipient is an endpoint.

Refer to Table 9-6 for a definition of which feature selector values are defined for which recipients.

The TEST_MODE feature is only defined for a device recipient (i.e., bmRequestType = 0) and the lower byte of wIndex must be zero. Setting the TEST_MODE feature puts the device upstream facing port into test mode. The device will respond with a request error if the request contains an invalid test selector. The transition to test mode must be complete no later than 3 ms after the completion of the status stage of the request. The transition to test mode of an upstream facing port must not happen until after the status stage of the request. The power to the device must be cycled to exit test mode of an upstream facing port of a device. See Section 7.1.20 for definitions of each test mode. A device must support the TEST_MODE feature when in the Default, Address or Configured high-speed device states.

A SetFeature() request that references a feature that cannot be set or that does not exist causes a STALL to be returned in the Status stage of the request.

Table 9-7. Test Mode Selectors

Value	Description
00H	Reserved
01H	Test_J
02H	Test_K
03H	Test_SE0_NAK
04H	Test_Packet
05H	Test_Force_Enable
06H-3FH	Reserved for standard test selectors
3FH-BFH	Reserved
C0H-FFH	Reserved for vendor-specific test modes.

If the feature selector is *TEST_MODE*, then the most significant byte of *wIndex* is used to specify the specific test mode. The recipient of a *SetFeature(TEST_MODE...)* must be the device; i.e., the lower byte of *wIndex* must be zero and the *bmRequestType* must be set to zero. The device must have its power cycled to exit test mode. The valid test mode selectors are listed in Table 9-7. See Section 7.1.20 for more information about the specific test modes.

If *wLength* is non-zero, then the behavior of the device is not specified.

If an endpoint or interface is specified that does not exist, then the device responds with a Request Error.

Default state: A device must be able to accept a *SetFeature(TEST_MODE, TEST_SELECTOR)* request when in the Default State. Device behavior for other *SetFeature* requests while the device is in the Default state is not specified.

Address state: If an interface or an endpoint other than endpoint zero is specified, then the device responds with a Request Error.

Configured state: This is a valid request when the device is in the Configured state.

9.4.10 Set Interface

This request allows the host to select an alternate setting for the specified interface.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
0000001B	SET_INTERFACE	Alternate Setting	Interface	Zero	None

Some USB devices have configurations with interfaces that have mutually exclusive settings. This request allows the host to select the desired alternate setting. If a device only supports a default setting for the specified interface, then a *STALL* may be returned in the Status stage of the request. This request cannot be used to change the set of configured interfaces (the *SetConfiguration()* request must be used instead).

If the interface or the alternate setting does not exist, then the device responds with a Request Error. If *wLength* is non-zero, then the behavior of the device is not specified.

- Default state:** Device behavior when this request is received while the device is in the Default state is not specified.
- Address state:** The device must respond with a Request Error.
- Configured state:** This is a valid request when the device is in the Configured state.

9.4.11 Synch Frame

This request is used to set and then report an endpoint’s synchronization frame.

bmRequestType	bRequest	wValue	wIndex	wLength	Data
10000010B	SYNCH_FRAME	Zero	Endpoint	Two	Frame Number

When an endpoint supports isochronous transfers, the endpoint may also require per-frame transfers to vary in size according to a specific pattern. The host and the endpoint must agree on which frame the repeating pattern begins. The number of the frame in which the pattern began is returned to the host.

If a high-speed device supports the Synch Frame request, it must internally synchronize itself to the zeroth microframe and have a time notion of classic frame. Only the frame number is used to synchronize and reported by the device endpoint (i.e., no microframe number). The endpoint must synchronize to the zeroth microframe.

This value is only used for isochronous data transfers using implicit pattern synchronization. If *wValue* is non-zero or *wLength* is not two, then the behavior of the device is not specified.

If the specified endpoint does not support this request, then the device will respond with a Request Error.

- Default state:** Device behavior when this request is received while the device is in the Default state is not specified.
- Address state:** The device shall respond with a Request Error.
- Configured state:** This is a valid request when the device is in the Configured state.

9.5 Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type.

Using descriptors allows concise storage of the attributes of individual configurations because each configuration may reuse descriptors or portions of descriptors from other configurations that have the same characteristics. In this manner, the descriptors resemble individual data records in a relational database.

Where appropriate, descriptors contain references to string descriptors that provide displayable information describing a descriptor in human-readable form. The inclusion of string descriptors is optional. However, the reference fields within descriptors are mandatory. If a device does not support string descriptors, string reference fields must be reset to zero to indicate no string descriptor is available.

If a descriptor returns with a value in its length field that is less than defined by this specification, the descriptor is invalid and should be rejected by the host. If the descriptor returns with a value in its length

field that is greater than defined by this specification, the extra bytes are ignored by the host, but the next descriptor is located using the length returned rather than the length expected.

A device may return class- or vendor-specific descriptors in two ways:

1. If the class or vendor specific descriptors use the same format as standard descriptors (e.g., start with a length byte and followed by a type byte), they must be returned interleaved with standard descriptors in the configuration information returned by a `GetDescriptor(Configuration)` request. In this case, the class or vendor-specific descriptors must follow a related standard descriptor they modify or extend.
2. If the class or vendor specific descriptors are independent of configuration information or use a non-standard format, a `GetDescriptor()` request specifying the class or vendor specific descriptor type and index may be used to retrieve the descriptor from the device. A class or vendor specification will define the appropriate way to retrieve these descriptors.

9.6 Standard USB Descriptor Definitions

The standard descriptors defined in this specification may only be modified or extended by revision of the Universal Serial Bus Specification.

Note: An extension to the USB 1.0 standard endpoint descriptor has been published in Device Class Specification for Audio Devices Revision 1.0. This is the only extension defined outside USB Specification that is allowed. Future revisions of the USB Specification that extend the standard endpoint descriptor will do so as to not conflict with the extension defined in the Audio Device Class Specification Revision 1.0.

9.6.1 Device

A device descriptor describes general information about a USB device. It includes information that applies globally to the device and all of the device's configurations. A USB device has only one device descriptor.

A high-speed capable device that has different device information for full-speed and high-speed must also have a `device_qualifier` descriptor (see Section 9.6.2).

The `DEVICE` descriptor of a high-speed capable device has a version number of 2.0 (0200H). If the device is full-speed only or low-speed only, this version number indicates that it will respond correctly to a request for the `device_qualifier` descriptor (i.e., it will respond with a request error).

The `bcdUSB` field contains a BCD version number. The value of the `bcdUSB` field is 0xJJMN for version JJ.M.N (JJ – major version number, M – minor version number, N – sub-minor version number), e.g., version 2.1.3 is represented with value 0x0213 and version 2.0 is represented with a value of 0x0200.

The `bNumConfigurations` field indicates the number of configurations at the current operating speed. Configurations for the other operating speed are not included in the count. If there are specific configurations of the device for specific speeds, the `bNumConfigurations` field only reflects the number of configurations for a single speed, not the total number of configurations for both speeds.

If the device is operating at high-speed, the `bMaxPacketSize0` field must be 64 indicating a 64 byte maximum packet. High-speed operation does not allow other maximum packet sizes for the control endpoint (endpoint 0).

All USB devices have a Default Control Pipe. The maximum packet size of a device's Default Control Pipe is described in the device descriptor. Endpoints specific to a configuration and its interface(s) are described in the configuration descriptor. A configuration and its interface(s) do not include an endpoint descriptor for the Default Control Pipe. Other than the maximum packet size, the characteristics of the Default Control Pipe are defined by this specification and are the same for all USB devices.

The `bNumConfigurations` field identifies the number of configurations the device supports. Table 9-8 shows the standard device descriptor.

Table 9-8. Standard Device Descriptor

Offset	Field	Size	Value	Description
0	<i>bLength</i>	1	Number	Size of this descriptor in bytes
1	<i>bDescriptorType</i>	1	Constant	DEVICE Descriptor Type
2	<i>bcdUSB</i>	2	BCD	USB Specification Release Number in Binary-Coded Decimal (i.e., 2.10 is 210H). This field identifies the release of the USB Specification with which the device and its descriptors are compliant.
4	<i>bDeviceClass</i>	1	Class	<p>Class code (assigned by the USB-IF).</p> <p>If this field is reset to zero, each interface within a configuration specifies its own class information and the various interfaces operate independently.</p> <p>If this field is set to a value between 1 and FEH, the device supports different class specifications on different interfaces and the interfaces may not operate independently. This value identifies the class definition used for the aggregate interfaces.</p> <p>If this field is set to FFH, the device class is vendor-specific.</p>
5	<i>bDeviceSubClass</i>	1	SubClass	<p>Subclass code (assigned by the USB-IF).</p> <p>These codes are qualified by the value of the <i>bDeviceClass</i> field.</p> <p>If the <i>bDeviceClass</i> field is reset to zero, this field must also be reset to zero.</p> <p>If the <i>bDeviceClass</i> field is not set to FFH, all values are reserved for assignment by the USB-IF.</p>

Table 9-8. Standard Device Descriptor (Continued)

Offset	Field	Size	Value	Description
6	<i>bDeviceProtocol</i>	1	Protocol	<p>Protocol code (assigned by the USB-IF). These codes are qualified by the value of the <i>bDeviceClass</i> and the <i>bDeviceSubClass</i> fields. If a device supports class-specific protocols on a device basis as opposed to an interface basis, this code identifies the protocols that the device uses as defined by the specification of the device class.</p> <p>If this field is reset to zero, the device does not use class-specific protocols on a device basis. However, it may use class-specific protocols on an interface basis.</p> <p>If this field is set to FFH, the device uses a vendor-specific protocol on a device basis.</p>
7	<i>bMaxPacketSize0</i>	1	Number	Maximum packet size for endpoint zero (only 8, 16, 32, or 64 are valid)
8	<i>idVendor</i>	2	ID	Vendor ID (assigned by the USB-IF)
10	<i>idProduct</i>	2	ID	Product ID (assigned by the manufacturer)
12	<i>bcdDevice</i>	2	BCD	Device release number in binary-coded decimal
14	<i>iManufacturer</i>	1	Index	Index of string descriptor describing manufacturer
15	<i>iProduct</i>	1	Index	Index of string descriptor describing product
16	<i>iSerialNumber</i>	1	Index	Index of string descriptor describing the device's serial number
17	<i>bNumConfigurations</i>	1	Number	Number of possible configurations

9.6.2 Device_Qualifier

The device_qualifier descriptor describes information about a high-speed capable device that would change if the device were operating at the other speed. For example, if the device is currently operating at full-speed, the device_qualifier returns information about how it would operate at high-speed and vice-versa. Table 9-9 shows the fields of the device_qualifier descriptor.

