US009703468B2

(12) **United States Patent**
Reeves et al.

(10) **Patent No.: US 9,703,468 B2**
(45) **Date of Patent: Jul. 11, 2017**

(54) **UNIFIED DESKTOP INDEPENDENT FOCUS IN AN APPLICATION MANAGER**

(71) Applicant: **Z124**, George Town (KY)

(72) Inventors: **Paul E. Reeves**, Oakville (CA); **Sanjiv Sirpal**, Oakville (CA); **Martin Gimpl**, Helsinki (FI)

(73) Assignee: **Z124**, George Town (KY)

(*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35 U.S.C. 154(b) by 983 days.

(21) Appl. No.: **13/627,679**

(22) Filed: **Sep. 26, 2012**

(65) **Prior Publication Data**

US 2013/0111371 A1 May 2, 2013

(57) **ABSTRACT**

Methods and devices for selectively presenting a user interface or "desktop" across two devices are provided. More particularly, a unified desktop is presented across a device and a computer system that comprise a unified system. The unified desktop acts as a single user interface that presents data and receives user interaction in a seamless environment that emulates a personal computing environment. To function within the personal computing environment, the unified desktop includes a process for docking and undocking the device with the computer system. The unified desktop presents a new user interface to allow access to functions of the unified desktop.

The entire disclosure of all the applications or patents listed herein are hereby incorporated by reference, for all that they teach and for all purposes.

BACKGROUND

A substantial number of handheld computing devices, such as cellular phones, tablets, and E-Readers, make use of a touch screen display not only to deliver display information to the user but also to receive inputs from user interface commands. While touch screen displays may increase the configurability of the handheld device and provide a wide variety of user interface options, this flexibility typically comes at a price. The dual use of the touch screen to provide content and receive user commands, while flexible for the user, may obfuscate the display and cause visual clutter, thereby leading to user frustration and loss of productivity.

The small form factor of handheld computing devices requires a careful balancing between the displayed graphics and the area provided for receiving inputs. On the one hand, the small display constrains the display space, which may increase the difficulty of interpreting actions or results. On the other hand, a virtual keypad or other user interface scheme is superimposed on or positioned adjacent to an executing application, requiring the application to be squeezed into an even smaller portion of the display.

This balancing act is particularly difficult for single display touch screen devices. Single display touch screen devices are crippled by their limited screen space. When users are entering information into the device, through the single display, the ability to interpret information in the display can be severely hampered, particularly when a complex interaction between display and interface is required.

Current handheld computing devices may be connected to larger computing devices, e.g., personal computers (PCs), or peripheral screens to provide more display area. Current handheld devices do not include features that allow it to provide both PC functionality and the functionality associated with the handheld device, e.g., phone, text, or other communication functionality. Instead, a peripheral screen connected to a handheld device merely provides more display area for the handheld computing device. When connecting the handheld device to another computing system, such as a PC, the handheld device is typically recognized by the computing system as a peripheral device. The functionality of the handheld device is typically not integrated with the functionality of the larger computing system.

SUMMARY

There is a need for a dual multi-display handheld computing device that provides for enhanced power and/or versatility compared to conventional single display handheld computing devices. These and other needs are addressed by the various aspects, embodiments, and/or configurations of the present disclosure. Also, while the disclosure is presented in terms of exemplary embodiments, it should be appreciated that individual aspects of the disclosure can be separately claimed.

Embodiments provide for a handheld device with a unified desktop for integrating the functionality of the handheld device with a larger computing system, e.g., a PC. When connected to a peripheral display and/or a display of a PC, the handheld device provides a unified desktop displayed across the screen(s) of the handheld device and the additional display. The unified desktop unifies the PC functionality provided on the additional display with the handheld functionality, such as communication applications (e.g., phone, SMS, MMS) provided on the screen(s) of the handheld device. A user can seamlessly interact with applications, e.g., open, drag, close, receive notifications, on the unified desktop whether the applications are displayed on the screens of the handheld device, or the peripheral display of the larger computing system. Each portion of the unified desktop (i.e., the portion on the handheld device and the portion on the peripheral screen) may display different applications, information, and/or have a different layout. Also, in embodiments, each portion of the desktop may display similar information in different formats. For example, battery level of the handheld device, wireless network signal strength, notifications, can be displayed in both portions of the desktop, with a larger format being used on the portion of the unified desktop displayed on the peripheral screen, and a smaller format used on the screen(s) of the peripheral device.

Further embodiments provide for devices, computer-executable instructions, and methods for providing a unified

desktop. Upon docking a device with a computer system, a unified system generates a unified desktop. The unified desktop can include a first user interface associated with the device and a second user interface associated with the computer system. While docked, the unified system can receive a first user interface input on the first user interface. In response to receiving the first user interface input, the unified system may display a first application manager interface on the first user interface. The unified system can then receive a second user interface input on the second user interface. And, in response to receiving the second user interface input, the unified system can display a second application manager interface on the second user interface;

receiving a third user interface input, wherein the third user interface input reorders one or more application representations in the second application manager interface

The phrases "at least one", "one or more", and "and/or" are open-ended expressions that are both conjunctive and disjunctive in operation. For example, each of the expressions "at least one of A, B and C", "at least one of A, B, or C", "one or more of A, B, and C", "one or more of A, B, or C" and "A, B, and/or C" means A alone, B alone, C alone, A and B together, A and C together, B and C together, or A, B and C together.

The term "a" or "an" entity refers to one or more of that entity. As such, the terms "a" (or "an"), "one or more" and "at least one" can be used interchangeably herein. It is also to be noted that the terms "comprising", "including", and "having" can be used interchangeably.

The term "automatic" and variations thereof, as used herein, refers to any process or operation done without material human input when the process or operation is performed. However, a process or operation can be automatic, even though performance of the process or operation uses material or immaterial human input, if the input is received before performance of the process or operation. Human input is deemed to be material if such input influences how the process or operation will be performed. Human input that consents to the performance of the process or operation is not deemed to be "material".

The term "computer-readable medium" as used herein refers to any tangible storage and/or transmission medium that participate in providing instructions to a processor for execution. Such a medium may take many forms, including but not limited to, non-volatile media, volatile media, and transmission media. Non-volatile media includes, for example, NVRAM, or magnetic or optical disks. Volatile media includes dynamic memory, such as main memory. Common forms of computer-readable media include, for example, a floppy disk, a flexible disk, hard disk, magnetic tape, or any other magnetic medium, magneto-optical medium, a CD-ROM, any other optical medium, punch cards, paper tape, any other physical medium with patterns of holes, a RAM, a PROM, and EPROM, a FLASH-EPROM, a solid state medium like a memory card, any other memory chip or cartridge, a carrier wave as described hereinafter, or any other medium from which a computer can read. A digital file attachment to e-mail or other self-contained information archive or set of archives is considered a distribution medium equivalent to a tangible storage medium. When the computer-readable media is configured as a database, it is to be understood that the database may be any type of database, such as relational, hierarchical, object-oriented, and/or the like. Accordingly, the disclosure is considered to include a tangible storage medium or distribution medium and prior art-recognized equivalents and successor media, in which the software implementations of the present disclosure are stored.

The term "desktop" refers to a metaphor used to portray systems. A desktop is generally considered a "surface" that typically includes pictures, called icons, widgets, folders, etc. that can activate show applications, windows, cabinets, files, folders, documents, and other graphical items. The icons are generally selectable to initiate a task through user interface interaction to allow a user to execute applications or conduct other operations.

The term "screen," "touch screen," or "touchscreen" refers to a physical structure that includes one or more hardware components that provide the device with the ability to render a user interface and/or receive user input. A screen can encompass any combination of gesture capture region, a touch sensitive display, and/or a configurable area. The device can have one or more physical screens embedded in the hardware. However a screen may also include an external peripheral device that may be attached and detached from the device. In embodiments, multiple external devices may be attached to the device. Thus, in embodiments, the screen can enable the user to interact with the device by touching areas on the screen and provides information to a user through a display. The touch screen may sense user contact in a number of different ways, such as by a change in an electrical parameter (e.g., resistance or capacitance), acoustic wave variations, infrared radiation proximity detection, light variation detection, and the like. In a resistive touch screen, for example, normally separated conductive and resistive metallic layers in the screen pass an electrical current. When a user touches the screen, the two layers make contact in the contacted location, whereby a change in electrical field is noted and the coordinates of the contacted location calculated. In a capacitive touch screen, a capacitive layer stores electrical charge, which is discharged to the user upon contact with the touch screen, causing a decrease in the charge of the capacitive layer. The decrease is measured, and the contacted location coordinates determined. In a surface acoustic wave touch screen, an acoustic wave is transmitted through the screen, and the acoustic wave is disturbed by user contact. A receiving transducer detects the user contact instance and determines the contacted location coordinates.

The term "display" refers to a portion of one or more screens used to display the output of a computer to a user. A display may be a single-screen display or a multi-screen display, referred to as a composite display. A composite display can encompass the touch sensitive display of one or more screens. A single physical screen can include multiple displays that are managed as separate logical displays. Thus, different content can be displayed on the separate displays although part of the same physical screen.

The term "displayed image" refers to an image produced on the display. A typical displayed image is a window or desktop. The displayed image may occupy all or a portion of the display.

The term "display orientation" refers to the way in which a rectangular display is oriented by a user for viewing. The two most common types of display orientation are portrait and landscape. In landscape mode, the display is oriented such that the width of the display is greater than the height of the display (such as a 4:3 ratio, which is 4 units wide and 3 units tall, or a 16:9 ratio, which is 16 units wide and 9 units tall). Stated differently, the longer dimension of the display is oriented substantially horizontal in landscape mode while the shorter dimension of the display is oriented substantially vertical. In the portrait mode, by contrast, the display is oriented such that the width of the display is less than the

height of the display. Stated differently, the shorter dimension of the display is oriented substantially horizontal in the portrait mode while the longer dimension of the display is oriented substantially vertical.

The term "composite display" refers to a logical structure that defines a display that can encompass one or more screens. A multi-screen display can be associated with a composite display that encompasses all the screens. The composite display can have different display characteristics based on the various orientations of the device.

The term "gesture" refers to a user action that expresses an intended idea, action, meaning, result, and/or outcome. The user action can include manipulating a device (e.g., opening or closing a device, changing a device orientation, moving a trackball or wheel, etc.), movement of a body part in relation to the device, movement of an implement or tool in relation to the device, audio inputs, etc. A gesture may be made on a device (such as on the screen) or with the device to interact with the device.

The term "module" as used herein refers to any known or later developed hardware, software, firmware, artificial intelligence, fuzzy logic, or combination of hardware and software that is capable of performing the functionality associated with that element.

The term "gesture capture" refers to a sense or otherwise a detection of an instance and/or type of user gesture. The gesture capture can occur in one or more areas of the screen, A gesture region can be on the display, where it may be referred to as a touch sensitive display or off the display where it may be referred to as a gesture capture area.

A "multi-screen application" or "multiple-display application" refers to an application that is capable of multiple modes. The multi-screen application mode can include, but is not limited to, a single screen mode (where the application is displayed on a single screen) or a composite display mode (where the application is displayed on two or more screens). A multi-screen application can have different layouts optimized for the mode. Thus, the multi-screen application can have different layouts for a single screen or for a composite display that can encompass two or more screens. The different layouts may have different screen/display dimensions and/or configurations on which the user interfaces of the multi-screen applications can be rendered. The different layouts allow the application to optimize the application's user interface for the type of display, e.g., single screen or multiple screens. In single screen mode, the multi-screen application may present one window pane of information. In a composite display mode, the multi-screen application may present multiple window panes of information or may provide a larger and a richer presentation because there is more space for the display contents. The multi-screen applications may be designed to adapt dynamically to changes in the device and the mode depending on which display (single or composite) the system assigns to the multi-screen application. In alternative embodiments, the user can use a gesture to request the application transition to a different mode, and, if a display is available for the requested mode, the device can allow the application to move to that display and transition modes.

A "single-screen application" refers to an application that is capable of single screen mode. Thus, the single-screen application can produce only one window and may not be capable of different modes or different display dimensions. A single-screen application may not be capable of the several modes discussed with the multi-screen application.

The term "window" refers to a, typically rectangular, displayed image on at least part of a display that contains or provides content different from the rest of the screen. The window may obscure the desktop.

The terms "determine", "calculate" and "compute," and variations thereof, as used herein, are used interchangeably and include any type of methodology, process, mathematical operation or technique.

It shall be understood that the term "means" as used herein shall be given its broadest possible interpretation in accordance with 35 U.S.C., Section 112, Paragraph 6. Accordingly, a claim incorporating the term "means" shall cover all structures, materials, or acts set forth herein, and all of the equivalents thereof. Further, the structures, materials or acts and the equivalents thereof shall include all those described in the summary of the invention, brief description of the drawings, detailed description, abstract, and claims themselves.

The preceding is a simplified summary of the disclosure to provide an understanding of some aspects of the disclosure. This summary is neither an extensive nor exhaustive overview of the disclosure and its various aspects, embodiments, and/or configurations. It is intended neither to identify key or critical elements of the disclosure nor to delineate the scope of the disclosure but to present selected concepts of the disclosure in a simplified form as an introduction to the more detailed description presented below. As will be appreciated, other aspects, embodiments, and/or configurations of the disclosure are possible utilizing, alone or in combination, one or more of the features set forth above or described in detail below.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1**A includes a first view of an embodiment of a multi-screen user device;

FIG. **1**B includes a second view of an embodiment of a multi-screen user device;

FIG. **1**C includes a third view of an embodiment of a multi-screen user device;

FIG. **1**D includes a fourth view of an embodiment of a multi-screen user device;

FIG. **1**E includes a fifth view of an embodiment of a multi-screen user device;

FIG. **1**F includes a sixth view of an embodiment of a multi-screen user device;

FIG. **1**G includes a seventh view of an embodiment of a multi-screen user device;

FIG. **1**H includes a eighth view of an embodiment of a multi-screen user device;

FIG. **1**I includes a ninth view of an embodiment of a multi-screen user device;

FIG. **1**J includes a tenth view of an embodiment of a multi-screen user device;

FIG. **2** is a block diagram of an embodiment of the hardware of the device;

FIG. **3**A is a block diagram of an embodiment of the state model for the device based on the device's orientation and/or configuration;

FIG. **3**B is a table of an embodiment of the state model for the device based on the device's orientation and/or configuration;

FIG. **4**A is a first representation of an embodiment of user gesture received at a device;

FIG. **4**B is a second representation of an embodiment of user gesture received at a device;

FIG. **4**C is a third representation of an embodiment of user gesture received at a device;

FIG. **4**D is a fourth representation of an embodiment of user gesture received at a device;

FIG. **4**E is a fifth representation of an embodiment of user gesture received at a device;

FIG. **4**F is a sixth representation of an embodiment of user gesture received at a device;

FIG. **4**G is a seventh representation of an embodiment of user gesture received at a device;

FIG. **4**H is a eighth representation of an embodiment of user gesture received at a device;

FIG. **5**A is a block diagram of an embodiment of the device software and/or firmware;

FIG. **5**B is a second block diagram of an embodiment of the device software and/or firmware;

FIG. **6**A is a first representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**B is a second representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**C is a third representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**D is a fourth representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**E is a fifth representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**F is a sixth representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**G is a seventh representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**H is a eighth representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**I is a ninth representation of an embodiment of a device configuration generated in response to the device state;

FIG. **6**J is a tenth representation of an embodiment of a device configuration generated in response to the device state;

FIG. **7**A is representation of a logical window stack;

FIG. **7**B is another representation of an embodiment of a logical window stack;

FIG. **7**C is another representation of an embodiment of a logical window stack;

FIG. **7**D is another representation of an embodiment of a logical window stack;

FIG. **7**E is another representation of an embodiment of a logical window stack;

FIG. **8** is block diagram of an embodiment of a logical data structure for a window stack;

FIG. **9** is a flow chart of an embodiment of a method for creating a window stack;

FIG. **10** is a flow chart of an embodiment of a method for managing the execution of an application;

FIG. **11** is a block diagram of an embodiment of the hardware of a unified system;

FIG. **12** is a block diagram of an embodiment of the hardware of a computer system;

FIG. **13** is a representation of an embodiment of a unified desktop;

FIG. **14** is a representation of an embodiment of a user interface presented in a unified desktop;

FIG. **15** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **16** is a flow chart of an embodiment of a method for providing status indicators in a unified desktop;

FIG. **17** is a flow chart of an embodiment of a method for providing status indicators in a unified desktop;

FIG. **18** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **19** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **20** is a flow chart of an embodiment of a method for providing a freeform window in a unified desktop;

FIG. **21** is another flow chart of an embodiment of a method for providing a freeform window in a unified desktop;

FIG. **22** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **23** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **24** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **25** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **26** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **27** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **28** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **29** is a representation of a state diagram of a user interface in a sleep state presented in a unified desktop;

FIG. **30** is a flow chart of an embodiment of a method for providing a common wake and unlock strategy for a unified desktop;

FIG. **31** is another representation of an embodiment of user interfaces presented before docking a device with a computer system to form a unified desktop;

FIG. **32** is another representation of an embodiment of a user interface presented in a unified desktop after docking;

FIG. **33** is another representation of an embodiment of a user interface presented in a unified desktop after docking;

FIG. **34** is a flow chart of an embodiment of a method for docking a device with a computer system to form a unified desktop;

FIG. **35** is another representation of an embodiment of a user interface presented in a unified desktop before undocking;

FIG. **36** is another representation of an embodiment of user interfaces presented after undocking a device with a computer system to dismantle a unified desktop;

FIG. **37** is a flow chart of an embodiment of a method for undocking a device with a computer system;

FIG. **38** is a representation of a rules diagram for different rules that govern the docking and undocking of a device and a computer system;

FIG. **39** is a block diagram of an embodiment of the computing environment of a unified system;

FIG. **40** is a representation of an embodiment of a user interface presented in a unified desktop;

FIG. **41**A is a block diagram of an embodiment of a user interface data structure associated with the unified desktop;

FIG. **41**B is another block diagram of another embodiment of a user interface data structure associated with the unified desktop;

FIG. **42** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **43**A is a block diagram of an embodiment of a user interface data structure associated with the unified desktop;

FIG. **43**B is another block diagram of another embodiment of a user interface data structure associated with the unified desktop;

FIG. **44** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **45**A is a block diagram of an embodiment of a user interface data structure associated with the unified desktop;

FIG. **45**B is another block diagram of another embodiment of a user interface data structure associated with the unified desktop;

FIG. **46** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **47**A is a block diagram of an embodiment of a user interface data structure associated with the unified desktop;

FIG. **47**B is another block diagram of another embodiment of a user interface data structure associated with the unified desktop;

FIG. **48** is a flow chart of an embodiment of a method for managing the user interface when docking a device with a computer system;

FIG. **49** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **50** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **51** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **52** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **53** is a block diagram of an embodiment of data structure associated windows previously displayed when the device was previously docked with the computer system;

FIG. **54** is a flow chart of an embodiment of a method for managing window stickiness;

FIG. **55**A is another block diagram of another embodiment of modules associated with the device docked with the computer system;

FIG. **55**B is another block diagram of another embodiment of modules associated with the computer system docked with the device;

FIG. **56** is a flow chart of an embodiment of a method for processing events in the unified system;

FIG. **57** is another flow chart of another embodiment of a method for processing events in the unified system;

FIG. **58** is another flow chart of another embodiment of a method for processing events in the unified system;

FIG. **59** is a flow chart of an embodiment of a method for the device assuming the role of master in the unified system;

FIG. **60** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **61**A is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **61**B is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **61**C is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **62** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **63** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **64** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **65** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **66**A is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **66**B is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **67** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **68** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **69** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **70** is a flow chart of an embodiment of a method for providing a triad control in the unified system;

FIG. **71** is a flow chart of an embodiment of a method for providing an application manager interface in the unified system;

FIG. **72** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **73** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **74** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **75** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **76** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **77** is a flow chart of an embodiment of a method for providing an application manager interface in the unified system;

FIG. **78** is another representation of an embodiment of a user interface presented in a unified desktop

FIG. **79** is a flow chart of an embodiment of a method for providing a big brother application in the unified system;

FIG. **80** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **81** is another representation of an embodiment of a user interface presented in a unified desktop;

FIG. **82** is a flow chart of an embodiment of a method for providing a big brother application in the unified system;

FIG. **83** is an embodiment of a data structure associated with a big brother application in a unified desktop.

