The present invention also relates to the pharmaceutically acceptable acid addition salts of compounds of the formula I. The acids which are used to prepare the pharmaceutically acceptable acid addition salts of the aforementioned base compounds of this invention are those which form non-toxic acid addition salts, i.e., salts containing pharmacologically acceptable anions, such as the hydrochloride, hydrobromide, hydroiodide, nitrate, sulfate, bisulfate, phosphate, acid phosphate, acetate, lactate, citrate, acid citrate, tartrate, bitartrate, succinate, maleate, fumarate, gluconate, saccharate, benzoate, methanesulfonate, ethanesulfonate, benzenesulfonate, p-toluenesulfonate and pamoate [i.e., 1,1'-methylene-bis-(2-hydroxy-3naphthoate)]salts.

The invention also relates to base addition salts of formula I. The chemical bases that may be used as reagents to prepare pharmaceutically acceptable base salts of those compounds of formula I that are acidic in nature are those that form non-toxic base salts with such compounds. Such non-toxic base salts include, but are not limited to those derived from such pharmacologically accepiable cations such as alkali metal cations (e.g., potassium and sodium) and alkaline earth metal cations (e.g., calcium and magnesium), ammonium or watersoluble amine addition salts such as N -methylglucamine-(meglumine), trimethyl-ammonium or diethylammonium, and the lower alkanolammonium salts such tris-(hydroxymethyl)methylammonium and other base salts of pharmaceutically acceptable organic amines.

The compounds of the formula I which are basic in nature are capable of forming a wide variety of different salts with various inorganic and organic acids. Although such salts must be pharmaceutically acceptable for administration to animals, it is often desirable in practice to initially isolate a compound of the formula I from the reaction mixture as a pharmaceutically unacceptable salt and then simply convert the latter back to the free base compound by treatment with an alkaline reagent, and subsequently convert the free base to a pharmaceutically acceptable acid addition salt. The acid addition salts of the base compounds of this invention are readily prepared by treating the base compound with a substantially equivalent amount of the chosen mineral or organic acid in an aqueous solvent medium or in a suitable organic solvent such as methanol or ethanol. Upon careful evaporation of the solvent, the desired solid salt is obtained.

The acids which are used to prepare the pharmaceutically acceptable acid addition salts of the base compounds of this invention are those which form non-toxic acid addition salts, i.e., salts containing pharmacologically acceptable anions, such as hydrochloride, hydrobromide, hydroiodide, nitrate, sulfate or bisulfate, phosphate or acid phosphate, acetate, lactate, citrate or acid citrate, tartrate or bitartrate, succinate, maleate, fumarate, gluconate, saccharate, benzoate, methanesulfonate and pamoate [i.e., 1, 1 '-methylene-bis-(2-hydroxy-3naphthoate)] salts.

Those compounds of the formula I which are also acidic in nature, are capable of forming base salts with various pharmacologically acceptable cations. Examples of such salts include the alkali metal or alkaline-earth metal salts and particularly, the sodium and potassium salts. These salts are all prepared by conventional techniques. The chemical bases which are used as reagents to prepare the pharmaceutically acceptable base salts of this invention are those which form non-toxic base salts with the herein described acidic compounds of formula I. These non-toxic base salts include those derived from such pharmacologically acceptable cations as sodium, potassium, calcium and magnesium, etc. These salts can easily be prepared by treating the corresponding acidic compounds with an aqueous solution containing the desired pharmacologically acceptable cations, and then evaporating the resulting solution to dryness, preferably under reduced pressure. Alternatively, they may also be prepared by mixing lower alkanolic solutions of the acidic
compounds and the desired alkali metal alkoxide together, and then evaporating the resulting solution to dryness in the same manner as before. In either case, stoichiometric quantities of reagents are preferably employed in order to ensure completeness of reaction and maximum product yields.

The ability of the compounds of formula I or their pharmaceutically acceptable salts (hereinafter also referred to as the compounds of the present invention) to inhibit matrix metalloproteinases or the pruduction of tumor necrosis factor (TNF) and, consequently, demonstrate their effectiveness for treating diseases characterized by matrix metalioproteinase or the production of tumor necrosis factor is shown by the following in vitro assay tests.

## Biological Assay

Inhibition of Human Collagenase (MMP-1)
Human recombinant collagenase is activated with trypsin using the following ratio: 10 mg trypsin per 100 mg of collagenase. The trypsin and collagenase are incubated at room temperature for 10 minutes then a five fold excess ( $50 \mathrm{mg} / 10 \mathrm{mg}$ trypsin) of soybean trypsin inhibitor is added.

10 mM stock solutions of inhibitors are made up in dimethyl sulfoxide and then diluted using the following Scheme:

10 mM ——— $120 \mu \mathrm{M} \longrightarrow 12 \mu \mathrm{M} \rightarrow 1.2 \mu \mathrm{M}$ ———> $0.12 \mu \mathrm{M}$
Twenty-five microliters of each concentration is then added in triplicate to appropriate wells of a 96 well microfluor plate. The final concentration of inhibitor will be a $1: 4$ dilution after addition of enzyme and substrate. Positive controls (enzyme, no inhibitor) are set up in wells D1D6 and blanks (no enzyme, no inhibitors) are set in wells D7-D12.

Collagenase is diluted to $400 \mathrm{ng} / \mathrm{ml}$ and 25 ml is then added to appropriate wells of the microfluor plate. Final concentration of collagenase in the assay is $100 \mathrm{ng} / \mathrm{ml}$.

Substrate (DNP-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)- $\mathrm{NH}_{2}$ ) is made as a 5 mM stock in dimethyl sulfoxide and then diluted to 20 mM in assay buffer. The assay is initiated by the addition of 50 ml substrate per well of the microfluor plate to give a final concentration of 10 mM .

Fluorescence readings ( 360 nM excitation, 460 nm emission) were taken at time 0 and then at 20 minute intervals. The assay is conducted at room temperature with a typical assay time of 3 hours.

Fluorescence vs time is then plotted for both the blank and collagenase containing samples (data from triplicate determinations is averaged). A time point that provides a good signal (the blank) and that is on a linear part of the curve (usually around 120 minutes) is chosen to determine $I C_{50}$ values. The zero time is used as a blank for each compound at each
concentration and these values are subtracted from the 120 minute data. Data is plotted as inhibitor concentration vs \% control (inhibitor fluorescence divided by fluorescence of collagenase alone $\times 100$ ). $1 \mathrm{C}_{50}$ 's are determined from the concentration of inhibitor that gives a signal that is $50 \%$ of the control.

If $\mathrm{IC}_{50}$ 's are reported to be $<0.03 \mathrm{mM}$ then the inhibitors are assayed at concentrations of $0.3 \mathrm{mM}, 0.03 \mathrm{mM}, 0.03 \mathrm{mM}$ and 0.003 mM .

Inhibition of Gelatinase (MMP-2)
Inhibition of gelatinase activity is assayed using the Dnp-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)- $\mathrm{NH}_{2}$ substrate ( 10 mM ) under the same conditions as inhibition of human collagenase (MMP-1).

72 kD gelatinase is activated with 1 mM APMA ( p -aminophenyl mercuric acetate) for 15 hours at $4^{\circ} \mathrm{C}$ and is diluted to give a final concentration in the assay of $100 \mathrm{mg} / \mathrm{ml}$. Inhibitors are diluted as for inhibition of human collagenase (MMP-1) to give final concentrations in the assay of $30 \mathrm{mM}, 3 \mathrm{mM}, 0.3 \mathrm{mM}$ and 0.03 mM . Each concentration is done in triplicate.

Fluorescence readings ( 360 nm excitation, 460 emission) are taken at time zero and then at 20 minutes intervals for 4 hours.
$\mathrm{IC}_{50}$ 's are determined as per inhibition of human collagenase (MMP-1). If $\mathrm{IC}_{50}$ 's are reported to be less than 0.03 mM , then the inhibitors are assayed at final concentrations of 0.3 $\mathrm{mM}, 0.03 \mathrm{mM}, 0.003 \mathrm{mM}$ and 0.003 mM .

Inhibition of Stromelysin Activity (MMP-3)
Inhibition of stromelysin activity is based on a modified spectrophotometric assay described by Weingarten and Feder (Weingarten, H. and Feder, J., Spectrophotometric Assay for Vertebrate Collagenase, Anal. Biochem. 147, 437-440 (1985)). Hydrolysis of the thio peptolide substrate $\left[\right.$ Ac-Pro-Leu-Gly-SCH $\left.\left[\mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right] \mathrm{CO}-L e u-G l y-\mathrm{OC}_{2} \mathrm{H}_{5}\right]$ yields a mercaptan fragment that can be monitored in the presence of Ellman's reagent.

Human recombinant prostromelysin is activated with trypsin using a ratio of 1 ml of a 10 $\mathrm{mg} / \mathrm{ml}$ trypsin stock per 26 mg of stromelysin. The trypsin and stromelysin are incubated at $37^{\circ} \mathrm{C}$ for 15 minutes followed by 10 ml of $10 \mathrm{mg} / \mathrm{ml}$ soybean trypsin inhibitor for 10 minutes at $37^{\circ} \mathrm{C}$ for 10 minutes at $37^{\circ} \mathrm{C}$ to quench trypsin activity.

Assays are conducted in a total volume of 250 ml of assay buffer ( 200 mM sodium chloride, 50 mM MES, and 10 mM calcium chloride, pH 6.0 ) in 96 -well microliter plates. Activated stromelysin is diluted in assay buffer to $25 \mathrm{mg} / \mathrm{ml}$. Ellman's reagent (3-Carboxy-4nitrophenyl disulfide) is made as a 1 M stock in dimethyl formamide and diluted to 5 mM in assay buffer with 50 ml per well yielding at 1 mM final concentration.

10 mM stock solutions of inhibitors are made in dimethyl sulfoxide and diluted serially in assay buffer such that addition of 50 mL to the appropriate wells yields final concentrations of 3 $\mathrm{mM}, 0.3 \mathrm{mM}, 0.003 \mathrm{mM}$, and 0.0003 mM . All conditions are completed in triplicate.

A 300 mM dimethyl sulfoxide stock solution of the peptide substrate is diluted to 15 mM in assay buffer and the assay is initiated by addition of 50 ml to each well to give a final concentration of 3 mM substrate. Blanks consist of the peptide substrate and Ellman's reagent without the enzyme. Product formation was monitored at 405 nm with a Molecular Devices UVmax plate reader.
$\mathrm{IC}_{50}$ values were determined in the same manner as for collagenase.

## Inhibition of MMP-13

Human recombinant MMP-13 is activated with 2 mM APMA ( p -aminophenyl mercuric acetate) for 1.5 hours, at $37^{\circ} \mathrm{C}$ and is diluted to $400 \mathrm{mg} / \mathrm{ml}$ in assay buffer ( 50 mM Tris, pH 7.5 , 200 mM sodium chloride, 5 mM calcium chloride, 20 mM zinc chloride, $0.02 \%$ brij). Twenty-five microliters of diluted enzyme is added per well of a 96 well microfluor plate. The enzyme is then diluted in a $1: 4$ ratio in the assay by the addition of inhibitor and substrate to give a final concentration in the assay of $100 \mathrm{mg} / \mathrm{ml}$.

10 mM stock solutions of inhibitors are made up in dimethyl sulfoxide and then diluted in assay buffer as per the inhibitor dilution scheme for inhibition of human collagenase (MMP-1): Twenty-five microliters of each concentration is added in triplicate to the microfluor plate. The final concentrations in the assay are $30 \mathrm{mM}, 3 \mathrm{mM}, 0.3 \mathrm{mM}$, and 0.03 mM .

Substrate (Dnp-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)-NH2) is prepared as for inhibition of human collagenase (MMP-1) and 50 ml is added to each well to give a final assay concentration of 10 mM . Fluorescence readings ( 360 nM excitation; 450 emission) are taken at time 0 and every 5 minutes for 1 hour.

Positive controls consist of enzyme and substrate with no inhibitor and blanks consist of substrate only.
$I C_{50}$ 's are determined as per inhibition of human collagenase (MMP-1). If $I C_{50}$ 's are reported to be less than 0.03 mM , inhibitors are then assayed at final concentrations of 0.3 mM , $0.03 \mathrm{mM}, 0.003 \mathrm{mM}$ and 0.0003 mM .

All of the compounds of the invention that were tested in the Inhibition of MMP-13 assay had $\mathrm{IC}_{50}$ 's of less than 50 nm .

## Inhibition of TNF Production

The ability of the compounds or the pharmaceutically acceptable salts thereof to inhibit the production of TNF and, consequently, demonstrate their effectiveness for treating diseases involving the production of TNF is shown by the following in vitro assay:

Human mononuclear cells were isolated from anti-coagulated human blood using a onestep Ficoll-hypaque separation technique. (2) The mononuclear cells were washed three times in Hanks balanced salt solution (HBSS) with divalent cations and resuspended to a density of 2 x $10^{6} / \mathrm{ml}$ in HBSS containing $1 \%$ BSA. Differential counts determined using the Abbott Cell Dyn 3500 analyzer indicated that monocytes ranged from 17 to $24 \%$ of the total cells in these preparations.

180 m of the cell suspension was aliquoted into flat bottom 96 well plates (Costar). Additions of compounds and LPS ( $100 \mathrm{ng} / \mathrm{ml}$ final concentration) gave a final volume of 200 ml . All conditions were performed in triplicate. After a four hour incubation at $37^{\circ} \mathrm{C}$ in an humidified $\mathrm{CO}_{2}$ incubator, plates were removed and centrifuged ( 10 minutes at approximately $250 \times \mathrm{g}$ ) and the supernatants removed and assayed for TNF $\alpha$ using the R\&D ELISA Kit $®$.

For administration to mammals, including humans, for the inhibition of matrix metalloproteinases or the production of tumor necrosis factor (TNF), a variety of conventional routes may be used including oral, parenteral (e.g., intravenous, intramuscular or subcutaneous), buccal, anal and topical. In general, the active compound will be administered at dosages between about 0.1 and $25 \mathrm{mg} / \mathrm{kg}$ body weight of the subject to be treated per day, preferably from about 0.3 to $5 \mathrm{mg} / \mathrm{kg}$. Preferably the active compound will be administered orally or parenterally. However, some variation in dosage will necessarily occur depending on the condition of the subject being treated. The person responsible for administration will, in any event, determine the appropriate dose for the individual subject.

The compounds of the present invention can be administered in a wide variety of different dosage forms, in general, the therapeutically effective compounds of this invention are present in such dosage forms at concentration levels ranging from about $5.0 \%$ to about $70 \%$ by weight.

For oral administration, tablets containing various excipients such as microcrystalline cellulose, sodium citrate, calcium carbonate, dicalcium phosphate and glycine may be employed along with various disintegrants such as starch (and preferably corn, potato or tapioca starch), alginic acid and certain complex silicates, together with granulation binders like polyvinylpyrrolidone, sucrose, gelation and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl sulfate and talc are often very useful for tabletting purposes. Solid compositions of a similar type may also be employed as fillers in gelatin capsules; preferred materials in this connection also include lactose or milk sugar as well as high molecular weight polyethylene glycols. When aqueous suspensions and/or elixirs are desired for oral administration, the active ingredient may be combined with various sweetening or flavoring agents, coloring matter or dyes. and, if so desired, emulsifying and/or suspending agents as well,
together with such diluents as water, ethanol, propylene glycol, glycerin and various like combinations thereof. In the case of animals, they are advantageously contained in an animal feed or drinking water in a concentration of $5-5000 \mathrm{ppm}$, preferably 25 to 500 ppm .

For parenteral administration (intramuscular, intraperitoneal, subcutaneous and intravenous use) a sterile injectable solution of the active ingredient is usually prepared. Solutions of a therapeutic compound of the present invention in either sesame or peanut oil or in aqueous propylene glycol may be employed. The aqueous solutions should be suitably adjusted and buffered, preferably at a pH of greater than 8 , if necessary and the liquid diluent first rendered isotonic. These aqueous solutions are suitable intravenous injection purposes. The oily solutions are suitable for intraarticular, intramuscular and subcutaneous injection purposes. The preparation of all these solutions under sterile conditions is readily accomplished by standard pharmaceutical techniques well known to those skilled in the art. in the case of animals, compounds can be administered intramuscularly or subcutaneously at dosage levels of about 0.1 to $50 \mathrm{mg} / \mathrm{kg} /$ day, advantageously 0.2 to $10 \mathrm{mg} / \mathrm{kg} /$ day given in a single dose or up to 3 divided doses.

The active compounds of the invention may also be formulated in rectal compositions such as suppositories or retention enemas, e.g., containing conventional suppository bases such as cocoa butter or other glycerides.

For intranasal administration or administration by inhalation, the active compounds of the invention are conveniently delivered in the form of a solution or suspension from a pump spray container that is squeezed or pumped by the patient or as an aerosol spray presentation from a pressurized container or a nebulizer, with the use of a suitable propellant, e.g., dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafiuoroethane, carbon dioxide or other suitable gas. In the case of a pressurized aerosol, the dosage unit may be determined by providing a valve to deliver a metered amount. The pressurized container or nebulizer may contain a solution or suspension of the active compound. Capsules and cartridges (made, for example, from gelatin) for use in an inhaler or insufflator may be formulated containing a powder mix of a compound of the invention and a suitable powder base such as lactose or starch.

The following Examples illustrate the preparation of the compounds of the present invention. Melting points are uncorrected. NMR data are reported in parts per million (d) and are referenced to the deuterium lock signal from the sample solvent (deuteriochloroform unless otherwise specified). Commercial reagents were utilized without further purification. THF refers to tetrahydrofuran. DMF refers to $\mathrm{N}, \mathrm{N}$-dimethylformamide. Chromatography refers to column chromatography performed using $32-63 \mathrm{~mm}$ silica gel and executed under
nitrogen pressure (flash chromatography) conditions. Room or ambient temperature refers to $20-25^{\circ} \mathrm{C}$. All non-aqueous reactions were run under a nitrogen atmosphere for convenience and to maximize yields. Concentration at reduced pressure means that a rotary evaporator was used.

## ARYLSULFONYL HYDROXAMIC ACID DERIVATIVES

## Background of the Invention

The present invention relates to arylsulfonyl hydroxamic acid derivatives which are inhibitors of matrix metalloproteinases or the production of tumor necrosis factor (TNF) and as such are useful in the treatment of a condition selected from the group consisting of arthritis, cancer, tissue ulceration, restenosis, periodontal disease, epidermolysis bullosa, scleritis and other diseases characterized by matrix metalloproteinase activity, AIDS, sepsis, septic shock and other diseases involving the production of TNF. In addition, the compounds of the present invention may be used in combination therapy with standard non-steroidal anti-inflammatory drugs (hereinafter NSAID'S) and analgesics for the treatment of arthritis, and in combination with cytotoxic drugs such as adriamycin, daunomycin, cis-platinum, etoposide, taxol, taxotere and alkaloids, such as vincristine, in the treatment of cancer.

This invention also relates to a method of using such compounds in the treatment of the above diseases in mammals, especially humans, and to pharmaceutical compositions useful therefor.

There are a number of enzymes which effect the breakdown of structural proteins and which are structurally related metalloproteases. Matrix-degrading metalloproteinases, such as gelatinase, stromelysin and collagenase, are involved in tissue matrix degradation (e.g. collagen collapse) and have been implicated in many pathological conditions involving abnormal connective tissue and basement membrane matrix metabolism, such as arthritis (e.g. osteoarthritis and meumatoid arthritis), tissue ulceration (e.g. comeal, epidermal and gastric ulceration), abnormal wound healing, periodontal disease, bone disease (e.g. Paget's disease and osteoporosis), tumor metastasis or invasion, as well as HIV-infection (J. Leuk. Biol., 52 (2): 244-248, 1992).

Tumor necrosis factor is recognized to be involved in many infectious and autoimmune diseases (W. Fiers, FEBS Letters, 1991, 285, 199). Furthermore, it has been shown that TNF is the prime mediator of the inflammatory response seen in sepsis and septic shock (C.E. Spooner et al., Clinical Immunology and Immunopathology, 1992, 62 S11).

Preparation 1 refers to the preparation of intermediates of the formula VI . Compounds of the formula VI are converted to compounds of the formula I according to the methods of Scheme 1. The starting materials of formula XVI can be prepared according to methods well known to those of ordinary skill in the art.

In reaction 1 of Preparation 1, the compound of formula XVI is converted to the corresponding hydroxy ester compound of formula VI by first reacting XVI with an arylsulfonylhalide in the presence of triethylamine and an aprotic solvent, such as methylene chloride, tetrahydrofuran or dioxane, at a temperature between about $20^{\circ} \mathrm{C}$ to about $30^{\circ} \mathrm{C}$, preferably at room temperature. The compound so formed is further reacted with a compound of the formula

wherein $R^{25}$ is carbobenzyloxy, $\left(C_{1}-C_{8}\right)$ alkyl, benzyl, allyi or tert-butyl, in the presence of sodium hexamethyldisilazane and a tetrahydrofuran-dimethylformamide solvent mixture at a temperature between about $-20^{\circ} \mathrm{C}$ to about $20^{\circ} \mathrm{C}$, preferably about $0^{\circ} \mathrm{C}$, to form the hydroxy ester compound of formula VI.