Table 9-9. Device_Qualifier Descriptor

Offset	Field	Size	Value	Description
0	<i>bLength</i>	1	Number	Size of descriptor
1	<i>bDescriptorType</i>	1	Constant	Device Qualifier Type
2	<i>bcdUSB</i>	2	BCD	USB specification version number (e.g., 0200H for V2.00)
4	<i>bDeviceClass</i>	1	Class	Class Code
5	<i>bDeviceSubClass</i>	1	SubClass	SubClass Code
6	<i>bDeviceProtocol</i>	1	Protocol	Protocol Code
7	<i>bMaxPacketSize0</i>	1	Number	Maximum packet size for other speed
8	<i>bNumConfigurations</i>	1	Number	Number of Other-speed Configurations
9	<i>bReserved</i>	1	Zero	Reserved for future use, must be zero

The vendor, product, device, manufacturer, product, and serialnumber fields of the standard device descriptor are not included in this descriptor since that information is constant for a device for all supported speeds. The version number for this descriptor must be at least 2.0 (0200H).

The host accesses this descriptor using the GetDescriptor() request. The descriptor type in the GetDescriptor() request is set to device_qualifier (see Table 9-5).

If a full-speed only device (with a device descriptor version number equal to 0200H) receives a GetDescriptor() request for a device_qualifier, it must respond with a request error. The host must not make a request for an other_speed_configuration descriptor unless it first successfully retrieves the device_qualifier descriptor.

9.6.3 Configuration

The configuration descriptor describes information about a specific device configuration. The descriptor contains a *bConfigurationValue* field with a value that, when used as a parameter to the SetConfiguration() request, causes the device to assume the described configuration.

The descriptor describes the number of interfaces provided by the configuration. Each interface may operate independently. For example, an ISDN device might be configured with two interfaces, each providing 64 Kb/s bi-directional channels that have separate data sources or sinks on the host. Another configuration might present the ISDN device as a single interface, bonding the two channels into one 128 Kb/s bi-directional channel.

When the host requests the configuration descriptor, all related interface and endpoint descriptors are returned (refer to Section 9.4.3).

Universal Serial Bus Specification Revision 2.0

A USB device has one or more configuration descriptors. Each configuration has one or more interfaces and each interface has zero or more endpoints. An endpoint is not shared among interfaces within a single configuration unless the endpoint is used by alternate settings of the same interface. Endpoints may be shared among interfaces that are part of different configurations without this restriction.

Once configured, devices may support limited adjustments to the configuration. If a particular interface has alternate settings, an alternate may be selected after configuration. Table 9-10 shows the standard configuration descriptor.

Table 9-10. Standard Configuration Descriptor

Offset	Field	Size	Value	Description
0	<i>bLength</i>	1	Number	Size of this descriptor in bytes
1	<i>bDescriptorType</i>	1	Constant	CONFIGURATION Descriptor Type
2	<i>wTotalLength</i>	2	Number	Total length of data returned for this configuration. Includes the combined length of all descriptors (configuration, interface, endpoint, and class- or vendor-specific) returned for this configuration.
4	<i>bNumInterfaces</i>	1	Number	Number of interfaces supported by this configuration
5	<i>bConfigurationValue</i>	1	Number	Value to use as an argument to the SetConfiguration() request to select this configuration
6	<i>iConfiguration</i>	1	Index	Index of string descriptor describing this configuration

Table 9-10. Standard Configuration Descriptor (Continued)

Offset	Field	Size	Value	Description
7	<i>bmAttributes</i>	1	Bitmap	<p>Configuration characteristics</p> <p>D7: Reserved (set to one) D6: Self-powered D5: Remote Wakeup D4...0: Reserved (reset to zero)</p> <p>D7 is reserved and must be set to one for historical reasons.</p> <p>A device configuration that uses power from the bus and a local source reports a non-zero value in <i>bMaxPower</i> to indicate the amount of bus power required and sets D6. The actual power source at runtime may be determined using the <i>GetStatus(DEVICE)</i> request (see Section 9.4.5).</p> <p>If a device configuration supports remote wakeup, D5 is set to one.</p>
8	<i>bMaxPower</i>	1	mA	<p>Maximum power consumption of the USB device from the bus in this specific configuration when the device is fully operational. Expressed in 2 mA units (i.e., 50 = 100 mA).</p> <p>Note: A device configuration reports whether the configuration is bus-powered or self-powered. Device status reports whether the device is currently self-powered. If a device is disconnected from its external power source, it updates device status to indicate that it is no longer self-powered.</p> <p>A device may not increase its power draw from the bus, when it loses its external power source, beyond the amount reported by its configuration.</p> <p>If a device can continue to operate when disconnected from its external power source, it continues to do so. If the device cannot continue to operate, it fails operations it can no longer support. The USB System Software may determine the cause of the failure by checking the status and noting the loss of the device's power source.</p>

9.6.4 Other_Speed_Configuration

The *other_speed_configuration* descriptor shown in Table 9-11 describes a configuration of a high-speed capable device if it were operating at its other possible speed. The structure of the *other_speed_configuration* is identical to a configuration descriptor.

Table 9-11. Other_Speed_Configuration Descriptor

Offset	Field	Size	Value	Description
0	<i>bLength</i>	1	Number	Size of descriptor
1	<i>bDescriptorType</i>	1	Constant	Other_speed_Configuration Type
2	<i>wTotalLength</i>	2	Number	Total length of data returned
4	<i>bNumInterfaces</i>	1	Number	Number of interfaces supported by this speed configuration
5	<i>bConfigurationValue</i>	1	Number	Value to use to select configuration
6	<i>iConfiguration</i>	1	Index	Index of string descriptor
7	<i>bmAttributes</i>	1	Bitmap	Same as Configuration descriptor
8	<i>bMaxPower</i>	1	mA	Same as Configuration descriptor

The host accesses this descriptor using the GetDescriptor() request. The descriptor type in the GetDescriptor() request is set to other_speed_configuration (see Table 9-5).

9.6.5 Interface

The interface descriptor describes a specific interface within a configuration. A configuration provides one or more interfaces, each with zero or more endpoint descriptors describing a unique set of endpoints within the configuration. When a configuration supports more than one interface, the endpoint descriptors for a particular interface follow the interface descriptor in the data returned by the GetConfiguration() request. An interface descriptor is always returned as part of a configuration descriptor. Interface descriptors cannot be directly accessed with a GetDescriptor() or SetDescriptor() request.

An interface may include alternate settings that allow the endpoints and/or their characteristics to be varied after the device has been configured. The default setting for an interface is always alternate setting zero. The SetInterface() request is used to select an alternate setting or to return to the default setting. The GetInterface() request returns the selected alternate setting.

Alternate settings allow a portion of the device configuration to be varied while other interfaces remain in operation. If a configuration has alternate settings for one or more of its interfaces, a separate interface descriptor and its associated endpoints are included for each setting.

If a device configuration supported a single interface with two alternate settings, the configuration descriptor would be followed by an interface descriptor with the *bInterfaceNumber* and *bAlternateSetting* fields set to zero and then the endpoint descriptors for that setting, followed by another interface descriptor and its associated endpoint descriptors. The second interface descriptor's *bInterfaceNumber* field would also be set to zero, but the *bAlternateSetting* field of the second interface descriptor would be set to one.

If an interface uses only endpoint zero, no endpoint descriptors follow the interface descriptor. In this case, the *bNumEndpoints* field must be set to zero.

An interface descriptor never includes endpoint zero in the number of endpoints. Table 9-12 shows the standard interface descriptor.

Table 9-12. Standard Interface Descriptor

Offset	Field	Size	Value	Description
0	<i>bLength</i>	1	Number	Size of this descriptor in bytes
1	<i>bDescriptorType</i>	1	Constant	INTERFACE Descriptor Type
2	<i>bInterfaceNumber</i>	1	Number	Number of this interface. Zero-based value identifying the index in the array of concurrent interfaces supported by this configuration.
3	<i>bAlternateSetting</i>	1	Number	Value used to select this alternate setting for the interface identified in the prior field
4	<i>bNumEndpoints</i>	1	Number	Number of endpoints used by this interface (excluding endpoint zero). If this value is zero, this interface only uses the Default Control Pipe.
5	<i>bInterfaceClass</i>	1	Class	<p>Class code (assigned by the USB-IF).</p> <p>A value of zero is reserved for future standardization.</p> <p>If this field is set to FFH, the interface class is vendor-specific.</p> <p>All other values are reserved for assignment by the USB-IF.</p>
6	<i>bInterfaceSubClass</i>	1	SubClass	<p>Subclass code (assigned by the USB-IF). These codes are qualified by the value of the <i>bInterfaceClass</i> field.</p> <p>If the <i>bInterfaceClass</i> field is reset to zero, this field must also be reset to zero.</p> <p>If the <i>bInterfaceClass</i> field is not set to FFH, all values are reserved for assignment by the USB-IF.</p>

Table 9-12. Standard Interface Descriptor (Continued)

Offset	Field	Size	Value	Description
7	<i>bInterfaceProtocol</i>	1	Protocol	<p>Protocol code (assigned by the USB). These codes are qualified by the value of the <i>bInterfaceClass</i> and the <i>bInterfaceSubClass</i> fields. If an interface supports class-specific requests, this code identifies the protocols that the device uses as defined by the specification of the device class.</p> <p>If this field is reset to zero, the device does not use a class-specific protocol on this interface.</p> <p>If this field is set to FFH, the device uses a vendor-specific protocol for this interface.</p>
8	<i>iInterface</i>	1	Index	Index of string descriptor describing this interface

9.6.6 Endpoint

Each endpoint used for an interface has its own descriptor. This descriptor contains the information required by the host to determine the bandwidth requirements of each endpoint. An endpoint descriptor is always returned as part of the configuration information returned by a `GetDescriptor(Configuration)` request. An endpoint descriptor cannot be directly accessed with a `GetDescriptor()` or `SetDescriptor()` request. There is never an endpoint descriptor for endpoint zero. Table 9-13 shows the standard endpoint descriptor.