In the appended figures, similar components and/or features may have the same reference label. Further, various components of the same type may be distinguished by following the reference label by a letter that distinguishes among the similar components. If only the first reference label is used in the specification, the description is applicable to any one of the similar components having the same first reference label irrespective of the second reference label.

DETAILED DESCRIPTION

Presented herein are embodiments of a device. The device can be a communications device, such as a cellular telephone, or other smart device. The device can include two screens that are oriented to provide several unique display configurations. Further, the device can receive user input in unique ways. The overall design and functionality of the device provides for an enhanced user experience making the device more useful and more efficient.

Mechanical Features:

FIGS. **1**A-**1**J illustrate a device **100** in accordance with embodiments of the present disclosure. As described in greater detail below, device **100** can be positioned in a number of different ways each of which provides different functionality to a user. The device **100** is a multi-screen device that includes a primary screen **104** and a secondary screen **108**, both of which are touch sensitive. In embodiments, the entire front surface of screens **104** and **108** may be touch sensitive and capable of receiving input by a user

touching the front surface of the screens **104** and **108**. Primary screen **104** includes touch sensitive display **110**, which, in addition to being touch sensitive, also displays information to a user. Secondary screen **108** includes touch sensitive display **114**, which also displays information to a user. In other embodiments, screens **104** and **108** may include more than one display area.

Primary screen **104** also includes a configurable area **112** that has been configured for specific inputs when the user touches portions of the configurable area **112**. Secondary screen **108** also includes a configurable area **116** that has been configured for specific inputs. Areas **112***a* and **116***a* have been configured to receive a "back" input indicating that a user would like to view information previously displayed. Areas **112***b* and **116***b* have been configured to receive a "menu" input indicating that the user would like to view options from a menu. Areas **112***c* and **116***c* have been configured to receive a "home" input indicating that the user would like to view information associated with a "home" view. In other embodiments, areas **112***a-c* and **116***a-c* may be configured, in addition to the configurations described above, for other types of specific inputs including controlling features of device **100**, some non-limiting examples including adjusting overall system power, adjusting the volume, adjusting the brightness, adjusting the vibration, selecting of displayed items (on either of screen **104** or **108**), operating a camera, operating a microphone, and initiating/terminating of telephone calls. Also, in some embodiments, areas **112***a-c* and **116***a-c* may be configured for specific inputs depending upon the application running on device **100** and/or information displayed on touch sensitive displays **110** and/or **114**.

In addition to touch sensing, primary screen **104** and secondary screen **108** may also include areas that receive input from a user without requiring the user to touch the display area of the screen. For example, primary screen **104** includes gesture capture area **120**, and secondary screen **108** includes gesture capture area **124**. These areas are able to receive input by recognizing gestures made by a user without the need for the user to actually touch the surface of the display area. In comparison to touch sensitive displays **110** and **114**, the gesture capture areas **120** and **124** are commonly not capable of rendering a displayed image.

The two screens **104** and **108** are connected together with a hinge **128**, shown clearly in FIG. **1**C (illustrating a back view of device **100**). Hinge **128**, in the embodiment shown in FIGS. **1**A-**1**J, is a center hinge that connects screens **104** and **108** so that when the hinge is closed, screens **104** and **108** are juxtaposed (i.e., side-by-side) as shown in FIG. **1**B (illustrating a front view of device **100**). Hinge **128** can be opened to position the two screens **104** and **108** in different relative positions to each other. As described in greater detail below, the device **100** may have different functionalities depending on the relative positions of screens **104** and **108**.

FIG. **1**D illustrates the right side of device **100**. As shown in FIG. **1**D, secondary screen **108** also includes a card slot **132** and a port **136** on its side. Card slot **132** in embodiments, accommodates different types of cards including a subscriber identity module (SIM). Port **136** in embodiments is an input/output port (I/O port) that allows device **100** to be connected to other peripheral devices, such as a display, keyboard, or printing device. As can be appreciated, these are merely some examples and in other embodiments device **100** may include other slots and ports such as slots and ports for accommodating additional memory devices and/or for connecting other peripheral devices. Also shown in FIG. **1**D is an audio jack **140** that accommodates a tip, ring, sleeve (TRS) connector for example to allow a user to utilize headphones or a headset.

Device **100** also includes a number of buttons **158**. For example, FIG. **1**E illustrates the left side of device **100**. As shown in FIG. **1**E, the side of primary screen **104** includes three buttons **144**, **148**, and **152**, which can be configured for specific inputs. For example, buttons **144**, **148**, and **152** may be configured to, in combination or alone, control a number of aspects of device **100**. Some non-limiting examples include overall system power, volume, brightness, vibration, selection of displayed items (on either of screen **104** or **108**), a camera, a microphone, and initiation/termination of telephone calls. In some embodiments, instead of separate buttons two buttons may be combined into a rocker button. This arrangement is useful in situations where the buttons are configured to control features such as volume or brightness. In addition to buttons **144**, **148**, and **152**, device **100** also includes a button **156**, shown in FIG. **1**F, which illustrates the top of device **100**. In one embodiment, button **156** is configured as an on/off button used to control overall system power to device **100**. In other embodiments, button **156** is configured to, in addition to or in lieu of controlling system power, control other aspects of device **100**. In some embodiments, one or more of the buttons **144**, **148**, **152**, and **156** are capable of supporting different user commands. By way of example, a normal press has a duration commonly of less than about 1 second and resembles a quick tap. A medium press has a duration commonly of 1 second or more but less than about 12 seconds. A long press has a duration commonly of about 12 seconds or more. The function of the buttons is normally specific to the application that is currently in focus on the respective display **110** and **114**. In a telephone application for instance and depending on the particular button, a normal, medium, or long press can mean end call, increase in call volume, decrease in call volume, and toggle microphone mute. In a camera or video application for instance and depending on the particular button, a normal, medium, or long press can mean increase zoom, decrease zoom, and take photograph or record video.

There are also a number of hardware components within device **100**. As illustrated in FIG. **1**C, device **100** includes a speaker **160** and a microphone **164**. Device **100** also includes a camera **168** (FIG. **1**B). Additionally, device **100** includes two position sensors **172**A and **172**B, which are used to determine the relative positions of screens **104** and **108**. In one embodiment, position sensors **172**A and **172**B are Hall effect sensors. However, in other embodiments other sensors can be used in addition to or in lieu of the Hall effect sensors. An accelerometer **176** may also be included as part of device **100** to determine the orientation of the device **100** and/or the orientation of screens **104** and **108**. Additional internal hardware components that may be included in device **100** are described below with respect to FIG. **2**.

The overall design of device **100** allows it to provide additional functionality not available in other communication devices. Some of the functionality is based on the various positions and orientations that device **100** can have. As shown in FIGS. **1**B-**1**G, device **100** can be operated in an "open" position where screens **104** and **108** are juxtaposed. This position allows a large display area for displaying information to a user. When position sensors **172**A and **172**B determine that device **100** is in the open position, they can generate a signal that can be used to trigger different events such as displaying information on both screens **104** and **108**. Additional events may be triggered if accelerometer **176**

determines that device **100** is in a portrait position (FIG. **1**B) as opposed to a landscape position (not shown).

In addition to the open position, device **100** may also have a "closed" position illustrated in FIG. **1**H. Again, position sensors **172**A and **172**B can generate a signal indicating that device **100** is in the "closed" position. This can trigger an event that results in a change of displayed information on screen **104** and/or **108**. For example, device **100** may be programmed to stop displaying information on one of the screens, e.g., screen **108**, since a user can only view one screen at a time when device **100** is in the "closed" position. In other embodiments, the signal generated by position sensors **172**A and **172**B, indicating that the device **100** is in the "closed" position, can trigger device **100** to answer an incoming telephone call. The "closed" position can also be a preferred position for utilizing the device **100** as a mobile phone.

Device **100** can also be used in an "easel" position which is illustrated in FIG. **1**I. In the "easel" position, screens **104** and **108** are angled with respect to each other and facing outward with the edges of screens **104** and **108** substantially horizontal. In this position, device **100** can be configured to display information on both screens **104** and **108** to allow two users to simultaneously interact with device **100**. When device **100** is in the "easel" position, sensors **172**A and **172**B generate a signal indicating that the screens **104** and **108** are positioned at an angle to each other, and the accelerometer **176** can generate a signal indicating that device **100** has been placed so that the edge of screens **104** and **108** are substantially horizontal. The signals can then be used in combination to generate events that trigger changes in the display of information on screens **104** and **108**.

FIG. **1**J illustrates device **100** in a "modified easel" position. In the "modified easel" position, one of screens **104** or **108** is used as a stand and is faced down on the surface of an object such as a table. This position provides a convenient way for information to be displayed to a user in landscape orientation. Similar to the easel position, when device **100** is in the "modified easel" position, position sensors **172**A and **172**B generate a signal indicating that the screens **104** and **108** are positioned at an angle to each other. The accelerometer **176** would generate a signal indicating that device **100** has been positioned so that one of screens **104** and **108** is faced downwardly and is substantially horizontal. The signals can then be used to generate events that trigger changes in the display of information of screens **104** and **108**. For example, information may not be displayed on the screen that is face down since a user cannot see the screen.

Transitional states are also possible. When the position sensors **172**A and B and/or accelerometer indicate that the screens are being closed or folded (from open), a closing transitional state is recognized. Conversely when the position sensors **172**A and B indicate that the screens are being opened or folded (from closed), an opening transitional state is recognized. The closing and opening transitional states are typically time-based, or have a maximum time duration from a sensed starting point. Normally, no user input is possible when one of the closing and opening states is in effect. In this manner, incidental user contact with a screen during the closing or opening function is not misinterpreted as user input. In embodiments, another transitional state is possible when the device **100** is closed. This additional transitional state allows the display to switch from one screen **104** to the second screen **108** when the device **100** is closed based on some user input, e.g., a double tap on the screen **110**,**114**.

As can be appreciated, the description of device **100** is made for illustrative purposes only, and the embodiments are not limited to the specific mechanical features shown in FIGS. **1**A-**1**J and described above. In other embodiments, device **100** may include additional features, including one or more additional buttons, slots, display areas, hinges, and/or locking mechanisms. Additionally, in embodiments, the features described above may be located in different parts of device **100** and still provide similar functionality. Therefore, FIGS. **1**A-**1**J and the description provided above are non-limiting.

Hardware Features:

FIG. **2** illustrates components of a device **100** in accordance with embodiments of the present disclosure. In general, the device **100** includes a primary screen **104** and a secondary screen **108**. While the primary screen **104** and its components are normally enabled in both the opened and closed positions or states, the secondary screen **108** and its components are normally enabled in the opened state but disabled in the closed state. However, even when in the closed state a user or application triggered interrupt (such as in response to a phone application or camera application operation) can flip the active screen, or disable the primary screen **104** and enable the secondary screen **108**, by a suitable command. Each screen **104**, **108** can be touch sensitive and can include different operative areas. For example, a first operative area, within each touch sensitive screen **104** and **108**, may comprise a touch sensitive display **110**, **114**. In general, the touch sensitive display **110**, **114** may comprise a full color, touch sensitive display. A second area within each touch sensitive screen **104** and **108** may comprise a gesture capture region **120**, **124**. The gesture capture region **120**, **124** may comprise an area or region that is outside of the touch sensitive display **110**, **114** area, and that is capable of receiving input, for example in the form of gestures provided by a user. However, the gesture capture region **120**, **124** does not include pixels that can perform a display function or capability.

A third region of the touch sensitive screens **104** and **108** may comprise a configurable area **112**, **116**. The configurable area **112**, **116** is capable of receiving input and has display or limited display capabilities. In embodiments, the configurable area **112**, **116** may present different input options to the user. For example, the configurable area **112**, **116** may display buttons or other relatable items. Moreover, the identity of displayed buttons, or whether any buttons are displayed at all within the configurable area **112**, **116** of a touch sensitive screen **104** or **108**, may be determined from the context in which the device **100** is used and/or operated. In an exemplary embodiment, the touch sensitive screens **104** and **108** comprise liquid crystal display devices extending across at least those regions of the touch sensitive screens **104** and **108** that are capable of providing visual output to a user, and a capacitive input matrix over those regions of the touch sensitive screens **104** and **108** that are capable of receiving input from the user.

One or more display controllers **216***a*, **216***b* may be provided for controlling the operation of the touch sensitive screens **104** and **108**, including input (touch sensing) and output (display) functions. In the exemplary embodiment illustrated in FIG. **2**, a separate touch screen controller **216***a* or **216***b* is provided for each touch screen **104** and **108**. In accordance with alternate embodiments, a common or shared touch screen controller may be used to control each of the included touch sensitive screens **104** and **108**. In accordance with still other embodiments, the functions of a

touch screen controller may be incorporated into other components, such as a processor **204**.

The processor **204** may comprise a general purpose programmable processor or controller for executing application programming or instructions. In accordance with at least some embodiments, the processor **204** may include multiple processor cores, and/or implement multiple virtual processors. In accordance with still other embodiments, the processor **204** may include multiple physical processors. As a particular example, the processor **204** may comprise a specially configured application specific integrated circuit (ASIC) or other integrated circuit, a digital signal processor, a controller, a hardwired electronic or logic circuit, a programmable logic device or gate array, a special purpose computer, or the like. The processor **204** generally functions to run programming code or instructions implementing various functions of the device **100**.

A communication device **100** may also include memory **208** for use in connection with the execution of application programming or instructions by the processor **204**, and for the temporary or long term storage of program instructions and/or data. As examples, the memory **208** may comprise RAM, DRAM, SDRAM, or other solid state memory. Alternatively or in addition, data storage **212** may be provided. Like the memory **208**, the data storage **212** may comprise a solid state memory device or devices. Alternatively or in addition, the data storage **212** may comprise a hard disk drive or other random access memory.

In support of communications functions or capabilities, the device **100** can include a cellular telephony module **228**. As examples, the cellular telephony module **228** can comprise a GSM, CDMA, FDMA and/or analog cellular telephony transceiver capable of supporting voice, multimedia and/or data transfers over a cellular network. Alternatively or in addition, the device **100** can include an additional or other wireless communications module **232**. As examples, the other wireless communications module **232** can comprise a Wi-Fi, BLUETOOTH™, WiMax, infrared, or other wireless communications link. The cellular telephony module **228** and the other wireless communications module **232** can each be associated with a shared or a dedicated antenna **224**.

A port interface **252** may be included. The port interface **252** may include proprietary or universal ports to support the interconnection of the device **100** to other devices or components, such as a dock, which may or may not include additional or different capabilities from those integral to the device **100**. In addition to supporting an exchange of communication signals between the device **100** and another device or component, the docking port **136** and/or port interface **252** can support the supply of power to or from the device **100**. The port interface **252** also comprises an intelligent element that comprises a docking module for controlling communications or other interactions between the device **100** and a connected device or component.

An input/output module **248** and associated ports may be included to support communications over wired networks or links, for example with other communication devices, server devices, and/or peripheral devices. Examples of an input/output module **248** include an Ethernet port, a Universal Serial Bus (USB) port, Institute of Electrical and Electronics Engineers (IEEE) 1394, or other interface.

An audio input/output interface/device(s) **244** can be included to provide analog audio to an interconnected speaker or other device, and to receive analog audio input from a connected microphone or other device. As an example, the audio input/output interface/device(s) **244** may comprise an associated amplifier and analog to digital converter. Alternatively or in addition, the device **100** can include an integrated audio input/output device **256** and/or an audio jack for interconnecting an external speaker or microphone. For example, an integrated speaker and an integrated microphone can be provided, to support near talk or speaker phone operations.

Hardware buttons **158** can be included for example for use in connection with certain control operations. Examples include a master power switch, volume control, etc., as described in conjunction with FIGS. **1**A through **1**J. One or more image capture interfaces/devices **240**, such as a camera, can be included for capturing still and/or video images. Alternatively or in addition, an image capture interface/device **240** can include a scanner or code reader. An image capture interface/device **240** can include or be associated with additional elements, such as a flash or other light source.

The device **100** can also include a global positioning system (GPS) receiver **236**. In accordance with embodiments of the present invention, the GPS receiver **236** may further comprise a GPS module that is capable of providing absolute location information to other components of the device **100**. An accelerometer(s) **176** may also be included. For example, in connection with the display of information to a user and/or other functions, a signal from the accelerometer **176** can be used to determine an orientation and/or format in which to display that information to the user.

Embodiments of the present invention can also include one or more position sensor(s) **172**. The position sensor **172** can provide a signal indicating the position of the touch sensitive screens **104** and **108** relative to one another. This information can be provided as an input, for example to a user interface application, to determine an operating mode, characteristics of the touch sensitive displays **110**, **114**, and/or other device **100** operations. As examples, a screen position sensor **172** can comprise a series of Hall effect sensors, a multiple position switch, an optical switch, a Wheatstone bridge, a potentiometer, or other arrangement capable of providing a signal indicating of multiple relative positions the touch screens are in.

Communications between various components of the device **100** can be carried by one or more buses **222**. In addition, power can be supplied to the components of the device **100** from a power source and/or power control module **260**. The power control module **260** can, for example, include a battery, an AC to DC converter, power control logic, and/or ports for interconnecting the device **100** to an external source of power.

Device State:

FIGS. **3**A and **3**B represent illustrative states of device **100**. While a number of illustrative states are shown, and transitions from a first state to a second state, it is to be appreciated that the illustrative state diagram may not encompass all possible states and/or all possible transitions from a first state to a second state. As illustrated in FIG. **3**, the various arrows between the states (illustrated by the state represented in the circle) represent a physical change that occurs to the device **100**, that is detected by one or more of hardware and software, the detection triggering one or more of a hardware and/or software interrupt that is used to control and/or manage one or more functions of device **100**.

As illustrated in FIG. **3**A, there are twelve exemplary "physical" states: closed **304**, transition **308** (or opening transitional state), easel **312**, modified easel **316**, open **320**, inbound/outbound call or communication **324**, image/video capture **328**, transition **332** (or closing transitional state),

landscape **340**, docked **336**, docked **344** and landscape **348**. Next to each illustrative state is a representation of the physical state of the device **100** with the exception of states **324** and **328**, where the state is generally symbolized by the international icon for a telephone and the icon for a camera, respectfully.