Preparation 2 refers to an alternate method of preparing compounds of the formula VI. The starting materials of formula XVIII can be prepared according to methods well known to those of ordinary skill in the art. In reaction 1 of Preparation $\underline{2}$, the amine compound of formula XVIII, wherein $\mathrm{R}^{25}$ is as defined above, is converted to the corresponding aryisulfonyl amine compound of formula XVII by (1) reacting XVIII with an arylsulfonylhalide in the presence of triethylamine and an aprotic solvent, such as methylene chloride, tetrahydrofuran, or dioxane, at a temperature between about $20^{\circ} \mathrm{C}$ to about $30^{\circ} \mathrm{C}$, preferably at room temperature, (2) reacting the compound so formed with a compound of the formula

in the presence of sodium hexamethyldisilazane and a tetrahydrofurandimethylformamide solvent mixture at a temperature between about $-20^{\circ} \mathrm{C}$ to about $20^{\circ} \mathrm{C}$. preferably about $0^{\circ} \mathrm{C}$, and (3) further reacting the compound so formed with ozone in a methylene chloride-methanol solution at a temperature between about $-90^{\circ} \mathrm{C}$
to about $-70^{\circ} \mathrm{C}$, preferably about $-78^{\circ} \mathrm{C}$. The unstable ozonide compound so formed is then reacted with triphenylphosphine to form the arylsulfonyl amine compound formula XVII. In Reaction 2 of Preparation 2, the aryisulfonyl amine compound of formula XVII is converted to the corresponding hydroxy ester compound of formula VI by reacting XVII with a compound of the formula

wherein $W$ is lithium, magnesium, copper or chromium.
Scheme 1 refers to the preparation of compounds of the formula II, which are compounds of the formula $I$, wherein $X$ and $Y$ are carbon; $R^{4}, R^{0}$ and $R^{7}$ are hydrogen; and the dashed line between $X$ and $Y$ is absent. In reaction 1 of Scheme 1, the compound of formula VI, wherein the $R^{25}$ protecting group is carbobenzyloxy, ( $C,-\mathrm{C}_{6}$ ) alkyl, benzyl, allyl or tert-butyl, is converted to the corresponding morpholinone compound of formula $V$ by lactonization and subsequent Claisen rearrangement of the compound of formula VI. The reaction is facilitated by the removal of the $R^{25}$ protecting group from the compound of formula VI and is carried out under conditions appropriate for that particular $R^{25}$ protecting group in use. Such conditions include: (a) treatment with hydrogen and a hydrogenation catalyst, such as $10 \%$ palladium on carbon, where $R^{25}$ is carbobenzyloxy, (b) saponification where $R^{25}$ is lower alkyl, (c) hydrogenolysis where $R^{25}$ is benzyl, (d) treatment with a strong acid, such as trifluoroacetic acid or hydrochloric acid, where $R^{25}$ is tert-butyl, or (e) treatment with tributyltinhydride and acetic acid in the presence of catalytic bis(triphenylphosphine) palladium (II) chloride where $R^{25}$ is allyl.

In reaction 2 of Scheme 1 , the morpholinone compound of formula $V$ is converted to the carboxylic acid compound of formula IV by reacting $\mathbf{V}$ with lithium hexamethyldisilazane in an aprotic solvent, such as tetrahydrofuran, at a temperature between about $-90^{\circ} \mathrm{C}$ to about $-70^{\circ} \mathrm{C}$, preferably about $-78^{\circ} \mathrm{C}$. Trimethylsilyt chloride is then added to the reaction mixture and the solvent, tetrahydroturan, is removed in vacuo and replaced with toluene. The resuling reaction mixture is heated to a temperature between about $100^{\circ} \mathrm{C}$ to about $120^{\circ} \mathrm{C}$, preferably about $110^{\circ} \mathrm{C}$, and treated with hydrochloric acid to form the carboxylic acid compound of formula IV.

In reaction 3 of Scheme 1, the carboxylic acid compound of formula IV is converted to the corresponding hydroxamic acid compound of formula III by treating IV with 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide and 1-hydroxybenztriazole in a polar solvent, such as dimethylformamide, followed by the addition of hydroxylamine to the reaction mixture after a time period between about 15 minutes to about 1 hour, preferably about 30 minutes. The hydroxylamine is preferably generated in situ from a salt form, such as hydroxylamine hydrochloride, in the presence of a base, such as N -methylmorpholine. Alternatively, a protected derivative of hydroxylamine or its salt form, where the hydroxyl group is protected as a tert-butyl, benzyl or allyl ether, may be used in the presence of (benzotriazol-1-yloxy)tris(dimethylamino) phosphonium hexafiuorphosphate and a base, such as $N$-methylmorpholine. Removal of the hydroxylamine protecting group is carried out by hydrogenolysis for a benzyl protecting group or treatment with a strong acid, such as trifluoroacetic acid, for a tert-butyl protecting group. The allyl protecting group may be removed by treatment with tributyltinhydride and acetic acid in the presence of catalytic bis(triphenylphosphine) palladium (II) chloride. N,O-bis(4-methoxybenzyl)hydroxylamine may also be used as the protected hydroxylamine derivative where deprotection is achieved using a mixture of methanesulfonic acid and trifluoroacetic acid.

In reaction 4 of Scheme 1, the hydroxamic acid compound of formula III is converted, if desired, to the corresponding piperidine compound of formula II by treating III with hydrogen and a hydrogenation catayst, such a $10 \%$ paladium on carbon.

Scheme 2 refers to the preparation of compounds of the formula VII, which are compound of the formula I wherein $Y$ is nitrogen; $X$ is carbon; $R^{1}, R^{2}, R^{3}, R^{4}, R^{7}$ and $R^{8}$ are hydrogen, and $R^{0}$ is absent. The starting materials of formula $I X$ can be prepared according to methods well known to those of ordinary skill in the art. In reaction 1 of Scheme 2, the arylsulfonylpiperazine compound of formula $I X$, wherein $R^{26}$ is carbobenzyloxy, benzyt or carbotertbutyloxy, is converted to the compound of formula VIII by reacting IX with a protected derivative of hydroxylamine of the formula

$$
\mathrm{R}^{27} \mathrm{ONH}_{2} \cdot \mathrm{HCl}
$$

wherein $R^{27}$ is tertbutyl, benzyl or allyl, in the presence of dicyclohexylcarbodimide, dimethylaminopyridine and an aprotic solvent, such as methylene chloride. The $R^{20}$ protecting group is chosen such that it may be selectively removed in the presence of an without loss of the $R^{27}$ protecting group, therefore, $R^{26}$ cannot be the same as $R^{27}$.

Removal of the $\mathrm{R}^{26}$ protecting group from the compound of formula X is carried out under conditions appropriate for that particular $R^{20}$ protecting group in use. Such conditions include; (a) treatment with a hydrogen and a hydrogenation catalyst, such as $10 \%$ palladium on carbon, where $R^{26}$ is carbobenzyioxy, (b) hydrogenolysis where $R^{26}$ is benzyl or (c) treatment with a strong acid, such as trifluoroacetic acid or hydrochloric acid where $\mathrm{R}^{20}$ is carbotertbutyloxy.

In reaction 2 of Scheme 2, the compound of formula VIII is converted to the corresponding hydroxamic acid compound of formula VII, wherein $R^{5}$ is hydrogen or ( $C_{1}-C_{0}$ )alkyl, by reacting, if desired, VIII with an alkylhalide when $R^{5}$ is $\left(C_{1}-C_{0}\right)$ alkyl. Subsequent removal of the $\mathrm{R}^{27}$ hydroxylamine protecting group is carried out by hydrogenolysis for a benzyl protecting group or treatment with a strong acid, such as trifluoroacetic acid, for a tert-butyl protecting group. The allyl protecting group may be removed by treatment with tributyitinhydride and acetic acid in the presence of catalytic bis(triphenylphosphine) palladium (II) chloride.

Scheme 3 refers to the preparation of compounds of the formula $X$, which are compounds of the formula I wherein $Y$ is nitrogen; $X$ is carbon; $R^{2}, R^{7}, R^{8}$ and $R^{8}$ are hydrogen; $R^{3}$ and $R^{4}$ taken together are carbonyl; $R^{5}$ is hydrogen, and $R^{6}$ is absent. In reaction 1 of Scheme 3 , the aryisulfonylamine compound of formula XII, wherein $R^{25}$ is as defined above, is converted to the corresponding piperazine compound of formula XI by reacting XII with a carbodiimide and a base, such as triethylamine. The compound of formula XI is further reacted to give the hydroxamic acid compound of formula $X$ according to the procedure described above in reaction 3 of Scheme 1.

Scheme 4 refers to the preparation of compounds of the formula XIII. The starting materials of formula XVIII can be prepared according to methods well known to those of ordinary skill in the art. Compounds of the formula XIII are compounds of the formula I wherein $X$ is carbon, and the dotted line between $X$ and $Y$ is absent. In reaction 1 of Scheme 4 , removal of the $R^{28}$ protecting group and subsequent reductive amination of the compound of formula XXII, wherein $Y$ is oxygen, sulfur or carbon, to give the corresponding imine compound of formula XXI is carried out under conditions appropriate for that particular $\mathrm{R}^{28}$ protecting group in use. Such conditions include those used above for removal of the $R^{2 \theta}$ protecting group in reaction 1 of Scheme 2 .

In reaction 2 of Scheme 4, the imine compound of formula XXI is converted to the corresponding piperidine compound of formula $\mathbf{X X}$ by reacting $\mathbf{X X I}$ with a nucleophile of the formula $R^{2} M$ wherein $M$ is lithium, magnesium halide or cerium
halide. The reaction is carried out in ether solvents, such as diethyl ether or tetrahydrofuran, at a temperature between about $-78^{\circ} \mathrm{C}$ to about $0^{\circ} \mathrm{C}$, preferably about $-70^{\circ} \mathrm{C}$.

In reaction 3 of Scheme 4, the sulfonation of the piperidine compound of formula $\mathbf{X X}$ to given the corresponding aryisulfonyipiperidine compound of formula XIX is carried out by reacting XX with an arylsulfonylhalide in the presence of triethylamine and an aprotic solvent, such as methylene chloride, tetrahydrofuran or dioxane, at a temperature between about $20^{\circ} \mathrm{C}$ to about $30^{\circ} \mathrm{C}$, preferably at room temperature.

In reaction 4 of Scheme 4 , the arylsulfonyipiperidine compound of formula XIX is converted to the hydroxamic acid compound of formula XIII according to the procedure described above in reaction 3 of Scheme 1.

Scheme 5 refers to the preparation of compounds of the formula XIV, which are compounds of formula $I$ wherein $Y$ is nitrogen, $X$ is carbon, the dotted line between $X$ and $Y$ is absent, $R^{5}$ is hydrogen and $R^{0}$ is absent. In reaction 1 of Scheme 5 , the compound of formula $X X Y 1$, wherein the $R^{29}$ and $R^{39}$ protecting groups are each independently selected from the group consisting of carbobenzyloxy, benzyl and carbotertbutyloxy and $R^{30}$ is carbobenzyloxy, $\left(C_{1}-C_{6}\right)$ alkyl, benzyl, allyt or tert-butyl, is converted to the corresponding imine compound of formula XOV by the removal of the $R^{29}$ protecting group and subsequent reductive amination of the compound of formula XXVI. The $R^{29}$ protecting group is chosen such that it may be selectively removed in the presence of and without loss of the $R^{31}$ protecting group. Removal of the $R^{29}$ protecting group from the compound of formula $X X V I$ is carried out under conditions appropriate for that particular $R^{29}$ protecting group in use which will not affect the $R^{31}$ protecting group. Such conditions include; (a) treatment with hydrogen and a hydrogenation catalyst, such as $10 \%$ palladium on carbon, where $R^{29}$ is carbobenzytoxy and $R^{31}$ is tert-butyl, (b) saponification where $R^{29}$ is $\left(C_{1}-C_{6}\right)$ alkyl and $R^{31}$ is tert-butyl, (c) hydrogenolysis where $R^{29}$ is benzyi and $R^{31}$ is $\left(C_{1}-C_{8}\right)$ alkyl or tert-butyl, (d) treatment with a strong acid such as trifluoroacetic acid or hydrochloric acid where $R^{29}$ is tert-butyl and $R^{31}$ is $\left(C_{1}-C_{8}\right)$ alkyl, benzyi or allyl, or $(e)$ treatment with tributyitinhydride and acetic acid in the presence of catalytic bis(triphenyiphosphine) palladium (II) chloride where $R^{29}$ is allyl and $R^{31}$ is $\left(C_{1}-C_{8}\right)$ alkyl, benzyl or tert-butyl. The $R^{30}$ protective group may be selected such that it is removed in the same reaction step as the $R^{29}$ protecting group.

In reaction 2 of Scheme 5 , the imine compound of formula XXV is converted to the corresponding compound of formula XXIV by reacting XXV with a nucleophile of the formula $R^{2} M$ wherein $M$ is lithium, magnesium halide or calcium halide. The reaction is carried out in ether solvents, such as diethyl ether or tetrahydrofuran, at a temperature between about $-78^{\circ} \mathrm{C}$ to about $0^{\circ} \mathrm{C}$, preferably about $-70^{\circ} \mathrm{C}$.

In reaction 3 of Scheme 5 , the sulfonation of the piperidine compound of formula XXIV to give the corresponding aryisulfonylpiperidine compound of formula III is carried out according to the procedure described above in reaction 3 of Scheme 4.

In reaction 4 of Scheme $\underline{5}$, the aryisulfonylpiperidine compound of formula XXIII is converted to the hydroxamic acid compound of formula XIV by (1) removing the $R^{30}$, if needed, and $\mathrm{R}^{31}$ protecting groups from XXIII followed by (2) reacting XXIII according to the procedure described above in reaction 3 of Scheme 1. Removal of the $R^{30}$ and $R^{31}$ protecting groups from the compound of formula XXIII is carried out under conditions appropriate for that particular $R^{30}$ and $R^{31}$ protecting group in use. Such conditions include those used above for removal of the $R^{25}$ protecting group in reaction 1 of Scheme 1.

Pharmaceutically acceptable saits of the acidic compounds of the invention are salts formed with bases, namely cationic salts such as alkali and alkaline earth metal saits, such as sodium, lithium, potassium, calcium, magnesium, as well as ammonium slats, such as ammonium, trimethyl-ammonium, diethylammonium, and tris-(hydroxymethyl)-methylammonium salts.

Similarly acid addition salts, such as of mineral acids, organic carboxylic and organic sulfonic acids e.g. hydrochloric acid, methanesulfonic acid, maleic acid, are also possible provided a basic group, such as pyridyl, constitutes part of the structure.

The ability of the compounds of formula I or their pharmaceutically acceptable salts (the compounds of the invention) to inhibit matrix metalloproteinases or the production of tumor necrosis factor (TNF) and, consequently, demonstrate their effectiveness for treating diseases characterized by matrix metalloproteinase or the production of tumor necrosis factor is shown by the following in vitro assay tests.

## Biological Assay

## Inhibition of Human Collagenase (MMP-1)

Human recombinant collagenase is activated with trypsin using the following ratio: $10 \mu \mathrm{~g}$ trypsin per $100 \mu \mathrm{~g}$ of collagenase. The trypsin and collagenase are incubated at room temperature for 10 minutes then a five fold excess ( $50 \mu \mathrm{~g} / 10 \mu \mathrm{~g}$ trypsin) of soybean trypsin inhibitor is added.

10 mM stock solutions of inhibitors are made up in dimethyl sulfoxide and then diluted using the following Scheme:
$10 \mathrm{mM} \longrightarrow 120 \mu \mathrm{M} \longrightarrow 12 \mu \mathrm{M} \longrightarrow 1.2 \mu \mathrm{M} \longrightarrow 0.12 \mu \mathrm{M}$
Twenty-five microliters of each concentration is then added in triplicate to appropriate wells of a 96 well microfluor plate. The final concentration of inhibitor will be a 1:4 dilution after addition of enzyme and substrate. Positive controls (enzyme, no inhibitor) are set up in wells D1-D6 and blanks (no enzyme, no inhibitors) are set in wells D7-D12.

Collagenase is diluted to $400 \mathrm{ng} / \mathrm{ml}$ and $25 \mu$ is then added to appropriate wells of the microfluor plate. Final concentration of collagenase in the assay is $100 \mathrm{ng} / \mathrm{ml}$.

Substrate (DNP-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)-NH2) is made as a 5 mM stock in dimethyl sulfoxide and then diluted to $20 \mu \mathrm{M}$ in assay buffer. The assay is initiated by the addition of $50 \mu$ l substrate per well of the microfluor plate to give a final concentration of $10 \mu \mathrm{M}$.

Fluorescence readings ( 360 nM excitation, 460 nm emission) were taken at time 0 and then at 20 minute intervals. The assay is conducted at room temperature with a typical assay time of 3 hours.

Fluorescence vs time is then plotted for both the blank and collagenase containing samples (data from triplicate determinations is averaged). A time point that provides a good signal (the blank) and that is on a linear part of the curve (usually around 120 minutes) is chosen to determine $I C_{50}$ values. The zero time is used as a blank for each compound at each concentration and these values are subtracted from the 120 minute data. Data is plotted as inhibitor concentration vs $\%$ control (inhibitor fluorescence divided by fluorescence of collagenase alone $\times 100$ ). $\quad 1 C_{50}$ 's are determined from the concentration of inhibitor that gives a signal that is $50 \%$ of the control.

If $1 C_{50}$ 's are reported to be $<0.03 \mu \mathrm{M}$ then the inhibitors are assayed at concentrations of $0.3 \mu \mathrm{M}, 0.03 \mu \mathrm{M}, 0.03 \mu \mathrm{M}$ and $0.003 \mu \mathrm{M}$.

Inhibition of Gelatinase (MMP-2)
Inhibition of gelatinase activity is assayed using the Dnp-Pro-Cha-Gly-Cys(Me)- His-Ala-Lys(NMA)-NH2 substrate ( $10 \mu \mathrm{M}$ ) under the same conditions as inhibition of human collagenase (MMP-1).

72 kD gelatinase is activated with 1 mM APMA ( p -aminophenyl mercuric acetate) for 15 hours at $4^{\circ} \mathrm{C}$ and is diluted to give a final concentration in the assay of 100 $\mathrm{mg} / \mathrm{ml}$. Inhibitors are diluted as for inhibition of human collagenase (MMP-1) to give final concentrations in the assay of $30 \mu \mathrm{M}, 3 \mu \mathrm{M}, 0.3 \mu \mathrm{M}$ and $0.03 \mu \mathrm{M}$. Each concentration is done in triplicate.

Fluorescence readings ( $\mathbf{3 6 0} \mathrm{nm}$ excitation, 460 emission) are taken at time zero and then at 20 minutes intervals for 4 hours.
$1 C_{50}{ }^{\prime}$ 's are determined as per inhibition of human collagenase (MMP-1). If $I C_{50}$ 's are reported to be less than $0.03 \mu \mathrm{M}$, then the inhibitors are assayed at final concentrations of $0.3 \mu \mathrm{M}, 0.03 \mu \mathrm{M}, 0.003 \mu \mathrm{M}$ and $0.003 \mu \mathrm{M}$.

Inhibition of Stromelysin Activity (MMP-3)
Inhibition of stromelysin activity is based on a modified spectrophotometric assay described by Weingarten and Feder (Weingarten, H. and Feder, J., Spectrophotometric Assay for Vertebrate Collagenase, Anal. Biochem. 147, 437-440 (1985)). Hydrolysis of the thio peptolide substrate [Ac-Pro-Leu-Gly$\mathrm{SCH}\left[\mathrm{CH}_{2} \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right] \mathrm{CO}$-Leu-Gly- $\left.\mathrm{OC}_{2} \mathrm{H}_{5}\right]$ yields a mercaptan fragment that can be monitored in the presence of Ellman's reagent.

Human recombinant prostromelysin is activated with trypsin using a ratio of $1 \mu \mathrm{l}$ of a $10 \mathrm{mg} / \mathrm{ml}$ trypsin stock per $26 \mu \mathrm{~g}$ of stromelysin. The trypsin and stromelysin are incubated at $37^{\circ} \mathrm{C}$ for 15 minutes followed by $10 \mu$ of $10 \mathrm{mg} / \mathrm{ml}$ soybean trypsin inhibitor for 10 minutes at $37^{\circ} \mathrm{C}$ for 10 minutes at $37^{\circ} \mathrm{C}$ to quench trypsin activity.

Assays are conducted in a total volume of $250 \mu$ of assay buffer $(200 \mathrm{mM}$ sodium chioride, 50 mM MES, and 10 mM calcium chloride, pH 6.0 ) in 96 -well microliter plates. Activated stromelysin is diluted in assay buffer to $25 \mu \mathrm{~g} / \mathrm{ml}$. Ellman's reagent (3-Carboxy-4-nitrophenyl disulfide) is made as a 1 M stock in dimethyl formamide and diluted to 5 mM in assay buffer with $50 \mu$ per well yielding at 1 mM final concentration.

10 mM stock solutions of inhibitors are made in dimethyl sulfoxide and diluted serially in assay buffer such that addition of $50 \mu \mathrm{~L}$ to the appropriate wells yieids final
concentrations of $3 \mu \mathrm{M}, 0.3 \mu \mathrm{M}, 0.003 \mu \mathrm{M}$, and $0.0003 \mu \mathrm{M}$. All conditions are completed in triplicate.