Table 9-13. Standard Endpoint Descriptor

Offset	Field	Size	Value	Description
0	<i>bLength</i>	1	Number	Size of this descriptor in bytes
1	<i>bDescriptorType</i>	1	Constant	ENDPOINT Descriptor Type
2	<i>bEndpointAddress</i>	1	Endpoint	<p>The address of the endpoint on the USB device described by this descriptor. The address is encoded as follows:</p> <ul style="list-style-type: none"> Bit 3...0: The endpoint number Bit 6...4: Reserved, reset to zero Bit 7: Direction, ignored for control endpoints <ul style="list-style-type: none"> 0 = OUT endpoint 1 = IN endpoint

Table 9-13. Standard Endpoint Descriptor (Continued)

Offset	Field	Size	Value	Description
3	<i>bmAttributes</i>	1	Bitmap	<p>This field describes the endpoint's attributes when it is configured using the <i>bConfigurationValue</i>.</p> <p>Bits 1..0: Transfer Type 00 = Control 01 = Isochronous 10 = Bulk 11 = Interrupt</p> <p>If not an isochronous endpoint, bits 5..2 are reserved and must be set to zero. If isochronous, they are defined as follows:</p> <p>Bits 3..2: Synchronization Type 00 = No Synchronization 01 = Asynchronous 10 = Adaptive 11 = Synchronous</p> <p>Bits 5..4: Usage Type 00 = Data endpoint 01 = Feedback endpoint 10 = Implicit feedback Data endpoint 11 = Reserved</p> <p>Refer to Chapter 5 for more information.</p> <p>All other bits are reserved and must be reset to zero. Reserved bits must be ignored by the host.</p>

Table 9-13. Standard Endpoint Descriptor (Continued)

Offset	Field	Size	Value	Description
4	<i>wMaxPacketSize</i>	2	Number	<p>Maximum packet size this endpoint is capable of sending or receiving when this configuration is selected.</p> <p>For isochronous endpoints, this value is used to reserve the bus time in the schedule, required for the per-(micro)frame data payloads. The pipe may, on an ongoing basis, actually use less bandwidth than that reserved. The device reports, if necessary, the actual bandwidth used via its normal, non-USB defined mechanisms.</p> <p>For all endpoints, bits 10..0 specify the maximum packet size (in bytes).</p> <p>For high-speed isochronous and interrupt endpoints: Bits 12..11 specify the number of additional transaction opportunities per microframe: 00 = None (1 transaction per microframe) 01 = 1 additional (2 per microframe) 10 = 2 additional (3 per microframe) 11 = Reserved</p> <p>Bits 15..13 are reserved and must be set to zero. Refer to Chapter 5 for more information.</p>
6	<i>bInterval</i>	1	Number	<p>Interval for polling endpoint for data transfers. Expressed in frames or microframes depending on the device operating speed (i.e., either 1 millisecond or 125 μs units).</p> <p>For full-/high-speed isochronous endpoints, this value must be in the range from 1 to 16. The <i>bInterval</i> value is used as the exponent for a $2^{bInterval-1}$ value; e.g., a <i>bInterval</i> of 4 means a period of 8 (2^{4-1}).</p> <p>For full-/low-speed interrupt endpoints, the value of this field may be from 1 to 255.</p> <p>For high-speed interrupt endpoints, the <i>bInterval</i> value is used as the exponent for a $2^{bInterval-1}$ value; e.g., a <i>bInterval</i> of 4 means a period of 8 (2^{4-1}). This value must be from 1 to 16.</p> <p>For high-speed bulk/control OUT endpoints, the <i>bInterval</i> must specify the maximum NAK rate of the endpoint. A value of 0 indicates the endpoint never NAKs. Other values indicate at most 1 NAK each <i>bInterval</i> number of microframes. This value must be in the range from 0 to 255.</p> <p>See Chapter 5 description of periods for more detail.</p>

The *bmAttributes* field provides information about the endpoint’s Transfer Type (bits 1..0) and Synchronization Type (bits 3..2). In addition, the Usage Type bit (bits 5..4) indicate whether this is an endpoint used for normal data transfers (bits 5..4=00B), whether it is used to convey explicit feedback information for one or more data endpoints (bits 5..4=01B) or whether it is a data endpoint that also serves

Universal Serial Bus Specification Revision 2.0

as an implicit feedback endpoint for one or more data endpoints (bits 5..4=10B). Bits 5..2 are only meaningful for isochronous endpoints and must be reset to zero for all other transfer types.

If the endpoint is used as an explicit feedback endpoint (bits 5..4=01B), then the Transfer Type must be set to isochronous (bits 1..0 = 01B) and the Synchronization Type must be set to No Synchronization (bits 3..2=00B).

A feedback endpoint (explicit or implicit) needs to be associated with one (or more) isochronous data endpoints to which it provides feedback service. The association is based on endpoint number matching. A feedback endpoint always has the opposite direction from the data endpoint(s) it services. If multiple data endpoints are to be serviced by the same feedback endpoint, the data endpoints must have ascending ordered—but not necessarily consecutive—endpoint numbers. The first data endpoint and the feedback endpoint must have the same endpoint number (and opposite direction). This ensures that a data endpoint can uniquely identify its feedback endpoint by searching for the first feedback endpoint that has an endpoint number equal or less than its own endpoint number.

Example: Consider the extreme case where there is a need for five groups of OUT asynchronous isochronous endpoints and at the same time four groups of IN adaptive isochronous endpoints. Each group needs a separate feedback endpoint and the groups are composed as shown in Figure 9-7.

OUT Group	Nr of OUT Endpoints	IN Group	Nr of IN Endpoints
1	1	6	1
2	2	7	2
3	2	8	3
4	3	9	4
5	3		

Figure 9-7. Example of Feedback Endpoint Numbers

The endpoint numbers can be intertwined as illustrated in Figure 9-8.

Figure 9-8. Example of Feedback Endpoint Relationships

High-speed isochronous and interrupt endpoints use bits 12..11 of *wMaxPacketSize* to specify multiple transactions for each microframe specified by *bInterval*. If bits 12..11 of *wMaxPacketSize* are zero, the maximum packet size for the endpoint can be any allowed value (as defined in Chapter 5). If bits 12..11 of *wMaxPacketSize* are not zero (0), the allowed values for *wMaxPacketSize* bits 10..0 are limited as shown in Table 9-14.

Table 9-14. Allowed *wMaxPacketSize* Values for Different Numbers of Transactions per Microframe

<i>wMaxPacketSize</i> bits 12..11	<i>wMaxPacketSize</i> bits 10..0 Values Allowed
00	1 – 1024
01	513 – 1024
10	683 – 1024
11	N/A; reserved

For high-speed bulk and control OUT endpoints, the *bInterval* field is only used for compliance purposes; the host controller is not required to change its behavior based on the value in this field.

9.6.7 String

String descriptors are optional. As noted previously, if a device does not support string descriptors, all references to string descriptors within device, configuration, and interface descriptors must be reset to zero.

String descriptors use UNICODE encodings as defined by *The Unicode Standard, Worldwide Character Encoding, Version 3.0*, The Unicode Consortium, Addison-Wesley Publishing Company, Reading, Massachusetts (URL: <http://www.unicode.com>). The strings in a USB device may support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a sixteen-bit language ID (LANGID) defined by the USB-IF. The list of currently defined USB LANGIDs can be found at <http://www.usb.org/developers/docs.html>. String index zero for all languages returns a string descriptor that contains an array of two-byte LANGID codes supported by the device. Table 9-15 shows the LANGID code array. A USB device may omit all string descriptors. USB devices that omit all string descriptors must not return an array of LANGID codes.

The array of LANGID codes is not NULL-terminated. The size of the array (in bytes) is computed by subtracting two from the value of the first byte of the descriptor.

Table 9-15. String Descriptor Zero, Specifying Languages Supported by the Device

Offset	Field	Size	Value	Description
0	<i>bLength</i>	1	N+2	Size of this descriptor in bytes
1	<i>bDescriptorType</i>	1	Constant	STRING Descriptor Type
2	<i>wLANGID[0]</i>	2	Number	LANGID code zero
...
N	<i>wLANGID[x]</i>	2	Number	LANGID code x

The UNICODE string descriptor (shown in Table 9-16) is not NULL-terminated. The string length is computed by subtracting two from the value of the first byte of the descriptor.

Table 9-16. UNICODE String Descriptor

Offset	Field	Size	Value	Description
0	<i>bLength</i>	1	Number	Size of this descriptor in bytes
1	<i>bDescriptorType</i>	1	Constant	STRING Descriptor Type
2	<i>bString</i>	N	Number	UNICODE encoded string

9.7 Device Class Definitions

All devices must support the requests and descriptor definitions described in this chapter. Most devices provide additional requests and, possibly, descriptors for device-specific extensions. In addition, devices may provide extended services that are common to a group of devices. In order to define a class of devices, the following information must be provided to completely define the appearance and behavior of the device class.