In state **304**, the device is in a closed state with the device **100** generally oriented in the portrait direction with the primary screen **104** and the secondary screen **108** back-to-back in different planes (see FIG. **1**H). From the closed state, the device **100** can enter, for example, docked state **336**, where the device **100** is coupled with a docking station, docking cable, or in general docked or associated with one or more other devices or peripherals, or the landscape state **340**, where the device **100** is generally oriented with the primary screen **104** facing the user, and the primary screen **104** and the secondary screen **108** being back-to-back.

In the closed state, the device can also move to a transitional state where the device remains closed but the display is moved from one screen **104** to another screen **108** based on a user input, e.g., a double tap on the screen **110**, **114**. Still another embodiment includes a bilateral state. In the bilateral state, the device remains closed, but a single application displays at least one window on both the first display **110** and the second display **114**. The windows shown on the first and second display **110**, **114** may be the same or different based on the application and the state of that application. For example, while acquiring an image with a camera, the device may display the view finder on the first display **110** and displays a preview for the photo subjects (full screen and mirrored left-to-right) on the second display **114**.

In state **308**, a transition state from the closed state **304** to the semi-open state or easel state **312**, the device **100** is shown opening with the primary screen **104** and the secondary screen **108** being rotated around a point of axis coincidence with the hinge. Upon entering the easel state **312**, the primary screen **104** and the secondary screen **108** are separated from one another such that, for example, the device **100** can sit in an easel-like configuration on a surface.

In state **316**, known as the modified easel position, the device **100** has the primary screen **104** and the secondary screen **108** in a similar relative relationship to one another as in the easel state **312**, with the difference being one of the primary screen **104** or the secondary screen **108** are placed on a surface as shown.

State **320** is the open state where the primary screen **104** and the secondary screen **108** are generally on the same plane. From the open state, the device **100** can transition to the docked state **344** or the open landscape state **348**. In the open state **320**, the primary screen **104** and the secondary screen **108** are generally in the portrait-like orientation while in landscaped state **348** the primary screen **104** and the secondary screen **108** are generally in a landscape-like orientation.

State **324** is illustrative of a communication state, such as when an inbound or outbound call is being received or placed, respectively, by the device **100**. While not illustrated for clarity, it should be appreciated the device **100** can transition to the inbound/outbound call state **324** from any state illustrated in FIG. **3**. In a similar manner, the image/video capture state **328** can be entered into from any other state in FIG. **3**, with the image/video capture state **328** allowing the device **100** to take one or more images via a camera and/or videos with a video capture device **240**.

Transition state **332** illustratively shows primary screen **104** and the secondary screen **108** being closed upon one another for entry into, for example, the closed state **304**.

FIG. **3**B illustrates, with reference to the key, the inputs that are received to detect a transition from a first state to a second state. In FIG. **3**B, various combinations of states are shown with in general, a portion of the columns being directed toward a portrait state **352**, a landscape state **356**, and a portion of the rows being directed to portrait state **360** and landscape state **364**.

In FIG. **3**B, the Key indicates that "H" represents an input from one or more Hall Effect sensors, "A" represents an input from one or more accelerometers, "T" represents an input from a timer, "P" represents a communications trigger input and "I" represents an image and/or video capture request input. Thus, in the center portion **376** of the chart, an input, or combination of inputs, are shown that represent how the device **100** detects a transition from a first physical state to a second physical state.

As discussed, in the center portion of the chart **376**, the inputs that are received enable the detection of a transition from, for example, a portrait open state to a landscape easel state—shown in bold—"HAT." For this exemplary transition from the portrait open to the landscape easel state, a Hall Effect sensor ("H"), an accelerometer ("A") and a timer ("T") input may be needed. The timer input can be derived from, for example, a clock associated with the processor.

In addition to the portrait and landscape states, a docked state **368** is also shown that is triggered based on the receipt of a docking signal **372**. As discussed above and in relation to FIG. **3**, the docking signal can be triggered by the association of the device **100** with one or more other device **100**s, accessories, peripherals, smart docks, or the like.

User Interaction:

FIGS. **4**A through **4**H depict various graphical representations of gesture inputs that may be recognized by the screens **104**, **108**. The gestures may be performed not only by a user's body part, such as a digit, but also by other devices, such as a stylus, that may be sensed by the contact sensing portion(s) of a screen **104**, **108**. In general, gestures are interpreted differently, based on where the gestures are performed (either directly on the display **110**, **114** or in the gesture capture region **120**, **124**). For example, gestures in the display **110**,**114** may be directed to a desktop or application, and gestures in the gesture capture region **120**, **124** may be interpreted as for the system.

With reference to FIGS. **4**A-**4**H, a first type of gesture, a touch gesture **420**, is substantially stationary on the screen **104**,**108** for a selected length of time. A circle **428** represents a touch or other contact type received at particular location of a contact sensing portion of the screen. The circle **428** may include a border **432**, the thickness of which indicates a length of time that the contact is held substantially stationary at the contact location. For instance, a tap **420** (or short press) has a thinner border **432***a* than the border **432***b* for a long press **424** (or for a normal press). The long press **424** may involve a contact that remains substantially stationary on the screen for longer time period than that of a tap **420**. As will be appreciated, differently defined gestures may be registered depending upon the length of time that the touch remains stationary prior to contact cessation or movement on the screen.

With reference to FIG. **4**C, a drag gesture **400** on the screen **104**,**108** is an initial contact (represented by circle **428**) with contact movement **436** in a selected direction. The initial contact **428** may remain stationary on the screen **104**,**108** for a certain amount of time represented by the border **432**. The drag gesture typically requires the user to contact an icon, window, or other displayed image at a first location followed by movement of the contact in a drag

direction to a new second location desired for the selected displayed image. The contact movement need not be in a straight line but have any path of movement so long as the contact is substantially continuous from the first to the second locations.

With reference to FIG. **4**D, a flick gesture **404** on the screen **104**,**108** is an initial contact (represented by circle **428**) with truncated contact movement **436** (relative to a drag gesture) in a selected direction. In embodiments, a flick has a higher exit velocity for the last movement in the gesture compared to the drag gesture. The flick gesture can, for instance, be a finger snap following initial contact. Compared to a drag gesture, a flick gesture generally does not require continual contact with the screen **104**,**108** from the first location of a displayed image to a predetermined second location. The contacted displayed image is moved by the flick gesture in the direction of the flick gesture to the predetermined second location. Although both gestures commonly can move a displayed image from a first location to a second location, the temporal duration and distance of travel of the contact on the screen is generally less for a flick than for a drag gesture.

With reference to FIG. **4**E, a pinch gesture **408** on the screen **104**,**108** is depicted. The pinch gesture **408** may be initiated by a first contact **428***a* to the screen **104**,**108** by, for example, a first digit and a second contact **428***b* to the screen **104**,**108** by, for example, a second digit. The first and second contacts **428***a,b* may be detected by a common contact sensing portion of a common screen **104**,**108**, by different contact sensing portions of a common screen **104** or **108**, or by different contact sensing portions of different screens. The first contact **428***a* is held for a first amount of time, as represented by the border **432***a*, and the second contact **428***b* is held for a second amount of time, as represented by the border **432***b*. The first and second amounts of time are generally substantially the same, and the first and second contacts **428** *a, b* generally occur substantially simultaneously. The first and second contacts **428** *a, b* generally also include corresponding first and second contact movements **436** *a, b*, respectively. The first and second contact movements **436** *a, b* are generally in opposing directions. Stated another way, the first contact movement **436***a* is towards the second contact **436***b*, and the second contact movement **436***b* is towards the first contact **436***a*. More simply stated, the pinch gesture **408** may be accomplished by a user's digits touching the screen **104**,**108** in a pinching motion.

With reference to FIG. **4**F, a spread gesture **410** on the screen **104**,**108** is depicted. The spread gesture **410** may be initiated by a first contact **428***a* to the screen **104**,**108** by, for example, a first digit and a second contact **428***b* to the screen **104**,**108** by, for example, a second digit. The first and second contacts **428***a,b* may be detected by a common contact sensing portion of a common screen **104**,**108**, by different contact sensing portions of a common screen **104**,**108**, or by different contact sensing portions of different screens. The first contact **428***a* is held for a first amount of time, as represented by the border **432***a*, and the second contact **428***b* is held for a second amount of time, as represented by the border **432***b*. The first and second amounts of time are generally substantially the same, and the first and second contacts **428** *a, b* generally occur substantially simultaneously. The first and second contacts **428** *a, b* generally also include corresponding first and second contact movements **436***a, b*, respectively. The first and second contact movements **436** *a, b* are generally in a common direction. Stated another way, the first and second contact movements **436** *a, b* are away from the first and second contacts **428***a, b*. More simply stated, the spread gesture **410** may be accomplished by a user's digits touching the screen **104**,**108** in a spreading motion.

The above gestures may be combined in any manner, such as those shown by FIGS. **4**G and **4**H, to produce a determined functional result. For example, in FIG. **4**G a tap gesture **420** is combined with a drag or flick gesture **412** in a direction away from the tap gesture **420**. In FIG. **4**H, a tap gesture **420** is combined with a drag or flick gesture **412** in a direction towards the tap gesture **420**.

The functional result of receiving a gesture can vary depending on a number of factors, including a state of the device **100**, display **110**, **114**, or screen **104**, **108**, a context associated with the gesture, or sensed location of the gesture. The state of the device commonly refers to one or more of a configuration of the device **100**, a display orientation, and user and other inputs received by the device **100**. Context commonly refers to one or more of the particular application(s) selected by the gesture and the portion(s) of the application currently executing, whether the application is a single- or multi-screen application, and whether the application is a multi-screen application displaying one or more windows in one or more screens or in one or more stacks. Sensed location of the gesture commonly refers to whether the sensed set(s) of gesture location coordinates are on a touch sensitive display **110**, **114** or a gesture capture region **120**, **124**, whether the sensed set(s) of gesture location coordinates are associated with a common or different display or screen **104**,**108**, and/or what portion of the gesture capture region contains the sensed set(s) of gesture location coordinates.

A tap, when received by an a touch sensitive display **110**, **114**, can be used, for instance, to select an icon to initiate or terminate execution of a corresponding application, to maximize or minimize a window, to reorder windows in a stack, and to provide user input such as by keyboard display or other displayed image. A drag, when received by a touch sensitive display **110**, **114**, can be used, for instance, to relocate an icon or window to a desired location within a display, to reorder a stack on a display, or to span both displays (such that the selected window occupies a portion of each display simultaneously). A flick, when received by a touch sensitive display **110**, **114** or a gesture capture region **120**, **124**, can be used to relocate a window from a first display to a second display or to span both displays (such that the selected window occupies a portion of each display simultaneously). Unlike the drag gesture, however, the flick gesture is generally not used to move the displayed image to a specific user-selected location but to a default location that is not configurable by the user.

The pinch gesture, when received by a touch sensitive display **110**, **114** or a gesture capture region **120**, **124**, can be used to minimize or otherwise increase the displayed area or size of a window (typically when received entirely by a common display), to switch windows displayed at the top of the stack on each display to the top of the stack of the other display (typically when received by different displays or screens), or to display an application manager (a "pop-up window" that displays the windows in the stack). The spread gesture, when received by a touch sensitive display **110**, **114** or a gesture capture region **120**, **124**, can be used to maximize or otherwise decrease the displayed area or size of a window, to switch windows displayed at the top of the stack on each display to the top of the stack of the other display (typically when received by different displays or

screens), or to display an application manager (typically when received by an off-screen gesture capture region on the same or different screens).

The combined gestures of FIG. **4**G, when received by a common display capture region in a common display or screen **104**,**108**, can be used to hold a first window stack location in a first stack constant for a display receiving the gesture while reordering a second window stack location in a second window stack to include a window in the display receiving the gesture. The combined gestures of FIG. **4**H, when received by different display capture regions in a common display or screen **104**,**108** or in different displays or screens, can be used to hold a first window stack location in a first window stack constant for a display receiving the tap part of the gesture while reordering a second window stack location in a second window stack to include a window in the display receiving the flick or drag gesture. Although specific gestures and gesture capture regions in the preceding examples have been associated with corresponding sets of functional results, it is to be appreciated that these associations can be redefined in any manner to produce differing associations between gestures and/or gesture capture regions and/or functional results.

Firmware and Software:

The memory **508** may store and the processor **504** may execute one or more software components. These components can include at least one operating system (OS) **516**, an application manager **562**, a desktop **566**, and/or one or more applications **564***a* and/or **564***b* from an application store **560**. The OS **516** can include a framework **520**, one or more frame buffers **548**, one or more drivers **512**, previously described in conjunction with FIG. **2**, and/or a kernel **518**. The OS **516** can be any software, consisting of programs and data, which manages computer hardware resources and provides common services for the execution of various applications **564**. The OS **516** can be any operating system and, at least in some embodiments, dedicated to mobile devices, including, but not limited to, Linux, ANDROID™, iPhone OS (IOS™), WINDOWS PHONE 7™, etc. The OS **516** is operable to provide functionality to the phone by executing one or more operations, as described herein.

The applications **564** can be any higher level software that executes particular functionality for the user. Applications **564** can include programs such as email clients, web browsers, texting applications, games, media players, office suites, etc. The applications **564** can be stored in an application store **560**, which may represent any memory or data storage, and the management software associated therewith, for storing the applications **564**. Once executed, the applications **564** may be run in a different area of memory **508**.

The framework **520** may be any software or data that allows the multiple tasks running on the device to interact. In embodiments, at least portions of the framework **520** and the discrete components described hereinafter may be considered part of the OS **516** or an application **564**. However, these portions will be described as part of the framework **520**, but those components are not so limited. The framework **520** can include, but is not limited to, a Multi-Display Management (MDM) module **524**, a Surface Cache module **528**, a Window Management module **532**, an Input Management module **536**, a Task Management module **540**, an Application Model Manager **542**, a Display Controller, one or more frame buffers **548**, a task stack **552**, one or more window stacks **550** (which is a logical arrangement of windows and/or desktops in a display area), and/or an event buffer **556**.

The MDM module **524** includes one or more modules that are operable to manage the display of applications or other data on the screens of the device. An embodiment of the MDM module **524** is described in conjunction with FIG. **5**B. In embodiments, the MDM module **524** receives inputs from the other OS **516** components, such as, the drivers **512**, and from the applications **564** to determine continually the state of the device **100**. The inputs assist the MDM module **524** in determining how to configure and allocate the displays according to the application's preferences and requirements, and the user's actions. Once a determination for display configurations is made, the MDM module **524** can bind the applications **564** to a display. The configuration may then be provided to one or more other components to generate a window with a display.

The Surface Cache module **528** includes any memory or storage and the software associated therewith to store or cache one or more images of windows. A series of active and/or non-active windows (or other display objects, such as, a desktop display) can be associated with each display. An active window (or other display object) is currently displayed. A non-active windows (or other display objects) were opened and, at some time, displayed but are now not displayed. To enhance the user experience, before a window transitions from an active state to an inactive state, a "screen shot" of a last generated image of the window (or other display object) can be stored. The Surface Cache module **528** may be operable to store a bitmap of the last active image of a window (or other display object) not currently displayed. Thus, the Surface Cache module **528** stores the images of non-active windows (or other display objects) in a data store.

In embodiments, the Window Management module **532** is operable to manage the windows (or other display objects) that are active or not active on each of the displays. The Window Management module **532**, based on information from the MDM module **524**, the OS **516**, or other components, determines when a window (or other display object) is visible or not active. The Window Management module **532** may then put a non-visible window (or other display object) in a "not active state" and, in conjunction with the Task Management module Task Management **540** suspends the application's operation. Further, the Window Management module **532** may assign, through collaborative interaction with the MDM module **524**, a display identifier to the window (or other display object) or manage one or more other items of data associated with the window (or other display object). The Window Management module **532** may also provide the stored information to the application **564**, the Task Management module **540**, or other components interacting with or associated with the window (or other display object). The Window Management module **532** can also associate an input task with a window based on window focus and display coordinates within the motion space.

The Input Management module **536** is operable to manage events that occur with the device. An event is any input into the window environment, for example, a user interface interactions with a user. The Input Management module **536** receives the events and logically stores the events in an event buffer **556**. Events can include such user interface interactions as a "down event," which occurs when a screen **104**, **108** receives a touch signal from a user, a "move event," which occurs when the screen **104**, **108** determines that a user's finger is moving across a screen(s), an "up event, which occurs when the screen **104**, **108** determines that the user has stopped touching the screen **104**, **108**, etc. These events are received, stored, and forwarded to other modules

by the Input Management module **536**. The Input Management module **536** may also map screen inputs to a motion space which is the culmination of all physical and virtual display available on the device.

The motion space is a virtualized space that includes all touch sensitive displays **110**,**114** "tiled" together to mimic the physical dimensions of the device **100**. For example, when the device **100** is unfolded, the motion space size may be 960×800, which may be the number of pixels in the combined display area for both touch sensitive displays **110**, **114**. If a user touches on a first touch sensitive display **110** on location (**40**, **40**), a full screen window can receive touch event with location (**40**, **40**). If a user touches on a second touch sensitive display **114**, with location (**40**, **40**), the full screen window can receive touch event with location (**520**, **40**), because the second touch sensitive display **114** is on the right side of the first touch sensitive display **110**, so the device **100** can offset the touch by the first touch sensitive display's **110** width, which is 480 pixels. When a hardware event occurs with location info from a driver **512**, the framework **520** can up-scale the physical location to the motion space because the location of the event may be different based on the device orientation and state. The motion space may be as described in U.S. patent application Ser. No. 13/187,026, filed Jul. 20, 2011, entitled "Systems and Methods for Receiving Gesture Inputs Spanning Multiple Input Devices," which is hereby incorporated by reference in its entirety for all that it teaches and for all purposes.

A task can be an application and a sub-task can be an application component that provides a window with which users can interact to do something, such as dial the phone, take a photo, send an email, or view a map. Each task may be given a window in which to draw a user interface. The window typically fills a display (for example, touch sensitive display **110**,**114**), but may be smaller than the display **110**,**114** and float on top of other windows. An application usually consists of multiple sub-tasks that are loosely bound to each other. Typically, one task in an application is specified as the "main" task, which is presented to the user when launching the application for the first time. Each task can then start another task or sub-task to perform different actions.

The Task Management module **540** is operable to manage the operation of one or more applications **564** that may be executed by the device. Thus, the Task Management module **540** can receive signals to launch, suspend, terminate, etc. an application or application sub-tasks stored in the application store **560**. The Task Management module **540** may then instantiate one or more tasks or sub-tasks of the application **564** to begin operation of the application **564**. Further, the Task Management Module **540** may launch, suspend, or terminate a task or sub-task as a result of user input or as a result of a signal from a collaborating framework **520** component. The Task Management Module **540** is responsible for managing the lifecycle of applications (tasks and sub-task) from when the application is launched to when the application is terminated.

The processing of the Task Management Module **540** is facilitated by a task stack **552**, which is a logical structure associated with the Task Management Module **540**. The task stack **552** maintains the state of all tasks and sub-tasks on the device **100**. When some component of the operating system **516** requires a task or sub-task to transition in its lifecycle, the OS **516** component can notify the Task Management Module **540**. The Task Management Module **540** may then locate the task or sub-task, using identification information, in the task stack **552**, and send a signal to the task or sub-task indicating what kind of lifecycle transition the task needs to execute. Informing the task or sub-task of the transition allows the task or sub-task to prepare for the lifecycle state transition. The Task Management Module **540** can then execute the state transition for the task or sub-task. In embodiments, the state transition may entail triggering the OS kernel **518** to terminate the task when termination is required.