A 300 mM dimethyl sulfoxide stock solution of the peptide substrate is diluted to 15 mM in assay buffer and the assay is initiated by addition of $50 \mu$ to each well to give a final concentration of 3 mM substrate. Blanks consist of the peptide substrate and Ellman's reagent without the enzyme. Product formation was monitored at 405 nm with a Molecular Devices UVmax plate reader.
$1 C_{50}$ values were determined in the same manner as for collagenase.
Inhibition of MMP-13
Human recombinant MMP-13 is activated with 2mM APMA (p-aminophenyl mercuric acetate) for 1.5 hours, at $37^{\circ} \mathrm{C}$ and is diluted to $400 \mathrm{mg} / \mathrm{ml}$ in assay buffer ( 50 mM Tris, $\mathrm{pH} 7.5,200 \mathrm{mM}$ sodium chloride, 5 mM calcium chloride, $20 \mu \mathrm{M}$ zinc chloride, $0.02 \%$ brij). Twenty-five microliters of diluted enzyme is added per well of a 96 well microfluor plate. The enzyme is then diluted in a $1: 4$ ratio in the assay by the addition of inhibitor and substrate to give a final concentration in the assay of $100 \mathrm{mg} / \mathrm{ml}$.

10 mM stock solutions of inhibitors are made up in dimethyl sulfoxide and then diluted in assay buffer as per the inhibitor dilution scheme for inhibition of human collagenase (MMP-1): Twenty-five microliters of each concentration is added in triplicate to the microfluor plate. The final concentrations in the assay are $30 \mu \mathrm{M}, 3 \mu \mathrm{M}$, $0.3 \mu \mathrm{M}$, and $0.03 \mu \mathrm{M}$.

Substrate (Dnp-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)-NH2) is prepared as for inhibition of human collagenase (MMP-1) and $50 \mu$ lis added to each well to give a final assay concentration of $10 \mu \mathrm{M}$. Fluorescence readings ( 360 nM excitation; 450 emission) are taken at time 0 and every 5 minutes for 1 hour.

Positive controls consist of enzyme and substrate with no inhibitor and blanks consist of substrate only.
$1 C_{50}$ 's are determined as per inhibition of human collagenase (MMP-1). If IC $C_{50}$ 's are reported to be less than $0.03 \mu \mathrm{M}$, inhibitors are then assayed at final concentrations of $0.3 \mu \mathrm{M}, 0.03 \mu \mathrm{M}, 0.003 \mu \mathrm{M}$ and $0.0003 \mu \mathrm{M}$.

Inhibition of TNF Production
The ability of the compounds or the pharmaceutically acceptable salts thereof to inhibit the production of TNF and, consequently, demonstrate their effectiveness for treating diseases involving the production of TNF is shown by the following in vitro assay:

Human mononuclear cells were isolated from anti-coagulated human blood using a one-step Ficoll-hypaque separation technique. (2) The mononuclear cells were washed three times in Hanks balanced salt solution (HBSS) with divalent cations and resuspended to a density of $2 \times 10^{\circ} / \mathrm{ml}$ in HBSS containing $1 \%$ BSA. Differential counts determined using the Abbott Cell Dyn 3500 analyzer indicated that monocytes ranged from 17 to $24 \%$ of the total cells in these preparations.
$180 \mu$ of the cell suspension was aliquoted into flate bottom 96 well plates (Costar). Additions of compounds and LPS (100ng/ml final concentration) gave a final volume of $200 \mu$. All conditions were performed in triplicate. After a four hour incubation at $37^{\circ} \mathrm{C}$ in an humidified $\mathrm{CO}_{2}$ incubator, plates were removed and centrifuged ( 10 minutes at approximately $250 \times \mathrm{g}$ ) and the supernatants removed and assayed for TNFa using the R\&D EUSA Kit.

For administration to mammais, including humans, for the inhibition of matrix metalloproteinases or the production of tumor necrosis factor (TNF), a variety of conventional routes may be used including orally, parenterally and topically. In general, the compound of the invention will be administered orally or parenterally at dosages between about 0.1 and $25 \mathrm{mg} / \mathrm{kg}$ body weight of the subject to be treated per day, preferably from about 0.3 to $5 \mathrm{mg} / \mathrm{kg}$. However, some variation in dosage will necessarily occur depending on the condition of the subject being treated. The person responsible for administration will, in any event, determine the appropriate dose for the individual subject.

The compounds of the invention can be administered in a wide variety of different dosage forms. In general, the therapeutically effective compounds of this invention are present in such dosage forms at concentration levels ranging from about $5.0 \%$ to about $70 \%$ by weight.

For oral administration, tablets containing various excipients such as microcrystalline cellulose, sodium citrate, calcium carbonate, dicalcium phosphate and glycine may be employed along with various disintegrants such as starch (and preferably com, potato or tapioca starch), alginic acid and certain complex silicates, together with granulation binders like polyvinylpyrrolidone, sucrose, gelation and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl suifate and talc are often very useful for tabletting purposes. Solid compositions of a similar type may also be employed as fillers in gelatin capsules; preferred materials in this connection aiso include lactose or milk sugar as well as high molecular weight
polyethylene glycols. When aqueous suspensions and/or elixirs are desired for oral administration, the active ingredient may be combined with various sweetening or flavoring agents, coloring matter or dyes, and, if so desired, emulsifying and/or suspending agents as well, together with such diluents as water, ethanol, propylene glycol, glycerin and various like combinations thereof. In the case of animais, they are advantageously contained in an animal feed or drinking water in a concentration of 55000 ppm, preferably 25 to 500 ppm.

For parenteral administration (intramuscular, intraperitoneal, subcutaneous and intravenous use) a sterile injectable solution of the active ingredient is usually prepared. Solutions of a therapeutic compound of the present invention in either sesame or peanut oil or in aqueous propylene glycol may be employed. The aqueous solutions should be suitably adjusted and buffered, preferably at a pH of greater than 8 , if necessary and the liquid diluent first rendered isotonic. These aqueous solutions are suitable intravenous injection purposes. The oily solutions are suitable for intraarticular, intramuscular and subcutaneous injection purposes. The preparation of all these solutions under sterile conditions is readily accomplished by standard pharmaceutical techniques well known to those skilled in the art. In the case of animals, compounds can be administered intramuscularly or subcutaneously at dosage levels of about 0.1 to $50 \mathrm{mg} / \mathrm{kg} /$ day, advantageously 0.2 to $10 \mathrm{mg} / \mathrm{kg} /$ day given in a single dose or up to 3 divided doses.

The present invention is illustrated by the following examples, but it is not limited to the details thereof.

Org. Chem., 55, 1711-1721 (1990) and J. Med. Chem., 39, 73-85 (1996), in 30 mL of tetrahydrofuran was added lithium bis(trimethylsilyl)amide ( $40 \mathrm{~mL}, 1 \mathrm{M}$ in tetrahydrofuran, 39.8 mmol ). The resulting mixture was stirred for 1 hour at $-45^{\circ} \mathrm{C}$ and then recooled to $-78^{\circ} \mathrm{C}$. Allyl bromide ( $5.2 \mathrm{~mL}, 63.7 \mathrm{mmol}$ ) was then added. After 2 hours the reaction was quenched by the addition of 1 M aqueous hydrogen chloride at $-78^{\circ} \mathrm{C}$. The mixture was then extracted with diethyl ether. The combined ethereal

After filtration and concentration of the filtrate, the crude product was purified by silica gel chromatography (elution with 1:5 ethyl acetate/hexanes) to provide (2R,4R)-4-allyl-2-benzyloxycarbonylamino-pentanedioic acid 1-tert-butyl ester 5-methyl ester.
(b) Ozone gas was bubbled through a stirred, cold ( $-78^{\circ} \mathrm{C}$ ) solution of (2R,4R)-4-allyl-2-benzyloxycarbonylamino-pentanedioic acid 1-tert-butyl ester 5-methyl ester (5.0 $\mathrm{g}, 12.8 \mathrm{mmol}$ ) in 100 mL of $10: 1$ methanol/methylene chloride, and 0.73 mL of acetic acid until a blue color persisted. Nitrogen gas was then bubbled through the solution until the blue color dissipated. The mixture was warmed to ambient temperature and dimethyl sulfide ( $2.8 \mathrm{~mL}, 3.83 \mathrm{mmol}$ ) was added. The mixture was stirred for 48 hours, diluted with methylene chloride, and washed with $10 \%$ aqueous sodium carbonate, brine, and the mixture was dried over sodium sulfate. ## 3-(4-Fluorophenoxy)-propane-1-8ulfonyi chioride

To a stirred solution of 4-fluorophenol ( $5.0 \mathrm{~g}, 44.6 \mathrm{mmol}$ ) in 50 mL of toluene was added sodium hydride ( $60 \%$ dispersion in mineral oil, $1.78 \mathrm{~g}, 44.6 \mathrm{mmol}$ ) at ambient temperature ( $22^{\circ} \mathrm{C}$ ). After 20 minutes, a solution of 1,3 -propane sulfone ( $3.9 \mathrm{~mL}, 44.6 \mathrm{mmol}$ ) in toluene was added slowly and the mixture was stirred for 16 hours. The reaction was quenched by the addition of methanol and the mixture was concentrated in vacuo to an off-white solid. This solid was suspended in ethyi acetate, filtered, and the solids were collected and dried to give 10.9 g of 3-(4-fluorophenoxy)-propane-1-sulfonic acid sodium salt as an off-white powder. A stirred solution of 3-(4-fluorophenoxy)-propane-1-sulfonic acid sodium salt ( $2.0 \mathrm{~g}, 7.8 \mathrm{mmol}$ ) in 10 mL of thionyl chloride and one drops of dimethylformamide was heated at reflux for 16 hours. The mixture was then cooled to $0^{\circ} \mathrm{C}$, diluted with 25 mL of diethyl ether, and the reaction was quenched by the slow addition of water. The organic layer was removed and the aqueous layer was extracted with 25 mL of diethyl ether. The combined organic layers were washed with brine and dried over
sodium sulfate. Filtration and concentration gave 1.75 g of 3-(4-fluoro-phenoxy)-propane-1-sulfonyl chloride as a yellow oil: ${ }^{1} \mathrm{H} \operatorname{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 6.96-7.00$ $(\mathrm{m}, 2 \underline{H}), 6.80-6.84(\mathrm{~m}, 2 \underline{\mathrm{H}}), 4.10(\mathrm{t}, 2 \underline{\mathrm{H}}, \underline{\mathrm{J}}=5.5 \mathrm{~Hz}), 3.91(\mathrm{t}, 2 \underline{H}, \underline{J}=7.5 \mathrm{~Hz}) 2.47-$ 2.54 ( $\mathrm{m}, 2 \underline{\mathrm{H}}$ ).

## Preparation 3

## 4'-Fluorobiphenylsulfonyl chloride

Chiorosulfonic acid ( $8.7 \mathrm{~mL}, 0.13$ moie) was added dropwise to stirred cold $\left(0^{\circ} \mathrm{C}\right)$ 4-fluorobiphenyl ( $10.2 \mathrm{~g}, 59 \mathrm{mmol}$ ). After 30 minutes at $0^{\circ} \mathrm{C}$ the reaction mixture was poured onto ice. The resulting white precipitate was collected by
10 filtration and dissolved in chloroform. The chloroform solution was washed with water, brine, dried over magnesium sulfate, and concentrated to afford a white solid.
The desired $4^{\prime}$-fluorobiphenylsulfonyl chloride ( 4.3 g ), was separated from 4'fluorobiphenylsulfonic acid by crystallization of the latter from ethyl acetate and crystallization of the remaining material from hexanes.

## -1.

ARYLOXYARYLSULFONYLAMINO HYDROXAMIC ACID DERIVATIVES
Background of the Invention
The present invention relates to aryloxyarylsulfonylamino hydroxamic acid derivatives. These compounds are selective inhibitors of matrix metalloproteinase-13 and as such are useful in the treatment of a condition selected from the group consisting of arthritis, cancer, tissue ulceration, restenosis, periodontal disease, epidermolysis bullosa, bone resorption, loosening of artificial joint implants, atherosclerosis, multiple sclerosis, occular angiogenisis (for example macular degeneration) and other diseases characterized by matrix metalloproteinase activity.

This invention also relates to a method of using such compounds in the treatment of the above diseases in mammals, especially humans, and to the pharmaceutical compositions useful therefor.

There are a number of enzymes which effect the breakdown of structural proteins and which are structurally related metalloproteases. Matrix-degrading metalloproteinases, such as gelatinase, stromelysin and collagenase, are involved in tissue matrix degradation (e.g. collagen collapse) and have been implicated in many pathological conditions involving abnormal connective tissue and basement membrane matrix metabolism, such as arthritis (e.g. osteoarthritis and theumatoid arthritis), tissue uiceration (e.g. comeal, epidermal and gastric ulceration), abnormal wound healing, periodontal disease, bone disease (e.g. Paget's disease and osteoporosis), tumor metastasis or invasion, as well as HIV-infection (J. Leuk. Biol., 52 (2): 244-248, 1992).

Tumor necrosis factor is recognized to be involved in many infectious and auto-immune diseases (W. Friers, FEBS Letters, 1991, 285. 199). Furthermore, it has been shown that TNF is the prime mediator of the inflammatory response seen in sepsis and septic shock (C.E. Spooner et al., Clinical Immunology and Immunopathology, 1992, $\underline{62}$ S11).

Summary of the Invention
The present invention relates to a compound of the formula

1
or the pharmaceutically acceptable salts thereof, wherein
$R^{1}$ is ( $C_{1}-C_{6}$ )alkyl:
$R^{2}$ is ( $C_{1}-C_{6}$ )alky);
or $R^{1}$ and $R^{2}$ taken together with the carbon atom to which they are attached form a ring selected from ( $\mathrm{C}_{5}-\mathrm{C}_{7}$ )cycloalkyl, 4-tetrahydropyranyl and 4-piperidinyl;
$R^{3}$ is hydrogen or ( $C_{1}-C_{6}$ )alkyl; and
$Y$ is a substituent on any of the carbon atoms of the phenyl ring capable of supporting an additional bond, preferably from 1 to 2 substituents (more preferably one substituent, most preferably one substituent in the 4 -position) on the phenyl ring, independently selected from hydrogen, fluoro, chloro, trifluoromethyl, ( $C_{1}-C_{6}$ )alkoxy. trifluoromethoxy, difluoromethoxy and ( $\mathrm{C}_{1}-\mathrm{C}_{6}$ ) alkyl.

The term "alkyl", as used herein. unless otherwise indicated, includes saturated monovalent hydrocarbon radicals having straight, branched or cyclic moieties or combinations thereof.

The term "alkoxy", as used herein. includes O-alkyl groups wherein "alkyl" is defined above.

The present invention also relates to the pharmaceutically acceptable acid addition salts of compounds of the formula I. The acids which are used to prepare the pharmaceutically acceptable acid addition salts of the aforementioned base compounds of this invention are those which form non-toxic acid addition salts, i.e., salts containing pharmacologically acceptable anions, such as the hydrochloride, hydrobromide, hydroiodide, nitrate, sulfate, bisulfate, phosphate, acid phosphate, acetate, lactate, citrate, acid citrate, tartrate, bitartrate, succinate, maleate, fumarate, gluconate, saccharate, benzoate, methanesulfonate, ethanesulfonate, benzenesulfonate, p-toluenesulfonate and pamoate [i.e., 1,1'-methylene-bis-(2-hydroxy-3naphthoate) ]salts.

The invention also relates to base addition salts of formula 1 . The chemical bases that may be used as reagents to prepare pharmaceutically acceptable base salts of those
compounds of formula I that are acidic in nature are those that form non-toxic base salts with such compounds. Such non-toxic base salts include, but are not limited to those derived from such pharmacologically acceptable cations such as alkali metal cations (e.g., potassium and sodium) and alkaline earth metal cations (e.g., calcium and magnesium), ammonium or watersoluble amine addition salts such as N -methylglucamine-(meglumine), and the lower alkanolammonium and other base salts of pharmaceutically acceptable organic amines.

Scheme 1 refers to the preparation of compounds of the formula 1 from compounds of the formula VII. Referring to Scheme 1, the amino acid compound of formula VII, wherein $R^{16}$ is benzyl, is converted to the corresponding compound of formula VI by reaction with a reactive functional derivative of an arylsulfonic acid compound of the formula

VIII

The reaction mixture is stirred, at room temperature, for a time period between about 10 minutes to about 24 hours, preferably about 60 minutes.

The aryisulfonylamino compound of formula $V 1$, wherein $R^{16}$ is benzyl, is converted to the corresponding compound of formula $V$, wherein $R^{18}$ is the group 3-tert-butyldimethylsilanyloxypropanyl by reaction with tert-butyl-(3-halo-propoxy)dimethylsilane, preferably the iodide derivative, in the presence of a base, such as potassium carbonate, cesium carbonate, potassium hexamethyldisilazide, or sodium hydride. preferably potassium hexamethyldisilazide. The reaction is stirred in a polar solvent, such as dimethylformamide or N -methyipyrrolidin-2-one. at room temperature, for a time period between about 2 hours to about 48 hours, preferably about 18 hours.

The compound of formula $\mathbf{V}$ is converted to a carboxylic acid derivative of formula $\mathbf{N}$ by reaction with boron trifluoride-etherate complex to form an intermediate alcohol, followed by oxidation and protection by esterification. Specifically, the reaction with boron trifuoride-etherate complex is performed in an inert solvent such as methylene chioride, chloroform, preferably methylene chloride, at room temperature for about 15 minutes to about 4 hours, preferably about one hour. Oxidation of the alcohol is facilitated by using chromium trioxide in aqueous suffuric acid (Jones Reagent) at about $0^{\circ} \mathrm{C}$ for about one to about 6 hours, preferably about 2 hours. Protection of the carboxylic acid is facilitated by treatment of the free acid with an alkylating agent such as $R^{3}-L$, wherein $L$ is a leaving group such as iodo, bromo, mesylate, or tosylate, preferably iodo, with a base, such potassium carbonate or cesium carbonate, preferably potassium carbonate, in a polar solvent such as dimethylformamide, N -methylpyrrolidin-2-one or tetrahydrofuran, preferably dimethyl formamide, for about 1 to about 24 hours, preferably 16 hours, at about room temperature.

The compound of formula $I V$ is converted to a compound of formula Ill by removal of the $R^{16}$ protecting group by hydrogenolysis using palladium on carbon in a solvent such as methanol or ethanol, for a period from about 30 minutes to about 48 hours, preferably 16 hours, at a temperature of about $20^{\circ} \mathrm{C}$ to about $25^{\circ} \mathrm{C}$, i.e. room temperature.

The carboxylic acid compound of formula III is converted to the hydroxamic acid derivative of formula II, wherein $\mathrm{R}^{16}$ is benzyl, by activation of the compound of formula III followed by reaction with benzylhydroxylamine. Suitable solvents inciude $\mathrm{N}, \mathrm{N}$-dimethylformamide or N -methylpyrolidin- 2 -one, preferably $\mathrm{N}, \mathrm{N}$-dimethylformamide.

The compound of formula II is converted into a compound I by removal of the hydroxyl amine protecting group. Removal of the hydroxyiamine protecting group is carried out by hydrogenolysis of the benzyl protecting group using catalytic palladium on barium sulfate in a polar solvent at a temperature from about $20^{\circ} \mathrm{C}$ to about $25^{\circ} \mathrm{C}$, i.e. room temperature, for a period of about I hour to about 5 hours, preferably about 3 hours.

Compounds of formula VII and VIII are commercially available or can be made by methods well known to those of ordinary skill in the art

Pharmaceutically acceptable salts of the acidic compounds of the invention are salts formed with bases, namely cationic salts such as alkali and alkaline earth metal salts, such as sodium, lithium, potassium, calcium, magnesium, as well as ammonium salts, such as ammonium, trimethyl-ammonium, diethylammonium, and tris-(hydroxymethyl)-methylammonium slats.

Similarly acid addition salts, such as of mineral acids, organic carboxylic and organic sulfonic acids e.g. hydrochloric acid, methanesulfonic acid, maleic acid, are also possible provided a basic group, such as pyridyl, constitutes part of the structure.

The compounds of the formula I which are basic in nature are capable of forming a wide variety of different salts with various inorganic and organic acids. Although such salts must be pharmaceutically acceptable for administration to animals, it is often desirable in practice to initially isolate a compound of the formula I from the reaction mixture as a pharmaceutically unacceptable salt and then simply convert the latter back to the free base
compound by treatment with an alkaline reagent, and subsequently convert the free base to a pharmaceutically acceptable acid addition salt. The acid addition salts of the base compounds of this invention are readily prepared by treating the base compound with a substantially equivalent amount of the chosen mineral or organic acid in an aqueous solvent medium or in a suitable organic solvent such as methanol or ethanol. Upon careful evaporation of the solvent, the desired solid salt is obtained.