9.7.1 Descriptors

If the class requires any specific definition of the standard descriptors, the class definition must include those requirements as part of the class definition. In addition, if the class defines a standard extended set of descriptors, they must also be fully defined in the class definition. Any extended descriptor definitions must follow the approach used for standard descriptors; for example, all descriptors must begin with a length field.

9.7.2 Interface(s) and Endpoint Usage

When a class of devices is standardized, the interfaces used by the devices, including how endpoints are used, must be included in the device class definition. Devices may further extend a class definition with proprietary features as long as they meet the base definition of the class.

9.7.3 Requests

All of the requests specific to the class must be defined.

Chapter 10

USB Host: Hardware and Software

The USB interconnect supports data traffic between a host and a USB device. This chapter describes the host interfaces necessary to facilitate USB communication between a software client, resident on the host, and a function implemented on a device. The implementation described in this chapter is not required. This implementation is provided as an example to illustrate the host system behavior expected by a USB device. A host system may provide a different host software implementation as long as a USB device experiences the same host behavior.

10.1 Overview of the USB Host

10.1.1 Overview

The basic flow and interrelationships of the USB communications model are shown in Figure 10-1.

Figure 10-1. Interlayer Communications Model

The host and the device are divided into the distinct layers depicted in Figure 10-1. Vertical arrows indicate the actual communication on the host. The corresponding interfaces on the device are implementation-specific. All communications between the host and device ultimately occur on the physical USB wire. However, there are logical host-device interfaces between each horizontal layer. These communications, between client software resident on the host and the function provided by the device, are typified by a contract based on the needs of the application currently using the device and the capabilities provided by the device.

This client-function interaction creates the requirements for all of the underlying layers and their interfaces.

Universal Serial Bus Specification Revision 2.0

This chapter describes this model from the point of view of the host and its layers. Figure 10-2 illustrates, based on the overall view introduced in Chapter 5, the host's view of its communication with the device.

Figure 10-2. Host Communications

Universal Serial Bus Specification Revision 2.0

There is only one host for each USB. The major layers of a host consist of the following:

- USB bus interface
- USB System
- Client

The USB bus interface handles interactions for the electrical and protocol layers (refer to Chapter 7 and Chapter 8). From the interconnect point of view, a similar USB bus interface is provided by both the USB device and the host, as exemplified by the Serial Interface Engine (SIE). On the host, however, the USB bus interface has additional responsibilities due to the unique role of the host on the USB and is implemented as the Host Controller. The Host Controller has an integrated root hub providing attachment points to the USB wire.

The USB System uses the Host Controller to manage data transfers between the host and USB devices. The interface between the USB System and the Host Controller is dependent on the hardware definition of the Host Controller. The USB System, in concert with the Host Controller, performs the translation between the client's view of data transfers and the USB transactions appearing on the interconnect. This includes the addition of any USB feature support such as protocol wrappers. The USB System is also responsible for managing USB resources, such as bandwidth and bus power, so that client access to the USB is possible.

The USB System has three basic components:

- Host Controller Driver
- USB Driver
- Host Software

The Host Controller Driver (HCD) exists to more easily map the various Host Controller implementations into the USB System, such that a client can interact with its device without knowing to which Host Controller the device is connected. The USB Driver (USBD) provides the basic host interface (USBBI) for clients to USB devices. The interface between the HCD and the USBD is known as the Host Controller Driver Interface (HCBI). This interface is never available directly to clients and thus is not defined by the USB Specification. A particular HCBI is, however, defined by each operating system that supports various Host Controller implementations.

The USBD provides data transfer mechanisms in the form of I/O Request Packets (IRPs), which consist of a request to transport data across a specific pipe. In addition to providing data transfer mechanisms, the USBD is responsible for presenting to its clients an abstraction of a USB device that can be manipulated for configuration and state management. As part of this abstraction, the USBD owns the default pipe (see Chapter 5 and Chapter 9) through which all USB devices are accessed for the purposes of standard USB control. This default pipe represents a logical communication between the USBD and the abstraction of a USB device as shown in Figure 10-2.

In some operating systems, additional non-USB System Software is available that provides configuration and loading mechanisms to device drivers. In such operating systems, the device driver shall use the provided interfaces instead of directly accessing the USBBI mechanisms.

The client layer describes all the software entities that are responsible for directly interacting with USB devices. When each device is attached to the system, these clients might interact directly with the peripheral hardware. The shared characteristics of the USB place USB System Software between the client and its device; that is, a client cannot directly access the device's hardware.

Overall, the host layers provide the following capabilities:

- Detecting the attachment and removal of USB devices
- Managing USB standard control flow between the host and USB devices
- Managing data flow between the host and USB devices
- Collecting status and activity statistics
- Controlling the electrical interface between the Host Controller and USB devices, including the provision of a limited amount of power

The following sections describe these responsibilities and the requirements placed on the USBDI in greater detail. The actual interfaces used for a specific combination of host platform and operating system are described in the appropriate operating system environment guide.

All hubs (see Chapter 11) report internal status changes and their port change status via the status change pipe. This includes a notification of when a USB device is attached to or removed from one of their ports. A USBDI client generically known as the hub driver receives these notifications as owner of the hub's Status Change pipe. For device attachments, the hub driver then initiates the device configuration process. In some systems, this hub driver is a part of the host software provided by the operating system for managing devices.

10.1.2 Control Mechanisms

Control information may be passed between the host and a USB device using in-band or out-of-band signaling. In-band signaling mixes control information with data in a pipe outside the awareness of the host. Out-of-band signaling places control information in a separate pipe.

There is a message pipe called the default pipe for each attached USB device. This logical association between a host and a USB device is used for USB standard control flow such as device enumeration and configuration. The default pipe provides a standard interface to all USB devices. The default pipe may also be used for device-specific communications, as mediated by the USBDI, which owns the default pipes of all of the USB devices.

A particular USB device may allow the use of additional message pipes to transfer device-specific control information. These pipes use the same communications protocol as the default pipe, but the information transferred is specific to the USB device and is not standardized by the USB Specification.

The USBDI supports the sharing of the default pipe, which it owns and uses, with its clients. It also provides access to any other control pipes associated with the device.

10.1.3 Data Flow

The Host Controller is responsible for transferring streams of data between the host and USB devices. These data transfers are treated as a continuous stream of bytes. The USB supports four basic types of data transfers:

- Control transfers
- Isochronous transfers
- Interrupt transfers
- Bulk transfers

For additional information on transfer types, refer to Chapter 5.

Each device presents one or more interfaces that a client may use to communicate with the device. Each interface is composed of zero or more pipes that individually transfer data between the client and a particular endpoint on the device. The USBDI establishes interfaces and pipes at the explicit request of the Host Software. The Host Controller provides service based on parameters provided by the Host Software when the configuration request is made.

A pipe has several characteristics based on the delivery requirements of the data to be transferred. Examples of these characteristics include the following:

- The rate at which data needs to be transferred
- Whether data is provided at a steady rate or sporadically
- How long data may be delayed before delivery
- Whether the loss of data being transferred is catastrophic

A USB device endpoint describes the characteristics required for a specific pipe. Endpoints are described as part of a USB device's characterization information. For additional details, refer to Chapter 9.

10.1.4 Collecting Status and Activity Statistics

As a common communicant for all control and data transfers between the host and USB devices, the USB System and the Host Controller are well-positioned to track status and activity information. Such information is provided upon request to the Host Software, allowing that software to manage status and activity information. This specification does not identify any specific information that should be tracked or require any particular format for reporting activity and status information.

10.1.5 Electrical Interface Considerations

The host provides power to USB devices attached to the root hub. The amount of power provided by a port is specified in Chapter 7.

10.2 Host Controller Requirements

In all implementations, Host Controllers perform the same basic duties with regard to the USB and its attached devices. These basic duties are described below.

The Host Controller has requirements from both the host and the USB. The following is a brief overview of the functionality provided. Each capability is discussed in detail in subsequent sections.

State Handling	As a component of the host, the Host Controller reports and manages its states.
Serializer/Deserializer	For data transmitted from the host, the Host Controller converts protocol and data information from its native format to a bit stream transmitted on the USB. For data being received into the host, the reverse operation is performed.
(micro)frame Generation	The Host Controller produces SOF tokens at a period of 1 ms when operating with full-speed devices, and at a period of 125 μ s when operating with high-speed devices.
Data Processing	The Host Controller processes requests for data transmission to and from the host.
Protocol Engine	The Host Controller supports the protocol specified by the USB.
Transmission Error Handling	All Host Controllers exhibit the same behavior when detecting and reacting to the defined error categories.
Remote Wakeup	All Host Controllers must have the ability to place the bus into the Suspended state and to respond to bus wakeup events.

Root Hub	The root hub provides standard hub function to link the Host Controller to one or more USB ports.
Host System Interface	Provides a high-speed data path between the Host Controller and host system.

The following sections present a more detailed discussion of the required capabilities of the Host Controller.

10.2.1 State Handling

The Host Controller has a series of states that the USB System manages. Additionally, the Host Controller provides the interface to the following two areas of USB-relevant state:

- State change propagation
- Root hub

The root hub presents to the hub driver the same standard states as other USB devices. The Host Controller supports these states and their transitions for the hub. For detailed discussions of USB states, including their interrelations and transitions, refer to Chapter 9.

The overall state of the Host Controller is inextricably linked with that of the root hub and of the overall USB. Any Host Controller state changes that are visible to attached devices must be reflected in the corresponding device state change information such that the resulting Host Controller and device states are consistent.

USB devices request a wakeup through the use of resume signaling (refer to Chapter 7). The Host Controller must notify the rest of the host of a resume event through a mechanism or mechanisms specific to that system's implementation. The Host Controller itself may cause a resume event through the same signaling method.

10.2.2 Serializer/Deserializer

The actual transmission of data across the physical USB takes places as a serial bit stream. A Serial Interface Engine (SIE), whether implemented as part of the host or a USB device, handles the serialization and deserialization of USB transmissions. On the host, this SIE is part of the Host Controller.