Further, the Task Management module **540** may suspend the application **564** based on information from the Window Management Module **532**. Suspending the application **564** may maintain application data in memory but may limit or stop the application **564** from rendering a window or user interface. Once the application becomes active again, the Task Management module **540** can again trigger the application to render its user interface. In embodiments, if a task is suspended, the task may save the task's state in case the task is terminated. In the suspended state, the application task may not receive input because the application window is not visible to the user.

The frame buffer **548** is a logical structure(s) used to render the user interface. The frame buffer **548** can be created and destroyed by the OS kernel **518**. However, the Display Controller **544** can write the image data, for the visible windows, into the frame buffer **548**. A frame buffer **548** can be associated with one screen or multiple screens. The association of a frame buffer **548** with a screen can be controlled dynamically by interaction with the OS kernel **518**. A composite display may be created by associating multiple screens with a single frame buffer **548**. Graphical data used to render an application's window user interface may then be written to the single frame buffer **548**, for the composite display, which is output to the multiple screens **104**,**108**. The Display Controller **544** can direct an application's user interface to a portion of the frame buffer **548** that is mapped to a particular display **110**,**114**, thus, displaying the user interface on only one screen **104** or **108**. The Display Controller **544** can extend the control over user interfaces to multiple applications, controlling the user interfaces for as many displays as are associated with a frame buffer **548** or a portion thereof. This approach compensates for the multiple physical screens **104**,**108** that are in use by the software component above the Display Controller **544**.

The Application Manager **562** is an application that provides a presentation layer for the window environment. Thus, the Application Manager **562** provides the graphical model for rendering by the Task Management Module **540**. Likewise, the Desktop **566** provides the presentation layer for the Application Store **560**. Thus, the desktop provides a graphical model of a surface having selectable application icons for the Applications **564** in the Application Store **560** that can be provided to the Window Management Module **556** for rendering.

Further, the framework can include an Application Model Manager (AMM) **542**. The Application Manager **562** may interface with the AMM **542**. In embodiments, the AMM **542** receives state change information from the device **100** regarding the state of applications (which are running or suspended). The AMM **542** can associate bit map images from the Surface Cache Module **528** to the tasks that are alive (running or suspended). Further, the AMM **542** can convert the logical window stack maintained in the Task Manager Module **540** to a linear ("film strip" or "deck of cards") organization that the user perceives when the using the off gesture capture area **120** to sort through the windows.

Further, the AMM **542** may provide a list of executing applications to the Application Manager **562**.

An embodiment of the MDM module **524** is shown in FIG. **5**B. The MDM module **524** is operable to determine the state of the environment for the device, including, but not limited to, the orientation of the device, whether the device **100** is opened or closed, what applications **564** are executing, how the applications **564** are to be displayed, what actions the user is conducting, the tasks being displayed, etc. To configure the display, the MDM module **524** interprets these environmental factors and determines a display configuration, as described in conjunction with FIGS. **6**A-**6**J. Then, the MDM module **524** can bind the applications **564** or other device components to the displays. The configuration may then be sent to the Display Controller **544** and/or the other components within the OS **516** to generate the display. The MDM module **524** can include one or more of, but is not limited to, a Display Configuration Module **568**, a Preferences Module **572**, a Device State Module **574**, a Gesture Module **576**, a Requirements Module **580**, an Event Module **584**, and/or a Binding Module **588**.

The Display Configuration Module **568** determines the layout for the display. In embodiments, the Display Configuration Module **568** can determine the environmental factors. The environmental factors may be received from one or more other MDM modules **524** or from other sources. The Display Configuration Module **568** can then determine from the list of factors the best configuration for the display. Some embodiments of the possible configurations and the factors associated therewith are described in conjunction with FIGS. **6**A-**6**F.

The Preferences Module **572** is operable to determine display preferences for an application **564** or other component. For example, an application can have a preference for Single or Dual displays. The Preferences Module **572** can determine an application's display preference (e.g., by inspecting the application's preference settings) and may allow the application **564** to change to a mode (e.g., single screen, dual screen, max, etc.) if the device **100** is in a state that can accommodate the preferred mode. However, some user interface policies may disallow a mode even if the mode is available. As the configuration of the device changes, the preferences may be reviewed to determine if a better display configuration can be achieved for an application **564**.

The Device State Module **574** is operable to determine or receive the state of the device. The state of the device can be as described in conjunction with FIGS. **3**A and **3**B. The state of the device can be used by the Display Configuration Module **568** to determine the configuration for the display. As such, the Device State Module **574** may receive inputs and interpret the state of the device. The state information is then provided to the Display Configuration Module **568**.

The Gesture Module **576** is shown as part of the MDM module **524**, but, in embodiments, the Gesture module **576** may be a separate Framework **520** component that is separate from the MDM module **524**. In embodiments, the Gesture Module **576** is operable to determine if the user is conducting any actions on any part of the user interface. In alternative embodiments, the Gesture Module **576** receives user interface actions from the configurable area **112**,**116** only. The Gesture Module **576** can receive touch events that occur on the configurable area **112**,**116** (or possibly other user interface areas) by way of the Input Management Module **536** and may interpret the touch events (using direction, speed, distance, duration, and various other parameters) to determine what kind of gesture the user is performing. When a gesture is interpreted, the Gesture Module **576** can initiate the processing of the gesture and, by collaborating with other Framework **520** components, can manage the required window animation. The Gesture Module **576** collaborates with the Application Model Manager **542** to collect state information with respect to which applications are running (active or paused) and the order in which applications must appear when a user gesture is performed. The Gesture Module **576** may also receive references to bitmaps (from the Surface Cache Module **528**) and live windows so that when a gesture occurs it can instruct the Display Controller **544** how to move the window(s) across the display **110**,**114**. Thus, suspended applications may appear to be running when those windows are moved across the display **110**,**114**.

Further, the Gesture Module **576** can receive task information either from the Task Manage Module **540** or the Input Management module **536**. The gestures may be as defined in conjunction with FIGS. **4**A through **4**H. For example, moving a window causes the display to render a series of display frames that illustrate the window moving. The gesture associated with such user interface interaction can be received and interpreted by the Gesture Module **576**. The information about the user gesture is then sent to the Task Management Module **540** to modify the display binding of the task.

The Requirements Module **580**, similar to the Preferences Module **572**, is operable to determine display requirements for an application **564** or other component. An application can have a set display requirement that must be observed. Some applications require a particular display orientation. For example, the application "Angry Birds" can only be displayed in landscape orientation. This type of display requirement can be determined or received, by the Requirements Module **580**. As the orientation of the device changes, the Requirements Module **580** can reassert the display requirements for the application **564**. The Display Configuration Module **568** can generate a display configuration that is in accordance with the application display requirements, as provided by the Requirements Module **580**.

The Event Module **584**, similar to the Gesture Module **576**, is operable to determine one or more events occurring with an application or other component that can affect the user interface. Thus, the Event Module **584** can receive event information either from the event buffer **556** or the Task Management module **540**. These events can change how the tasks are bound to the displays. The Event Module **584** can collect state change information from other Framework **520** components and act upon that state change information. In an example, when the phone is opened or closed or when an orientation change has occurred, a new message may be rendered in a secondary screen. The state change based on the event can be received and interpreted by the Event Module **584**. The information about the events then may be sent to the Display Configuration Module **568** to modify the configuration of the display.

The Binding Module **588** is operable to bind the applications **564** or the other components to the configuration determined by the Display Configuration Module **568**. A binding associates, in memory, the display configuration for each application with the display and mode of the application. Thus, the Binding Module **588** can associate an application with a display configuration for the application (e.g. landscape, portrait, multi-screen, etc.). Then, the Binding Module **588** may assign a display identifier to the display. The display identifier associated the application with a particular display of the device **100**. This binding is then stored and provided to the Display Controller **544**, the other

components of the OS **516**, or other components to properly render the display. The binding is dynamic and can change or be updated based on configuration changes associated with events, gestures, state changes, application preferences or requirements, etc.

User Interface Configurations:

With reference now to FIGS. **6**A-J, various types of output configurations made possible by the device **100** will be described hereinafter.

FIGS. **6**A and **6**B depict two different output configurations of the device **100** being in a first state. Specifically, FIG. **6**A depicts the device **100** being in a closed portrait state **304** where the data is displayed on the primary screen **104**. In this example, the device **100** displays data via the touch sensitive display **110** in a first portrait configuration **604**. As can be appreciated, the first portrait configuration **604** may only display a desktop or operating system home screen. Alternatively, one or more windows may be presented in a portrait orientation while the device **100** is displaying data in the first portrait configuration **604**.

FIG. **6**B depicts the device **100** still being in the closed portrait state **304**, but instead data is displayed on the secondary screen **108**. In this example, the device **100** displays data via the touch sensitive display **114** in a second portrait configuration **608**.

It may be possible to display similar or different data in either the first or second portrait configuration **604**, **608**. It may also be possible to transition between the first portrait configuration **604** and second portrait configuration **608** by providing the device **100** a user gesture (e.g., a double tap gesture), a menu selection, or other means. Other suitable gestures may also be employed to transition between configurations. Furthermore, it may also be possible to transition the device **100** from the first or second portrait configuration **604**, **608** to any other configuration described herein depending upon which state the device **100** is moved.

An alternative output configuration may be accommodated by the device **100** being in a second state. Specifically, FIG. **6**C depicts a third portrait configuration where data is displayed simultaneously on both the primary screen **104** and the secondary screen **108**. The third portrait configuration may be referred to as a Dual-Portrait (PD) output configuration. In the PD output configuration, the touch sensitive display **110** of the primary screen **104** depicts data in the first portrait configuration **604** while the touch sensitive display **114** of the secondary screen **108** depicts data in the second portrait configuration **608**. The simultaneous presentation of the first portrait configuration **604** and the second portrait configuration **608** may occur when the device **100** is in an open portrait state **320**. In this configuration, the device **100** may display one application window in one display **110** or **114**, two application windows (one in each display **110** and **114**), one application window and one desktop, or one desktop. Other configurations may be possible. It should be appreciated that it may also be possible to transition the device **100** from the simultaneous display of configurations **604**, **608** to any other configuration described herein depending upon which state the device **100** is moved. Furthermore, while in this state, an application's display preference may place the device into bilateral mode, in which both displays are active to display different windows in the same application. For example, a Camera application may display a viewfinder and controls on one side, while the other side displays a mirrored preview that can be seen by the photo subjects. Games involving simultaneous play by two players may also take advantage of bilateral mode.

FIGS. **6**D and **6**E depicts two further output configurations of the device **100** being in a third state. Specifically, FIG. **6**D depicts the device **100** being in a closed landscape state **340** where the data is displayed on the primary screen **104**. In this example, the device **100** displays data via the touch sensitive display **110** in a first landscape configuration **612**. Much like the other configurations described herein, the first landscape configuration **612** may display a desktop, a home screen, one or more windows displaying application data, or the like.

FIG. **6**E depicts the device **100** still being in the closed landscape state **340**, but instead data is displayed on the secondary screen **108**. In this example, the device **100** displays data via the touch sensitive display **114** in a second landscape configuration **616**. It may be possible to display similar or different data in either the first or second portrait configuration **612**, **616**. It may also be possible to transition between the first landscape configuration **612** and second landscape configuration **616** by providing the device **100** with one or both of a twist and tap gesture or a flip and slide gesture. Other suitable gestures may also be employed to transition between configurations. Furthermore, it may also be possible to transition the device **100** from the first or second landscape configuration **612**, **616** to any other configuration described herein depending upon which state the device **100** is moved.

FIG. **6**F depicts a third landscape configuration where data is displayed simultaneously on both the primary screen **104** and the secondary screen **108**. The third landscape configuration may be referred to as a Dual-Landscape (LD) output configuration. In the LD output configuration, the touch sensitive display **110** of the primary screen **104** depicts data in the first landscape configuration **612** while the touch sensitive display **114** of the secondary screen **108** depicts data in the second landscape configuration **616**. The simultaneous presentation of the first landscape configuration **612** and the second landscape configuration **616** may occur when the device **100** is in an open landscape state **340**. It should be appreciated that it may also be possible to transition the device **100** from the simultaneous display of configurations **612**, **616** to any other configuration described herein depending upon which state the device **100** is moved.

FIGS. **6**G and **6**H depict two views of a device **100** being in yet another state. Specifically, the device **100** is depicted as being in an easel state **312**. FIG. **6**G shows that a first easel output configuration **618** may be displayed on the touch sensitive display **110**. FIG. **6**H shows that a second easel output configuration **620** may be displayed on the touch sensitive display **114**. The device **100** may be configured to depict either the first easel output configuration **618** or the second easel output configuration **620** individually. Alternatively, both the easel output configurations **618**, **620** may be presented simultaneously. In some embodiments, the easel output configurations **618**, **620** may be similar or identical to the landscape output configurations **612**, **616**. The device **100** may also be configured to display one or both of the easel output configurations **618**, **620** while in a modified easel state **316**. It should be appreciated that simultaneous utilization of the easel output configurations **618**, **620** may facilitate two-person games (e.g., Battleship®, chess, checkers, etc.), multi-user conferences where two or more users share the same device **100**, and other applications. As can be appreciated, it may also be possible to transition the device **100** from the display of one or both configurations **618**, **620** to any other configuration described herein depending upon which state the device **100** is moved.

FIG. **6**I depicts yet another output configuration that may be accommodated while the device **100** is in an open portrait state **320**. Specifically, the device **100** may be configured to present a single continuous image across both touch sensitive displays **110**, **114** in a portrait configuration referred to herein as a Portrait-Max (PMax) configuration **624**. In this configuration, data (e.g., a single image, application, window, icon, video, etc.) may be split and displayed partially on one of the touch sensitive displays while the other portion of the data is displayed on the other touch sensitive display. The Pmax configuration **624** may facilitate a larger display and/or better resolution for displaying a particular image on the device **100**. Similar to other output configurations, it may be possible to transition the device **100** from the Pmax configuration **624** to any other output configuration described herein depending upon which state the device **100** is moved.

FIG. **6**J depicts still another output configuration that may be accommodated while the device **100** is in an open landscape state **348**. Specifically, the device **100** may be configured to present a single continuous image across both touch sensitive displays **110**, **114** in a landscape configuration referred to herein as a Landscape-Max (LMax) configuration **628**. In this configuration, data (e.g., a single image, application, window, icon, video, etc.) may be split and displayed partially on one of the touch sensitive displays while the other portion of the data is displayed on the other touch sensitive display. The Lmax configuration **628** may facilitate a larger display and/or better resolution for displaying a particular image on the device **100**. Similar to other output configurations, it may be possible to transition the device **100** from the Lmax configuration **628** to any other output configuration described herein depending upon which state the device **100** is moved.

The device **100** manages desktops and/or windows with at least one window stack **700**, **728**, as shown in FIGS. **7**A and **7**B. A window stack **700**, **728** is a logical arrangement of active and/or inactive windows for a multi-screen device. For example, the window stack **700**, **728** may be logically similar to a deck of cards, where one or more windows or desktops are arranged in order, as shown in FIGS. **7**A and **7**B. An active window is a window that is currently being displayed on at least one of the touch sensitive displays **110**, **114**. For example, windows **104** and **108** are active windows and are displayed on touch sensitive displays **110** and **114**. An inactive window is a window that was opened and displayed but is now "behind" an active window and not being displayed. In embodiments, an inactive window may be for an application that is suspended, and thus, the window is not displaying active content. For example, windows **712**, **716**, **720**, and **724** are inactive windows.

A window stack **700**, **728** may have various arrangements or organizational structures. In the embodiment shown in FIG. **7**A, the device **100** includes a first stack **760** associated with a first touch sensitive display **110** and a second stack associated with a second touch sensitive display **114**. Thus, each touch sensitive display **110**, **114** can have an associated window stack **760**, **764**. These two window stacks **760**, **764** may have different numbers of windows arranged in the respective stacks **760**, **764**. Further, the two window stacks **760**, **764** can also be identified differently and managed separately. Thus, the first window stack **760** can be arranged in order from a first window **704** to a next window **720** to a last window **724** and finally to a desktop **722**, which, in embodiments, is at the "bottom" of the window stack **760**. In embodiments, the desktop **722** is not always at the "bottom" as application windows can be arranged in the window stack below the desktop **722**, and the desktop **722** can be brought to the "top" of a stack over other windows during a desktop reveal. Likewise, the second stack **764** can be arranged from a first window **708** to a next window **712** to a last window **716**, and finally to a desktop **718**, which, in embodiments, is a single desktop area, with desktop **722**, under all the windows in both window stack **760** and window stack **764**. A logical data structure for managing the two window stacks **760**, **764** may be as described in conjunction with FIG. **8**.

Another arrangement for a window stack **728** is shown in FIG. **7**B. In this embodiment, there is a single window stack **728** for both touch sensitive displays **110**, **114**. Thus, the window stack **728** is arranged from a desktop **758** to a first window **744** to a last window **756**. A window can be arranged in a position among all windows without an association to a specific touch sensitive display **110**, **114**. In this embodiment, a window is in the order of windows. Further, at least one window is identified as being active. For example, a single window may be rendered in two portions **732** and **736** that are displayed on the first touch sensitive screen **110** and the second touch sensitive screen **114**. The single window may only occupy a single position in the window stack **728** although it is displayed on both displays **110**, **114**.

Yet another arrangement of a window stack **760** is shown in FIGS. **7**C through **7**E. The window stack **760** is shown in three "elevation" views. In FIG. **7**C, the top of the window stack **760** is shown. Two sides of the window stack **760** are shown in FIGS. **7**D and **7**E. In this embodiment, the window stack **760** resembles a stack of bricks. The windows are stacked on each other. Looking from the top of the window stack **760** in FIG. **7**C, only the top most windows in the window stack **760** are seen in different portions of the composite display **764**. The composite display **764** represents a logical model for the entire display area of the device **100**, which can include touch sensitive display **110** and touch sensitive display **114**. A desktop **786** or a window can occupy part or all of the composite display **764**.

In the embodiment shown, the desktop **786** is the lowest display or "brick" in the window stack **760**. Thereupon, window **1** **782**, window **2** **782**, window **3** **768**, and window **4** **770** are layered. Window **1** **782**, window **3** **768**, window **2** **782**, and window **4** **770** only occupy a portion of the composite display **764**. Thus, another part of the stack **760** includes window **8** **774** and windows **5** through **7** shown in section **790**. Only the top window in any portion of the composite display **764** is actually rendered and displayed. Thus, as shown in the top view in FIG. **7**C, window **4** **770**, window **8** **774**, and window **3** **768** are displayed as being at the top of the display in different portions of the window stack **760**. A window can be dimensioned to occupy only a portion of the composite display **760** to "reveal" windows lower in the window stack **760**. For example, window **3** **768** is lower in the stack than both window **4** **770** and window **8** **774** but is still displayed. A logical data structure to manage the window stack can be as described in conjunction with FIG. **8**.

When a new window is opened, the newly activated window is generally positioned at the top of the stack. However, where and how the window is positioned within the stack can be a function of the orientation of the device **100**, the context of what programs, functions, software, etc. are being executed on the device **100**, how the stack is positioned when the new window is opened, etc. To insert the window in the stack, the position in the stack for the window is determined and the touch sensitive display **110**,

114 to which the window is associated may also be determined. With this information, a logical data structure for the window can be created and stored. When user interface or other events or tasks change the arrangement of windows, the window stack(s) can be changed to reflect the change in arrangement. It should be noted that these same concepts described above can be used to manage the one or more desktops for the device **100**.