The acids which are used to prepare the pharmaceutically acceptable acid addition salts of the base compounds of this invention are those which form non-toxic acid addition salts, i.e., salts containing pharmacologically acceptable anions, such as hydrochloride, hydrobromide, hydroiodide, nitrate, sulfate or bisulfate, phosphate or acid phosphate, acetate, lactate, citrate or acid citrate, tartrate or bitartrate, succinate, maleate, fumarate, gluconate, saccharate, benzoate, methanesulfonate and pamoate [i.e.. 1.1'-methyiene-bis-(2-hydroxy-3naphthoate)] salts.

Those compounds of the formula I which are also acidic in nature, e.g., where $R^{3}$ is hydrogen, are capable of forming base salts with various pharmacologically acceptable cations. Examples of such salts include the alkali metal or alkaline-earth metal salts and particularly, the sodium and potassium salts. These salts are all prepared by conventional techniques. The chemical bases which are used as reagents to prepare the pharmaceutically acceptable base salts of this invention are those which form non-toxic base salts with the herein described acidic compounds of formula 1 . These non-toxic base salts include those derived from such pharmacologically acceptable cations as sodium, potassium, calcium and magnesium, etc. These salts can easily be prepared by treating the corresponding acidic compounds with an aqueous solution containing the desired pharmacologically acceptable cations, and then evaporating the resulting solution to dryness, preferably under reduced pressure. Alternatively, they may also be prepared by mixing lower alkanolic solutions of the acidic compounds and the desired alkali metal alkoxide together, and then evaporating the resulting solution to dryness in the same manner as before. In either case, stoichiometric quantities of reagents are preferably employed in order to ensure completeness of reaction and maximum product yields.

The ability of the compounds of formula 1 or their pharmaceutically acceptable salts (hereinafter also referred to as the MMP-13 selective compounds of the present invention) to inhibit matrix metalloproteinase-13 (collagenase 3) and, consequently, demonstrate their effectiveness for treating diseases characterized by matrix metalloproteinase- 13 is shown by the following in vitro assay tests.

Biological Assay
Inhibition of Human Collagenase (MMP-1)
Human recombinant collagenase is activated with trypsin using the following ratio: 10 mg trypsin per 100 mg of collagenase. The trypsin and collagenase are incubated at room temperature for 10 minutes then a five fold excess ( $50 \mathrm{mg} / 10 \mathrm{mg}$ trypsin) of soybean trypsin inhibitor is added.

10 mM stock solutions of inhibitors are made up in dimethyl sulfoxide and then diluted using the following Scheme:
$10 \mathrm{mM} \longrightarrow 120 \mu \mathrm{M} \longrightarrow 12 \mu \mathrm{M} \longrightarrow 1.2 \mu \mathrm{M} \longrightarrow 0.12 \mu \mathrm{M}$
Twenty-five microliters of each concentration is then added in triplicate to appropriate wells of a 96 well microfluor plate. The final concentration of inhibitor will be a $1: 4$ dilution after addition of enzyme and substrate. Positive controls (enzyme, no inhibitor) are set up in wells D1-D6 and blanks (no enzyme, no inhibitors) are set in wells D7-D12.

Collagenase is diluted to $400 \mathrm{ng} / \mathrm{ml}$ and 25 ml is then added to appropriate wells of the microfluor plate. Final concentration of collagenase in the assay is $100 \mathrm{ng} / \mathrm{ml}$.

Substrate (DNP-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys $\left(\mathrm{NMA}^{( }\right)-\mathrm{NH}_{2}$ ) is made as a 5 mM stock in dimethyl suffoxide and then diluted to 20 mM in assay buffer. The assay is initiated by the addition of 50 ml substrate per well of the microfluor plate to give a final concentration of 10 mM.

Fluorescence readings ( 360 nM excitation. 460 nm emission) were taken at time 0 and then at 20 minute intervals. The assay is conducted at room temperature with a typical assay time of 3 hours.

Fluorescence vs time is then plotted for both the blank and collagenase containing samples (data from triplicate determinations is averaged). A time point that provides a good signal (the blank) and that is on a linear part of the curve (usually around 120 minutes) is chosen to determine $I C_{50}$ values. The zero time is used as a blank for each compound at each concentration and these values are subtracted from the 120 minute data. Data is plotted as inhibitor concentration vs \% control (inhibitor fluorescence divided by fluorescence of collagenase alone $\times 100$ ). $I C_{50}$ 's are determined from the concentration of inhibitor that gives a signal that is $50 \%$ of the control.

If $\mathrm{IC}_{50}$ 's are reported to be $<0.03 \mathrm{mM}$ then the inhibitors are assayed at concentrations of $0.3 \mathrm{mM}, 0.03 \mathrm{mM}, 0.03 \mathrm{mM}$ and 0.003 mM .

Inhibition of MMP-13
Human recombinant MMP-13 is activated with 2mM APMA (p-aminophenyl mercuric acetate) for 1.5 hours, at $37^{\circ} \mathrm{C}$ and is diluted to $400 \mathrm{mg} / \mathrm{ml}$ in assay buffer ( 50 mM Tris, pH 7.5 , 200 mM sodium chloride, 5 mM calcium chloride, 20 mM zinc chloride, $0.02 \%$ brij). Twenty-five
microliters of diluted enzyme is added per well of a 96 well microfluor plate. The enzyme is then diluted in a $1: 4$ ratio in the assay by the addition of inhibitor and substrate to give a final concentration in the assay of $100 \mathrm{mg} / \mathrm{ml}$.

10 mM stock solutions of inhibitors are made up in dimethyl sulfoxide and then diluted in assay buffer as per the inhibitor dilution scheme for inhibition of human collagenase (MMP-1): Twenty-five microliters of each concentration is added in triplicate to the microfluor plate. The final concentrations in the assay are $30 \mathrm{mM}, 3 \mathrm{mM}, 0.3 \mathrm{mM}$, and 0.03 mM .

Substrate (Dnp-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)-NH2) is prepared as for inhibition of human collagenase (MMP-1) and 50 ml is added to each well to give a final assay concentration of 10 mM . Fiuorescence readings ( 360 nM excitation; 450 emission) are taken at time 0 and every 5 minutes for 1 hour.

Positive controls consist of enzyme and substrate with no inhibitor and blanks consist of substrate only.
$1 C_{50}$ 's are determined as per inhibition of human collagenase (MMP-1). If $I C_{50}$ 's are reported to be less than 0.03 mM , inhibitors are then assayed at final concentrations of 0.3 mM , $0.03 \mathrm{mM}, 0.003 \mathrm{mM}$ and 0.0003 mM .

The compounds of the present invention possess surprisingly selective activity against matrix metalloproteinase-13 (collagenase 3) as compared to matrix metalloproteinase-1 (collagenase 1). Specifically, the compounds of the formula I are 100 times more selective for matrix metalloproteinase-13 (collagenase 3) than matrix metalloproteinase-1 (collagenase 1) and have $I_{50}$ 's of less than $10 n \mathrm{M}$ against matrix metalloproteinase-13 (collagenase 3). Table 1 lists several compounds that demonstrate the unexpected selectivity of the compounds of the invention.

For administration to humans for the inhibition of matrix metalloproteinase-13 or the production of tumor necrosis factor (TNF), a variety of conventional routes may be used including orally, parenterally and topically. In general, the active compound will be administered orally or parenterally at dosages between about 0.1 and $25 \mathrm{mg} / \mathrm{kg}$ body weight of the subject to be treated per day, preferably from about 0.3 to $5 \mathrm{mg} / \mathrm{kg}$. However, some variation in dosage will necessarily occur depending on the condition of the subject being treated. The person
responsible for administration will, in any event, determine the appropriate dose for the individual subject.

The compounds of the present invention can be administered in a wide variety of different dosage forms, in general, the therapeutically effective compounds of this invention are present in such dosage forms at concentration levels ranging from about $5.0 \%$ to about $70 \%$ by weight.

For oral administration, tablets containing various excipients such as microcrystalline cellulose, sodium citrate, calcium carbonate, dicalcium phosphate and glycine may be employed along with various disintegrants such as starch (and preferably corn, potato or tapioca starch), alginic acid and certain complex silicates, together with granulation binders like polyvinylpyrrolidone, sucrose, gelation and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl sulfate and talc are often very useful for tabletting purposes. Solid compositions of a similar type may also be employed as fillers in gelatin capsules; preferred materials in this connection also include lactose or milk sugar as well as high molecular weight polyethyiene glycols. When aqueous suspensions and/or elixirs are desired for oral administration, the active ingredient may be combined with various sweetening or flavoring agents, coloring matter or dyes, and, if so desired, emulsifying and/or suspending agents as well, together with such diluents as water, ethanol, propylene glycol, glycerin and various like combinations thereof.

For parenteral administration (intramuscular, intraperitoneal, subcutaneous and intravenous use) a sterile injectable solution of the active ingredient is usually prepared. Solutions of a therapeutic compound of the present invention in either sesame or peanut oil or in aqueous propylene glycol may be employed. The aqueous solutions should be suitably adjusted and buffered, preferably at a pH of greater than 8 , if necessary and the liquid diluent first rendered isotonic. These aqueous solutions are suitable intravenous injection purposes. The oily solutions are suitable for intraarticular, intramuscular and subcutaneous injection purposes. The preparation of all these solutions under sterile conditions is readily accomplished by standard pharmaceutical techniques well known to those skilled in the art.

The following Examples illustrate the preparation of the compounds of the present invention. Melting points are uncorrected. NMR data are reported in parts per million ( $\delta$ ) and are referenced to the deuterium lock signal from the sample solvent (deuteriodimethylsulfoxide unless otherwise specified). Commercial reagents were utilized without further purification. THF refers to tetrahydrofuran. DMF refers to N,N-dimethylformamide. Chromatography refers to column chromatography performed using 32-63 mm silica gel and executed under nitrogen pressure (flash chromatography) conditions. Room or ambient temperature refers to 20 to $25^{\circ} \mathrm{C}$. All non-aqueous reactions were run under
a nitrogen atmosphere for convenience and to maximize yields. Concentration at reduced pressure means that a rotary evaporator was used.

The mixture was extracted with ethyl acetate and the extract was washed sequentially with water, saturated aqueous sodium bicarbonate solution and brine. The solution was dried over magnesium sulfate and concentrated to give crude 3 \{(1-benzyloxycarbamoylcyclopentyl)-[4-(4-fluorophenoxy)benzenesulfonyl]amino\}propionic acid ethyl ester as a yellow oil (164 grams).
F) A solution of crude 3-\{(1-benzyloxycarbamoylcyclopentyl)-[4-(4-fluorophenoxy)benzenesulfonyllamino)propionic acid ethyl ester ( 164 grams ) in ethanol ( 2.4 L ) was treated with $5 \%$ palladium on barium sulfate ( 50 grams) and hydrogenated in a Parr TM shaker at 3 atmospheres pressure for 3 hours. After filtration through nylon (pore size $0.45 \mu \mathrm{~m}$ ) to remove the catalyst, the solvent was evaporated to afford an oil. After addition of ethyl acetate and hexane, 3-[[4-(4-fluorophenoxy)benzenesulfonyl]-(1-hydroxy-carbamoylcyclopentyl)aminoj-propionic acid ethyl ester, a white crystalline solid ( 73.5 grams ) was collected by filtration. The filtrate was concentrated and the residue was chromatographed on silica gel eluting with $40 \%$ ethyl acetate hexane to provide more of the desired product ( 32.5 grams).

## HYDROXAMIC ACID DERIVATIVES AS MATRIX METALLOPROTEASE (MMP) INHIBITORS

This invention relates to a series of substituted $\alpha$-aminosulphonyl- acetohydroxamic acids which are inhibitors of zinc-dependent metalloprotease enzymes. In particular, the compounds are inhibitors of certain members of the matrix metalloprotease (MMP) family.

Matrix metalloproteases (MMPs) constitute a family of structurally similar zinc-containing metalloproteases, which are involved in the remodelling and degradation of extracellular matrix proteins, both as part of normal physiological processes and in pathological conditions. Since they have high destructive potential, MMPs are usually under close regulation and failure to maintain MMP regulation may be a component of a number of diseases and pathological conditions, including atherosclerotic plaque rupture, heart failure, restenosis, periodontal disease, tissue ulceration, wound repair, cancer metastasis, tumour angiogenesis, age-related macular degeneration, fibrotic disease, rheumatoid arthritis, osteoarthritis and inflammatory diseases dependent on migratory inflammatory cells.

Another important function of certain MMPs is to activate various enzymes, including other MMPs, by cleaving the pro-domains from their protease domains. Thus some MMPs act to regulate the activities of other MMPs, so that over-production of one MMP may lead to excessive proteolysis of extracellular matrix by another. Moreover, MMPs have different substrate preferences (shown in the following Table for selected family members) and different functions within normal and pathological conditions. For recent reviews of MMPs, see Current Pharmaceutical Design, 1996, 2, 624 and Exp. Opin. Ther. Patents, 1996, 6, 1305.

Excessive production of MMP-3 is thought to be responsible for

5 pathological tissue breakdown which underlies a number of diseases and conditions. For example, MMP-3 has been found in the synovium and cartilage of osteoarthritis and rheumatoid arthritis patients, thus implicating MMP-3 in the joint damage caused by these diseases: see Biochemistry, 1989, 28, 8691 and Biochem. J., 1989, 258, 115. MMP-13 is also thought to play an important role in the pathology of osteoarthritis and rheumatoid arthritis: see Lab. Invest., 1997, 76, 717 and Arthritis Rheum., 1997, 40, 1391. The compounds of the present invention inhibit both MMP-3 and MMP-13 and thus may be of utility in treating these diseases.

The over-expression of MMP-3 is also thought to be responsible for much of the tissue damage and chronicity of chronic wounds, such as venous ulcers, diabetic ulcers and pressure sores: see Brit. J. Dermatology, 1996, 135, 52.

Furthermore, the production of MMP-3 may also cause tissue damage in conditions where there is ulceration of the colon (as in ulcerative colitis and Crohn's disease: see J. Immunol., 1997 158, 1582 and J. Clin. Pathol., 1994, 47, 113) or of the duodenum (see Am. J. Pathol., 1996, 148, 519).

Moreover, MMP-3 may also be involved in skin diseases such as dystrophic epidermolysis bullosa (see Arch. Dermatol. Res., 1995, 287, 428) and dermatitis herpetiformis (see J. Invest. Dermatology, 1995, 105, 184).

Finally, rupture of atherosclerotic plaques by MMP-3 may lead to cardiac or cerebral infarction: see Circulation, 1997, 96, 396. Thus, MMP-3 inhibitors may find utility in the prevention of heart attack and stroke.

Studies of human cancers have shown that MMP-2 is activated on the invasive tumour cell surface (see J. Biol.Chem., 1993, 268, 14033) and BB-94, a non-selective peptidic hydroxamate MMP inhibitor, has been reported to decrease the tumour burden and prolong the survival of mice carrying human ovarian carcinoma xenografts (see Cancer Res., 1993, 53, 2087). Certain compounds of the present invention inhibit MMP-2 and therefore may be useful in the treatment of cancer metastasis and tumour angiogenesis.

Various series of MMP inhibitors have appeared in the patent literature. For example, $\alpha$-arylsulphonamido-substituted acetohydroxamic acids are disclosed in EP-A-0606046, WO-A-9627583 and WO-A-9719068, whilst EP-A0780386 discloses certain related sulphone-substituted hydroxamic acids.

The compounds of the present invention are inhibitors of some of the members of the MMP family. In particular, they are potent inhibitors of MMP-3 and MMP-13, with certain compounds exhibiting varying degrees of selectivity over other MMPs, such as MMP-1, MMP-2 and MMP-9. Certain of the compounds are potent MMP-2 inhibitors.
-4-
Thus, according to the present invention, there is provided a compound of formula ( 1 ):

or a pharmaceutically or veterinarily acceptable salt thereof, or a pharmaceutically or veterinarily acceptable solvate (including hydrate) of either entity,
wherein the broken line represents an optional bond;
$A$ is C or CH ;
B is $\mathrm{CH}_{2}, \mathrm{O}$ or absent;

In a further aspect, the present invention provides processes for the preparation of a compound of formula (I), or a pharmaceutically or veterinarily acceptable salt thereof, or a pharmaceutically or veterinarily acceptable solvate (including hydrate) of either entity, as illustrated below.

It will be appreciated by persons skilled in the art that, within certain of the processes described, the order of the synthetic steps employed may be varied and will depend inter alia on factors such as the nature of other functional groups present in a particular substrate, the availability of key intermediates and the protecting group strategy (if any) to be adopted. Clearly, such factors will also influence the choice of reagent for use in the said synthetic steps.

Illustrative of protecting group strategies are the synthetic routes to Example 64, in which an O-benzyl protected hydroxamate is formed prior to the required Suzuki reaction step, and to Example 66, in which alcohol protection using a t-butyldiphenylsilyl group is employed.
-9-
It will also be appreciated that various standard substituent or functional group interconversions and transformations within certain compounds of formula (I) will provide other compounds of formula (I). An example is the conversion of the tetrahydropyridine derivative (Example 28) to the piperidine derivative (Example 29) by hydrogenation.

The following processes are illustrative of the general synthetic procedures which may be adopted in order to obtain the compounds of the invention.

A compound of formula (I) may be prepared directly from an ester of formula (II):

wherein $R^{5}$ is $C_{1}$ to $C_{3}$ alkyl, and the broken line, $A, B, R^{1}, R^{2}, R^{3}, R^{4}, m$ and $n$ are as previously defined for formula ( 1 ), or via the intermediacy of the corresponding carboxylic acid of formula (II) wherein $R^{5}$ is hydrogen.

When prepared directly from an ester of formula (II), the reaction may be carried out by treatment of the ester with up to a 3 -fold excess of hydroxylamine in a suitable solvent at from about room temperature to about $85^{\circ} \mathrm{C}$. The hydroxylamine is conveniently generated in situ from its hydrochloride salt by conducting the reaction in the presence of a molar equivalent amount of a suitable base such as an alkali metal carbonate or bicarbonate, e.g. potassium carbonate. Preferably the solvent is methanol, optionally combined with tetrahydrofuran or dichloromethane as co-solvent, and the reaction temperature is from about 65 to $70^{\circ} \mathrm{C}$.

Alternatively, the ester may be converted by conventional hydrolysis to the corresponding carboxylic acid which is then transformed to the required hydroxamic acid of formula (I).

Preferably the hydrolysis is effected under basic conditions using up to about a 6-fold excess of an alkali metal hydroxide in aqueous solution, optionally in the presence of a co-solvent, at from about room temperature to about $85^{\circ} \mathrm{C}$. Typically the co-solvent is selected from methanol, 1,4-dioxan, a mixture of methanol and tetrahydrofuran and a mixture of methanol and 1,4dioxan and the reaction temperature is from about 40 to about $70^{\circ} \mathrm{C}$.

The subsequent coupling step may be achieved using conventional amide-bond forming techniques, e.g. via the acyl chloride derivative and hydroxylamine hydrochloride in the presence of an excess of a tertiary amine such as triethylamine or pyridine to act as acid-scavenger, optionally in the presence of a catalyst such as 4-dimethylaminopyridine, in a suitable solvent such as dichloromethane, at from about $0^{\circ} \mathrm{C}$ to about room temperature. For convenience, pyridine may also be used as the solvent.

In particular, any one of a host of amino acid coupling variations may be used. For example, the acid of formula (II) wherein $R^{5}$ is hydrogen may be activated using a carbodiimide such as 1,3-dicyclohexylcarbodiimide or 1-ethyl-3-(3-dimethylaminoprop-1-yl)carbodiimide optionally in the presence of 1hydroxybenzotriazole and/or a catalyst such as 4-dimethylaminopyridine, or by using a halotrisaminophosphonium salt such as bromotris(pyrrolidino)phosphonium hexafluorophosphate. Either type of coupling is conducted in a suitable solvent such as dichloromethane or dimethylformamide, optionally in the presence of a tertiary amine such as N -methylmorpholine or N ethyldiisopropylamine (for example when either the hydroxylamine or the
activating reagent is presented in the form of an acid addition salt), at from about $0^{\circ} \mathrm{C}$ to about room temperature. Typically, from 1.1 to 2.0 molecular equivalents of the activating reagent and from 1.0 to 4.0 molecular equivalents of any tertiary amine present are employed.

A preferred reagent for mediating the coupling reaction is $\mathrm{O}-(7-$ azabenzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (HATU).

Preferably a solution of the acid and from 1.0 to 1.2 molecular equivalents of $N$-ethyldiisopropylamine in a suitable solvent such as anhydrous dimethylformamide or anhydrous 1-methylpyrrolidin-2-one, under nitrogen, is treated with up to a $50 \%$ excess of HATU at about room temperature followed, after about 15 to 30 minutes, with up to about a 3-fold excess of hydroxylamine hydrochloride and up to about a 4-fold excess of N -ethyldiisopropylamine, optionally in the same solvent, at the same temperature.

An ester of formula (II) may be prepared from an amine of formula (III):

wherein the broken line, $A, B, R^{3}, R^{4}, m$ and $n$ are as previously defined for formula (II), by sulphonylation with a compound of formula (IV):

wherein $Z$ is halo, $R^{5}$ is $C_{1}$ to $C_{3}$ alkyl and $R^{1}$ and $R^{2}$ are as previously defined for formula (II). Preferably, Z is chloro.

When $R^{6}$ is hydrogen, it will normally be advantageous to protect this secondary amino linkage with a conventional amine protecting group.