10.2.3 Frame and Microframe Generation

It is the Host Controller's responsibility to partition USB time into quantities called "frames" when operating with full-speed devices, and "microframes" when operating with high-speed devices. Frames and microframes are created by the Host Controller through issuing Start-of-Frame (SOF) tokens as shown in Figure 10-3. The SOF token is the first transmission in the (micro)frame period. Host controllers operating with high-speed devices generate SOF tokens at 125 μ s intervals. Host controllers operating with full-speed devices generate SOF tokens at 1.00 ms intervals. After issuing an SOF token, the Host Controller is free to transmit other transactions for the remainder of the (micro)frame period. When the Host Controller is in its normal operating state, SOF tokens must be continuously generated at appropriate periodic rate, regardless of other bus activity or lack thereof. If the Host Controller enters a state where it is not providing power on the bus, it must not generate SOFs. When the Host Controller is not generating SOFs, it may enter a power-reduced state.

Figure 10-3. Frame and Microframe Creation

The SOF token holds the highest priority access to the bus. Babble circuitry in hubs electrically isolates any active transmitters during the End-of-microframe or End-of-Frame (EOF) interval, providing an idle bus for the SOF transmission.

The Host Controller maintains the current (micro)frame number that may be read by the USB System.

The following apply to the current (micro)frame number maintained by the host:

- Used to uniquely identify one (micro)frame from another
- Incremented at the end of every (micro)frame period
- Valid through the subsequent (micro)frame

Host controllers operating with full-speed devices maintain a current frame number (at least 11 bits) that increments at a 1 ms period. The host transmits the lower 11 bits of the current frame number in each SOF token transmission.

Host controllers operating with high-speed devices maintain a current microframe number (at least 14 bits) that increments at a 125 μ s period. The host transmits bits 3 through 13 of the current microframe number in each SOF token transmission. This results in the same SOF packet value being transmitted for eight consecutive microframes before the SOF packet value increments.

When requested from the Host Controller, the current (micro)frame number is the (micro)frame number in existence at the time the request was fulfilled. The current (micro)frame number as returned by the host (Host Controller or HCD) is at least 32 bits, although the Host Controller itself is not required to maintain more than 11 bits when operating with full-speed devices or 14 bits when operating with high-speed devices.

The Host Controller shall cease transmission during the EOF interval. When the EOF interval begins, any transactions scheduled specifically for the (micro)frame that has just passed are retired. If the Host Controller is executing a transaction at the time the EOF interval is encountered, the Host Controller terminates the transaction.

10.2.4 Data Processing

The Host Controller is responsible for receiving data from the USB System and sending it to the USB and for receiving data from the USB and sending it to the USB System. The particular format used for the data communications between the USB System and the Host Controller is implementation specific, within the rules for transfer behavior described in Chapter 5.

10.2.5 Protocol Engine

The Host Controller manages the USB protocol level interface. It inserts the appropriate protocol information for outgoing transmissions. It also strips and interprets, as appropriate, the incoming protocol information.

10.2.6 Transmission Error Handling

The Host Controller must be capable of detecting the following transmission error conditions, which are defined from the host's point of view:

- Timeout conditions after a host-transmitted token or packet. These errors occur when the addressed endpoint is unresponsive or when the structure of the transmission is so badly damaged that the targeted endpoint does not recognize it.
- Data errors resulting in missing or invalid transmissions:
 - The Host Controller is unable to completely send or receive a packet for host specific reasons, for example, a transmission extending beyond EOF or a lack of resources available to the Host Controller.
 - An invalid CRC field on a received data packet.
- Protocol errors:
 - An invalid handshake PID, such as a malformed or inappropriate handshake
 - A false EOP
 - A bit stuffing error

For each bulk, control, and interrupt transaction, the host must maintain an error count tally. Errors result from the conditions described above, not as a result of an endpoint NAKing a request. This value reflects the number of times the transaction has encountered a transmission error. It is recommended that the error count not be incremented when there was an error due to host specific reasons (buffer underrun or overrun), and that whenever a transaction does not encounter a transmission error, the error count is reset to zero.

If the error count for a given transaction reaches three, the host retires the transfer. When a transfer is retired due to excessive errors, the last error type must be indicated. Isochronous transactions are attempted only once, regardless of outcome, and, therefore, no error count is maintained for this type.

10.2.7 Remote Wakeup

If USB System wishes to place the bus in the Suspended state, it commands the Host Controller to stop all bus traffic, including SOFs. This causes all USB devices to enter the Suspended state. In this state, the USB System may enable the Host Controller to respond to bus wakeup events. This allows the Host Controller to respond to bus wakeup signaling to restart the host system.

10.2.8 Root Hub

The root hub provides the connection between the Host Controller and one or more USB ports. The root hub provides the same functionality for dealing with USB topology as other hubs (see Chapter 11), except that the hardware and software interface between the root hub and the Host Controller is defined by the specific hardware implementation.

10.2.8.1 Port Resets

Section 7.1.7.5 describes the requirements of a hub to ensure all upstream resume attempts are overpowered with a long reset downstream. Root hubs must provide an aggregate reset period of at least 50 ms. If the reset duration is controlled in hardware and the hardware timer is <50 ms, the USB System can issue several consecutive resets to accumulate the specified reset duration as described in Section 7.1.7.5.

10.2.9 Host System Interface

The Host Controller provides a high-speed bus-mastering interface to and from main system memory. The physical transfer between memory and the USB wire is performed automatically by the Host Controller. When data buffers need to be filled or emptied, the Host Controller informs the USB System.

10.3 Overview of Software Mechanisms

The HCD and the USBD present software interfaces based on different levels of abstraction. They are, however, expected to operate together in a specified manner to satisfy the overall requirements of the USB System (see Figure 10-2). The requirements for the USB System are expressed primarily as requirements for the USBDI. The division of duties between the USBD and the HCD is not defined. However, the one requirement of the HCDI that must be met is that it supports, in the specified operating system context, multiple Host Controller implementations.

The HCD provides an abstraction of the Host Controller and an abstraction of the Host Controller's view of data transfer across the USB. The USBD provides an abstraction of the USB device and of the data transfers between the client of the USBD and the function on the USB device. Overall, the USB System acts as a facilitator for transmitting data between the client and the function and as a control point for the USB-specific interfaces of the USB device. As part of facilitating data transfer, the USB System provides buffer management capabilities and allows the synchronization of the data transmittal to the needs of the client and the function.

The specific requirements for the USBDI are described later in this chapter. The exact functions that fulfill these requirements are described in the relevant operating system environment guide for the HCDI and the USBDI. The procedures involved in accomplishing data transfers via the USBDI are described in the following sections.

10.3.1 Device Configuration

Different operating system environments perform device configuration using different software components and different sequences of events. The USB System does not assume a specific operating system method. However, there are some basic requirements that must be fulfilled by any USB System implementation. In some operating systems, existing host software provides these requirements. In others, the USB System provides the capabilities.

The USB System assumes a specialized client of the USBD, called a hub driver, that acts as a clearinghouse for the addition and removal of devices from a particular hub. Once the hub driver receives such notifications, it will employ additional host software and other USBD clients, in an operating system specific manner, to recognize and configure the device. This model, shown in Figure 10-4, is the basis of the following discussion.

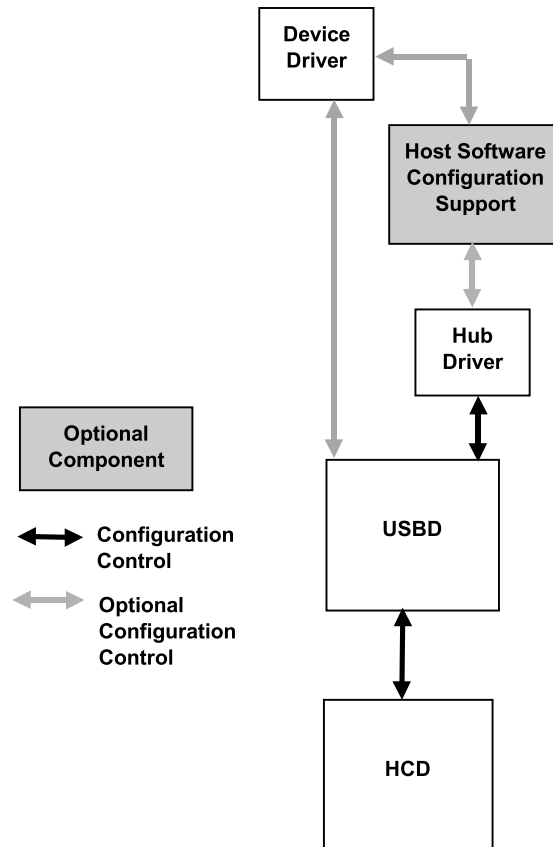

Figure 10-4. Configuration Interactions

When a device is attached, the hub driver receives a notification from the hub detecting the change. The hub driver, using the information provided by the hub, requests a device identifier from the USB D. The USB D in turn sets up the default pipe for that device and returns a device identifier to the hub driver.

The device is now ready to be configured for use. For each device, there are three configurations that must be complete before that device is ready for use:

1. **Device Configuration:** This includes setting up all of the device's USB parameters and allocating all USB host resources that are visible to the device. This is accomplished by setting the configuration value on the device. A limited set of configuration changes, such as alternate settings, is allowed without totally reconfiguring the device. Once the device is configured, it is, from its point of view, ready for use.
2. **USB Configuration:** In order to actually create a USB D pipe ready for use by a client, additional USB information, not visible to the device, must be specified by the client. This information, known as the Policy for the pipe, describes how the client will use the pipe. This includes such items as the maximum amount of data the client will transfer with one IRP, the maximum service interval the client will use, the client's notification identification, and so on.
3. **Function Configuration:** Once configuration types 1 and 2 have been accomplished, the pipe is completely ready for use from the USB's point of view. However, additional vendor- or class-specific setup may be required before the client can actually use the pipe. This configuration is a private matter between the device and the client and is not standardized by the USB D.