A logical data structure **800** for managing the arrangement of windows or desktops in a window stack is shown in FIG. **8**. The logical data structure **800** can be any data structure used to store data whether an object, record, file, etc. The logical data structure **800** can be stored in any type of database or data storage system, regardless of protocol or standard. In embodiments, the logical data structure **800** includes one or more portions, fields, attributes, etc. that store data in a logical arrangement that allows for easy storage and retrieval of the information. Hereinafter, these one or more portions, fields, attributes, etc. shall be described simply as fields. The fields can store data for a window identifier **804**, dimensions **808**, a stack position identifier **812**, a display identifier **816**, and/or an active indicator **820**. Each window in a window stack can have an associated logical data structure **800**. While only a single logical data structure **800** is shown in FIG. **8**, there may be more or fewer logical data structures **800** used with a window stack (based on the number of windows or desktops in the stack), as represented by ellipses **824**. Further, there may be more or fewer fields than those shown in FIG. **8**, as represented by ellipses **828**.

A window identifier **804** can include any identifier (ID) that uniquely identifies the associated window in relation to other windows in the window stack. The window identifier **804** can be a globally unique identifier (GUID), a numeric ID, an alphanumeric ID, or other type of identifier. In embodiments, the window identifier **804** can be one, two, or any number of digits based on the number of windows that can be opened. In alternative embodiments, the size of the window identifier **804** may change based on the number of windows opened. While the window is open, the window identifier **804** may be static and remain unchanged.

Dimensions **808** can include dimensions for a window in the composite display **760**. For example, the dimensions **808** can include coordinates for two or more corners of the window or may include one coordinate and dimensions for the width and height of the window. These dimensions **808** can delineate what portion of the composite display **760** the window may occupy, which may the entire composite display **760** or only part of composite display **760**. For example, window **4 770** may have dimensions **880** that indicate that the window **770** will occupy only part of the display area for composite display **760**, as shown in FIGS. **7***c* through **7**E. As windows are moved or inserted in the window stack, the dimensions **808** may change.

A stack position identifier **812** can be any identifier that can identify the position in the stack for the window or may be inferred from the window's control record within a data structure, such as a list or a stack. The stack position identifier **812** can be a GUID, a numeric ID, an alphanumeric ID, or other type of identifier. Each window or desktop can include a stack position identifier **812**. For example, as shown in FIG. **7**A, window **1 704** in stack **1 760** can have a stack position identifier **812** of 1 identifying that window **704** is the first window in the stack **760** and the active window. Similarly, window **6 724** can have a stack position identifier **812** of 3 representing that window **724** is the third window in the stack **760**. Window **2 708** can also have a stack position identifier **812** of 1 representing that window **708** is the first window in the second stack **764**. As shown in FIG. **7**B, window **1 744** can have a stack position identifier **812** of 1, window **3**, rendered in portions **732** and **736**, can have a stack position identifier **812** of 3, and window **6 756** can have a stack position identifier **812** of 6. Thus, depending on the type of stack, the stack position identifier **812** can represent a window's location in the stack.

A display identifier **816** can identify that the window or desktop is associated with a particular display, such as the first display **110** or the second display **114**, or the composite display **760** composed of both displays. While this display identifier **816** may not be needed for a multi-stack system, as shown in FIG. **7**A, the display identifier **816** can indicate whether a window in the serial stack of FIG. **7**B is displayed on a particular display. Thus, window **3** may have two portions **732** and **736** in FIG. **7**B. The first portion **732** may have a display identifier **816** for the first display while the second portion **736** may have a display identifier **816** for the second display **114**. However, in alternative embodiments, the window may have two display identifier **816** that represent that the window is displayed on both of the displays **110**, **114**, or a display identifier **816** identifying the composite display. In another alternate embodiment, the window may have a single display identifier **816** to represent that the window is displayed on both of the displays **110**, **114**.

Similar to the display identifier **816**, an active indicator **820** may not be needed with the dual stack system of FIG. **7**A, as the window in stack position **1** is active and displayed. In the system of FIG. **7**B, the active indicator **820** can indicate which window(s) in the stack is being displayed. Thus, window **3** may have two portions **732** and **736** in FIG. **7**. The first portion **732** may have an active indicator **820** while the second portion **736** may also have an active indicator **820**. However, in alternative embodiments, window **3** may have a single active indicator **820**. The active indicator **820** can be a simple flag or bit that represents that the window is active or displayed.

An embodiment of a method **900** for creating a window stack is shown in FIG. **9**. While a general order for the steps of the method **900** is shown in FIG. **9**. Generally, the method **900** starts with a start operation **904** and ends with an end operation **928**. The method **900** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **9**. The method **900** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **900** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-8**.

A multi-screen device **100** can receive activation of a window, in step **908**. In embodiments, the multi-screen device **100** can receive activation of a window by receiving an input from the touch sensitive display **110** or **114**, the configurable area **112** or **116**, a gesture capture region **120** or **124**, or some other hardware sensor operable to receive user interface inputs. The processor may execute the Task Management Module **540** may receive the input. The Task Management Module **540** can interpret the input as requesting an application task to be executed that will open a window in the window stack.

In embodiments, the Task Management Module **540** places the user interface interaction in the task stack **552** to be acted upon by the Display Configuration Module **568** of the Multi-Display Management Module **524**. Further, the Task Management Module **540** waits for information from

the Multi-Display Management Module **524** to send instructions to the Window Management Module **532** to create the window in the window stack.

The Multi-Display Management Module **524**, upon receiving instruction from the Task Management Module **540**, determines to which touch portion of the composite display **760**, the newly activated window should be associated, in step **912**. For example, window **4 770** is associated with the a portion of the composite display **764** In embodiments, the device state module **574** of the Multi-Display Management Module **524** may determine how the device is oriented or in what state the device is in, e.g., open, closed, portrait, etc. Further, the preferences module **572** and/or requirements module **580** may determine how the window is to be displayed. The gesture module **576** may determine the user's intentions about how the window is to be opened based on the type of gesture and the location of where the gesture is made.

The Display Configuration Module **568** may use the input from these modules and evaluate the current window stack **760** to determine the best place and the best dimensions, based on a visibility algorithm, to open the window. Thus, the Display Configuration Module **568** determines the best place to put the window at the top of the window stack **760**, in step **916**. The visibility algorithm, in embodiments, determines for all portions of the composite display, which windows are at the top of the stack. For example, the visibility algorithm determines that window **3 768**, window **4 770**, and window **8 774** are at the top of the stack **760** as viewed in FIGS. **7**C through **7**E. Upon determining where to open the window, the Display Configuration Module **568** can assign a display identifier **816** and possibly dimensions **808** to the window. The display identifier **816** and dimensions **808** can then be sent back to the Task Management Module **540**. The Task Management Module **540** may then assign the window a stack position identifier **812** indicating the windows position at the top of the window stack.

In embodiments, the Task Management Module **540** sends the window stack information and instructions to render the window to the Window Management Module **532**. The Window Management Module **532** and the Task Management Module **540** can create the logical data structure **800**, in step **924**. Both the Task Management Module **540** and the Window Management Module **532** may create and manage copies of the window stack. These copies of the window stack can be synchronized or kept similar through communications between the Window Management Module **532** and the Task Management Module **540**. Thus, the Window Management Module **532** and the Task Management Module **540**, based on the information determined by the Multi-Display Management Module **524**, can assign dimensions **808**, a stack position identifier **812** (e.g., window **1 782**, window **4 770**, etc.), a display identifier **816** (e.g., touch sensitive display **1 110**, touch sensitive display **2 114**, composite display identifier, etc,), and an active indicator **820**, which is generally always set when the window is at the "top" of the stack. The logical data structure **800** may then be stored by both the Window Management Module **532** and the Task Management Module **540**. Further, the Window Management Module **532** and the Task Management Module **540** may thereinafter manage the window stack and the logical data structure(s) **800**.

An embodiment of a method **1000** for executing an application, such as a phone application, is shown in FIG. **10**. While a general order for the steps of the method **1000** is shown in FIG. **10**. Generally, the method **1000** starts with a start operation **1004** and ends with an end operation **1040**. The method **1000** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **10**. The method **1000** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **1000** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1**-**9**.

An application, such as a phone application, is executed, in step **1008**. In embodiments, a processor **204** receives indication to execute an application through a user interface **110**, **114**, **112**, **116**, etc. The indication can be a selection of an icon associated with the application. In other embodiments, the indication can be a signal generated from another application or event, such as receiving a phone call or other communication, which causes the application to execute automatically. The processor **204** can retrieve the application **564***a* from the application store **560** and begin its execution. In executing the application **564***a*, a user interface can be generated for a user.

In creating a user interface, the application **564***a* can begin executing to create a manifest, in step **1012**. A manifest is a data structure that indicates the capabilities of the application **564***a*. The manifest can generally be created from the resources in the resources directory of the application **564***a*. The resources directory can indicate the types of modes, locations, or other indications for how the user interface should be configured in the multi-display device **100**. For example, the several modes can include: "classic mode" that indicates that the application **564***a* is capable of being displayed on a single screen or display **110**/**114**; "dual mode" that indicates that the application **564***a* is capable of being displaced on two or more displays **110** and **114**; "max mode" that indicates the application **564***a* is capable of being displayed or desires to be displayed across multiple displays **110** and **114**; and/or "bilateral mode" that indicates that the application **564***a* is capable of being displayed on 2 or more displays **110** and **114** when the device **100** is in easel mode (see FIGS. **1**I and/or **1**J).

Similarly, the manifest can include a desired or allowed location within the displays **110**/**114**. The possible locations can include: "left", which indicates that the application **564***a* desires to be displayed on the left display **110**; "right", which indicates that the application **564***a* desires to be displayed on the right display **114**; and/or other indications of where a location should be including possible "top" and/or "bottom" of one or more of the displays **110**/**114**.

The application **564***a* can also indicate that it desires to be displayed in a "minimum" window, which is a window that occupies less than the full area of a single display. There may be other modes possible for the application **564***a*, which may be included in the manifest. The manifest can be sent from the application **564***a* to the multi-display management module **524**.

The multi-display management module **524** can receive the manifest, in step **1016**. In receiving the manifest, the multi-display management module **524** can use the information to determine a display binding for the application **564***a*. The manifest may be received more than once from the application **564***a* based on changes in how the application **564***a* is being executed, where the application **564***a* desires to have a different display setting for the new mode. Thus, with the manifest, the application **564***a* can indicate to the multi-display management module **524** how best to or what is the desired for the application's user interface. The multi-display management module **524** can use the infor-

mation in the manifest to determine the best fit for the user interface depending on how the device **100** is currently configured.

The multi-display management module **524** can determine the application display mode, in step **1020**. Here the multi-display management module **524** receives or retrieves an indication of the device **100** configuration. For example, the multi-display management module **524** can determine if the device is in single display configuration (see FIG. **6**A, **6**B, **6**D, or **6**E), dual display configuration (see FIG. **6**C or **6**F), bilateral display configuration (see FIG. **6**G or **6**H), or one of the other display configurations (see FIG. **6**I or **6**J).

Further, the multi-display management module **524** can determine if the device **100** is in a portrait or landscape orientation. With this information, the multi-display management module **524** may then consider the capabilities or preferences listed for the application **564***a* in the received manifest. The combined information may then allow the multi-display management module **524** to determine a display binding. The display binding can include which of the one or more displays **110** and/or **114** are going to be used to display the application's user interface(s). For example, the multi-display management module **524** can determine that the primary display **110**, the secondary display **114**, or all displays **110** and **114** of the device **100** will be used to display the application's user interface.

The display modes setting can be assigned by creating or setting a number in the display binding. This number can be "0" for the primary display **110**, "1" for the secondary display **114**, or "2" for dual displays **110** and **114**. The display mode setting can also indicate if the application **564***a* should display the user interface in portrait or landscape orientation. Further, there may be other settings, for example, providing a max mode or other setting that may indicate how the application **564***a* is to be displayed on the device. The display binding information is stored in a data structure to create and set a binding, in step **1024**.

The established display binding may then be provided, by the multi-display management module **524**, to the application **564***a*, in step **1028**. The provided display binding data structure can become an attribute of the application **564***a*. An application **564***a* may thereinafter store the display binding attribute in the memory of the device **100**. The application **564***a* with the display binding may then generate a user interface based on this display binding. The application **564***a* may be unaware of the position of the display **110**/**114** but may be able to determine, from the display binding, the size of the available user interface to generate a window that has particular characteristics for that display setting.

When a configuration change happens to the device **100**, the multi-display management module **524** may change the display binding and send a new display binding to the application **564***a*. In embodiments, the multi-display management module **524** may indicate to the application **564***a* that there is a new binding or, in other embodiments, the application **564***a* may request a display configuration change or a new display binding, in which case the multi-display management module **524** may send a new display binding to the application **564***a*. Thus, the multi-display management module **524** can change the configuration of the display for the application **564***a* by altering the display binding for the application **564***a* during the execution of that application **564***a*.

The multi-display management module **524** thereinafter, while the application **564***a* is executing, can determine if there has been a configuration change to the device **100**, in step **1032**. The configuration change may be an event (see FIGS. **3**A and **3**B) triggered by one or more signals from one or more hardware sensor **172**, **176**, etc. For example, if the device **100** is changed from portrait **304** to landscape **340** orientation, Hall effect sensors **172** may indicate to the framework **520** that a display configuration change has been made. Other changes may include transitions from a single display **304** to a dual display configuration **320**, by opening the device. Other types of configuration changes may be possible and may be signaled to alert the multi-display management module **524** of the configuration change. If a configuration change has been made, the method **1000** proceeds YES to step **1020** so that the multi-display management module **524** can determine new application display mode settings and create a new display binding, which may be passed to the application **564***a*. If there are no configuration changes, the method **1000** precedes NO to step **1036**.

In step **1036**, a new application mode change may be determined. Application mode changes can also occur in the application **564***a*, and thus, the application **564***a* can determine if something has occurred within the application **564***a* that requires a different display setting. Modes are described hereinafter with respect to FIG. **51**. The mode change can create a desire to change the display **110**/**114**, and thus, require the application **564***a* to generate a new manifest. If the application **564***a* does sense a mode change or an event has occurred that requires a change in display setting, the method **1000** proceeds YES back to step **1012**. At step **1012**, a new manifest or preference is created by the application **564***a* that may be received by the multi-display management module **524** to determine if the multi-display management module **524** can change the display binding. If it is possible to provide the preferred display, the multi-display management module **524** can create a new display binding and send display binding back to the application **564***a* and allow the application **564***a* to alter its user interface. If no mode change is sensed or an event is not received to create a mode change, the method **1000** proceeds NO to end operation **1040**.

Unified System:

An embodiment of a unified system **1100** is shown in FIG. **11**. In embodiments, the unified system **1100** includes a computer system **1104** and the device **100**. The computer system **1104** may be as described in conjunction with FIG. **11**. The device **100** may be as described herein in conjunction with FIG. **1**A through FIG. **10**. The device **100** may be physically connected to the computer system **1104** with a docking cradle or other wired connection. In other embodiments, the device **100** and computer system **1104** may communicate or be connected wirelessly using a wireless system and/or protocol (e.g., Bluetooth™, 802.11g, etc.). Upon connection of the device **100** and the computer system **1104**, the device **100** can recognize the connection either manually (through user input) or automatically and functionally connect the device **100** with the computer system **1104** to form the unified system. The unified system **1100** functions as to allow the device **100** to communicate with, interact with, and/or control the function of the computer system **1104** when functionally connected. As such, when executed, the unified system appears to be a single system where the device **100** and the computer system **1104** function in concert. The components and/or software that enable the unified system, the communications or functions of the unified system, and other description of the unified system is described in U.S. Provisional Applications 61/61/507,206, 61/507,201, 61/507,199, 61/507,209, 61/507,203, and 61/389,117, which are each incorporated herein, by reference, for all that they teach and for all purposes. Further, the

unified system is also described in U.S. patent application Ser. Nos. 12/948,585 and 12/948,676, which are each incorporated herein, by reference, for all that they teach and for all purposes.

FIG. **11** illustrates one embodiment of a computer system **1100** upon which the test system may be deployed or executed. The computer system **1100** is shown comprising hardware elements that may be electrically coupled via a bus **1155**. The hardware elements may include one or more central processing units (CPUs) **1105**; one or more input devices **1110** (e.g., a mouse, a keyboard, etc.); and one or more output devices **1115** (e.g., a display device, a printer, etc.). The computer system **1100** may also include one or more storage devices **1120**. By way of example, storage device(s) **1120** may be disk drives, optical storage devices, solid-state storage devices, such as a random access memory ("RAM") and/or a read-only memory ("ROM"), which can be programmable, flash-updateable, and/or the like.

The computer system **1100** may additionally include a computer-readable storage media reader **1125**; a communications system **1130** (e.g., a modem, a network card (wireless or wired), an infra-red communication device, etc.); and working memory **1140**, which may include RAM and ROM devices as described above. In some embodiments, the computer system **1100** may also include a processing acceleration unit **1135**, which can include a DSP, a special-purpose processor and/or the like

The computer-readable storage media reader **1125** can further be connected to a computer-readable storage medium, together (and, optionally, in combination with storage device(s) **1120**) comprehensively representing remote, local, fixed, and/or removable storage devices plus storage media for temporarily and/or more permanently containing computer-readable information. The communications system **1130** may permit data to be exchanged with the network **1120** and/or any other computer described above with respect to the system **1100**. Moreover, as disclosed herein, the term "storage medium" may represent one or more devices for storing data, including read only memory (ROM), random access memory (RAM), magnetic RAM, core memory, magnetic disk storage mediums, optical storage mediums, flash memory devices, and/or other machine readable mediums for storing information.

The computer system **1100** may also comprise software elements, shown as being currently located within a working memory **1140**, including an operating system **1145** and/or other code **1150**, such as program code implementing the components and software described herein. It should be appreciated that alternate embodiments of a computer system **1100** may have numerous variations from that described above. For example, customized hardware might also be used and/or particular elements might be implemented in hardware, software (including portable software, such as applets), or both. Further, connection to other computing devices such as network input/output devices may be employed.

Unified Desktop:

An embodiment of a unified desktop **1300** is shown in FIG. **13**. The unified desktop **1330** is the user interface for the unified system **1100**. Thus, the unified desktop **1300** is formed from the user interface **1304** in the screen **1215** associated with the computer system **1104** and the user interface **1308** in the screen(s) **104**, **108** associated with the device **100**. As a unified desktop **1300**, the user interface **1304** and **1308** function together to provide parallel displays, exchange windows or other user interface elements, and generally present a cohesive user interface across both the computers system **1104** and the device **100**. In other words, the unified desktop spans or is provided over at least one of the screens **104**, **108** of the device **100** and the screen **1215** of the computer system **1104**. The device **100** can assume the form factor and function of both device **100** and the computer system **1104**; the design of the unified desktop can provide a seamless user experience across the device **100** and the computer system **1104**, enabling the user to access shared content, manage applications and peripherals regardless of which system **100** or **1104** presents the user interface action. Hereinafter, specific user interface actions related to the unified desktop shall be presented.