The reaction may be effected in the presence of up to a $50 \%$ excess of an appropriate base in a suitable solvent at from about $0^{\circ} \mathrm{C}$ to about room temperature. For example, when both $R^{1}$ and $R^{2}$ are hydrogen, an appropriate base is 1,8-diazabicyclo[5.4.0]undec-7-ene and a suitable solvent is dichloromethane.

Alternatively, the anion of (III) may be generated initially using up to a $20 \%$ excess of a strong base in a suitable solvent, under nitrogen, and then the sulphonylation with from 1.0 to 1.2 molecular equivalents of (IV) effected.

Conveniently, such a coupling may be carried out at room temperature with N,O-bis(trimethylsilyl)acetamide as base and anhydrous tetrahydrofuran as solvent.

Further routes to the preparation of an ester of formula (II), wherein $R^{3}$ is $R^{7}$, rely on exploitation of either a Suzuki reaction or a Stille reaction with an ester of formula (II) wherein $R^{3}$ (but not $R^{4}$ ) is either bromo or iodo.

Thus, in the Suzuki reaction, the latter ester is treated with from 1.0 to 1.5 molecular equivalents of a boronic acid of formula $\mathrm{R}^{7} \mathrm{~B}(\mathrm{OH})_{2}$, in the presence of from 2.0 to 3.0 molecular equivalents of an alkali metal fluoride, about 0.1 molecular equivalents of a triarylphosphine and about 0.05 molecular equivalents of a palladium catalyst in a suitable solvent, under nitrogen, at from about 65 to about $100^{\circ} \mathrm{C}$. Typically, the fluoride is cesium fluoride, the phosphine is tri-o-tolylphosphine, the catalyst is tris(dibenzylideneacetone)dipalladium (0) and the solvent is degassed 1,2-dimethoxyethane optionally with 1-methylpyrrolidin-2-one as co-solvent.

In the Stille reaction, the aforementioned ester starting material of formula (II) is treated with from 1.0 to 2.0 molecular equivalents of a suitable trialkylstannane derivative of formula $R^{7} \operatorname{Sn}(a l k y l){ }_{3}$ wherein alkyl is, for example, n-butyl, in the presence of from 2.0 to 3.0 molecular equivalents of a tertiary base, from 0.3 to 0.6 molecular equivalents of a triarylphosphine and from 0.05 to 0.2 molecular equivalents of a palladium catalyst in a suitable solvent, under nitrogen, at from about 65 to about $100^{\circ} \mathrm{C}$. Typically, the base is triethylamine, the phosphine is tri-o-tolylphosphine, the catalyst is palladium(II) acetate optionally in the presence of tetrakis(triphenylphosphine)palladium(0) and the solvent is anhydrous acetonitrile.

Certain esters of formula (II) wherein at least one of $R^{1}$ and $R^{2}$ is other than hydrogen may be conveniently obtained from the $\alpha$-carbanion of an ester of formula (II) wherein at least one of $R^{1}$ and $R^{2}$ is hydrogen by conventional $C$ alkylation procedures using an alkylating agent of formula (VA) or (VB):

| $R X$ | $X-W-Y$ |
| :--- | :---: |
| $(V A)$ | $(V B)$ |

wherein $R$ is as previously defined for $R^{1}$ or $R^{2}$ but is not hydrogen, $X$ and $Y$ may be the same or different and are suitable leaving groups, and $W$ is a $C_{2}$ to $\mathrm{C}_{5}$ alkylene group which optionally incorporates a heteroatom linkage selected from $\mathrm{O}, \mathrm{SO}, \mathrm{SO}_{2}$ and $\mathrm{NR}^{6}$ or which is optionally benzo-fused. When $\mathrm{R}^{6}$ is to be hydrogen in a compound of formula ( 1 ), then a conventional amine protecting group strategy may be of advantage during this alkylation procedure.

A suitable leaving group may be selected from halo (e.g. chloro, bromo or iodo), $\mathrm{C}_{1}-\mathrm{C}_{4}$ alkanesulphonyloxy, trifluoromethanesulphonyloxy and arylsulphonyloxy (e.g. benzenesulphonyloxy or p-toluenesulphonyloxy).

Preferably, $X$ and $Y$ are selected from bromo, iodo and $p$ toluenesulphonyloxy.

The carbanion may be generated using an appropriate base in a suitable solvent. Typical base-solvent combinations may be selected from lithium, sodium or potassium hydride, lithium, sodium or potassium bis(trimethylsilyl)amide, lithium diisopropylamide and butyllithium, together with toluene, ether, 1,2-dimethoxyethane, tetrahydrofuran, 1,4-dioxan, dimethylformamide, $\mathrm{N}, \mathrm{N}$-dimethylacetamide, 1-methylpyrrolidin-2-one and any mixture thereof.

Preferably the base is sodium hydride and the solvent is anhydrous dimethylformamide, optionally with anhydrous tetrahydrofuran as co-solvent, or anhydrous 1-methylpyrrolidin-2-one. For monoalkylation, up to about a 10\% excess of base is employed whilst, for dialkylation, from about 2 to about 3 molar equivalents are generally appropriate.

Typically, the carbanion is generated at about room temperature, under nitrogen, and subsequently treated with up to about a $30 \%$ excess of the required alkylating agent at the same temperature.

Clearly, when dialkylation is required and $R^{1}$ and $R^{2}$ are different, the substituents may be introduced in tandem in a "one-pot reaction" or in separate steps.

A particularly convenient, alternative alkylation method involves treatment of the substrate with the required alkylating agent in the presence of from 3.0 to 3.5 molecular equivalents of anhydrous potassium carbonate in anhydrous dimethyl sulphoxide or anhydrous 1,2-dimethoxyethane, under nitrogen, at about room temperature.

Clearly, an alternative variation for preparing a compound of formula (II) is to introduce $R^{1}$ and/or $R^{2}$ into a suitable bromo or iodo intermediate before further elaboration via, for example, a Suzuki or Stille reaction.

An amine of formula (III) may be obtained by standard chemical procedures. For example, when $B$ is absent, $m$ is 2 and $n$ is 1 , a suitably $N$ protected piperidin-4-one of formula (VI):

(VI)
wherein $P$ is a conventional amine protecting group, is reacted with a carbanion derivative of a compound of formula (VII):

wherein $Z$ is as previously defined for formula (IV) and $R^{3}$ and $R^{4}$ are as previously defined for formula (III), to provide a compound of formula (VIII):

Preferably, $Z$ is chloro, bromo or iodo.
Conveniently (VII) is converted to an aryllithium or aryl Grignard derivative whilst, of the plethora of amine protecting groups available, P is typically t-butoxycarbonyl (Boc) or benzyl.

When P is Boc, (VIII) may be transformed directly to a compound of formula (III), wherein the broken line represents a bond, $A$ is $C, B$ is absent, $m$ is $2, n$ is 1 and $R^{3}$ and $R^{4}$ are as previously defined for formula (III), using trifluoroacetic acid optionally in a suitable solvent such as dichloromethane at about room temperature. Alternatively, when $P$ is benzyI, (VIII) may be converted in two steps to the same compound of formula (III). For example, in the first step, dehydration may be effected in refluxing toluene using ptoluenesulphonic acid and a Dean-Stark apparatus. N-Deprotection of the resulting alkene (1,2,3,6-tetrahydropyridine derivative), in the second step, may be achieved using 1-chloroethyl chloroformate in refluxing toluene followed by treatment of the reaction mixture, at room temperature, with either methanol or ethanol.

This unsaturated piperidine may be converted to a compound of formula (III) wherein the broken line does not represent a bond, A is $\mathrm{CH}, \mathrm{B}$ is absent, m is $2, n$ is 1 and $R^{3}$ and $R^{4}$ are as previously defined for formula (III) under conventional catalytic, or catalytic transfer, hydrogenation conditions. Alternatively, these hydrogenation conditions may be employed to convert the previously described $N$-benzyl alkene (1,2,3,6-tetrahydropyridine derivative) to the same piperidine derivative, directly in one step. Furthermore, this fully saturated piperidine is also available in one step from (VIII) when $P$ is Boc by standard ionic hydrogenation using, for example, triethylsilane and trifluoroacetic acid in dichloromethane.

Other amines of formula (III), when neither commercially available nor subsequently described, can be obtained either by analogy with the processes described in the Preparations section or by conventional synthetic procedures, in accordance with standard textbooks on organic chemistry or literature precedent, from readily accessible starting materials using appropriate reagents and reaction conditions.

Moreover, persons skilled in the art will be aware of variations of, and alternatives to, those processes described hereinafter in the Examples and Preparations sections which allow the compounds defined by formula (I) to be obtained.

The pharmaceutically and veterinarily acceptable base salts of the compounds of formula (i) may also be prepared in a conventional manner. For example a solution of the hydroxamic acid is treated with the appropriate base, either neat or in a suitable solvent, and the resulting salt isolated either by filtration or by evaporation under vacuum of the reaction solvent. Pharmaceutically and veterinarily acceptable acid addition salts can be obtained in an analogous manner by treating a solution of a basic compound of formula (I) with the appropriate acid. Both types of salt may be formed or interconverted using ion-exchange resin techniques.

The biological activities of the compounds of the present invention were determined by the following test methods, which are based on the ability of the compounds to inhibit the cleavage of various fluorogenic peptides by MMPs 1 , $2,3,9,13$ and 14.

The assays for MMPs 2, 3, 9 and 14 are based upon the original protocol described in FEBS, 1992, 296, 263, with the minor modifications described below.

The potency of inhibition was measured from the amount of substrate cleavage obtained using a range of test compound concentrations and, from the resulting dose-response curve, an $\mathrm{IC}_{50}$ value (the concentration of inhibitor required to inhibit $50 \%$ of the enzyme activity) was calculated.

## Inhibition of MMP-2. MMP-3 and MMP-9

For MMP-2 and MMP-9, a final concentration of 1 mM APMA was added, followed by incubation for 1 hour at $37^{\circ} \mathrm{C}$. MMP-3 was activated by the addition of 2 mM APMA, followed by incubation for 3 hours at $37^{\circ} \mathrm{C}$. The enzymes were then diluted in $\mathrm{Tris-HCl}$ assay buffer ( 100 mM Tris, $100 \mathrm{mM} \mathrm{NaCl}, 10 \mathrm{mM} \mathrm{CaCl}_{2}$ and $0.16 \% \mathrm{Brij} 35, \mathrm{pH}$ 7.5 ) to a concentration of 10 nM . This substrate was selected because it has a balanced hydrolysis rate against MMPs 2, 3 and $9\left(k_{c a t} / k_{m}\right.$ of $54,000,59,400$ and $55,300 \mathrm{~s}^{-1} \mathrm{M}^{-1}$ respectively). The final substrate concentration used in the assay was $5 \mu \mathrm{M}$.

## Determination of Enzyme Inhibition

The test compound was dissolved in dimethyl sulphoxide and diluted with assay buffer so that no more than $1 \%$ dimethyl sulphoxide was present. Test compound and enzyme were added to each well of a 96 well plate and allowed to equilibrate for 15 minutes at $37^{\circ} \mathrm{C}$ in an orbital shaker prior to the addition of substrate. Plates were then incubated for 1 hour at $37^{\circ} \mathrm{C}$, prior to determination of fluorescence using a fluorimeter (Fluostar; BMG LabTechnologies, Aylesbury, UK) at an excitation wavelength of 328 nm and emission wavelength of 393 nm . The potency of inhibition was measured from the amount of substrate cleavage obtained using a range of test compound concentrations and, from the resulting dose-response curve, an $\mathrm{IC}_{50}$ value (the concentration of inhibitor required to inhibit $50 \%$ of the enzyme activity) was calculated.

MMP-13 was then diluted in assay buffer ( 50 mM Tris, 200 mM $\mathrm{NaCl}, 5 \mathrm{mM} \mathrm{CaCl} 2,20 \mu \mathrm{M} \mathrm{ZnCl}_{2}$ and $0.02 \% \mathrm{Brij} 35, \mathrm{pH} 7.5$ ) to a concentration of 5.3 nM . The final concentration of enzyme used in the assay was 1.3 nM .

The potency of inhibition was measured from the amount of substrate cleavage obtained using a range of test compound concentrations and, from the resulting dose-response curve, an $I C_{50}$ value (the concentration of inhibitor required to inhibit $50 \%$ of the enzyme activity) was calculated.

Inhibition of MMP-14

## Enzyme Preparation

Catalytic domain MMP-14 was prepared in Pfizer Central Research laboratories. A $10 \mu \mathrm{M}$ enzyme stock solution was activated for 20 minutes at $25^{\circ} \mathrm{C}$ following the addition of $5 \mu \mathrm{~g} / \mathrm{ml}$ of trypsin (Sigma, Dorset, UK). The trypsin activity was then neutralised by the addition of $50 \mu \mathrm{~g} / \mathrm{ml}$ of soyabean trypsin inhibitor (Sigma, Dorset, UK), prior to dilution of this enzyme stock solution in Tris-HCl assay buffer ( 100 mM Tris, $100 \mathrm{nM} \mathrm{NaCl}, 10 \mathrm{mM} \mathrm{CaCl}{ }_{2}$, $0.16 \%$ Brij $35, \mathrm{pH} 7.5$ ) to a concentration of 10 nM . The final concentration of enzyme used in the assay was 1 nM .

## Substrate

The fluorogenic substrate used in this screen was Mca-Pro-Leu-Gly-Leu-Dpa-Ala-Arg-NH2 (Bachem Ltd., Essex, UK) as described in J.Biol.Chem., 1996, 271, 17119.

## Determination of enzyme inhibition

This was performed as described for MMPs 2, 3 and 9.

In human therapy, the compounds of formula (I), their pharmaceutically acceptable salts, and pharmaceutically acceptable solvates of either entity, can be administered alone, but will generally be administered in admixture with a pharmaceutical carrier selected with regard to the intended route of administration and standard pharmaceutical practice.

They may be administered orally in the form of tablets containing such excipients as starch or lactose, or in capsules or ovules either alone or in admixture with excipients, or in the form of elixirs, solution or suspensions containing flavouring or colouring agents. They can also be injected, for example intravenously, intramuscularly or subcutaneously, and are best used in the form of a sterile aqueous solution which may contain other substances, for example enough salts or monosaccarides to make the solution isotonic with blood. For other routes of parenteral administration, such as buccal or sublingual, they may be administered in the form of tablets or lozenges which can be formulated in a conventional manner.

In addition, the compounds and their salts may be administered topically in the form of sterile creams, gels, suspensions, lotions, ointments, dusting powders, sprays, drug-incorporated dressings or via a skin patch. For example, they can be incorporated into a cream consisting of an aqueous or oily emulsion of polyethylene glycols or liquid paraffin, or they can be incorporated into an ointment consisting of a white wax soft paraffin base, or as a hydrogel
with cellulose or polyacrylate derivatives or other viscosity modifiers, or as a dry powder or liquid spray or aerosol with butane/propane, HFA or CFC propellants, or as a drug-incorporated dressing either as a tulle dressing, with white soft paraffin or polyethylene glycol impregnated gauze dressings or with hydrogel, hydrocolloid, alginate or film dressings. Moreover, the compounds and salts may be administered intraocularly as an eye drop with appropriate buffers, viscosity modifiers (e.g. cellulose derivatives), preservatives (e.g. benzalkonium chlorides (BZK)) and agents to adjust tonicity (e.g. sodium chloride).

All such formulations may also contain stabilisers and preservatives.
Depending on the route of administration to human patients, the daily dosage level of the compounds of formula (1) and their salts may be from 0.001 to $20 \mathrm{mg} / \mathrm{kg}$, in single or divided doses. Thus, for example, tablets or capsules could contain from 0.02 to 500 mg of active compound for administration singly or two or more at a time as appropriate.

The physician in any event will determine the actual dosage which will be most suitable for an individual patient and it will vary with the age, weight and response of the particular patient. The above dosages are exemplary of the average case; there can of course be individual instances where higher or lower dosage ranges are merited and such are within the scope of this invention.

For veterinary use, a compound of formula (I), or a veterinarily acceptable salt thereof, or a veterinarily acceptable solvate of either entity, is administered as a suitably acceptable formulation in accordance with normal veterinary practice and the veterinary surgeon will determine the dosing regimen and route of administration which will be most appropriate for a particular animal.

Thus the invention provides a pharmaceutical composition comprising a compound of formula (I), or a pharmaceutically acceptable salt thereof, or a pharmaceutically acceptable solvate of either entity, together with a pharmaceutically acceptable diluent or carrier.

It further provides a veterinary formulation comprising a compound of formula (I), or a veterinarily acceptable salt thereof, or a veterinarily acceptable solvate of either entity, together with a veterinarily acceptable diluent or carrier.

The invention also provides a compound of formula (I), or a pharmaceutically acceptable salt thereof, or a pharmaceutically acceptable solvate of either entity, or a pharmaceutical composition containing any of the foregoing, for use as a human medicament.

In addition, it provides a compound of formula (I), or a veterinarily acceptable salt thereof, or a veterinarily acceptable solvate of either entity, or a veterinary formulation containing any of the foregoing, for use as an animal medicament.

In yet another aspect, the invention provides the use of a compound of formula (I), or a pharmaceutically acceptable salt thereof, or a pharmaceutically acceptable solvate of either entity, for the manufacture of a human medicament for the curative or prophylactic treatment of a medical condition for which a MMP inhibitor is indicated.

It also provides the use of a compound of formula (I), or a veterinarily acceptable salt thereof, or a veterinarily acceptable solvate of either entity, for the manufacture of an animal medicament for the curative or prophylactic treatment of a medical condition for which a MMP inhibitor is indicated.

Moreover, the invention provides the use of a compound of formula (I), or a pharmaceutically acceptable salt thereof, or a pharmaceutically acceptable solvate containing either entity, for the manufacture of a human medicament for the curative or prophylactic treatment of atherosclerotic plaque rupture,
myocardial infarction, heart failure, restenosis, stroke, periodontal disease, tissue ulceration, wound repair, skin diseases, cancer metastasis, tumour angiogenesis, age-related macular degeneration, fibrotic disease, rheumatoid arthritis, osteoarthritis and inflammatory diseases dependent on migratory inflammatory cells.

It also provides the use of a compound of formula (I), or a veterinarily acceptable salt thereof, or a veterinarily acceptable solvate containing either entity, for the manufacture of an animal medicament for the curative or prophylactic treatment of atherosclerotic plaque rupture, myocardial infarction, heart failure, restenosis, stroke, periodontal disease, tissue ulceration, wound repair, skin diseases, cancer metastasis, tumour angiogenesis, age-related macular degeneration, fibrotic disease, rheumatoid arthritis, osteoarthritis and inflammatory diseases dependent on migratory inflammatory cells.

Additionally, the invention provides a method of treating or preventing a medical condition for which a MMP inhibitor is indicated, in a mammal (including a human being), which comprises administering to said mammal a therapeutically effective amount of a compound of formula (I), or a pharmaceutically or veterinarily acceptable salt thereof, or a pharmaceutically or veterinarily acceptable solvate of either entity, or a pharmaceutical composition or veterinary formulation containing any of the foregoing.

Still further, the invention provides a method of treating or preventing atherosclerotic plaque rupture, myocardial infarction, heart failure, restenosis, stroke, periodontal disease, tissue ulceration, wound repair, skin diseases, cancer metastasis, tumour angiogenesis, age-related macular degeneration, fibrotic disease, rheumatoid arthritis, osteoarthritis and inflammatory diseases dependent on migratory inflammatory cells, in a mammal (including a human being), which comprises administering to said mammal a therapeutically effective amount of a compound of formula (I), or a pharmaceutically or
veterinarily acceptable salt thereof, or a pharmaceutically or veterinarily acceptable solvate of either entity, or a pharmaceutical composition or veterinary formulation containing any of the foregoing.

The invention also includes any novel intermediates described herein, for example those of formula (II).

The syntheses of the compound of the invention and of the intermediates for use therein are illustrated by the following Examples and Preparations.

Room temperature means 20 to $25^{\circ} \mathrm{C}$.
Flash chromatography refers to column chromatography on silica gel (Kieselgel 60, 230-400 mesh).

Melting points are uncorrected.
${ }^{1} \mathrm{H}$ Nuclear magnetic resonance (NMR) spectra were recorded using a Bruker AC300, a Varian Unity Inova-300 or a Varian Unity Inova-400 spectrometer and were in all cases consistent with the proposed structures. Characteristic chemical shifts ( $\delta$ ) are given in parts-per-million downfield from tetramethylsilane using conventional abbreviations for designation of major peaks: e.g. s, singlet; d, doublet; $t$, triplet; q, quartet; m, multiplet; br, broad. Mass spectra were recorded using a Finnigan Mat. TSQ 7000 or a Fisons Intruments Trio 1000 mass spectrometer. LRMS means low resolution mass spectrum and the calculated and observed ions quoted refer to the isotopic composition of lowest mass.