Universal Serial Bus Specification Revision 2.0

The following paragraphs describe the device and USB configuration requirements.

The responsible configuring software performs the actual device configuration. Depending on the particular operating system implementation, the software responsible for configuration can include the following:

- The hub driver
- Other host software
- A device driver

The configuring software first reads the device descriptor, then requests the description for each possible configuration. It may use the information provided to load a particular client, such as a device driver, which initially interacts with the device. The configuring software, perhaps with input from that device driver, chooses a configuration for the device. Setting the device configuration sets up all of the endpoints on the device and returns a collection of interfaces to be used for data transfer by USB clients. Each interface is a collection of pipes owned by a single client.

This initial configuration uses the default settings for interfaces and the default bandwidth for each endpoint. A USB implementation may additionally allow the client to specify alternate interfaces when selecting the initial configuration. The USB System will verify that the resources required for the support of the endpoint are available and, if so, will allocate the bandwidth required. Refer to Section 10.3.2 for a discussion of resource management.

The device is now configured, but the created pipes are not yet ready for use. The USB configuration is accomplished when the client initializes each pipe by setting a Policy to specify how it will interact with the pipe. Among the information specified is the client's maximum service interval and notification information. Among the actions taken by the USB System, as a result of setting the Policy, is determining the amount of buffer working space required beyond the data buffer space provided by the client. The size of the buffers required is based upon the usage chosen by the client and upon the per-transfer needs of the USB System.

The client receives notifications when IRPs complete, successfully or due to errors. The client may also wake up independently of USB notification to check the status of pending IRPs.

The client may also choose to make configuration modifications, such as enabling an alternate setting for an interface or changing the bandwidth allocated to a particular pipe. In order to perform these changes, the interface or pipe, respectively, must be idle.

10.3.2 Resource Management

Whenever a pipe is setup by the USB System for a given endpoint, the USB System must determine if it can support the pipe. The USB System makes this determination based on the requirements stated in the endpoint descriptor. One of the endpoint requirements, which must be supported in order to create a pipe for an endpoint, is the bandwidth necessary for that endpoint's transfers. There are two stages to check for available bandwidth. First the maximum execution time for a transaction is calculated. Then the (micro)frame schedule is consulted to determine if the indicated transaction will fit.

The allocation of the guaranteed bandwidth for isochronous and interrupt pipes, and the determination of whether a particular control or bulk transaction will fit into a given (micro)frame, can be determined by a software heuristic in the USB System. If the actual transaction execution time in the Host Controller exceeds the heuristically determined value, the Host Controller is responsible for ensuring that (micro)frame integrity is maintained (refer to Section 10.2.3). The following discussion describes the requirements for the USB System heuristic.

In order to determine if bandwidth can be allocated, or if a transaction can be fit into a particular (micro)frame, the maximum transaction execution time must be calculated. The calculation of the maximum transaction execution time requires that the following information be provided: (Note that an agent other than the client may provide some of this information.)

- Number of data bytes (*wMaxPacketSize*) to be transmitted.
- Transfer type.
- Depth in the topology. If less precision is allowed, the maximum topology depth may be assumed.

This calculation must include the bit transmission time, the signal propagation delay through the topology, and any implementation-specific delays, such as preparation or recovery time required by the Host Controller itself. Refer to Chapter 5 for examples of formulas that can be used for such calculations.

10.3.3 Data Transfers

The basis for all client-function communication is the interface: a bundle of related pipes associated with a particular USB device.

Exactly one client on the host manages a given interface. The client initializes each pipe of an interface by setting the Policy for that pipe. This includes the maximum amount of data to be transmitted per IRP and the maximum service interval for the pipe. A service interval is stated in milliseconds and describes the interval over which an IRP's data will be transmitted for an isochronous pipe. It describes the polling interval for an interrupt pipe. The client is notified when a specified request is completed. The client manages the size of each IRP such that its duty cycle and latency constraints are maintained. Additional Policy information includes the notification information for the client.

The client provides the buffer space required to hold the transmitted data. The USB System uses the Policy to determine the additional working space it will require.

The client views its data as a contiguous serial stream, which it manages in a similar manner to those streams provided over other types of bus technologies. Internally, the USB System may, depending on its own Policy and any Host Controller constraints, break the client request down into smaller requests to be sent across the USB. However, two requirements must be met whenever the USB System chooses to undertake such division:

- The division of the data stream into smaller chunks is not visible to the client.
- USB samples are not split across bus transactions.

When a client wishes to transfer data, it will send an IRP to the USBD. Depending on the direction of data transfer, a full or empty data buffer will be provided. When the request is complete (successfully or due to an error condition), the IRP and its status is returned to the client. Where relevant, this status is also provided on a per-transaction basis.

10.3.4 Common Data Definitions

In order to allow the client to receive request results as directly as possible from its device, it is desirable to minimize the amount of processing and copying required between the device and the client. To facilitate this, some control aspects of the IRP are standardized such that different layers in the stack may directly use the information provided by the client. The particular format for this data is dependent on the actualization of the USBDI in the operating system. Some data elements may in fact not be directly visible to the client at all but are generated as a result of the client request.

The following data elements define the relevant information for a request:

- Identification of the pipe associated with the request. Identifying this pipe also describes information such as transfer type for this request.
- Notification identification for the particular client.
- Location and length of data buffer that is to be transmitted or received.
- Completion status for the request. Both the summary status and, as required, detailed per-transaction status must be provided.
- Location and length of working space. This is implementation-dependent.

The actual mechanisms used to communicate requests to the USB D are operating system-specific. However, beyond the requirements stated above for what request-related information must be available, there are also requirements on how requests will be processed. The basic requirements are described in Chapter 5. Additionally, the USB D provides a mechanism to designate a group of isochronous IRPs for which the transmission of the first transaction of each IRP will occur in the same (micro)frame. The USB D also provides a mechanism for designating an uninterruptable set of vendor- or class-specific requests to a default pipe. No other requests to that default pipe, including standard, class, or vendor request may be inserted in the execution flow for such an uninterruptable set. If any request in this set fails, the entire set is retired.

10.4 Host Controller Driver

The Host Controller Driver (HCD) is an abstraction of Host Controller hardware and the Host Controller's view of data transmission over the USB. The HCDI meets the following requirements:

- Provides an abstraction of the Host Controller hardware.
- Provides an abstraction for data transfers by the Host Controller across the USB interconnect.
- Provides an abstraction for the allocation (and de-allocation) of Host Controller resources to support guaranteed service to USB devices.
- Presents the root hub and its behavior according to the hub class definition. This includes supporting the root hub such that the hub driver interacts with the root hub exactly as it would for any hub. In particular, even though a root hub can be implemented in a combination of hardware and software, the root hub responds initially to the default device address (from a client perspective), returns descriptor information, supports having its device address set, and supports the other hub class requests. However, bus transactions may or may not need to be generated to accomplish this behavior given the close integration possible between the Host Controller and the root hub.

The HCD provides a software interface (HCDI) that implements the required abstractions. The function of the HCD is to provide an abstraction, which hides the details of the Host Controller hardware. Below the Host Controller hardware is the physical USB and all the attached USB devices.

The HCD is the lowest tier in the USB software stack. The HCD has only one client: the Universal Serial Bus Driver (USB D). The USB D maps requests from many clients to the appropriate HCD. A given HCD may manage many Host Controllers.

The HCDI is not directly accessible from a client. Therefore, the specific interface requirements for the HCDI are not discussed here.

10.5 Universal Serial Bus Driver

The USB D provides a collection of mechanisms that operating system components, typically device drivers, use to access USB devices. The only access to a USB device is that provided by the USB D. The USB D implementations are operating system-specific. The mechanisms provided by the USB D are implemented, using as appropriate and augmenting as necessary, the mechanisms provided by the operating system environment in which the USB runs. The following discussion centers on the basic capabilities

required for all USBD implementations. For specifics of the USBD operation within a specific environment, see the relevant operating system environment guide for the USB. A single instance of the USBD directs accesses to one or more HCDs that in turn connect to one or more Host Controllers. If allowed, how USBD instancing is managed is dependent upon the operating system environment. However, from the client's point of view, the USBD with which the client communicates manages all of the attached USB devices.

10.5.1 USB Overview

Clients of USBD direct commands to devices or move streams of data to or from pipes. The USBD presents two groups of software mechanisms to clients: command mechanisms and pipe mechanisms.

Command mechanisms allow clients to configure and control USBD operation as well as to configure and generically control a USB device. In particular, command mechanisms provide all access to the device's default pipe.

Pipe mechanisms allow a USBD client to manage device specific data and control transfers. Pipe mechanisms do not allow a client to directly address the device's default pipe.

Figure 10-5 presents an overview of the USBD structure.

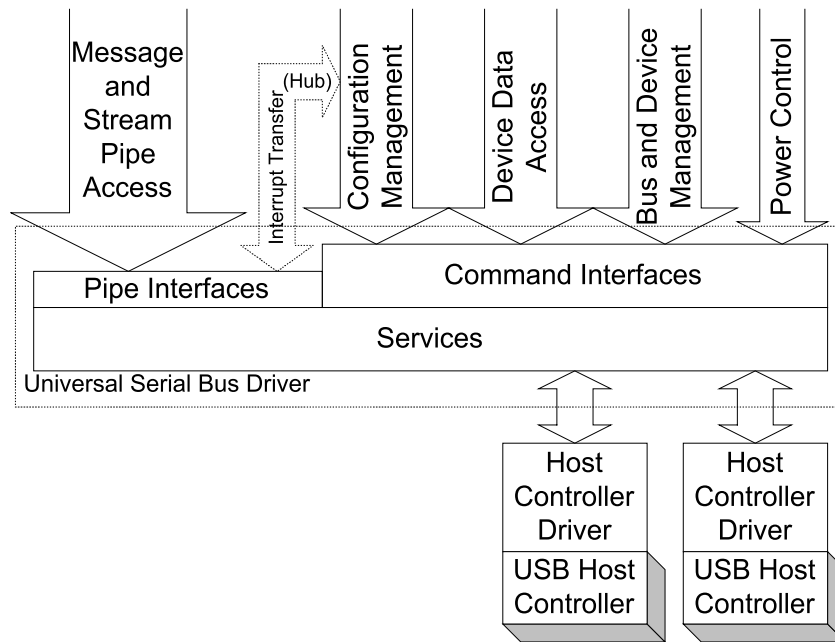

Figure 10-5. Universal Serial Bus Driver Structure

10.5.1.1 USB Initialization

Specific USBD initialization is operating system-dependent. When a particular USB managed by USBD is initialized, the management information for that USB is also created. Part of this management information is the default address device and its default pipe used to communicate to a newly reset device.