Status Indicators:

A portion of the unified desktop is shown in FIG. **14**. More particularly, the user interface **1304** of the unified desktop **1300** is shown, where a set of status indicators are provided in a portion **1400** of the unified desktop **1300**. The status indicators in the portion **1400** provide information about both the device **100** and the computer system **1104**. In embodiments, the portion **1400** is provided in only one of the user interface **1304** or user interface **1308**. Thus, status indicators associated with both the device **100** and the computer system **1104** are shown together in a screen **1215** or **104**, **108** associated with only the device **100** or the computer system **1104**.

The status indicators shown in FIG. **14** include a wireless fidelity (Wi-Fi) indicator **1404**, a Bluetooth indicator **1408**, a Network Traffic indicator **1412**, a signal strength indicator **1416**, a battery indicator **1420**, a power menu indicator **1430**, and a time indicator **1434**. In embodiments, one or more of the indicators may be selectable to provide further information or user interface devices that may be selected to configure the device **100** and/or the computer system **1104**. For example, as shown in FIG. **14**, the battery indicator **1420** has been selected, which caused the device **100** to provide a drop down user interface device **1425** in the user interface **1304**. The drop down user interface device **1425** provides further information **1438** about the amount of device battery life and a user interface device **1442** that can be selected to access the power settings for the device **100**. Thus, the user can configure the device **100** or the computer system **1104** by accessing menus or other user interface through the status indicators **1404** through **1434**. Some of the possible status indicators that may be displayed for the device **100**, and the menus or other information associated with the status indicators is provided in the table below:

Indicator	Menu content	Description	Label
Wi-Fi	Wi-Fi status	Presents the current status of Wi-Fi.	"Wi-Fi: <x>", where <x> stands for "Off", "Scanning . . . ", "Connecting to <SSID> . . . ", "Disconnected", "Connected".
	Wi-Fi ON/OFF toggle	Allows for turning Wi-Fi on and off.	"Turn Wi-Fi on", or "Turn Wi-Fi off"

-continued

Indicator	Menu content	Description	Label
	List of found Wi-Fi networks	Lists all the Wi-Fi networks that are found and known. List of networks is scanned whenever the menu is displayed. When clicked, tries to connect to the network, and shows a dialog if a password is required.	"<SSID>" and an icon to represent the network's strength and its security. The network currently connected to is marked.
	Command to connect to a hidden Wi-Fi network	Allows for connecting to a hidden Wi-Fi network. Shows a dialog for entering the SSID, a dropdown menu for security protocols, and a password field when required. Based on the same command in Android Settings.	"Add Wi-Fi network . . . "
	Link to Wi-Fi settings	Links to: Android Settings > Wireless & network settings	"Wi-Fi settings . . . "
Bluetooth	Bluetooth device name	The Bluetooth name of the handset.	"<device name>"
	Bluetooth status	Presents the current status of Bluetooth.	"Bluetooth: <x>", where <x> stands for "On", or "Off"
	Bluetooth ON/OFF toggle	Allows for turning Bluetooth on and off.	"Turn Bluetooth on", or "Turn Bluetooth off"
	Discoverability status	Turns on the discoverability of Bluetooth for 120 seconds (Android default)	"Make discoverable", or "Discoverable for <x> seconds"
	List of connected Bluetooth devices	Lists all paired and currently connected Bluetooth devices. List of devices is updated whenever the menu is displayed. Items are not clickable.	<Bluetooth device name> + icon representing the type of the device
	Link to Bluetooth settings	Links to: Android Settings > Wireless & network settings > Bluetooth settings	"Bluetooth devices & settings . . . "
Network traffic	Network status	Shows the current network speed (3G, 2G, . . .)	"Network: <x>", where <x> stands for the network speed
	Link to Network settings	Links to: Settings > Mobile networks	"Mobile network settings . . . "
Signal strength	Network status	Shows the current operator	"<operator name>"
	Network strength	Shows the current signal strength	"Signal strength: <x>", where <x> stands for "none", "poor", "good", "very good", "excellent" When airplane mode is on: "Airplane mode"
	Link to Network settings	Links to: Settings > Mobile networks	"Mobile network settings . . . "
Battery (phone)	Battery status	Shows the status of the handset's battery	"Phone battery: <x>%", when using battery power; <x> stands for the current charge, charge. "Phone battery charging (<x>%)", when the battery is being charged; <x> stands for the current "Phone battery charged", when the battery is fully charged and plugged in.
Battery (peripheral, when applicable)	Battery status	Shows the status of the second battery, provided by a peripheral.	"Peripheral battery: <x>%", when using battery power; <x>stands for the current charge. "Peripheral battery charging (<x>%)", when the battery is being charged; <x> stands for the current charge. "Peripheral battery charged", when the battery is fully charged and plugged in.

-continued

Indicator	Menu content	Description	Label
GPS	GPS status	Shows the current status of the GPS	"GPS status: <x>", where <x> stands for "On", "Off", or "Failure"
	GPS ON/OFF toggle	Allows for turning Bluetooth on and off.	"Turn GPS on", or "Turn GPS off"
	Link to GPS settings	Links to: Settings > Location & Security	"Location settings . . . "
Sync	Sync status	Shows the current status of the Sync	"Syncing in progress . . . "
	Link to Sync settings	Links to: Settings > Account & Sync	"Sync settings . . . "
Alarms	Integrated into date/time menu		
No SIM warning	Warning message	A warning message for not finding a SIM card	"No SIM card. Emergency calls only."
Speakerphone	Speakerphone status	Shows the status of speakerphone when in use	"Speaker on"
Roaming warnings	Roaming status	Shows roaming warnings	"Roaming"
	Link to Network settings	Links to: Settings > Mobile networks	"Mobile network settings . . . "
TTY	TTY status	Shows the Text Telephone Device or Telecommunication Device for the Deaf (TDD) status	"TTY enabled"

Some of the possible status indicators that may be displayed for the computer system **1104**, and the menus or other information associated with the status indicators is provided in the table below:

Indicator	Menu content	Description	Label
Volume (and silent/vibration)	Silent mode toggle	Turns on silent mode	"Turn Silent mode on", or "Turn Silent mode off"
	Volume slider	Allows for changing the volume level;	
	Link to Sound settings	Links to:	"Sound settings . . . "
Monitors	Use Unity menu		For settings label, use "Monitor settings . . . "
Keyboard	Use Unity menu		For settings label, use "Keyboard settings . . . "
Time/date	Use Unity menu		
	List of alarms	Lists all alarms that have been set up and enabled. Only shown when alarms have been set up.	"<alarm name>: <alarm time>-<repeat days>"; note that the alarm name and repeat days are optional. Examples: 8:30 AM-Mon, Tue, Wed, Thu, Fri10:00 AM-Sat, Sun Groceries: 6:40 PM Pills: 12:00 PM-Mon, Tue, Wed, Thu, Fri
	Link to Clock application	Opens the Android Clock application. Only shown when alarms have been set up.	"Manage alarms . . . "
	Link to date & time settings	Links to: Settings > Date & time settings	"Date & time settings . . . "
Power menu	Airplane mode	Toggle airplane mode on and off	"Turn Airplane mode on", or "Turn Airplane mode off"
	Sleep	Sleep	"Sleep"
	Power off	Power off	"Power off"
	Android Settings	Links to Android Settings application	"Phone settings . . . "
	PC Settings	Links to PC system settings	"Desktop settings . . . "

Other possible status indicators are contemplated and included as one skilled in the art would understand.

A user interface **1308** with other status indicators is shown in FIG. **15**. User interface **1308** is associated with the device **100**. The user interface **1308** may also include a portion **1500** that displays status indicators. In embodiments, the portion **1500** may include the same or different status indicators from portion **1400** and may display the status indicators substantially simultaneously with portion **1400**. For example, portion **1500** may include a Network Traffic indicator **1412**, a signal strength indicator **1416**, a battery indicator **1420**, and a time indicator **1434**. However, portion **1500** may include an alarm indicator **1504** that is not shown in portion **1400**. Thus, the portions **1400** and **1500** can show the same indicators, different indicators, and, in some embodiments, indicators associated with only the device **100** or the computer system **1104**.

An embodiment of a method **1600** for providing status indicators is shown in FIG. **16**. While a general order for the steps of the method **1600** is shown in FIG. **16**. Generally, the method **1600** starts with a start operation **1604** and ends with an end operation **1624**. The method **1600** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **16**. The method **1600** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **1600** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-15**.

A computer system **1104** and a device **100** can be connected, physically, electrically, wirelessly, etc. The device **100** can automatically recognize the connection and functionally connect the device **100** with the computer system **1104** to form a unified system **1100**, in step **1608**. In other embodiments, a user may provide input to functionally connect the device **100** with the computer system **1104**. In response to the function connection, the device **100** can generate a unified desktop **1300**, in step **1612**. the unified desktop **1300** can expand or create a single user interface for the unified system **1100** across the screens of the device **100** and the computer system **1104**.

The device **100** may then determine status indicators that would need to be displayed for the user, in step **1616**. In embodiments, the device **100** can request or discover the status indicators associated with the computer system **1104**. The status indicators associated with the computer system **1104** may be incorporated into a data structure or combined with the status indicators associated with the device **100**. The combined set of status indicators may then be provided in the unified desktop **1300**, in step **1620**. For example, the combined set of status indicators can be displayed in a portion **1400** of the user interface **1304**. Thus, in a single area of the unified desktop **1300** (and possibly only on one screen of either the device **100** or the computer system **1104**), the device **100** can provide status indicators for both the device **100** and the computer system **1104**.

An embodiment of a method **1700** for providing status indicators is shown in FIG. **17**. While a general order for the steps of the method **1700** is shown in FIG. **17**. Generally, the method **1700** starts with a start operation **1704** and ends with an end operation **1724**. The method **1700** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **17**. The method **1700** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **1700** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-16**.

The processor **204** of the device **100** can receive a selection of a status indicator, in step **1708**. A selection can be a user interface action conducted on a status indicator. For example, a user may hover a pointer over status indicator **1420**. In another example, the user may click the pointer on the status indicator **1420** to select it. Regardless, the user conducts a user interface action on a status indicator to generate an input into the unified desktop **1300**. In response to receiving the selection by the user, the device **100** can provide information and/or a user interface device in the unified desktop **1300**, in step **1712**. Information can include more detail about a status, as described in the tables above. For example, upon selecting the status indicator **1420**, the device **100** can provide more detailed information that the battery charge is at 50%, as shown in information **1438** in the drop down **1434**. A user interface device may be a selectable icon or other user interface display that will allow the user to access further functionality. For example, the user interface display **1442** in the drop down **1424** display can be selected by the user's pointer. Selection of the user interface display **1442** allows the user to access power settings for the device **100**. Other menus or functions can be accessed through the status indicators as shown in the tables above.

The processor **204** of the device **100** can receive a selection of a user interface device, in step **1716**. For example, the user may select user interface display **1442** by clicking on or near the user interface display **1442**. Upon receiving this selection, the device **100** can provide a menu or other functionality associated with the status indicator, in step **1720**. In embodiments, the device **100** presents a menu that can alter or address the status indicated by the status indicator. The menus or functionality that may be accessed may be as described in the tables above. For example, by selecting user interface display **1442**, the device may provide a power settings menu to the user that allows the user to change the power settings of the device **100**. The user may modify a function of the device **100** or the computer system **1104** by interaction with the provided menu or functionality. For example, the user may change the duration of inactivity required before a screen blacks out in the power settings menu.

Freedom Window Mode:

A unified desktop interface **1304** is shown with a window **1800** (showing a personal computing application user interface) and a freeform window **1804** in FIG. **18**. A freeform window **1804** is a shell that can encapsulate a user interface for a device application. A device application can be any application that typically executes on the device **100**. Thus, the device application may be configured to execute in a mobile device environment but not in a personal computing environment. The device application can be specific to the device and does not execute on the computer system. For example, gestures received with the device **100** can affect the device application but may not be received or understood in the personal computing environment. Device applications can include a phone application, a text messaging application, a utilities application, a game application, or a mobile application. The device application may be executed by the device **100** receiving a user selection of the device application. The selection may be a user selection of a shortcut displayed in the unified desktop. An example of a shortcut **1812** is shown in the user interface **1304**. The shortcut **1812** allows a device application to be opened in the personal computing environment like other personal computing applications.

The freeform window **1408** allows the device application user interface to behave as a typical window in a computer system environment. For example, as shown in FIG. **18**, freeform window **1804** allows the user interface **1808** of the device application to display at least partially over another window **1800**. In other embodiments, the freeform window **1804** allows the user interface **1808** of the device application to display at least partially behind another window (not shown). Thus, the freeform window **1804** provides display functionality to the user interface **1808** that would not normally be functional for a device application.

Upon executing the device application, the device application can generate a user interface **1808** which can be incorporated into the freeform window **1804**. An embodiment of the freeform window **1804** is shown in FIG. **19**. The freeform window **1804** includes a portion **1900** that includes

controls **1904-1912**. The controls can cause the user interface **1808** to complete actions associated with a personal computing environment. For example, control **1904** can cause the device **100** to close the user interface **1808** and stop execution of the device application associated therewith. Control **1908** can cause the device **100** to minimize or shrink the user interface **1808** of the device application. Control **1912** can cause the device **100** to maximize the user interface the user interface **1808** of the device application. A user may also user handles or other controls to expand or contract the freeform window **1804** and thus the user interface **1808**.

The freeform window **1804** can provide one or more user interface devices that allow the user interface **1808** to provide functionality (such as features or controls) in the freeform window **1804**. For example, a first user interface device **1916** may be a control or device to access previous information displayed by the user interface **1808** of the device application. A second user interface device **1924** can provide a control to exit or stop execution of the device application. A third user interface device **1928** can provide a feature to expand the user interface **1808** the device application into the entire available space of the freeform window **1804**. A fourth user interface device **1920** may provide a control to change the user interface **1808** to a second user interface that displays other information. Other user interface devices that provide other functionality are contemplated as one skilled in the art would understand.

An embodiment of a method **2000** for providing a freeform window is shown in FIG. **20**. While a general order for the steps of the method **2000** is shown in FIG. **20**. Generally, the method **2000** starts with a start operation **2004** and ends with an end operation **2024**. The method **2000** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **20**. The method **2000** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **2000** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-19**.

A computer system **1104** and a device **100** can be connected, physically, electrically, wirelessly, etc. The device **100** can automatically recognize the connection and functionally connect the device **100** with the computer system **1104** to form a unified system **1100**, in step **2008**. In other embodiments, a user may provide input to functionally connect the device **100** with the computer system **1104**. In response to the function connection, the device **100** can generate a unified desktop **1300**, in step **2012**. The unified desktop **1300** can expand or create a single user interface for the unified system **1100** across the screens of the device **100** and the computer system **1104**.

The device **100** may then execute a device application, in step **2020**. In embodiments, the device **100** may receive a selection of a device application from the unified desktop **1300**. For example, the user may select a shortcut **1812**. Regardless, the device **100** can execute the selected device application in the computer system environment. When the device **100** executes the device application, a freeform window **1804** may be created to encapsulate or display the user interface **1808** of the device application. Thus, the device **100** displays the user interface **1808** of the device application in the freeform window **1804**, in step **2020**.

An embodiment of a method **2100** for providing status indicators is shown in FIG. **21**. While a general order for the steps of the method **2100** is shown in FIG. **21**. Generally, the method **2100** starts with a start operation **2104** and ends with an end operation **2124**. The method **2100** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **21**. The method **2100** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **2100** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-20**.

The processor **204** of the device **100** can receive a selection of a device application, in step **2108**. A selection can be a user interface action conducted on a shortcut **1812** or other user interface device. Regardless, the user conducts a user interface action to execute a device application. In response to receiving the selection by the user, the device **100** can determine any device application feature, controls, or other functionality to be provided for the user interface **1808**, in step **2112**. The features, controls, etc. can be functions that conduct and action or complete a process for the device application and may not function in a typical computer system environment. These functions can include expanding or contracting the window, providing alternative displays, entering information, executing sub-processes, etc. Some possible features or controls are as discussed with FIG. **19**.

The processor **204** of the device **100** can provide a freeform window **1804** for the user interface **1808** of the device application, in step **2116**. The freeform window **1808** can be as described in FIGS. **18** and **19**. As part of the freeform window **1808**, the device may provide one or more user interface devices that enable the features or controls determined by the device **100**, in step **2120**. The user interface devices may be as described in conjunction with FIG. **19**.

Wake and Unlock:

FIGS. **22** through **28** show a unified desktop interface **1304** is shown while is sleep mode or in a state after waking or unlocking after sleep mode. Sleep mode is a mode where the user interface displays are inactive or "blackened". As shown in FIG. **22**, user interface **2204** and user interface **2208** do not show any content because the system **2200** is in "sleep mode." As described herein, the sleep state or sleep mode can include different types of states including a simple sleep state, a screen lock state, and/or a passcode lock state, as described herein. To leave sleep mode and continue to use the system **2200**, input may be received from a user in the keyboard **2212**, a user interface device **2216**, or by other means (e.g., mouse, power button, etc.). If such input is received, the system **2200** can change states of a user interface for the unified desktop during wake, unlock, passcode unlock, call received, and other states.

A table **2900** containing at least some of the possible sleep states and how to interact with the system **2200** in the state is shown in FIG. **29**. In embodiments, there may be three states **2904**, a simple "sleep" state represented in column **2908**, a "screen lock" state represented in column **2912**, and/or a "passcode lock" state represented in column **2916**. In embodiments, there may be more or fewer states. A sleep state may be chosen by a user and affected when the device **100** receives a selection of the sleep state from the user.

The table **2900** shows rules that govern the sleep state and how to wake from the selected sleep state. In a sleep state, the user interface **1304** is off without anything being displayed and the wake action is any interaction with the user interfaces of the unified desktop. In a screen lock state, the

user interface **1304** is off and the user interface, of at least the device **100**, requires a specified and predetermined user interaction (e.g., moving a bar on the user interface) to unlock the state. Generally, the bar or other user interface device that receives the specified user interaction is presented to the user after the user provides an initial user interface interaction to the unified desktop. In a passcode state, the system **2200** requires the entry of a passcode (e.g., a numeric code, a visual code, etc.) to exit the state. As with the screen lock state, a passcode user interface device that receives the passcode is presented to the user after the user provides an initial user interface interaction to the unified desktop. Thus, all the states appear as that shown in FIG. **22** but require different input to exit the state.

At least two events **2920** can cause the system **2200** to leave the states mentioned above. The first event may be a wake event represented in row **2924**. The second event may be a phone call represented in row **2928**. When these events occur, with the correct user input shown in the body of table **2900**, the system **2200** may exit from the state and allow the user to use or interact with the system.

An embodiment of a method **3000** for waking the system **2200** is shown in FIG. **30**. While a general order for the steps of the method **3000** is shown in FIG. **30**. Generally, the method **3000** starts with a start operation **3004** and ends with an end operation **3032**. The method **3000** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **30**. The method **3000** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **3000** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-29**.

A system **2200** may sleep, in step **3008**. The sleep state may include the states as described in conjunction with FIG. **29** or other states that render the system **2200** inactive. The system **2200** may appear as shown in FIG. **22**, where in user interface **2204** for the computer system **1104** and the user interface **2208** for the device **100** are inactive and do not display anything. The sleep state may be entered after the expiration of a period of time, automatically in response to an action or event, or in response to user interaction. Thus, the sleep state can render the system **2200** unusable until it is awakened or unlocked.