## PREPARATION 3

1-Benzyl-4-hydroxy-4-(4-phenylphenyl)piperidine
A 1.6 M solution of $n$-butyllithium in hexane ( $39 \mathrm{ml}, 63 \mathrm{mmol}$ ) was added to a stirred solution of 4-bromobiphenyl ( $11.7 \mathrm{~g}, 50 \mathrm{mmol}$ ) in anhydrous tetrahydrofuran ( 50 ml ), under nitrogen, at about $-50^{\circ} \mathrm{C}$, whilst ensuring that the reaction temperature was kept below $-40^{\circ} \mathrm{C}$. After a further 1 hour, a solution of 1-benzyl-4-oxopiperidine ( $10.4 \mathrm{~g}, 55 \mathrm{mmol}$ ) in anhydrous tetrahydrofuran ( 30 ml ) was added at such a rate that the reaction temperature was maintained below $-40^{\circ} \mathrm{C}$. ## (4-ARYLSULFONYLAMINO)-TETRAHYDROPYRAN-4-CARBOXYLIC ACID HYDROXAMIDES <br> Background of the Invention

The present invention relates to (4-arylsulfonylamino)-tetrahydropyran-4-carboxylic acid hydroxamide derivatives, and to pharmaceutical compositions and methods of treatment.

The compounds of the present invention are inhibitors of zinc metalloendopeptidases, especially those belonging to the matrix metalloproteinase (also called MMP or matrixin) and reprolysin (also known as adamylsin) subfamilies of the metzincins (Rawlings, et al., Methods in Enzymology, 248, 183-228 (1995) and Stocker, et al., Protein Science, 4, 823-840 (1995)).

The MMP subfamily of enzymes, currently contains seventeen members (MMP-1, MMP-2, MMP-3, MMP-7, MMP-8, MMP-9, MMP-10, MMP-11, MMP-12, MMP-13, MMP-14, MMP-15, MMP-16, MMP-17, MMP-18, MMP-19, MMP-20). The MMP's are most well known for their role in regulating the turn-over of extracellular matrix proteins and as such play important roles in normal physiological processes such as reproduction, development and differentiation. In addition, the MMP's are expressed in many pathological situations in which abnormal connective tissue turnover is occurring. For example, MMP-13 an enzyme with potent activity at degrading type II collagen (the principal collagen in cartilage), has been demonstrated to be overexpressed in osteoarthritic cartilage (Mitchell, et al., J. Clin. Invest., 97, 761 (1996)). Other MMPs (MMP-2, MMP-3, MMP-8, MMP-9, MMP-12) are also overexpressed in osteoarthritic cartilage and inhibition of some or all of these MMP's is expected to slow or block the accelerated loss of cartilage typical of joint diseases such as osteoarthritis or rheumatoid arthritis.

The mammalian reprolysins are known as ADAMs (A Disintegrin And Metalloproteinase) (Wolfberg, et al., J. Cell Biol., 131, 275-278 (1995)) and contain a disintegrin domain in addition to a metalloproteinase-like domain. To date twenty three distinct ADAM's have been identified.

ADAM-17, also known as tumor necrosis factor-alpha converting enzyme (TACE), is the most well known ADAM. ADAM-17 (TACE) is responsible for cleavage of cell bound tumor necrosis factor-alpha (TNF- $\alpha$, also known as cachectin). TNF- $\alpha$ is recognized to be involved in many infectious and auto-immune diseases (W. Friers, FEBS Letters, 285, 199 (1991)). Furthermore, it has been shown that TNF- $\alpha$ is the prime mediator of the inflammatory response seen in sepsis and septic shock (Spooner, et al., Clinical Immunology and Immunopathology, 62 S 11 (1992)). There are two forms of TNF- $\alpha$, a type II membrane protein of relative molecular mass $26,000(26 \mathrm{kD})$ and a soluble 17 kD form generated from the cell bound protein by specific proteolytic cleavage. The soluble 17 kD form of TNF- $\alpha$ is released by the cell and is associated with the deleterious effects of TNF- $\alpha$. This form of

TNF-a is also capable of acting at sites distant from the site of synthesis. Thus, inhibitors of TACE prevent the formation of soluble TNF- $\alpha$ and prevent the deleterious effects of the solucle factor

Select compounds of the invention are potent inhibitors of aggrecanase, an enzyme impcrtant in the degradation of cartilage aggrecan. Aggrecanase is also believed to be an ADAM. The loss of aggrecan from the cartilage matrix is an important factor in the progression of joint diseases such as osteoarthritis and rheumatoid arthritis and inhibition of aggrecanase is expected to slow or block the loss of cartilage in these diseases.

Other ADAMs that have shown expression in pathological situations include ADAM TS-1 (Kuno, et al., J. Biol. Chem., 272, 556-562 (1997)), and ADAM's 10, 12 and 15 (Wu, et al., Biochem. Biophys. Res. Comm., 235, 437-442, (1997)). As knowledge of the expression, physiological substrates and disease association of the ADAM's increases the full significance of the role of inhibition of this class of enzymes will be appreciated.

Diseases in which inhibition of MMP's and or ADAM's will provide therapeutic benefit include: arthritis (including osteoarthritis and rheumatoid arthritis), inflammatory bowel disease, Crohn's disease, emphysema, acute respiratory distress syndrome, asthma chronic obstructive pulmonary disease, Alzheimer's disease, organ transplant toxicity, cachexia, allergic reactions, allergic contact hypersensitivity, cancer, tissue ulceration, restenosis, periodontal disease, epidermolysis bullosa, osteoporosis, loosening of artificial joint implants, atherosclerosis (including atherosclerotic plaque rupture), aortic aneurysm (including abdominal aortic aneurysm and brain aortic aneurysm), congestive heart failure, myocardial infarction, stroke, cerebral ischemia, head trauma, spinal cord injury, neuro-degenerative disorders (acute and chronic), autoimmune disorders, Huntington's disease, Parkinson's disease, migraine, depression, peripheral neuropathy, pain, cerebral amyloid angiopathy, nootropic or cognition enhancement, amyotrophic lateral sclerosis, multiple scierosis, ocular angiogenesis, corneal injury, macular degeneration, abnormal wound healing, burns, diabetes, tumor invasion, tumor growth, tumor metastasis, corneal scarring, scleritis, AIDS, sepsis, septic shock and other diseases characterized by metalloproteinase or ADAM expression.

This invention also relates to a method of using the compounds of the invention in the treatment of the above diseases in mammals, especially humans, and to the pharmaceutical compositions useful therefore.

It is recognized that different combinations of MMP's and ADAM's are expressed in different pathological situations. As such inhibitors with specific selectivities for individual ADAM's and/or MMP's may be preferred for individual diseases. For example, rheumatoid arthritis is an inflammatory joint disease characterized by excessive TNF levels and the loss
of joint matrix constituents. In this case, a compound that inhibits TACE and aggrecanase as well as MMP's such as MMP-13 may be the preferred therapy. in contrast, in a less inflammatory joint disease such as osteoarthritis, compounds that inhibit matrix degrading MMP's such as MMP-13 but not TACE may be preferred.

The present inventors have also discovered that it is possible to design inhibitors with differential metalloprotease activity. Specifically, for example, the inventors have been able to design molecules which selectively inhibit matrix metalloprotease-13 (MMP-13) preferentially over MMP-1.

## Detailed Description of the Invention

The following reaction Scheme illustrates the preparation of the compounds of the present invention. Unless otherwise indicated, $Q$ in the reaction Schemes and the discussion that follows is defined as above.

Scheme 1 refers to the preparation of compounds of the formula I.
Referring to Scheme 1, the compound of formula I is prepared from the carboxylic acid of formula II by treatment with 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide and 1 hydroxybenztriazole in a polar solvent, such as $\mathrm{N}, \mathrm{N}$-dimethylformamide, followed by the addition of hydroxylamine to the reaction mixture after a time period between about 15 minutes to about 1 hour, preferably about 30 minutes. The hydroxylamine is preferably generated in situ from a salt form, such as hydroxylamine hydrochloride, in the presence of a base, such as triethylamine.

Alternatively the compound of formula I can be prepared from a compound of formula II by reaction with a protected derivative of hydroxylamine or its salt form, where the hydroxyl group is protected as a tert-butyl, benzyl, allyl or 2-trimethylsilylethyl ether. Removal of the hydroxyl protecting group is carried out by hydrogenolysis for a benzyl protecting group (5\% palladium on barium sulfate is the preferred catalyst) or treatment with a strong acid, such as trifluoroacetic acid, for a tert-butyl protecting group. The allyl protecting group may be removed by treatment with tributyltinhydride and acetic acid in the presence of catalytic bis(triphenylphosphine) palladium(II)chloride. The 2 -trimethylsilylethyl ether may be removed by reaction with a strong acid such as trifluoroacetic acid or by reaction with a fluoride source such as boron trifluoride etherate.

The reaction of II with hydroxylamine, a salt of hydroxylamine, a protected derivative of hydroxylamine or a salt of a protected derivative of hydroxylamine may also be carried out in the presence of (benztriazol-1-yloxy)tris(dimethylamino)-phosphonium hexafluorophosphate and a base such as triethylamine in an inert solvent, such as methylene chloride. The reaction mixture is stirred at a temperature between about $0^{\circ} \mathrm{C}$ to about $50^{\circ} \mathrm{C}$. preferably room temperature, for a time period between about 1 hour to about 3 days, preferably about 1 day.

Another procedure for converting a compound of formula II to a compound of formula $I$ is to react the compound of formula II with O-benzylhydroxylamine hydrochloride in the presence of (benztriazol-1-yloxy)tris(dimethylamino)phosphonium hexafluorophosphate and triethylamine using methylene chloride as solvent. Subsequent removal of the O-benzyl protecting group to afford a compound of formula $I$ is then carried out by hydrogenolysis under 3 atmospheres hydrogen at room temperature using $5 \%$ palladium on barium sulfate as catalyst. The preferred solvent is methanol. The reaction time may vary from about 1 hour to about 2 days ( 8 hours is preferred).

The preferred procedure for converting a compound of formula II to a compound of formula $I$ is to react the compound of formula II with oxalyl chloride in methylene chloride in the presence of a catalytic amount of DMF for 16 hours. The resulting acid chloride is reacted at $0^{\circ} \mathrm{C}$ with $\mathrm{N}, \mathrm{O}$ - bis trimethylsilyl hydroxylamine formed by reacting hydroxyamine hydrochloride with chlorotrimethyl-silane in pyridine at $0^{\circ} \mathrm{C}$ to room temperature. The product of formula I is
obtained after a few hours reactions at $0^{\circ} \mathrm{C}$ to room temperature followed by an acidic aqueous workup which removes all trimethyl silyl residues.

In certain instances it is preferred to obtain the compound of formula 1 by reaction of hydroxylamine, a salt of hydroxylamine, a protected derivative of hydroxylamine or a salt of a protected derivative of hydroxylamine with an activated ester of formula III. The reaction is carried out in an inert solvent, such as N,N-dimethyl-formamide at a temperature ranging from about room temperature to about $80^{\circ} \mathrm{C}$, preferably about $60^{\circ} \mathrm{C}$ for a time period of about 1 hour to about 2 days. If a protected derivative of hydroxylamine or a salt of a protected derivative of hydroxylamine is used, removal of the protecting group is carried out as described above. The activated ester derivative of formula III is obtained by treatment of the compound of formula II with (benztriazol-1-yloxy)tris(dimethylamino)-phosphonium hexafluorophosphate and a base such as triethylamine in an inert solvent, such as methylene chloride. The reaction mixture is stirred at a temperature between about $0^{\circ} \mathrm{C}$ to about $50^{\circ} \mathrm{C}$, preferably room temperature, for a time period between about 1 hour to about 3 days, preferably about 1 day.

The intermediate compound of formula II is prepared by saponification of a compound of formula IV. The reaction is carried out at in a solvent, such as aqueous ethanol, with an excess of a metal hydroxides, such as sodium hydroxide or lithium hydroxide, at a temperature of about $20^{\circ} \mathrm{C}$ to about $100^{\circ} \mathrm{C}$, (i.e. room temperature to the reflux temperature of the solvent), preferably about $80^{\circ} \mathrm{C}$. The reaction mixture is normally agitated at room temperature for a time period between about 30 minutes to about 1 week, preferably about 16 hours.

The compound of formula $\mathbf{N}$ is prepared by reacting a compound of formula $\mathbf{V}$ with a reactive functional derivative of a sulfonic acid $\left(\mathrm{QSO}_{2} \mathrm{OH}\right)$, such as the sulfonyl chloride $\left(\mathrm{QSO}_{2} \mathrm{Cl}\right)$, in the presence of a base. Suitable bases include sodium hydroxide, triethylamine or diisopropylethylamine, preferably triethylamine. Suitable solvents include dimethylformamide (DMF), methylene chloride, tetrahydrofuran, dioxane, water or acetonitrile, preferably DMF. The reaction mixture is stirred at a temperature between about $0^{\circ} \mathrm{C}$ to about $50^{\circ} \mathrm{C}$, preferably at about $20^{\circ} \mathrm{C}$ to about $25^{\circ} \mathrm{C}$ (i.e. room temperature), for a time period between about 10 minutes to about 2 days, preferably about 1 day.

The compound of formula $\mathbf{V}$ is prepared by hydrolysis of a compound of formula $\mathbf{N}$. Specifically, the compound of formula VI is treated with aqueous acid, preferably in the presence of an immiscible organic solvent such ethyl ether, diisopropyl ether or methylene chloride. Suitable acids include hydrochloric and sulfuric. The reaction mixture is stirred at a temperature between about $0^{\circ} \mathrm{C}$ to about $50^{\circ} \mathrm{C}$, preferably at about $20^{\circ} \mathrm{C}$ to about $25^{\circ} \mathrm{C}$ (i.e. room temperature), for a time period between about 10 minutes to about 2 days, preferably about 1 day.

The compound of formula $\mathbf{V I}$ is prepared by reaction of the amino acid derivative of the formula VII with a compound of the formula VIII in the presence of a base and a solvent. wherein $X$ is $\mathrm{Cl}, \mathrm{Br}, \mathrm{I}$, tosylate or mesylate. Suitable bases include ethlyene glycol, sodium hydride, lithium diisopropylamide, or sodium hexamethyl disilazide. Suitable solvents include dimethylether, dimethylformamide, tetrahydrofuran or dimethylsulfoxide. The reaction mixture is stirred at a temperature between about $-20^{\circ} \mathrm{C}$ to about $25^{\circ} \mathrm{C}$, preferably at about $0^{\circ} \mathrm{C}$ to about $20^{\circ} \mathrm{C}$ (i.e. room temperature), for a time period between about 10 minutes to about 2 days, preferably about 1 day.

The compounds of formulae VII and VIII can be prepared by methods well known to those of ordinary skill in the art. Examples of such compounds include methylglycine benzophenone imine and ethyl glycine benzophenone imine.

Pharmaceutically acceptable salts of the acidic compounds of the invention are salts formed with bases, namely cationic salts such as alkali and alkaline earth metal salts, such as sodium, lithium, potassium, calcium, magnesium, as well as ammonium salts, such as ammonium, trimethyl-ammonium, diethylammonium, and tris-(hydroxymethyl)-methylammonium slats.

The ability of the compounds of formula I or their pharmaceutically acceptable salts (hereinafter also referred to as the compounds of the present invention) to inhibit metalloproteinases or mammalian reprolysin and, consequently, demonstrate their effectiveness for treating diseases characterized by metalloproteinase or the production of tumor necrosis factor is shown by the following in vitro assay tests.

## Biological Assay

Inhibition of Human Collagenase (MMP-1)
Human recombinant collagenase is activated with trypsin. The amount of trypsin is optimized for each lot of collagenase-1 but a typical reaction uses the following ratio: $5 \mu \mathrm{~g}$ trypsin per $100 \mu \mathrm{~g}$ of collagenase. The trypsin and collagenase are incubated at room temperature for 10 minutes then a five fold excess ( $50 \mathrm{mg} / 10 \mathrm{mg}$ trypsin) of soybean trypsin inhibitor is added.

Stock solutions ( 10 mM ) of inhibitors are made up in dimethylsulfoxide and then diluted using the following scheme:
$10 \mathrm{mM} \longrightarrow 120 \mu \mathrm{M} \longrightarrow 12 \mu \mathrm{M} \longrightarrow 1.2 \mu \mathrm{M} \longrightarrow 0.12 \mu \mathrm{M}$
Twenty-five microliters of each concentration is then added in triplicate to appropriate wells of a 96 well microfluor plate. The final concentration of inhibitor will be a $1: 4$ dilution after
addition of enzyme and substrate. Positive controls (enzyme, no inhibitor) are set up in wells D7-D12 and negative controls (no enzyme, no inhibitors) are set in wells D1-D6.

Collagenase -1 is diluted to $240 \mathrm{ng} / \mathrm{ml}$ and 25 ml is then added to appropriate welis of the microfluor plate. Final concentration of collagenase in the assay is $60 \mathrm{ng} / \mathrm{ml}$.

Substrate (DNP-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)- $\mathrm{NH}_{2}$ ) is made as a 5 mM stock in dimethylsulfoxide and then diluted to $20 \mu \mathrm{M}$ in assay buffer. The assay is initiated by the addition of 50 ml substrate per well of the microfluor plate to give a final concentration of 10 mM .

Fluorescence readings ( 360 nM excitation, 460 nm emission) are taken at time 0 and then at 20 minute intervals. The assay is conducted at room temperature with a typical assay time of 3 hours

Fluorescence versus time is then plotted for both the blank and collagenase containing samples (data from triplicate determinations is averaged). A time point that provides a good signal (at least five fold over the blank) and that is on a linear part of the curve (usually around 120 minutes) is chosen to determine $\mathrm{IC}_{50}$ values. The zero time is used as a blank for each compound at each concentration and these values are subtracted from the 120 minute data. Data is plotted as inhibitor concentration versus \% control (inhibitor fluorescence divided by fluorescence of collagenase alone $\times 100$ ). $1 C_{50}$ 's are determined from the concentration of inhibitor that gives a signal that is $50 \%$ of the control.

If $I C_{50}$ 's are reported to be less than 0.03 mM then the inhibitors are assayed at
concentrations of $0.3 \mathrm{mM}, 0.03 \mathrm{mM}$, and 0.003 mM .

## Inhibition of Gelatinase (MMP-2)

Human recombinant 72 kD gelatinase (MMP-2, gelatinase A) is activated for 16-18 hours with 1 mM p-aminophenyl-mercuric acetate (from a freshly prepared 100 mM stock in 0.2 N NaOH ) at $4^{\circ} \mathrm{C}$, rocking gently.

10 mM dimethylsulfoxide stock solutions of inhibitors are diluted serially in assay buffer ( 50 mM TRIS, $\mathrm{pH} 7.5,200 \mathrm{mM} \mathrm{NaCl}, 5 \mathrm{mM} \mathrm{CaCl} 2.20 \mu \mathrm{M} \mathrm{ZnCl}_{2}$ and $0.02 \%$ BRIJ-35 (vol./vol.)) using the following scheme:
$10 \mathrm{mM} \longrightarrow 120 \mu \mathrm{M} \longrightarrow 12 \mu \mathrm{M} \longrightarrow 1.2 \mu \mathrm{M} \longrightarrow 0.12 \mu \mathrm{M}$
Further dilutions are made as necessary following this same scheme. A minimum of four inhibitor concentrations for each compound are performed in each assay. $25 \mu \mathrm{~L}$ of each concentration is then added to triplicate wells of a black 96 well U-bottomed microfluor plate. As the final assay volume is $100 \mu \mathrm{~L}$, final concentrations of inhibitor are the result of a further $1: 4$ dilution (i.e. $30 \mu \mathrm{M} \longrightarrow 3 \mu \mathrm{M} \longrightarrow 0.3 \mu \mathrm{M} \longrightarrow 0.03 \mu \mathrm{M}$, etc.). A blank (no enzyme, no inhibitor) and a positive enzyme control (with enzyme, no inhibitor) are also prepared in triplicate

Activated enzyme is diluted to $100 \mathrm{ng} / \mathrm{mL}$ in assay buffer, $25 \mu \mathrm{~L}$ per well is added to appropriate wells of the microplate. Final enzyme concentration in the assay is $25 \mathrm{ng} / \mathrm{mL}$ (0.34 nM).

A five mM dimethylsulfoxide stock solution of substrate (Mca-Pro-Leu-Gly-Leu-Dpa-Ala-Arg- $\mathrm{NH}_{2}$ ) is diluted in assay buffer to $20 \mu \mathrm{M}$. The assay is initiated by addition of $50 \mu \mathrm{~L}$ of diluted substrate yielding a final assay concentration of $10 \mu \mathrm{M}$ substrate. At time zero, fluorescence reading ( 320 excitation; 390 emission) is immediately taken and subsequent readings are taken every fifteen minutes at room temperature with a PerSeptive Biosystems CytoFluor Multi-Well Plate Reader with the gain at 90 units.

The average value of fluorescence of the enzyme and blank are plotted versus time. An early time point on the linear part of this curve is chosen for $\mathrm{IC}_{50}$ determinations. The zero time point for each compound at each dilution is subtracted from the latter time point and the data then expressed as percent of enzyme control (inhibitor fluorescence divided by fluorescence of positive enzyme control $\times 100$ ). Data is plotted as inhibitor concentration versus percent of enzyme control. IC $\mathrm{S}_{50}$ 's are defined as the concentration of inhibitor that gives a signal that is $50 \%$ of the positive enzyme control.