When a device is attached to a USB, it responds to a special address known as the default address (refer to Chapter 9) until its unique address is assigned by the bus enumerator. In order for the USB System to interact with the new device, the default device address and the device's default pipe must be available to the hub driver when a device is attached. During device initialization, the default address is changed to a unique address.

10.5.1.2 USB Pipe Usage

Pipes are the method by which a device endpoint is associated with a Host Software entity. Pipes are owned by exactly one such entity on the host. Although the basic concept of a pipe is the same no matter who the owner, some distinction of capabilities provided to the USB client occurs between two groups of pipes:

- Default pipes, which are owned and managed by the USB
- All other pipes, which are owned and managed by clients of the USB

Default pipes are never directly accessed by clients, although they are often used to fulfill some part of client requests relayed via command mechanisms.

10.5.1.2.1 Default Pipes

The USB is responsible for allocating and managing appropriate buffering to support transfers on the default pipe that are not directly visible to the client such as setting a device address. For those transfers that are directly visible to the client, such as sending vendor and class commands or reading a device descriptor, the client must provide the required buffering.

10.5.1.2.2 Client Pipes

Any pipe not owned and managed by the USB can be owned and managed by a USB client. From the USB viewpoint, a single client owns the pipe. In fact, a cooperative group of clients can manage the pipe, provided they behave as a single coordinated entity when using the pipe.

The client is responsible for providing the amount of buffering it needs to service the data transfer rate of the pipe within a service interval attainable by the client. Additional buffering requirements for working space are specified by the USB System.

10.5.1.3 USB Service Capabilities

The USB provides services in the following categories:

- Configuration via command mechanisms
- Transfer services via both command and pipe mechanisms
- Event notification
- Status reporting and error recovery

10.5.2 USB Command Mechanism Requirements

USB command mechanisms allow a client generic access to a USB device. Generally, these commands allow the client to make read or write accesses to one of potentially several device data and control spaces. The client provides as little as a device identifier and the relevant data or empty buffer pointer.

USB command transfers do not require that the USB device be configured. Many of the device configuration facilities provided by the USB are command transfers.

Following are the specific requirements on the command mechanisms provided.

10.5.2.1 Interface State Control

USB clients must be able to set a specified interface to any settable pipe state. Setting an interface state results in all of the pipes in that interface moving to that state. Additionally, all of the pipes in an interface may be reset or aborted.

10.5.2.2 Pipe State Control

USB D pipe state has two components:

- Host status
- Reflected endpoint status

Whenever the pipe status is reported, the value for both components will be identified. The pipe status reflected from the endpoint is the result of the endpoint being in a particular state. The USB D client manages the pipe state as reported by the USB D. For any pipe state reflected from the endpoint, the client must also interact with the endpoint to change the state.

A USB D pipe is in exactly one of the following states:

- **Active:** The pipe's Policy has been set and the pipe is able to transmit data. The client can query as to whether any IRPs are outstanding for a particular pipe. Pipes for which there are no outstanding IRPs are still considered to be in the Active state as long as they are able to accept new IRPs.
- **Halted:** An error has occurred on the pipe. This state may also be a reflection of the corresponding Halted endpoint on the device.

A pipe and endpoint are considered active when the device is configured and the pipe and/or endpoint is not stalled. Clients may manipulate pipe state in the following ways:

- **Aborting a Pipe:** All of the IRPs scheduled for a pipe are retired immediately and returned to the client with a status indicating they have been aborted. Neither the host state nor the reflected endpoint state of the pipe is affected.
- **Resetting a Pipe:** The pipe's IRPs are aborted. The host state is moved to Active. If the reflected endpoint state needs to be changed, that must be commanded explicitly by the USB D client.
- **Clearing a Halted pipe:** The pipe's state is cleared from *Halted* to *Active*.
- **Halting a Pipe:** The pipe's state is set to *Halted*.

10.5.2.3 Getting Descriptors

The USB D must provide a mechanism to retrieve standard device, configuration, and string descriptors, as well as any class- or vendor-specific descriptors.

10.5.2.4 Getting Current Configuration Settings

The USB D must provide a facility to return, for any specified device, the current configuration descriptor. If the device is not configured, no configuration descriptor is returned. This action is equivalent to returning the configuration descriptor for the current configuration by requesting the specific configuration descriptor. It does not, however, require the client to know the identifier for the current configuration. This will return all of the configuration information, including the following:

- All of the configuration descriptor information as stored on the device, including all of the alternate settings for all of the interfaces
- Indicators for which of the alternate settings for interfaces are active
- Pipe handles for endpoints in the active alternate settings for interfaces
- Actual *wMaxPacketSize* values for endpoints in the active alternate settings for interfaces

Additionally, for any specified pipe, the USB D must provide a facility to return the *wMaxPacketSize* that is currently being used by the pipe.

10.5.2.5 Adding Devices

The USBDI must provide a mechanism for the hub driver to inform USB D of the addition of a new device to a specified USB and to retrieve the USB D ID of the new USB device. The USB D tasks include assigning the device address and preparing the device's default pipe for use.

10.5.2.6 Removing Devices

The USBDI must provide a facility for the hub driver to inform the USB D that a specific device has been removed.

10.5.2.7 Managing Status

The USBDI must provide a mechanism for obtaining and clearing device-based status on a device, interface, or pipe basis.

10.5.2.8 Sending Class Commands

This USBDI mechanism is used by a client, typically a class-specific or adaptive driver, to send one or more class-specific commands to a device.

10.5.2.9 Sending Vendor Commands

This USBDI mechanism is used by a client to send one or more vendor-specific commands to a device.

10.5.2.10 Establishing Alternate Settings

The USBDI must provide a mechanism to change the alternate setting for a specified interface. As a result, the pipe handles for the previous setting are released and new pipe handles for the interface are returned. For this request to succeed, the interface must be idle; i.e., no data buffers may be queued for any pipes in the interface.

10.5.2.11 Establishing a Configuration

Configuring software requests a configuration by passing a buffer containing the configuration information to the USB D. The USB D requests resources for the endpoints in the configuration, and if all resource requests succeed, the USB D sets the device configuration and returns interface handles with corresponding pipe handles for all of the active endpoints. The default values are used for all alternate settings for interfaces.

Note: The interface implementing the configuration may require specific alternate settings to be identified.

10.5.2.12 Setting Descriptors

For devices supporting this behavior, the USBDI allows existing descriptors to be updated or new descriptors to be added.

10.5.3 USB D Pipe Mechanisms

This part of the USBDI offers clients the highest-speed, lowest overhead data transfer services possible. Higher performance is achieved by shifting some pipe management responsibilities from the USB D to the client. As a result, the pipe mechanisms are implemented at a more primitive level than the data transfer services provided by the USB D command mechanisms. Pipe mechanisms do not allow access to a device's default pipe.

USB D pipe transfers are available only after both the device and USB configuration have completed successfully. At the time the device is configured, the USB D requests the resources required to support all

device pipes in the configuration. Clients are allowed to modify the configuration, constrained by whether the specified interface or pipe is idle.

Clients provide full buffers to outgoing pipes and retrieve transfer status information following the completion of a request. The transfer status returned for an outgoing pipe allows the client to determine the success or failure of the transfer.

Clients provide empty buffers to incoming pipes and retrieve the filled buffers and transfer status information from incoming pipes following the completion of a request. The transfer status returned for an incoming pipe allows a client to determine the amount and the quality of the data received.

10.5.3.1 Supported Pipe Types

The four types of pipes supported, based on the four transfer types, are described in the following sections.

10.5.3.1.1 Isochronous Data Transfers

Each buffer queued for an isochronous pipe is required to be viewable as a stream of samples. As with all pipe transfers, the client establishes a Policy for using this isochronous pipe, including the relevant service interval for this client. Lost or missing bytes, which are detected on input, and transmission problems, which are noted on output, are indicated to the client.

The client queues a first buffer, starting the pipe streaming service. To maintain the continuous streaming transfer model used in all isochronous transfers, the client queues an additional buffer before the current buffer is retired.

The USBD is required to be able to provide a sample stream view of the client's data stream. In other words, using the client's specified method of synchronization, the precise packetization of the data is hidden from the client. Additionally, a given transaction is always contained completely within some client data buffer.

For an output pipe, the client provides a buffer of data. The USBD allocates the data across the (micro)frames for the service period using the client's chosen method of synchronization.

For an input pipe, the client must provide an empty buffer large enough to hold the maximum number of bytes the client's device will deliver in the service period. Where missing or invalid bytes are indicated, the USBD may leave the space that the bytes would have occupied in place in the buffer and identify the error. One of the consequences of using no synchronization method is that this reserved space is assumed to be the maximum packet size. The buffer-retired notification occurs when the IRP completes. Note that the input buffer need not be full when returned to the client.

The USBD may optionally provide additional views of isochronous data streams. The USBD is also required to be able to provide a packet stream view of the client's data stream.

10.5.3.1.2 Interrupt Transfers

The Interrupt out transfer originates in the client of the USBD and is delivered to the USB device. The Interrupt in transfer originates in a USB device and is delivered to a client of the USBD. The USB System guarantees that the transfers meet the maximum latency specified by the USB endpoint descriptor.