The device **100** or the computer system **1104** may receive an event in step **3012**. An event may be as described in conjunction with FIG. **29**. For example, the event may be a wake action received by a user. In alternative embodiments, the event may be a received phone call. Either event may be received with the correct user input to wake the system **2200**. The correct user input is based on the state in which the device currently resides.

Thus, the system **2200** may determine the state of the system, in step **3016**. The state may be set by the user or be automatically set. For example, a user may determine that a passcode lock is necessary and enter the passcode with the setting. However, if the user makes no change to the desired sleep state, the device **100** may determine to use the sleep state **2908**. Regardless, the system **2200** determines which state has been set when the device sleeps.

The system **2200** may then determine if the correct user interface input, associated with the determined state, has been entered to wake the system **2200**, in step **3020**. As shown in table **2900**, there is different input based on the event and the state. If the system **2200** is in a simple sleep state **2908**, then any input to the device **100** or computer system **1304** may wake the system **2200**. Thus, the user may hit a key on the keyboard **2212**, push a user interface device **2216** on the device **100**, touch the touch sensitive display **110**, **114**, the gesture capture area **120**, **124**, or another touch-sensitive area on the device **100**, or make some other input into the system **2200**. In the screen lock state **2912**, the device **100** may require the user to complete some form of user input (e.g., moving a slider bar or other orchestrated movement on the touch sensitive display **110**, **114**), either in addition to a first interaction or by itself, to unlock the device **100**. The computer system **1304** may not require any additional input. Thus, a first gesture may wake the computer system **1304**, while a second gesture is needed to unlock the device interface **2208**. If the correct input is received, the method **3000** proceeds YES to step **3028**.

However, if the incorrect input is received, the method **3000** proceeds NO to step **3024**, where the system **2200** may inform the user of the incorrect input. Thus, a user interface may be provided that indicates that the input was incorrect, for example, a pop-up message that states "The password or username is incorrect." In other embodiments, the system **2200** may revert to the locked state without unlocking the device, which can indicate to the user that the input was incorrect. In step **3028**, the system **2200** may wake. Thus, the system **2200** can transition, for example, for the display shown in FIG. **27** to that shown in FIG. **28**. The user may then have complete access to the system **2200** and view the desktop or open application after waking the system **2200**.

Docking and Undocking

An embodiment of a method **3400** for docking the device **1308** with the computer system **1304** to form a unified system **3100** is shown in FIG. **34**. While a general order for the steps of the method **3400** is shown in FIG. **34**. Generally, the method **3400** starts with a start operation **3404** and ends with an end operation **3432**. The method **3400** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **34**. The method **3400** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **3400** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-33** and FIG. **38**. In particular, FIGS. **31-33** show embodiments of user interfaces associated with the process of docking.

A device **1308** and a computer system **1304** may be provided, in step **3408**. The device **1308** may be a mobile device as described herein. In embodiments, the device **1308** may display one or more user interfaces **3108** and/or **3112** before docking occurs. The computer system **1104** can include a display **1304** that presents a user interface **3104**. The user interface **3104** can include any window or other display. In embodiments, the user interface **3104** shows a slide show in FIG. **31** before docking. After presenting the device **1308** and the computer system **1304**, the device **1308** may dock with the computer system **1304**, in step **3412**.

Docking the device **1308** may include electrically connecting the device with the computer system **1304**. The electrical connection may be made with a docking cradle, a wire interface, a wireless interface, or by other device or connection. Once docked, the computer system **1304** may be controlled or managed by the device **1308**. Thus, actions on the computer system **1304** may be handled by the device **1308**. Thus, docking the device **1308** creates the unified system and presents the unified interface for the computer system **1304** and the device **1308**.

The behavior of the unified system **3200**, as shown in FIG. **32** and after docking, may be governed by a set of docking rules, as described in conjunction with FIG. **38**. In embodiments, the computer system display **3204** may hide one or more displays or windows presented before docking. Rather, the computer system **1304** may present a desktop **3208** after docking, in step **3416**. The desktop **3208** can display a unified desktop theme with icons or other user interface devices (for example, icon **3212**) providing access to unified system **3200** functionality. Thus, the computer system **1304** hides pre-existing windows or displays to provide the unified desktop **3204**.

After docking, the device software (as described in FIGS. **5**A and **5**B) may determine if any application displays or windows were displayed on the device **1308** before docking, in step **3420**. The determination may include the processor **504** checking the display configuration in the frame buffers **548** or other type of check. If there were displays presented on the device **1308** before docking, the method **3400** may proceed YES to step **3428**. If there were on displays presented on the device **1308** before docking, the method **3400** may proceed NO to step **3424** where the unified desktop is also provided on the display(s) of the device **1308**, as seen in FIG. **33**.

If there were on displays (e.g., display **3108** and/or display **3112**) presented on the device **1308** before docking, the displays **3108** and/or **3112** may be migrated from the device interface **3304** to the computer system display **3204**, as shown in FIG. **33**. In embodiments, new freeform windows or big brother applications are invoked to migrate the displays. Thus, a new instance of the application window or interface is opened in the display of the computer system. In other embodiments, the display buffer is simply changed to reflect the migration. Thus, displays on the device **1308** preempt any displays on the computer system **1304** after docking.

An embodiment of a method **3700** for undocking the device **1308** with the computer system **1304** to is shown in FIG. **37**. While a general order for the steps of the method **3700** is shown in FIG. **37**. Generally, the method **3700** starts with a start operation **3704** and ends with an end operation **3728**. The method **3700** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **37**. The method **3700** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **3700** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-36** and FIG. **38**. In particular, FIGS. **35** and **36** show embodiments of user interfaces associated with the process of undocking.

A device **1308** and a computer system **1304** may be docked. The device **1308** may be a mobile device as described herein. In embodiments, the device **1308** may display one or more user interfaces **3504** before undocking occurs. The computer system **1104** can include a display **1304** that presents a display **3508** before undocking. Thereinafter, the device may be undocked from the computer system **1304**, in step **3708**.

Undocking the device **1308** may include electrically disconnecting the device from the computer system **1304**. The electrical connection may be made with a docking cradle, a wire interface, a wireless interface, or by other device or connection. To disconnect the device **1308**, the device **1308** may be separated from the docking cradles or wire interface or the wireless interface may be disconnected. Once undocked, the computer system **1304** may no longer be controlled or managed by the device **1308**. Thus, the computer system **1304** may resume control of its own actions. Thus, undocking the device **1308** dismantles the unified system and presents separate interfaces for the computer system **1304** and the device **1308**.

The behavior of the unified system **3200**, as shown in FIG. **36** after undocking, may be governed by a set of undocking rules, as described in conjunction with FIG. **38**. In embodiments, the computer system display **3204** may hide the unified desktop, in step **3712**, and display a window or other display **3604** that was hidden during docking, as shown in FIG. **36**. After undocking, the device software (as described in FIGS. **5**A and **5**B) may determine if any application displays or windows were displayed on the device **1308** before undocking, in step **3716**. The determination may include the processor **504** checking the display configuration in the frame buffers **548** or other type of check. If there were displays presented on the device **1308** before undocking, the method **3700** may proceed YES to step **3720**. If there were on displays presented on the device **1308** before undocking, the method **3700** may proceed NO to step **3724** where a device desktop is provided on the display(s) of the device **1308**.

If there were on displays (e.g., display **3504**) presented on the device **1308** before undocking, the display(s) **3504** may be maintained on the device interface, as shown in FIG. **35**. However, no windows or displays are migrated from the computer system **1304** to the device **1308**. Thus, the device **1308** maintains its display characteristics after undocking.

A table **3800** containing at least some of the docking and undocking rules and how to interact with the system **2200** during docking and undocking is shown in FIG. **38**. In embodiments, there two sets of rules **3804**—one set for docking represented in column **3808** and another for undocking represented in column **3812**. In embodiments, there may be more or fewer rules. Further, the docking rules may include a rule governing visible-to-visible transitions represented in column **3816** and a stickiness rule represented in column **3820**. The table **3800** shows rules that govern the components (represented by column **3824**) of the unified system. Thus, the rules govern how the displays of the device **1308** and computer system **1304** are managed during docking and undocking. The device interfaces are represented in row **3828** while the computer system interfaces are represented in row **3832**.

During docking, the user interface **1304** may display interfaces or a desktop for the computer system. However, upon docking, the interfaces and computer system desktop are hidden according to the visible-to-visible rules for the computer system. Further, if there was a previous docking and undocking, any application interfaces previously displayed during a past docking are re-displayed according to the stickiness rules for the computer system. It should be noted that the device or computer system may store an indicator of the previously displayed interfaces at the last docking and access the indicators to reinstate the interfaces upon re-docking. The device, during docking, will have interfaces displayed on the device moved to the display of the computer system according to the visible-to-visible rule.

During undocking, any interfaces displayed on the device remain displayed on the device according to the undocking rules for the device. For the computer system, applications displayed in the unified desktop are hidden but available if the device is re-docked. The computer system may then display other interfaces associated with the computer system

or the computer system desktop, according to the undocking rules for the computer system.

An embodiment of a method **4800** for applying a visible-to-visible rule during docking of a device is shown in FIG. **48**. While a general order for the steps of the method **4800** is shown in FIG. **48**. Generally, the method **4800** starts with a start operation **4804** and ends with an end operation **4840**. The method **4800** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **48**. The method **4800** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **4800** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-47**.

Device **1308** docks with a computer system (PC) **1304**. As shown in FIG. **39**, the device can include two displays **3908** and **3912**. The PC can include one display **3904**. When docked, the displays **3904**, **3908**, and/or **3912** can display a unified desktop, which may display one or more application windows. As explained in conjunction with FIG. **38**, the unified system maintains visible windows from the device **1308** on the unified desktop. Before docking, the PC **1304** and device **1308** may appear as shown in FIG. **40**. As shown in FIG. **40**, the device **1308** may display a first window **3108** and a second window **3112**. The PC **1304** may display a first window **4004** and a second window **4008**. Further, the device **1308** may display an application manager interface **4012** that displays windows (e.g., **4020**) on the first display **3908** of the device **1304** and an application manager interface **4016** that displays windows on the second display **3912** of the device **1304**. The application manager interfaces **4012**, **4016** can also display windows (e.g., **4024**) that are not currently displayed on the displays **3908**, **3912**.

A representation of a display buffer or data structure **4100** associated with the display **3904** is shown in FIG. **41**A. The data structure **4100** can store information about which windows are displayed before docking. For example, data object **4104** is associated with window **4004** and data object is associated with window **4008**. Further, a data object **4112** may be associated with a desktop displayed on the display **3904**. A window stack **4116** can represent the windows open, active, or inactive on the displays **3908**, **3912** before docking the device **1308**. For example, data object **4124** can represent window **3108**, data object **4120** can represent window **3112**, and data objects **4128**, **4132** can represent the desktop on the device **1308**.

At some time thereinafter, the device **1308** is docked with the PC **1304** to create the unified desktop **4200**, as shown in FIG. **42**. In response to docking the device **1308**, the windows **4004**, **4008** previously displayed on the PC **1304** can be hidden or closed, in step **4808**. The desktop **4204** may then be provided on the PC display **39**, in step **4812**. A processor on the device **1304** can then determine if there were any windows active and displayed on the device **1304** before docking, in step **4816**. The processor can scan the window stack **4116** to determine that windows **3108** and **3112** were open substantially simultaneously with the docking of the device **1304**.

After determining the windows that were open on the device **1308** before docking, the processor can instruct the PC **1304** to create windows that are similar to or associated with the programs or applications that were being executed on the device **1308**. For example, if an Internet Browser was being executed on the device **1308**, a browser application can be opened on the PC **1304**. After creating the windows, the active windows **3108**, **3112** are moved to the created windows. In embodiments, state information for the active windows **3108**, **3112** can be used to provide a new instance of the window on the PC **1304**. Thus, while, to the user, it appears the window is moved, a new window is actually instantiated. As shown in FIG. **42**, windows **3108**, **3112** are now open in display **3904**. The unified desktop **4204**, **4208** may be shown on the PC **1304** and the device **1308**, in step **4828**.

In response to the movement of the windows after docking, the processor modifies the window stack, in step **4832**. For example, the processor removes the windows from the window stack **4308**, as shown in FIG. **43**B. Further, the window stack **4308** is changed to reflect that the unified desktop **4312** is displayed on the device display **3912**, **3908**. Further, the processor modifies the computer system display buffer, in step **4836**. For example, the display buffer **4300** is changed to reflect that windows **4124**, **4120** are open on the PC display **3908**. The unified desktop **4304** may also be provided on the display **3904**, as shown in the window stack.

While docked, a window **3108** may be moved from the PC display **3904** to the device display **3908**, as shown in FIG. **44**. The display buffer **4500** can be changed to reflect the move, as shown in FIG. **45**A. Thus, the window **4124** is no longer shown in the window stack **4500** but shown in the window stack **4504** in FIG. **45**B. Upon undocking, the window **3108** remains visible on the device **1308**. The other window **3112** is no longer shown. The display buffer **4700** for the PC **1304** can now display the PC desktop **4110** but no other windows. The window stack **4704** may remain unchanged, as shown in FIG. **47**B.

An embodiment of a method **5400** for maintaining window stickiness during a re-dock of a device is shown in FIG. **54**. While a general order for the steps of the method **5400** is shown in FIG. **54**. Generally, the method **5400** starts with a start operation **5404** and ends with an end operation **5432**. The method **5400** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **54**. The method **5400** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **5400** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-53**.

Device **1308** docks with a computer system (PC) **1304**, in step **5408**. The docking is as described herein. During the docking, at least one window is opened on the unified desktop of the computing system **1304**, in step **5412**. For example, at least one of window **4904** or window **4908** are opened during the docked session. The docking of the unified system is represented by line **4912**. In embodiments, a desktop **4916** is shown on the device **1308**. However, the device **1308** might also have one or more open windows displayed on the device **1308**.

At some time thereinafter, the device **1308** is undocked from the PC **1304**, in step **5416**. The undocked device **1308** and computer system **1304** is shown in FIG. **50**, as system **5000**. The undocked system may be represented by the absence of line **4912**. Upon the occurrence of the undock event, recognized by the device **1308** and/or the computer system **1304**, the device **1308** and/or the computer system **1304** may save a data structure **5300**, in step **5420**. The data structure **5300** is as shown in FIG. **53**.

The data structure **5300** may include one or more data fields and may be stored as any type of data structure as described herein. In embodiments, the data structure **5300**

can include a timestamp **5304** of the last docking, an identifier (ID) for a window **5308**, and/or status and/or state information **5312**. The data structure **5300** can include more or fewer data items than that shown in FIG. **53** as represented by ellipses **5324**. In embodiments, the information contained in data structure **5300** is associated all windows that were open on the computer system **1304** before the last undocking. For example, the data structure **5300** may include information about window **4904** and window **4908** as shown in FIG. **49**.

Further, other data fields, such as window **2** ID **5316** and state information **5320**, may represent window **2 4908**, which was open on the computer system **1304** before undocking. There may be more or fewer data fields for more or fewer windows that may have been open on the computer system **1304** before undocking, as represented by ellipses **5328**. This data structure **5300** can be stored with the device **1308** and/or the computer system **1304**. The undocked system **5100**, as shown in FIG. **51**, may have one or more actions occur on the computer system **1304** or on the device **1308** while undocked. For example, window **3 5104** may be opened on the device **1308** while the device **1308** is undocked from the unified system.

At some time thereinafter the device **1308** may be re-docked with the computer system **1304** to recreate the unified system **5200** as shown in FIG. **52**, in system **5424**. Upon the occurrence of a re-dock, the computer system **1304** and/or the device **1308** may recognize the re-dock event and may access the data structure **5300**. Information from the data structure **5300** may be read to reopen one or more windows, in step **5428**. For example, as shown in FIG. **52**, window **1 4904** and window **2 4908** may be reopened as having been open during the last docked session. Thus, the open windows at undocking are sticky or re-open the next time that the device **1308** docks with the computer system **1304**. Further, windows that were open on the device **1308** during undock, may be moved to the computer system **1304**, as represented by window **3 5104** being displayed on the computer system display **1308**. If a window is moved from the device **1308** to the computer system **1304**, the desktop **5204** may be displayed on the device **1308**.

Embodiments of systems **5504**/**5520** for creating a unified system for the device **1308** and PC **1304** are shown in FIGS. **55**A and **55**B. The software components or modules that provide for the unified system on a computer system are shown in FIG. **55**B. The systems **5504** and/or **5520** for the device **1308** and the PC **1304** may be stored and executed in hardware as described herein. The software modules can include a first operating system **5508** and a second operating system **5512**. The two operating systems **5508** and **5512** may interact to create and manage the unified system. In embodiments, the second operating system **5512** may control the functions of the device **1308**. The first operating system **5508** may control or direct the operations of the computer system **1304**. Thus, the first operating system **5508** may communicate with the computer system interface **5516** that sends signals to the computing system **1304** through the docking hardware. Embodiments of the dual operating system are described in U.S. Provisional Patent Applications 61/507,199, filed Jul. 13, 2011, entitled "Dockable Mobile Software Architecture," 61/507,201, filed Jul. 13, 2011, entitled "Cross-environment communication framework," 61/507,203, filed Jul. 13, 2011, entitled "Multi-operating system," 61/507,206, filed Jul. 13, 2011, entitled "Auto-configuration of a docked system in a multi-OS environment," and 61/507,209, filed Jul. 13, 2011, entitled "Auto-waking of a suspended secondary OS in a dockable system".

The modules on the computer system **5520** may be installed or stored upon the first docking of the device **1308** to the computer system **1304**. The modules can include a device interface **5524** that communicates with the computer interface **5516**. Thus, the device interface **5524** can receive signals from the first operating system **5508** and may send signals or events to the first operating system **5508**. The device interface **5524** can communicate with an application-programming interface **5528**. In turn, the application-programming interface (API) **5528** can communicate with the operating system **5532** for the computer system. The API **5528** can act as an intermediary that both controls and directs the computing system OS **5532** or changes the operation thereof. Thus, the API **5528** can both subordinate normal computer system events for the PC **1304** and promote the events or signals sent from the device **1308**.

In embodiments, the API **5528** may include one or more modules. For example, the API **5528** can include an interceptor module **5536**, a relay module **5540**, an injector module **5544** and/or a receiver module **5548**. The interceptor module **5536** may be operable to intercept events or processor executions that are put on the stack for the computer system processor. Thus, the interceptor **5536** can erase, delete, or change the stack for the PC **1304**, thus controlling what actions are conducted by the PC **1304**. Any events that occur on the PC **1304** that are placed into the stack may be intercepted by the interceptor **5536** and provided to the relay **5540**, which may then relay the event through the device interface **5524** to the first operating system **5508**. The information sent from the relay **5540** allows the first operating system **5508** to respond to the event(s) for the PC **1304**.

Likewise signals from the OS **5508** to the PC **1304** may be received by a receiver **5548**. When the first operating system **5508** wants to control or have the personal computer **1304** conduct some action, the first operating system **5508** may send a signal through the PC interface **5516** to the receiver **5548**. The receiver **5548** may then pass the signal onto the injector **5544**, which may place the event or instruction into the stack for the computer operating system **5532**. Thus, the injector **5544** communicates signals to the computer system OS **5532** to control its actions.

