LIGHT EMITTING DEVICE

Background

5 Light emitting devices typically include a light
emitting diode (LED) located in a cavity. The walls of the
cavity may be reflective in order to increase the efficiency
of the light-emitting device. The cavity is filled with an
encapsulate, such as silicone, in order to protect the LED
10 and the reflector.

Encapsulants tend to delaminate or pull away from the
reflector walls. Once the delamination has started on a
small section of the wall, the delamination typically
continues rapidly. The delaminated areas may enable
15 contaminants to enter the light-emitting device and either
cause failure or a reduction in the efficiency of the light-
emitting device. The delamination may also adversely affect
the light pattern proximate the delaminated wall, which may
reduce or diffract the emitted light. Eventually, the
20 delamination may spread to the LED, which may cause damage
to the LED and failure of the light-emitting device.