The client queues a buffer large enough to hold the interrupt transfer data (typically a single USB transaction). When all of the data is transferred, or if the error threshold is exceeded, the IRP is returned to the client.

10.5.3.1.3 Bulk Transfers

Bulk transfers may originate either from the device or the client. No periodicity or guaranteed latency is assumed. When all of the data is transferred, or if the error threshold is exceeded, the IRP is returned to the client.

10.5.3.1.4 Control Transfers

All message pipes transfer data in both directions. In all cases, the client outputs a setup stage to the device endpoint. The optional data stage may be either input or output and the final status is always logically presented to the host. For details of the defined message protocol, refer to Chapter 8.

The client prepares a buffer specifying the command phase and any optional data or empty buffer space. The client receives a buffer-retired notification when all phases of the control transfer are complete, or an error notification, if the transfer is aborted due to transmission error.

10.5.3.2 USB Pipe Mechanism Requirements

The following pipe mechanisms are provided.

10.5.3.2.1 Aborting IRPs

The USBDI must allow IRPs for a particular pipe to be aborted.

10.5.3.2.2 Managing Pipe Policy

The USBDI must allow a client to set and clear the Policy for an individual pipe or for an entire interface. Any IRPs made by the client prior to successfully setting a Policy are rejected by the USBD.

10.5.3.2.3 Queuing IRPs

The USBDI must allow clients to queue IRPs for a given pipe. When IRPs are returned to the client, the request status is also returned. A mechanism is provided by the USBD to identify a group of isochronous IRPs whose first transactions will all occur in the same (micro)frame.

10.5.4 Managing the USB via the USBD Mechanisms

Using the provided USBD mechanisms, the following general capabilities are supported by any USB System.

10.5.4.1 Configuration Services

Configuration services operate on a per-device basis. The configuring software tells the USBD when to perform device configuration. A hub driver has a special role in device management and provides at least the following capabilities:

- Device attach/detach recognition, driven by an interrupt pipe owned by the hub driver
- Device reset, accomplished by the hub driver by resetting the hub port upstream of the device
- Tells the USBD to perform device address assignment
- Power control

The USBDI additionally provides the following configuration facilities, which may be used by the hub driver or other configuring software available on the host:

- Device identification and access to configuration information (via access to descriptors on the device)
- Device configuration via command mechanisms

When the hub driver informs the USBD of a device attachment, the USBD establishes the default pipe for the new device.

10.5.4.1.1 Configuration Management

Configuration management services are provided primarily as a set of specific interface commands that generate USB transactions on the default pipe. The notable exception is the use of an additional interrupt pipe that delivers hub status directly to the hub driver.

Every hub initiates an interrupt transfer when there is a change in the state of one of the hub ports. Generally, the port state change will be the connection or removal of a downstream USB device. (Refer to Chapter 11 for more information.)

10.5.4.1.2 Initial Device Configuration

The device configuration process begins when a hub reports, via its status change pipe, the connection of a new USB device.

Configuration management services allow configuring software to select a USB device configuration from the set of configurations listed in the device. The USBD verifies that adequate power is available and the data transfer rates given for all endpoints in the configuration do not exceed the capabilities of the USB with the current schedule before setting the device configuration.

10.5.4.1.3 Modifying a Device Configuration

Configuration management services allow configuring software to replace a USB device configuration with another configuration from the set of configurations listed in the device. The operation succeeds if adequate power is available and the data transfer rates given for all endpoints in the new configuration fit within the capabilities of the USB with the current schedule. If the new configuration is rejected, the previous configuration remains.

Configuration management services allow configuring software to return a USB device to a Not Configured state.

10.5.4.1.4 Device Removal

Error recovery and/or device removal processing begins when a hub reports via its status change pipe that the USB device has been removed.

10.5.4.2 Power Control

There are two cooperating levels of power management for the USB: bus and device level management. This specification provides mechanisms for managing power on the USB bus. Device classes may define class-specific power control capabilities.

All USB devices must support the Suspended state (refer to Chapter 9). The device is placed into the Suspended state via control of the hub port to which the device is attached. Normal device operation ceases in the Suspend State; however, if the device is capable of wakeup signaling and the device is enabled for remote wakeup, it may generate resume signaling in response to external events.

The power management system may transition a device to the Suspended state or power-off the device in order to control and conserve power. The USB provides neither requirements nor commands for the device state to be saved and restored across these transitions. Device classes may define class-specific device state save-and-restore capabilities.

The USB System coordinates the interaction between device power states and the Suspended state.

It is recommended that while a device is not being used by the system (i.e., no transactions are being transmitted to or from the device besides SOF tokens), the device be suspended as soon as possible by selectively suspending the port to which the device is attached. Suspending inactive devices reduces reliability issues due to high currents passing through a transceiver operating in high-speed mode in the presence of short circuit conditions described in Section 7.1.1. Some of these short circuit conditions are not detectable in the absence of transactions to the device. Suspending the unused device will place the

transceiver interface into full-speed mode which has a greater reliability in the presence of short circuit conditions.

10.5.4.3 Event Notifications

USB D clients receive several kinds of event notifications through a number of sources:

- Completion of an action initiated by a client.
- Interrupt transfers over stream pipes can deliver notice of device events directly to USB D clients. For example, hubs use an interrupt pipe to deliver events corresponding to changes in hub status.
- Event data can be embedded by devices in streams.
- Standard device interface commands, device class commands, vendor-specific commands, and even general control transfers over message pipes can all be used to poll devices for event conditions.

10.5.4.4 Status Reporting and Error Recovery Services

The command and pipe mechanisms both provide status reporting on individual requests as they are invoked and completed.

Additionally, USB device status is available to USB D clients using the command mechanisms.

The USB D provides clients with pipe error recovery mechanisms by allowing pipes to be reset or aborted.

10.5.4.5 Managing Remote Wakeup Devices

The USB System can minimize the resume power consumption of a suspended USB tree. This is accomplished by explicitly enabling devices capable of resume signaling and controlling propagation of resume signaling via selectively suspending and/or disabling hub ports between the device and the nearest self-powered, awake hub.

In some error-recovery scenarios, the USB System will need to re-enumerate sub-trees. The sub-tree may be partially or completely suspended. During error-recovery, the USB System must avoid contention between a device issuing resume signaling and simultaneously driving reset down the port. Avoidance is accomplished via management of the devices' remote wakeup feature and the hubs' port features. The rules are as follows:

- Issue a SetDeviceFeature(DVICE_REMOTE_WAKEUP) request to the leaf device, only just prior to selectively suspending any port between where the device is connected and the root port (via a SetPortFeature(PORT_SUSPEND) request).
- Do not reset a suspended port that has had a device enabled for remote wakeup without first enabling that port.
- Verify that after a remote wakeup, the devices in the subtree affected by the remote wakeup are still present. This will typically be done as part of determining which potential remote wakeup device was the source of the wakeup. This should be done to ensure that a suspended device is not disconnected (and possibly reconnected) or reset (e.g., by noise) during a suspend/resume process.

10.5.5 Passing USB Preboot Control to the Operating System

A single software driver owns the Host Controller. If the host system implements USB services before the operating system loads, the Host Controller must provide a mechanism that disables access by the preboot software and allows the operating system to gain control. Preboot USB configuration is not passed to the operating system. Once the operating system gains control, it is responsible to fully configure the bus. If the operating system provides a mechanism to pass control back to the preboot environment, the bus will be in an unknown state. The preboot software should treat this event as a powerup.

10.6 Operating System Environment Guides

As noted previously, the actual interfaces between the USB System and host software are specific to the host platform and operating system. A companion specification is required for each combination of platform and operating system with USB support. These specifications describe the specific interfaces used to integrate the USB into the host. Each operating system provider for the USB System identifies a compatible Universal USB Specification revision.

Chapter 11

Hub Specification

This chapter describes the architectural requirements for the USB hub. It contains a description of the three principal sub-blocks: the Hub Repeater, the Hub Controller, and the Transaction Translator. The chapter also describes the hub's operation for error recovery, reset, and suspend/resume. The second half of the chapter defines hub request behavior and hub descriptors.

The hub specification supplies sufficient additional information to permit an implementer to design a hub that conforms to the USB specification.

11.1 Overview

Hubs provide the electrical interface between USB devices and the host. Hubs are directly responsible for supporting many of the attributes that make USB user friendly and hide its complexity from the user. Listed below are the major aspects of USB functionality that hubs must support:

- Connectivity behavior
- Power management
- Device connect/disconnect detection
- Bus fault detection and recovery
- High-, full-, and low-speed device support

A hub consists of three components: the Hub Repeater, the Hub Controller, and the Transaction Translator. The Hub Repeater is responsible for connectivity setup and tear-down. It also supports exception handling, such as bus fault detection and recovery and connect/disconnect detect. The Hub Controller provides the mechanism for host-to-hub communication. Hub-specific status and control commands permit the host to configure a hub and to monitor and control its individual downstream facing ports. The Transaction Translator responds to high-speed split transactions and translates them to full-/low-speed transactions with full-/low-speed devices attached on downstream facing ports.

11.1.1 Hub Architecture

Figure 11-1 shows a hub and the locations of its upstream and downstream facing ports. A hub consists of a Hub Repeater section, a Hub Controller section, and a Transaction Translator section. The hub must operate at high-speed when its upstream facing port is connected at high-speed. The hub must operate at full-speed when its upstream facing port is connected at full-speed.

The Hub Repeater is responsible for managing connectivity between upstream and downstream facing ports which are operating at the same speed. The Hub Repeater supports full-/low-speed connectivity and high-speed connectivity. The Hub Controller provides status and control and permits host access to the hub. The Transaction Translator takes high-speed split transactions and translates them to full-/low-speed transactions when the hub is operating at high-speed and has full-/low-speed devices attached. The operating speed of a device attached on a downstream facing port determines whether the Routing Logic connects a port to the Transaction Translator or hub repeater sections.