Inhibition of Stromelysin Activity (MMP-3)
Human recombinant stromelysin (MMP-3, stromelysin-1) is activated for 20-22 hours with 2 mM p-aminophenyl-mercuric acetate (from a freshly prepared 100 mM stock in 0.2 N $\mathrm{NaOH})$ at $37^{\circ} \mathrm{C}$.

10 mM dimethylsulfoxide stock solutions of inhibitors are diluted serially in assay buffer ( 50 mM TRIS, $\mathrm{pH} 7.5,150 \mathrm{mM} \mathrm{NaCl}, 10 \mathrm{mM} \mathrm{CaCl} 2$ and $0.05 \% \mathrm{BRIJ}-35$ (vol./vol.)) using the following scheme:
$10 \mathrm{mM} \longrightarrow 120 \mu \mathrm{M} \longrightarrow 12 \mu \mathrm{M} \longrightarrow 1.2 \mu \mathrm{M} \longrightarrow 0.12 \mu \mathrm{M}$
Further dilutions are made as necessary following this same scheme. A minimum of four inhibitor concentrations for each compound are performed in each assay. $25 \mu \mathrm{~L}$ of each concentration is then added to triplicate wells of a black 96 well U-bottomed microfluor plate. As the final assay volume is $100 \mu \mathrm{~L}$, final concentrations of inhibitor are the result of a further $1: 4$ dilution (i.e. $30 \mu \mathrm{M} \longrightarrow 3 \mu \mathrm{M} \longrightarrow 0.3 \mu \mathrm{M} \longrightarrow 0.03 \mu \mathrm{M}$, etc.). A blank (no enzyme, no inhibitor) and a positive enzyme control (with enzyme, no inhibitor) are also prepared in triplicate.

Activated enzyme is diluted to $200 \mathrm{ng} / \mathrm{mL}$ in assay buffer, $25 \mu \mathrm{~L}$ per well is added to appropriate wells of the microplate. Final enzyme concentration in the assay is $50 \mathrm{ng} / \mathrm{mL}$ ( 0.875 nM ).

A ten mM dimethylsulfoxide stock solution of substrate (Mca-Arg-Pro-Lys-Pro-Val-Glu-Nva-Trp-Arg-Lys(Dnp)-NH2) is diluted in assay buffer to $6 \mu \mathrm{M}$. The assay is initiated by
addition of $50 \mu \mathrm{~L}$ of diluted substrate yielding a final assay concentration of $3 \mu \mathrm{M}$ substrate. At time zero, fluorescence reading ( 320 excitation; 390 emission) is immediately taken and subsequent readings are taken every fifteen minutes at room temperature with a PerSeptive Biosystems CytoFluor Multi-Well Plate Reader with the gain at 90 units.

The average value of fluorescence of the enzyme and blank are plotted versus time. An early time point on the linear part of this curve is chosen for $I C_{50}$ determinations. The zero time point for each compound at each dilution is subtracted from the latter time point and the data then expressed as percent of enzyme control (inhibitor fluorescence divided by fluorescence of positive enzyme control $\times 100$ ). Data is plotted as inhibitor concentration versus percent of enzyme control. $1 C_{50}$ 's are defined as the concentration of inhibitor that gives a signal that is $50 \%$ of the positive enzyme control.

## Inhibition of MMP-13

Human recombinant MMP-13 is activated with 2 mM APMA (p-aminophenyl mercuric acetate) for 2.0 hours, at $37^{\circ} \mathrm{C}$ and is diluted to $240 \mathrm{ng} / \mathrm{ml}$ in assay buffer ( 50 mM Tris, pH 7.5 , 200 mM sodium chloride, 5 mM calcium chloride, 20 mM zinc chloride, $0.02 \%$ brij 35). Twentyfive microliters of diluted enzyme is added per well of a 96 well microfiuor plate. The enzyme is then diluted in a $1: 4$ ratio in the assay by the addition of inhibitor and substrate to give a final concentration in the assay of $60 \mathrm{ng} / \mathrm{ml}$.

Stock solutions ( 10 mM ) of inhibitors are made up in dimethylsulfoxide and then diluted in assay buffer as per the inhibitor dilution scheme for inhibition of human collagenase -1 (MMP1): Twenty-five microliters of each concentration is added in triplicate to the microfluor plate. The final concentrations in the assay are $30 \mathrm{mM}, 3 \mathrm{mmM}, 0.3 \mathrm{~m} \mathrm{mM}$, and 0.03 mmM .

Substrate (Dnp-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)-NH2) is prepared as for inhibition of human collagenase (MMP-1) and $50 \mu$ is added to each well to give a final assay concentration of $10 \mu \mathrm{M}$. Fluorescence readings ( 360 nM excitation; 450 nM emission) are taken at time 0 and every 5 minutes for 1 hour.

Positive controls and negative controls are set up in triplicate as outlined in the MMP-1 assay.
$1 C_{50}$ 's are determined as per inhibition of human collagenase (MMP-1). If IC $C_{50}$ 's are reported to be less than 0.03 mM , inhibitors are then assayed at final concentrations of 0.3 mM , $0.03 \mathrm{mmM}, 0.003 \mathrm{mmM}$ and 0.0003 mM .

## Inhibition of TNF Production

The ability of the compounds or the pharmaceutically acceptable salts thereof to inhibit the production of TNF and, consequently, demonstrate their effectiveness for treating diseases involving the production of TNF is shown by the following in vitro assay:

Human mononuclear cells were isolated from anti-coagulated human blood using a onestep Ficoll-hypaque separation technique. (2) The mononuclear cells were washed three times in Hanks balanced salt solution (HBSS) with divalent cations and resuspended to a density of 2 $\times 10^{6} / \mathrm{ml}$ in HBSS containing $1 \%$ BSA. Differential counts determined using the Abbott Cell Dyn 3500 analyzer indicated that monocytes ranged from 17 to $24 \%$ of the total cells in these preparations.
$180 \mu \mathrm{l}$ of the cell suspension was aliquoted into flat bottom 96 well plates (Costar). Additions of compounds and LPS ( $100 \mathrm{ng} / \mathrm{ml}$ final concentration) gave a final volume of $200 \mu \mathrm{l}$. All conditions were performed in triplicate. After a four hour incubation at $37^{\circ} \mathrm{C}$ in an humidified $\mathrm{CO}_{2}$ incubator, plates were removed and centrifuged ( 10 minutes at approximately $250 \times \mathrm{g}$ ) and the supernatants removed and assayed for TNFa using the R\&D ELISA Kit.

Inhibition of Soluble TNF- $\alpha$ Production
The ability of the compounds or the pharmaceutically acceptable salts thereof to inhibit the cellular release of TNF- $\alpha$ and, consequently, demonstrate their effectiveness for treating diseases involving the disregulation of soluble TNF- $\alpha$ is shown by the following in vitro assay:

Method for the evaluation of recombinant TNF- $\alpha$ Converting Enzyme Activity

## Expression of recombinant TACE

A DNA fragment coding for the signal sequence, preprodomain, prodomain and catalytic domain of TACE (amino acids 1-473), can be amplified by polymerase chain reaction using a human lung cDNA library as a template. The amplified fragment is then cloned into pFastBac vector. The DNA sequence of the insert is confirmed for both the strands. A bacmid prepared using pFastBac in E. coli DH10Bac is transfected into SF9 insect cells. The virus particles is then amplified to P1, P2, P3 stages. The P3 virus is infected into both Sf9 and High Five insect cells and grown at $27^{\circ} \mathrm{C}$ for 48 hours. The medium is collected and used for assays and further purification.

## Preparation of fluorescent quenched substrate:

A model peptidic TNF- $\alpha$ substrate (LY-LeucineAlanineGlutamineAlanineValine-ArginineSerine-SerineLysine(CTMR)-Arginine (LY=Lucifer Yellow; CTMR=Carboxytetramethyl-Rhodamine)) is prepared and the concentration estimated by absorbance at 560 nm (E560, 60,000 M-1CM-1) according to the method of Geoghegan, KF, "Improved method for converting an unmodified peptide to an energy-transfer substrate for a
proteinase." Bioconjugate Chem. 7, 385-391 (1995). This peptide encompasses the cleavage cite on pro-TNF which is cleaved in vivo by TACE.

## Expression of recombinant TACE

A DNA fragment coding for the signal sequence, preprodomain, prodomain and catalytic domain of TACE (amino acids 1-473), is amplified by polymerase chain reaction using a human lung cDNA library as a template. The amplified fragment is cloned into pFastBac vector. The DNA sequence of the insert is confirmed for both the strands. A bacmid prepared using pFastBac in E. coli DH10Bac is transfected into SF9 insect cells. The virus particles were amplified to P1, P2, P3 stages. The P3 virus is infected into both Sf9 and High Five insect cells and grown at $27^{\circ} \mathrm{C}$ for 48 hours. The medium is collected and used for assays and further purification.

## Enzyme reaction.

The reaction, carried out in a 96 well plate (Dynatech), is comprised of $70 \mu \mathrm{l}$ of buffer solution ( 25 mM Hepes- $\mathrm{HCl}, \mathrm{pH} 7.5$, plus $20 \mathrm{uM} \mathrm{ZnCl}_{2}$ ), $10 \mu \mathrm{l}$ of $100 \mu \mathrm{M}$ fluorescent quenched substrate, $10 \mu \mathrm{l}$ of a DMSO (5\%) solution of test compound, and an amount of r-TACE enzyme which will cause $50 \%$ cleavage in 60 minutes - in a total volume of $100 \mu \mathrm{l}$. The specificity of the enzyme cleavage at the amide bond between alanine and valine is verified by HPLC and mass spectrometry. Initial rates of cleavage are monitored by measuring the rate of increase in fluorescence at 530 nm (excitation at 409 nm ) over 30 minutes. The experiment is controlled as follows: 1) for background fluorescence of substrate; 2) for fluorescence of fully cleaved substrate; 3) for fluorescence quenching or augmentation from solutions containing test compound.

Data is analyzed as follows. The rates from the non-test compound containing "control" reactions were averaged to establish the $100 \%$ value. The rate of reaction in the presence of test compound was compared to that in the absence of compound, and tabulated as "percent of non-test compound containing control. The results are plotted as "\% of control" vs. the $\log$ of compound concentration and a half-maximal point or $\mathrm{IC}_{50}$ value determined.

All of the compounds of the invention have $\mathrm{IC}_{50}$ of less than $1 \mu \mathrm{M}$, preferably less than 50 nM . Most preferred compounds of the invention are at least 100 fold less potent against r -MMP- 1 than in the above TACE assay.

Human Monocyte Assay
Human mononuclear cells are isolated from anti-coagulated human blood using a onestep Ficoll-hypaque separation technique. (2) The mononuclear cells are washed three times in Hanks balanced salt solution (HBSS) with divalent cations and resuspended to a density of $2 \times$ $10^{6} / \mathrm{ml}$ in HBSS containing $1 \%$ BSA. Differential counts determined using the Abbott Cell Dyn wash is allowed to sit on the plates in the incubator while making dilutions.

Media and dilutions can be made as described in the Table below.

| Control Media | DMEM alone (control media) |
| :---: | :---: |
| IL-1 Media | DMEM + IL-1 ( $5 \mathrm{ng} / \mathrm{ml}$ ) |
| Drug Dilutions | Make all compounds stocks at 10 mM in DMSO. <br> Make a 100 uM stock of each compound in DMEM in 96 well plate. <br> Store in freezer ovemight. <br> The next day perform serial dilutions in DMEM with IL-1 to 5 UM , 500 nM . and 50 nM . <br> Aspirate final wash from wells and add 50 ul of compound from above dilutions to 450 ul of IL-1 media in appropriate wells of the 48 well plates. <br> Final compound concentrations equal $500 \mathrm{nM}, 50 \mathrm{nM}$, and 5 nM . All samples completed in triplicate with Control and IL-1 alone samples on each plate. |

Plates are labeled and only the interior 24 wells of the plate are used. On one of the plates, several columns are designated as IL-1 (no drug) and Control (no IL-1, no drug). These control columns are periodically counted to monitor 35S-proteoglycan release. Control
and IL-1 media are added to wells ( 450 ul ) followed by compound ( 50 ul ) so as to initiate the assay. Plates are incubated at $37^{\circ} \mathrm{C}$, with a $5 \% \mathrm{CO}_{2}$ atmosphere.

At 40-50 \% release (when CPM from IL-1 media is 4-5 times control media) as assessed by liquid scintillation counting (LSC) of media samples, the assay is terminated (912 hours). Media is removed from all wells and placed in scintillation tubes. Scintillate is added and radioactive counts are acquired (LSC). To solubilize cell layers, 500 ul of papain digestion buffer ( 0.2 M Tris, $\mathrm{pH} 7.0,5 \mathrm{mM}$ EDTA, 5 mM DTT, and $1 \mathrm{mg} / \mathrm{ml}$ papain) is added to each well. Plates with digestion solution are incubated at $60^{\circ} \mathrm{C}$ overnight. The cell layer is removed from the plates the next day and placed in scintillation tubes. Scintillate is then added, and samples counted (LSC).

The percent of released counts from the total present in each well is determined. Averages of the triplicates are made with control background subtracted from each well. The percent of compound inhibition is based on IL-1 samples as 0\% inhibition (100\% of total counts).

For administration to mammals, including humans, for the inhibition of matrix metalloproteinases or the production of tumor necrosis factor (TNF), a variety of conventional routes may be used including orally, parenterally and topically. In general, the active compound will be administered orally or parenterally at dosages between about 0.1 and $25 \mathrm{mg} / \mathrm{kg}$ body weight of the subject to be treated per day, preferably from about 0.3 to $5 \mathrm{mg} / \mathrm{kg}$. However, some variation in dosage will necessarily occur depending on the condition of the subject being treated. The person responsible for administration will, in any event, determine the appropriate dose for the individual subject.

The compounds of the present invention can be administered in a wide variety of different dosage forms, in general, the therapeutically effective compounds of this invention are present in such dosage forms at concentration levels ranging from about $5.0 \%$ to about $70 \%$ by weight.

For oral administration, tablets containing various excipients such as microcrystalline cellulose, sodium citrate, calcium carbonate, dicalcium phosphate and glycine may be employed along with various disintegrants such as starch (and preferably corn, potato or tapioca starch). alginic acid and certain complex silicates, together with granulation binders like polyvinylpyrrolidone, sucrose, gelation and acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl sulfate and talc are often very useful for tabletting purposes. Solid compositions of a similar type may also be employed as fillers in gelatin capsules; preferred materials in this connection also include lactose or milk sugar as well as high molecular weight polyethylene glycols. When aqueous suspensions and/or elixirs are desired for oral administration, the active ingredient may be combined with various sweetening or
flavoring agents, coloring matter or dyes, and, if so desired, emulsifying and/or suspending agents as well, together with such diluents as water, ethanol, propylene glycol, glycerin and various like combinations thereof. In the case of animals, they are advantageously contained in an animal feed or drinking water in a concentration of $5-5000 \mathrm{ppm}$, preferably 25 to 500 ppm .

For parenteral administration (intramuscular, intraperitoneal, subcutaneous and intravenous use) a sterile injectable solution of the active ingredient is usually prepared. Solutions of a therapeutic compound of the present invention in either sesame or peanut oil or in aqueous propylene glycol may be employed. The aqueous solutions should be suitably adjusted and buffered, preferably at a pH of greater than 8 , if necessary and the liquid diluent first rendered isotonic. These aqueous solutions are suitable for intravenous injection purposes. The oily solutions are suitable for intraarticular, intramuscular and subcutaneous injection purposes. The preparation of all these solutions under sterile conditions is readily accomplished by standard pharmaceutical techniques well known to those skilled in the art in the case of animals, compounds can be administered intramuscularly or subcutaneously at dosage levels of about 0.1 to $50 \mathrm{mg} / \mathrm{kg} /$ day, advantageously 0.2 to $10 \mathrm{mg} / \mathrm{kg} /$ day given in a single dose or up to 3 divided doses.

For topical ocular administration, direct application to the affected eye may be employed in the form of a formulation as eyedrops, aerosol, gels or ointments, or can be incorporated into collagen (such as poly-2-hydroxyethylmethacrylate and co-polymers thereof), or a hydrophilic polymer shield. The materials can also be applied as a contact lens or via a local reservoir or as a subconjunctival formulation.

For intraorbital administration a sterile injectable solution of the active ingredient is usually prepared. Solutions of a therapeutic compound of the present invention in an aqueous solution or suspension (particle size less than 10 micron) may be employed. The aqueous solutions should be suitably adjusted and buffered, preferably at a pH between 5 and 8 , if necessary and the liquid diluent first rendered isotonic. Small amounts of polymers can be added to increase viscosity or for sustained release (such as cellulosic polymers, Dextran, polyethylene glycol, or alginic acid). These solutions are suitable for intraorbital injection purposes. The preparation of all these solutions under sterile conditions is readily accomplished by standard pharmaceutical techniques well known to those skilled in the art in the case of animals, compounds can be administered intraorbitally at dosage levels of about 0.1 to 50 $\mathrm{mg} / \mathrm{kg} /$ day, advantageously 0.2 to $10 \mathrm{mg} / \mathrm{kg} /$ day given in a single dose or up to 3 divided doses.

The active compounds of the invention may also be formulated in rectal compositions such as suppositories or retention enemas, e.g., containing conventional suppository bases such as cocoa butter or other glycerides.

For intranasal administration or administration by inhalation, the active compounds of the invention are conveniently delivered in the form of a solution or suspension from a pump spray container that is squeezed or pumped by the patient or as an aerosol spray presentation from a pressurized container or a nebulizer, with the use of a suitable propellant, e.g., dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In the case of a pressurized aerosol, the dosage unit may be determined by providing a valve to deliver a metered amount. The pressurized container or nebulizer may contain a solution or suspension of the active compound. Capsules and cartridges (made, for example, from gelatin) for use in an inhaler or insufflator may be formulated containing a powder mix of a compound of the invention and a suitable powder base such as lactose or starch.

The present invention is illustrated by the following Preparations and Examples, but it is not limited to the details thereof.

(A) 4-[N-(Diphenylmethylene)aminoltetrahydropyran-4-carboxylic acid ethyl ester

To a suspension of sodium hydride ( 6.56 grams. 0.164 mole) in ethylene glycol dimethyl ether ( 150 mL ) at $0^{\circ} \mathrm{C}$ was added a solution of the N -(diphenylmethylene)glycine ethyl ester ( 20.60 grams, 0.07398 mole) in ethylene glycol dimethyl ether ( 50 mL ) dropwise via addition funnel. A solution of 2-bromoethyl ether ( 23.21 grams, 0.090 mole) in ethylene glycol dimethyl ether ( 50 mL ) was then added, in 10 mL portions over approximately 5 minutes, to the ethylene glycol dimethyl ether solution. The ice bath was removed and the reaction was stirred at room temperature for 16 hours. The mixture was diluted with diethyl ether and washed with water. The aqueous layer was extracted with diethyl ether. The combined organic extracts were washed with brine, dried over magnesium sulfate, and concentrated to afford a cloudy yellow oil (28.692 grams). ## BICYCLIC HYDROXAMIC ACID DERIVATIVES

## Background of the Invention

The present invention relates to bicyclic hydroxamic acid derivatives, and to pharmaceutical compositions and methods of treatment.

The compounds of the present invention are inhibitors of zinc metalloendopeptidases, especially those belonging to the matrix metalloproteinase (also called MMP or matrixin) and reprolysin (also known as adamylsin) subfamilies of the metzincins (Rawlings, et al., Methods in Enzymology, 248, 183-228 (1995) and Stocker, et al., Protein Science, 4, 823-840 (1995)). The MMP subfamily of enzymes, currently contains seventeen members (MMP-1, MMP-2, MMP-3, MMP-7, MMP-8, MMP-9, MMP-10, MMP-11, MMP-12, MMP-13, MMP-14, MMP-15, MMP-16, MMP-17, MMP-18, MMP-19, MMP-20). The MMP's are most well known for their role in regulating the turn-over of extracellular matrix proteins and as such play important roles in normal physiological processes such as reproduction, development and differentiation. In addition, the MMP's are expressed in many pathological situations in which abnormal connective tissue turnover is occurring. For example, MMP-13 an enzyme with potent activity at degrading type II collagen (the principal collagen in cartilage), has been demonstrated to be overexpressed in osteoarthritic cartilage (Mitchell, et al., J. Clin. Invest., 97, 761 (1996)). Other MMPs (MMP-2, MMP-3, MMP-8, MMP-9, MMP-12) are also overexpressed in osteoarthritic cartilage and inhibition of some or all of these MMP's is expected to slow or block the accelerated loss of cartilage typical of joint diseases such as osteoarthritis or rheumatoid arthritis.

The mammalian reprolysins are known as ADAMs (A Disintegrin And Metalloproteinase) (Wolfberg, et al., J. Cell Biol., 131, 275-278 (1995)) and contain a disintegrin domain in addition to a metalloproteinase-like domain. To date twenty three distinct ADAM's have been identified.

ADAM-17, also known as tumor necrosis factor-alpha converting enzyme (TACE), is the most well known ADAM. ADAM-17 (TACE) is responsible for cleavage of cell bound tumor necrosis factor-alpha (TNF- $\alpha$, also known as cachectin). TNF- $\alpha$ is recognized to be involved in many infectious and auto-immune diseases (W. Friers, FEBS Letters, 285, 199 (1991)). Furthermore, it has been shown that TNF- $\alpha$ is the prime mediator of the inflammatory response seen in sepsis and septic shock (Spooner, et al., Clinical Immunology and Immunopathology, 62 S 11 (1992)). There are two forms of TNF- $\alpha$, a type II membrane protein of relative molecular mass $26,000(26 \mathrm{kD})$ and a soluble 17 kD form generated from the cell bound protein by specific proteolytic cleavage. The soluble 17 kD form of TNF- $\alpha$ is released by the cell and is associated with the deleterious effects of TNF- $\alpha$. This form of

TNF- $\alpha$ is also capable of acting at sites distant from the site of synthesis. Thus, inhibitors of TACE prevent the formation of soluble TNF- $\alpha$ and prevent the deleterious effects of the soluble factor.

Select compounds of the invention are potent inhibitors of aggrecanase, an enzyme important in the degradation of cartilage aggrecan. Aggrecanase is also believed to be an ADAM. The loss of aggrecan from the cartilage matrix is an important factor in the progression of joint diseases such as osteoarthritis and rheumatoid arthritis and inhibition of aggrecanase is expected to slow or block the loss of cartilage in these diseases.

Other ADAMs that have shown expression in pathological situations include ADAM TS-1 (Kuno, et al., J. Biol. Chem., 272, 556-562 (1997)). and ADAM's 10, 12 and 15 (Wu, et al., Biochem. Biophys. Res. Comm., 235, 437-442, (1997)). As knowledge of the expression, physiological substrates and disease association of the ADAM's increases the full significance of the role of inhibition of this class of enzymes will be appreciated.

Diseases in which inhibition of MMP's and or ADAM's will provide therapeutic benefit include: arthritis (including osteoarthritis and rheumatoid arthritis), inflammatory bowel disease, Crohn's disease, emphysema, acute respiratory distress syndrome, asthma chronic obstructive pulmonary disease, Alzheimer's disease, organ transplant toxicity, cachexia, allergic reactions, allergic contact hypersensitivity, cancer, tissue ulceration, restenosis, periodontal disease, epidermolysis bullosa, osteoporosis, loosening of artificial joint implants, atherosclerosis (including atherosclerotic plaque rupture), aortic aneurysm (including abdominal aortic aneurysm and brain aortic aneurysm), congestive heart failure, myocardial infarction, stroke, cerebral ischemia, head trauma, spinal cord injury, neuro-degenerative disorders (acute and chronic), autoimmune disorders, Huntington's disease, Parkinson's disease, migraine, depression, peripheral neuropathy, pain, cerebral amyloid angiopathy, nootropic or cognition enhancement, amyotrophic lateral sclerosis, multiple sclerosis, ocular angiogenesis, corneal injury, macular degeneration, abnormal wound healing, burns, diabetes, tumor invasion, tumor growth, tumor metastasis, corneal scarring, scleritis, AIDS, sepsis, septic shock and other diseases characterized by metalloproteinase or ADAM expression.

This invention also relates to a method of using the compounds of the invention in the treatment of the above diseases in mammals, especially humans, and to the pharmaceutical compositions useful therefore.

It is recognized that different combinations of MMP's and ADAM's are expressed in different pathological situations. As such inhibitors with specific selectivities for individual ADAM's and/or MMP's may be preferred for individual diseases. For example, rheumatoid arthritis is an inflammatory joint disease characterized by excessive TNF levels and the loss
of joint matrix constituents. In this case, a compound that inhibits TACE and aggrecanase as well as MMP's such as MMP-13 may be the preferred therapy. In contrast, in a less inflammatory joint disease such as osteoarthritis, compounds that inhibit matrix degrading MMP's such as MMP-13 but not TACE may be preferred.

The present inventors have also discovered that it is possible to design inhibitors with differential metalloprotease activity. Specifically, for example, the inventors have been able fo design molecules which selectively inhibit matrix metalloprotease-13 (MMP-13) preferentially over MMP-1.

Matrix metalloproteinase inhibitors are well known in the literature. Specifically, PCT Publication WO 96/33172, published October 24, 1996, refers to cyclic arylsulfonylamino hydroxamic acids that are useful as MMP inhibitors. United States Patent $5,672,615$, PCT Publication WO 97/20824, PCT Publication WO 98/08825, PCT publication WO 98/27069, and PCT Publication WO 98/34918, published August 13, 1998, entitled "Arylsulfonyl Hydroxamic Acid Derivatives" all refer to cyclic hydroxamic acids that are useful as MMP inhibitors. Suitable solvents include $\mathrm{N}, \mathrm{N}$-dimethylformamide, halogenated solvents such as methylene chloride or chloroform, or ethers such as THF or diethyl ether; preferably the solvent is $\mathrm{N}, \mathrm{N}$-dimethylformamide. The reaction is complete in about 4 hours to about 48 hours, preferably about 16 hours.

The aforesaid reaction is conducted at about $-78^{\circ} \mathrm{C}$ to about $0^{\circ} \mathrm{C}$, preferably at about $22^{\circ} \mathrm{C}$ (i.e., room temperature) for a period of 30 minutes to about 24 hours, preferably about 2 hours

Compounds of the formula $V$ are prepared from compounds of the formula VI by dehydration in the presence of a tertiary amine base, preferably triethylamine, optionally in the presence of 4-dimethylaminopyridine, and a dehydrating agent in an inert solvent. The preferred solvent system is water and ethanol. The reaction is conducted for a period of 30 minutes to 24 hours, preferably about 2 hours.

The compounds of the formula I which are basic in nature are capable of forming a wide variety of different salts with various inorganic and organic acids. Although such salts must be pharmaceutically acceptable for administration to animals, it is often desirable in practice to initially isolate a compound of the formula $l$ from the reaction mixture as a pharmaceutically unacceptable salt and then simply convert the latter back to the free base compound by treatment with an alkaline reagent, and subsequently convert the free base to a pharmaceutically acceptable acid addition salt. The acid addition salts of the base compounds of this invention are readily prepared by treating the base compound with a substantially equivalent amount of the chosen mineral or organic acid in an aqueous solvent medium or in a suitable organic solvent such as methanol or ethanol. Upon careful evaporation of the solvent, the desired solid salt is obtained.

The acids which are used to prepare the pharmaceutically acceptable acid addition salts of the base compounds of this invention are those which form non-toxic acid addition salts, i.e., salts containing pharmacologically acceptable anions, such as hydrochloride, hydrobromide, hydroiodide, nitrate, sulfate or bisulfate, phosphate or acid phosphate, acetate, lactate, citrate or acid citrate, tartrate or bitartrate, succinate, maleate, fumarate, gluconate, saccharate, benzoate, methanesulfonate and pamoate [i.e., 1,1'-methylene-bis-(2-hydroxy-3naphthoate)] salts.

Those compounds of the formula I which are also acidic in nature, are capable of forming base salts with various pharmacologically acceptable cations. Examples of such salts include the alkali metal or alkaline-earth metal salts and particularly, the sodium and potassium salts. These salts are all prepared by conventional techniques. The chemical bases which are used as reagents to prepare the pharmaceutically acceptable base salts of this invention are those which form non-toxic base salts with the herein described acidic compounds of formula 1 . These non-toxic base salts include those derived from such pharmacologically acceptable cations as sodium, potassium, calcium and magnesium, etc. These salts can easily be prepared by treating the corresponding acidic compounds with an aqueous solution containing the desired pharmacologically acceptable cations, and then evaporating the resulting solution to dryness, preferably under reduced pressure. Alternatively, they may also be prepared by mixing lower alkanolic solutions of the acidic compounds and the desired alkali metal alkoxide together, and then evaporating the resulting solution to dryness in the same manner as before. In either case, stoichiometric quantities of reagents are preferably employed in order to ensure completeness of reaction and maximum product yields.

The ability of the compounds of formula I or their pharmaceutically acceptable salts (hereinafter also referred to as the compounds of the present invention) to inhibit metalloproteinases or mammalian reprolysin and, consequently, demonstrate their effectiveness for treating diseases characterized by metalloproteinase or the production of tumor necrosis factor is shown by the following in vitro assay tests.

## Biological Assay

Inhibition of Human Collagenase (MMP-1)
Human recombinant collagenase is activated with trypsin. The amount of trypsin is optimized for each lot of collagenase-1 but a typical reaction uses the following ratio: $5 \mu \mathrm{~g}$ trypsin per $100 \mu \mathrm{~g}$ of collagenase. The trypsin and collagenase are incubated at room temperature for 10 minutes then a five fold excess ( $50 \mathrm{mg} / 10 \mathrm{mg}$ trypsin) of soybean trypsin inhibitor is added.

Stock solutions ( 10 mM ) of inhibitors are made up in dimethylsulfoxide and then diluted using the following scheme:
$10 \mathrm{mM} \longrightarrow 120 \mu \mathrm{M} \longrightarrow 12 \mu \mathrm{M} \longrightarrow 1.2 \mu \mathrm{M} \longrightarrow 0.12 \mu \mathrm{M}$
Twenty-five microliters of each concentration is then added in triplicate to appropriate wells of a 96 well microfluor plate. The final concentration of inhibitor will be a $1: 4$ dilution after addition of enzyme and substrate. Positive controls (enzyme, no inhibitor) are set up in wells D7-D12 and negative controls (no enzyme, no inhibitors) are set in wells D1-D6.

Collagenase-1 is diluted to $240 \mathrm{ng} / \mathrm{ml}$ and 25 ml is then added to appropriate wells of the microfluor plate. Final concentration of collagenase in the assay is $60 \mathrm{ng} / \mathrm{ml}$.

Substrate (DNP-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)- $\mathrm{NH}_{2}$ ) is made as a 5 mM stock in dimethylsulfoxide and then diluted to $20 \mu \mathrm{M}$ in assay buffer. The assay is initiated by the addition of 50 ml substrate per well of the microfluor plate to give a final concentration of 10 mM .

Fluorescence readings ( 360 nM excitation, 460 nm emission) are taken at time 0 and then at 20 minute intervals. The assay is conducted at room temperature with a typical assay time of 3 hours

Fluorescence versus time is then plotted for both the blank and collagenase containing samples (data from triplicate determinations is averaged). A time point that provides a good signal (at least five fold over the blank) and that is on a linear part of the curve (usually around 120 minutes) is chosen to determine $I C_{50}$ values. The zero time is used as a blank for each compound at each concentration and these values are subtracted from the 120 minute data. Data is plotted as inhibitor concentration versus \% control (inhibitor fluorescence divided by fluorescence of collagenase alone $\times 100$ ). $\quad \mathrm{IC}_{50}$ 's are determined from the concentration of inhibitor that gives a signal that is $50 \%$ of the control.

If $1 C_{50}$ 's are reported to be less than 0.03 mM then the inhibitors are assayed at concentrations of $0.3 \mathrm{mM}, 0.03 \mathrm{mM}$, and 0.003 mM .

## Inhibition of Gelatinase (MMP-2)

Human recombinant 72 kD gelatinase (MMP-2, gelatinase $A$ ) is activated for 16-18 hours with 1 mM p-aminophenyl-mercuric acetate (from a freshly prepared 100 mM stock in 0.2 N NaOH ) at $4^{\circ} \mathrm{C}$, rocking gently.

10 mM dimethylsulfoxide stock solutions of inhibitors are diluted serially in assay buffer ( 50 mM TRIS, $\mathrm{pH} 7.5,200 \mathrm{mM} \mathrm{NaCl}, 5 \mathrm{mM} \mathrm{CaCl} 2_{2}, 20 \mu \mathrm{M} \mathrm{ZnCl}_{2}$ and $0.02 \%$ BRIJ-35 (vol./vol.)) using the following scheme:
$10 \mathrm{mM} \longrightarrow 120 \mu \mathrm{M} \longrightarrow 12 \mu \mathrm{M} \longrightarrow 1.2 \mu \mathrm{M} \longrightarrow 0.12 \mu \mathrm{M}$
Further dilutions are made as necessary following this same scheme. A minimum of four inhibitor concentrations for each compound are performed in each assay. $25 \mu \mathrm{~L}$ of each concentration is then added to triplicate wells of a black 96 well U-bottomed microfluor plate. As the final assay volume is $100 \mu \mathrm{~L}$, final concentrations of inhibitor are the result of a further $1: 4$ dilution (i.e. $30 \mu \mathrm{M} \longrightarrow 3 \mu \mathrm{M} \longrightarrow 0.3 \mu \mathrm{M} \longrightarrow 0.03 \mu \mathrm{M}$, etc.). A blank (no enzyme, no inhibitor) and a positive enzyme control (with enzyme, no inhibitor) are also prepared in triplicate.

Activated enzyme is diluted to $100 \mathrm{ng} / \mathrm{mL}$ in assay buffer, $25 \mu \mathrm{~L}$ per well is added to appropriate wells of the microplate. Final enzyme concentration in the assay is $25 \mathrm{ng} / \mathrm{mL}$ (0.34 nM).

A five mM dimethylsulfoxide stock solution of substrate (Mca-Pro-Leu-Gly-Leu-Dpa-Ala-Arg- $\mathrm{NH}_{2}$ ) is diluted in assay buffer to $20 \mu \mathrm{M}$. The assay is initiated by addition of $50 \mu \mathrm{~L}$ of diluted substrate yielding a final assay concentration of $10 \mu \mathrm{M}$ substrate. At time zero, fluorescence reading ( 320 excitation; 390 emission) is immediately taken and subsequent readings are taken every fifteen minutes at room temperature with a PerSeptive Biosystems CytoFluor Multi-Well Plate Reader with the gain at 90 units.

The average value of fluorescence of the enzyme and blank are plotted versus time. An early time point on the linear part of this curve is chosen for $I C_{50}$ determinations. The zero time point for each compound at each dilution is subtracted from the latter time point and the data then expressed as percent of enzyme control (inhibitor fluorescence divided by fluorescence of positive enzyme control $\times 100$ ). Data is plotted as inhibitor concentration versus percent of enzyme control. $1 C_{50}$ 's are defined as the concentration of inhibitor that gives a signal that is $50 \%$ of the positive enzyme control.

## Inhibition of Stromelysin Activity (MMP-3)

Human recombinant stromelysin (MMP-3, stromelysin-1) is activated for 20-22 hours with 2 mM p-aminophenyl-mercuric acetate (from a freshly prepared 100 mM stock in 0.2 N $\mathrm{NaOH})$ at $37^{\circ} \mathrm{C}$.

10 mM dimethylsulfoxide stock solutions of inhibitors are diluted serially in assay buffer ( 50 mM TRIS, $\mathrm{pH} 7.5,150 \mathrm{mM} \mathrm{NaCl}, 10 \mathrm{mM} \mathrm{CaCl} \mathrm{m}_{2}$ and $0.05 \%$ BRIJ- 35 (vol./vol.)) using the following scheme:
$10 \mathrm{mM} \longrightarrow 120 \mu \mathrm{M} \longrightarrow-12 \mu \mathrm{M} \longrightarrow 1.2 \mu \mathrm{M} \longrightarrow 0.12 \mu \mathrm{M}$
Further dilutions are made as necessary following this same scheme. A minimum of four inhibitor concentrations for each compound are performed in each assay. $25 \mu \mathrm{~L}$ of each concentration is then added to triplicate wells of a black 96 well U-bottomed microfluor plate. As the final assay volume is $100 \mu \mathrm{~L}$, final concentrations of inhibitor are the result of a further $1: 4$ dilution (i.e. $30 \mu \mathrm{M} \rightarrow 3 \mu \mathrm{M} \longrightarrow 0.3 \mu \mathrm{M} \rightarrow 0.03 \mu \mathrm{M}$, etc.). A blank (no enzyme, no inhibitor) and a positive enzyme control (with enzyme, no inhibitor) are also prepared in triplicate.

Activated enzyme is diluted to $200 \mathrm{ng} / \mathrm{mL}$ in assay buffer, $25 \mu \mathrm{~L}$ per well is added to appropriate wells of the microplate. Final enzyme concentration in the assay is $50 \mathrm{ng} / \mathrm{mL}$ ( 0.875 nM ).

A ten mM dimethylsulfoxide stock solution of substrate (Mca-Arg-Pro-Lys-Pro-Val-Glu-Nva-Trp-Arg-Lys(Dnp)- $\mathrm{NH}_{2}$ ) is diluted in assay buffer to $6 \mu \mathrm{M}$. The assay is initiated by addition of $50 \mu \mathrm{~L}$ of diluted substrate yielding a final assay concentration of $3 \mu \mathrm{M}$ substrate. At time zero, fluorescence reading ( 320 excitation; 390 emission) is immediately taken and subsequent readings are taken every fifteen minutes at room temperature with a PerSeptive Biosystems CytoFluor Multi-Well Plate Reader with the gain at 90 units.

The average value of fluorescence of the enzyme and blank are plotted versus time. An early time point on the linear part of this curve is chosen for $1 C_{50}$ determinations. The zero time point for each compound at each dilution is subtracted from the latter time point and the data then expressed as percent of enzyme control (inhibitor fluorescence divided by fluorescence of positive enzyme control $\times 100$ ). Data is plotted as inhibitor concentration versus percent of enzyme control. $1 \mathrm{C}_{50}$ 's are defined as the concentration of inhibitor that gives a signal that is $50 \%$ of the positive enzyme control.

Alternatively, inhibition of stromelysin activity can be assayed using Mca-Arg-Pro-Lys-Pro-Val-Glu-Nva-Trp-Arg-Lys(Dnp)- $\mathrm{NH}_{2}(3 \mu \mathrm{M})$ under conditions similar as in inhibition of human collagenase (MMP-1).

Human stromelysin is activated for $20-24$ hours at $37^{\circ} \mathrm{C}$ with 2 mM APMA ( $p$ aminophenyl mercuric acetate) and is diluted to give a final concentration in the assay of 50
$\mathrm{ng} / \mathrm{ml}$. Inhibitors are diluted as for inhibition of human collagenase (MMP-1) to give final concentrations in the assay of $30 \mu \mathrm{M}, 3 \mu \mathrm{M}, 0.3 \mu \mathrm{M}$, and $0.03 \mu \mathrm{M}$. Each concentration is done in triplicate.

Fluorescence readings ( 320 nm excitation, 390 emission) are taken at time zero and then at 15 minute intervals for 3 hours.
$\mathrm{IC}_{50}$ 's are determined as per inhibition of human collagenase (MMP-1). If $\mathrm{IC}_{50}$ 's are reported to be less than $0.03 \mu \mathrm{M}$, then the inhibitors are assayed at final concentrations of 0.03 $\mu \mathrm{M}, 0.003 \mu \mathrm{M}, 0.0003 \mu \mathrm{M}$, and $0.00003 \mu \mathrm{M}$.
$I_{50}$ values were determined in the same manner as for collagenase.

## Inhibition of MMP-13

Human recombinant MMP-13 is activated with 2 mM APMA ( p -aminophenyl mercuric acetate) for 2.0 hours, at $37^{\circ} \mathrm{C}$ and is diluted to $240 \mathrm{ng} / \mathrm{ml}$ in assay buffer ( 50 mM Tris, pH 7.5 , 200 mM sodium chloride, 5 mM calcium chloride, 20 mM zinc chloride, $0.02 \%$ brij 35). Twentyfive microliters of diluted enzyme is added per well of a 96 well microfluor plate. The enzyme is then diluted in a $1: 4$ ratio in the assay by the addition of inhibitor and substrate to give a final concentration in the assay of $60 \mathrm{ng} / \mathrm{ml}$.

Stock solutions ( 10 mM ) of inhibitors are made up in dimethylsulfoxide and then diluted in assay buffer as per the inhibitor dilution scheme for inhibition of human collagenase-1 (MMP1): Twenty-five microliters of each concentration is added in triplicate to the microfluor plate. The final concentrations in the assay are $30 \mathrm{mM}, 3 \mathrm{mmM}, 0.3 \mathrm{~m} \mathrm{mM}$, and 0.03 mmM .

Substrate (Dnp-Pro-Cha-Gly-Cys(Me)-His-Ala-Lys(NMA)- $\mathrm{NH}_{2}$ ) is prepared as for inhibition of human collagenase (MMP-1) and $50 \mu \mathrm{l}$ is added to each well to give a final assay concentration of $10 \mu \mathrm{M}$. Fluorescence readings ( 360 nM excitation; 450 nM emission) are taken at time 0 and every 5 minutes for 1 hour.

Positive controls and negative controls are set up in triplicate as outlined in the MMP-1 assay.
$I C_{50}$ 's are determined as per inhibition of human collagenase (MMP-1). If $I C_{50}$ 's are reported to be less than 0.03 mM , inhibitors are then assayed at final concentrations of 0.3 mM , $0.03 \mathrm{mmM}, 0.003 \mathrm{mmM}$ and 0.0003 mM .

## Inhibition of TNF Production

The ability of the compounds or the pharmaceutically acceptable salts thereof to inhibit the production of TNF and, consequently, demonstrate their effectiveness for treating diseases involving the production of TNF is shown by the following in vitro assay:

Human mononuclear cells were isolated from anti-coagulated human blood using a onestep Ficoll-hypaque separation technique. (2) The mononuclear cells were washed three times in Hanks balanced salt solution (HBSS) with divalent cations and resuspended to a density of 2