An embodiment of the method **5600** for receiving an event for the unified desktop at the device **1308** is shown in FIG. **56**. While a general order for the steps of the method **5600** is shown in FIG. **56**. Generally, the method **5600** starts with a start operation **5604** and ends with an end operation **5636**. The method **5600** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **56**. The method **5600** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **5600** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1**-**55**B. The process **5600** may be described particularly in conjunction with FIGS. **55**A and **55**B.

The operating system **5512** may receive an event at the device **1308**, in step **5608**. An event may be any type of user interface input or other occurrence that may require attention from the device **1308**. An event may require action by the device or some type of response. Once an event is received, the second operating system **5512** can determine if the event is associated with the device **1308**, in step **5612**. For example, if the event is a user interface input that requires user interface output at the device **1308**, then the event is related to the device **1308**. However, if the event may be

related to output on the personal computer **1304**, the second operating system **5512** may determine that the event is related to the personal computer **1304**. If the event is related to the device **1308**, the method **5600** proceeds YES to step **5616**. In contrast, if the event is not associated with the device **1308**, the method **5600** proceeds NO to step **5624**.

In step **5616**, the second operating system **5512** can process the event for the device **1308**. The processing of an event by an operating system may be as understood in the art. Thus, the processing of the event may involve user interface output or completing an instruction for an application. If the processing requires output, the output may be displayed on the interface of the device **1308**, in step **5620**.

If the event is related to the computer system **1304**, operating system **2 5512** may send the event to the first operating system **5508**, in step **5624**. The first operating system **5508** may process events similarly to the second operating system **5512** but may process the events for the personal computer **1304**. Thus, the processing may include one or more steps or actions that may be unique to the computer system **1304** as opposed to the device **1308**. Thus, the operating system **5508** processes the event for the computer system **1304**, in step **5628**, and sends the processed or executed actions through the computing system interface **5516** to the device interface **5524**. The instructions or completed processing actions may be received by the receiver **5548** and sent to the injector **5544**. The injector **5544** may send the completed instructions or actions for the personal computer operation system (OS) **5532** to create a display or some other output. The personal computer OS **5532** can then display the output, in step **5632**. In this way, the device **1308** can both control the functions of the device **1308** and the personal computer **1304** for an event received by the device **1308** but applying to either the device **1308** or the personal computer **1304**.

An embodiment of a method **5700** for processing an event received on a personal computer **1304** is shown in FIG. **57**. While a general order for the steps of the method **5700** is shown in FIG. **57**. Generally, the method **5700** starts with a start operation **5704** and ends with an end operation **5720**. The method **5700** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **57**. The method **5700** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **5700** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-56**.

An event may be received on the personal computer **1304**, in step **5708**. The event may be as described previously in conjunction with FIG. **56**. The event may be received in the user interface of the personal computer **1304**. Upon receiving the event, the interceptor **5536** may intercept event information from the memory stack of the PC OS **5532** and provide that information to the relay **5540**. The relay **5540** may then package the information to send to the device, in step **5712**. The information may be sent in a message provided by the device interface **5524** to the computer interface **5516** and arriving at the first OS **5508**. The first OS **5508** may then process the event, in step **5716**. The processing of the event may be the same or similar as that described in conjunction with FIG. **56**. Further, the output provided by the first OS **5508** may then be sent back to the PC OS **5532** as described in conjunction with FIG. **56**.

An embodiment of the method **5800** for processing an event that may cross the personal computer **1304** and device **1308** is shown in FIG. **58**. While a general order for the steps of the method **5800** is shown in FIG. **58**. Generally, the method **5800** starts with a start operation **5804** and ends with an end operation **5820**. The method **5800** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **58**. The method **5800** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **5800** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-57**.

An event may be received that crosses both the personal computer **1304** and the device **1308**, in step **5808**. For example, a user may desire to move a window from the device interface to the computer interface by dragging that window from one interface to the other. This type of event would cross the boundary of the personal computer **1304** and device **1308** and thus create an event that may occur in both the device **1308** and the personal computer **1304**.

The event may be received in the second OS **5512**. Further, the interceptor **5536** may receiver or intercept the event in the personal computer OS **5532**. The intercepted event may be sent through the relay **5540** to the first OS **5508**, in step **5812**. The first and second OS **5508** and **5512** may then communicate about the events to coordinate the timing of the information. Thus, the determination may be made as to where an event started or stopped and which of the outputs should be processed first. Thus, both the second OS **5512** and the first OS **5508** may process the event or events, in step **5816**. The output may then be coordinated so as to provide a seamless user interaction for such an event. The second OS or the first OS may throttle the other operating system in the device **1308** to coordinate or to time the processing and then output of data as described in conjunction with FIG. **56**.

An embodiment of the method **5900** for the device **1308** to be master of the unified system, upon docking, as described and shown in FIG. **59**. While a general order for the steps of the method **5900** is shown in FIG. **59**. Generally, the method **5900** starts with a start operation **5904** and ends with an end operation **5924**. The method **5900** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **59**. The method **5900** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **5900** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-58**.

A docking event may be received, in step **5908**. The docking event may be created when the device **1308** is connected to the computer system **1304** as shown by the line **4912** in FIG. **49**. The docking event may occur in both the computer system **1304** and the device **1308**. In the device **1308**, the second OS **5512** may begin communicating with the first OS **5508** and instruct the first OS **5508** to begin signaling the computer system **1304** to control the computer system's actions. Further, in the computer system **1304**, the application programming interface **5528** may begin to be executed and begin scanning or monitoring the stack of the personal computer OS **5532** to intercept or inject instructions into the memory stack for the operating system **5532**. In embodiments, the first OS **5508** may send an instruction to the application programming interface **5528** to be executed. In other embodiments, the docking signal or event may cause the PC OS **5532** to begin executing the applica-

tion programming interface **5528**. Upon the execution of the API **5528** and the first OS **5508**, the device **1308** controls the personal computer **1304** as the master, in step **5912**. Thus, any actions being conducted on either the device **1308** or the computer system **1304** can be executed or handled with the device **1308**.

Upon the device **1308** becoming master over the personal computer **1304**, the computer system **1308** subordinates any functions the computer system **1308** normally executes independently, in step **5916**. For example, any windows or applications being executed by the personal computer **1304** before docking are hidden and those functions are paused while the device **1308** is docked. Thus, any functions normally executed on the computer system **1304** are subordinated to the master control of the device **1308**. One such subordination may be the computer system **1304** hiding any display, in step **5920**. The computer system **1304** displays a master or unified desktop on the display after having the computer system's other functions. Any windows or the previous desktop are hidden behind the unified system desktop or are replaced by the unified system desktop.

Triad Control

An embodiment of the unified system **6000** showing a triad control interface **6008** is shown in FIG. **60**. The unified system **6000** includes the device interface **1308** and the computer system interface **1304**. As shown in the device interface **1308**, a control window **6004** may be provided by user interface input or automatically through action of an application or other event. The user interface **6004** provides direct access to certain functionality including, but not limited to, a phone application, an application launcher, a file browser, etc. The provided functionality in the unified desktop **6000** may be ported to the computer system display **1304** in a new and novel user interface area **6008** called the triad control. The triad control area **6008** may be a separate popup bar that is navigable by a user interface device, for example, a mouse, that is hovered over a specific area of the user interface **1304**. Upon the recognition that the user desires to view the triad controls **6008**, the triad control **6008** may appear on the user interface **1304** as if sliding from of the screen and onto the top of the display **1304**.

The triad control **6008** can include at least some of the same functionality as in user interface **6004**. For example, the area **6012** shows several user selectable icons in the triad control **6008**. The user selectable icon **6016** can execute a file browser. The user selectable icon **6020** can execute an application launcher. The user selectable icon **6024** can execute an application manager. Further, the user selectable icon **6028** can provide a phone application that is executed by the device **1308** but appears on the computer system display **1304**. Likewise, a user selectable **6032** may provide a browser window that allows the user to browse the internet through the phone device **1308**. The selectable device icons **6012** provide functionality typically associated with the phone over the unified desktop **6000** by allowing access to those functions using a new selectable area **6012** for user icons in the triad control bar **6008**.

A series of windows shown in FIGS. **61**A-**61**C show a visual representation of how the triad control **6008** may be provided to a user in the user interface **1304**. As shown in FIG. **61**A, a user interface device **6104** may be shown in user interface **1304**. The user interface device **6104** may be controllable by a mouse, a finger on a touch sensor display, or by some other hardware means. The represented arrow icon can be moved from the device's position, as shown in FIG. **61**, to a position shown in FIG. **61**B. The position of the user interface device **6104**, in FIG. **61**B, can be recognized as being within a triad control area **6108**. Upon recognizing the presence and persistence of the user interface device **6104** in the triad control area **6108**, the triad control bar **6008** may begin to present itself by appearing to slide from the side of the screen. Thus, as the triad control bar **6008** slides, the triad control bar will become completely displayed, as shown in FIG. **61**C. If the user persists in maintaining the user interface device **6104** in the triad control area **6108**, the triad control bar **6112** can continue to be displayed and to be selectable for the user.

An embodiment of the application launcher user interface **6204**, presented to the user after user selectable icon **6020** is selected in triad control bar **6008**, is shown in FIG. **62**. The user may select the user interface device **6020** or user selectable icon **6020** in the triad control **6008**. Upon selecting icon **6020**, by user interface action, the application launcher user interface **6204** may be presented; the application launcher user interface **6204** presents selectable icons associated with applications that can be launched by the user. The applications may include a first group of one or more applications that are executed on the device and/or a second group of one or more applications executed on the computer system. Thus, the available applications for the user, presented in the application launcher user interface **6204** on the unified desktop, encompass applications executed both on the device and the computer system. The application launcher user interface **6204** may present the first and second group of applications in two, separate sections of the application launcher user interface **6024**. The first section presents applications executed on the device, and the second section presents applications executed on the computer system.

For example, the group of applications **6208** provide icons associated with PC productivity applications that may be executed by the computer system. In alternative embodiments, the PC productivity applications **6208** are applications executed by the device that may emulate computing system functionality. The applications shown in the group **6212** may be Android applications or other applications executed solely by the device. Thus, by providing the application launcher menu **6204**, the user can select one of the icons shown in either area **6208** or **6212** to launch an application in the unified desktop. Further, the window **6204** may provide a search area **6216** where the user may provide search criteria that can search for a certain application within the application launcher **6204**.

An embodiment of a process for using the search function in the application launcher user interface **6204** is shown in FIG. **63**. The search function can include a user interface **6216** in the application launcher user interface **6204**. The user interface **6216** may accept one or more characters of a search string through user interface input from a keyboard, drop down menu, or other user interface action. The search function can be progressive. In other words, as the letters are typed into the search function user interface, the unified system may search for applications containing or starting with the search string. For example, the user may have typed a letter "c" **6304** in the search window **6216**. Upon typing the letter within the search window **6216**, the window **6204** may present a more limited set of icons associated with applications that contain or begin with the letter "c." Thus, based on the search string, the application launcher presents one or more selectable icons associated with the search string. For example, the number of PC productivity applications shown in area **6208** has been reduced to the fewer number of applications, as shown in area **6308**. Further, the applications shown in area **6212** have been reduced to a less

numerous number of applications shown in area **6312**. The applications shown in areas **6308** or **6312** may have a "c" in the name of the application or may have a "c" that begins the application name. In this way, the searching function in **6216** allows for the user to quickly discern what applications are important and to select a more limited set of applications from the application launcher window **6204**.

Embodiments of a process for using an application manager, initiated by selecting icon **6024**, is shown in FIGS. **64** through **66**. In embodiments, the user may move a user interface device **6404** to select the application manager icon **6024** in the triad control **6008**. At the time of the selection of the icon **6024**, the computing system interface **1304** may be displaying at least one window **6408** or **6412**. Upon selecting the application manager icon **6024** in the triad control **6008**, a new menu or application launcher user interface display **6504** (shown in FIG. **65**) may be presented within the display **1304**. The new display **6504** may contain two or more areas or sections, e.g., area **6516** and area **6520**. The separation of the areas may be delineated by visual indicia, for example, a bar **6532** shown between area **6512** and area **6520**. Each area **6512**, **6520** may display different information. The areas **6512** and/or **6520** may display one or more representations of one or more applications executing on the unified system. The one or more representations may be a snapshot(s) of an application window associated with one or more application(s) executing on the unified system. The snapshot may be a last-presented view of the application window on the unified desktop. For example, snapshot **6408** shown in FIG. **65** is the same as or similar to window **6408** shown in FIG. **64**.

Area **6520** of the application launcher user interface **6504** can display one or more snapshots of applications currently executing or being displayed on the device. Likewise, area **6520** may display one or more snapshots of applications being executed or being displayed on the computing system. For example, windows **6412** and **6408** are shown in area **6520**. Thus, the display **6504** captures the windows that were currently being displayed in FIG. **64**. In further embodiments, an application window **6524** that was not being displayed but being executed on the device may be shown in area **6520**. The executed application is represented by window representation **6524** in area **6520**.

A user may manage the currently executing applications by selecting or conducting user interface actions on the snapshots or representations of the applications shown in window or user interface **6504**. Thus, if the user wishes to select, execute, or move the snapshot of a window being executed on the device, e.g., **6508** or **6512**, the user may select or conduct the user interface action on those windows **6508**, **6512** in area **6516**. In embodiments, when the user moves a snapshot or user interface device **6604** to select a window **6412** in the display **6504** such that the window **6412** may then become displayed in the personal computing interface **1304**, as shown on FIG. **66**. If a snapshot is moved between sections **6516** and **6520**, the application window associated with the snapshot may be moved from the user interface of the device to the user interface of the computer system, or vice versa. When selected in sections **6516** and **6520**, the displayed windows in the interface(s) **1304**, **1308** becomes highlighted and/or receives focus. Thus, in embodiments, the application manager window **6504** allows the user to manage applications currently executing in the unified desktop.

When the user selects the icon **6016**, a file manager window **6704** may appear within the user interface device **1304**, as shown in FIG. **67**. Thus, the triad control **6008** provides access to files that may be on the device or the computer system. The user interface window **6704** may provide an area for information about recently-used or recently-opened files **6708**; the area **6708** displays information associated with recently used files (e.g., filename, date when the file was last opened, the size of the file, etc.). A file may be associated with an application executed in the unified system. The icons or user interface devices may be selectable to open the represented files in area **6708**. Further, window **6704** may provide an area **6712** that includes a list of folders either automatically generated for the user or populated by user input. The folder icons in area **6712** may also be selectable to open a folder and access a file within the data storage of either the device or the computer system.

A phone manager user interface **6804** presented, after icon **6028** is selected in the triad control **6008**, is shown on FIG. **68**. The phone manager user interface **6804** may allow the user to select one or more icons displayed within the phone manager user interface **6804** to conduct a communication session. For example, the phone icon **6808** may allow the user to begin a telephone call or send a text message by selecting the icon **6808**. Further, in area **6812**, a call log may be listed that shows recent calls either received or sent by the device. In area **6816**, one or more icons may be provided that represent data about frequently called or contacted persons or entities. In area **6820**, one or more contacts that are communicated with often may be listed in a favorite's field. In field or area **6824**, all contacts may be listed. The list of contacts may be searchable or navigable by the user in the phone manager user interface **6804**. Any of these different fields may be searchable, by search function **6828**, presented in the phone manager user interface **6804**. The user interface of the search function can accept a search string and return one or more contacts associated with the search string. Each icon, in embodiments, within the phone manager user interface **6804**, may be selectable to conduct a communication session using the device, regardless of the fact that the icon was selected in the phone manager user interface **6804** presented in the computing system interface **1304**.

Like the phone functionality described in conjunction with FIG. **68**, if a user selects a browser icon **6032** within the triad control bar **6008**, a browser control user interface **6904** may be presented. The browser control user interface **6904** can present one or more items of information that are associated with the web browsing functionality of the device. The information is presented as one or more selectable icons. Thus, icon **6908** may be selected to begin or conduct a web browser session using the web browser application and network communication capability of the device.

The browser control user interface **6904** can be separated into two or more areas. For example, area **6912** may include bookmarks for the web browser bookmarked by the user in the device. A bookmark is a designated website that the user may frequent and stores the Uniform Resource Locator (URL) for the site in the bookmark information. Selecting the bookmark directs the web browser to contact the URL and provide the website information to the user. Area **6916** may provide a list of one or more names or URLS for the most visited websites that may be selectable by the user. Area **6920** may provide a list of downloads that have been recently downloaded by the device from a network. Area **6924** may provide a history of recently visited websites using the web browser. Any of these areas may be searchable by search function **6928** provided in windows **6904**. Each of the icons within windows **6904** may be selected to begin a web browsing session using the functionality of the phone,

while selectable within the computer system interface **1304**. Any of the different areas may be searchable, by search function **6928**, presented in the browser control user interface **6904**. The user interface of the search function can accept a search string and return one or more contacts associated with the search string.

An embodiment of a method **7000** for selecting or executing functions within the unified desktop using the triad control **6008** is shown in FIG. **70**. An embodiment of the method **7000** for receiving an event for the unified desktop at the device **100** is shown in FIG. **70**. A general order for the steps of the method **7000** is shown in FIG. **70**. Generally, the method **7000** starts with a start operation **7004** and ends with an end operation **7036**. The method **7000** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **70**. The method **7000** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **7000** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-69**. The method **7000** may be described with particular attention paid to FIGS. **60** through **69**.

A user interface event may be received in display **1304**, in step **7008**. The user interface event may occur within the triad control region **6108**. Upon receiving the user interface action that persists within the triad control region **6108**, the unified desktop may display a triad control **6008**, in step **7012**. In embodiments, the triad control **6008** display may be conducted as described in conjunction with FIGS. **61**A through **61**C.

Thereinafter, the unified desktop system may determine if an event is conducted within the triad control **6008** in step **7016**. An event may be a selection of a user selectable icon within region **6012** or some other icon presented within the triad control **6008**. If no action is conducted, the triad control **6008** may continue to be displayed on user interface device **1308**, in step **7028**. If an event does occur within the triad control **6008** in step **7016**, such as the selection of the one of the user selectable icons in area **6012**, the selected function may be provided in step **7020**.

The function provided may be the display of a window as described in conjunction with FIGS. **62** through **69**. The menus provided may include further functionality that may be accessed through the triad control **6008**. The unified desktop must then determine if a UI device is still in the triad control region **6108** or in one of the menus provided from the triad control **6008**, in step **7024**. If the user interface device remains within the triad control region **6108**, the triad control **6008** may continue to be displaced, in step **7028**. However, if the user interface device is no longer within the triad control region **6108**, the triad control **6008** may be hidden, in step **7032**. If a functionality provided within the menu is selected by a user, for example, selecting a user selectable icon within a menu presented in FIGS. **62** through **69**, the triad control **6008** may be hidden and the function provided.

An embodiment of a method **7100** for providing application manager interfaces within the unified desktop is shown in FIG. **71**. While a general order for the steps of the method **7100** is shown in FIG. **71**. Generally, the method **7100** starts with a start operation **7104** and ends with an end operation **7128**. The method **7100** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **71**. The method **7100** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **7100** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-70** and. The method **7100** may be described with particular attention paid to FIGS. **60** through **70**.

As explained in FIGS. **1** through **70**, a device **100** and computer system **1104** may be provided. The device **100** may then be docked with the computer system **1104** to form a unified system **1100** consisting of the device **100** and the computer system **1104**. When the device **100** is docked, the device **100** and computer system **1104** respond in generating a unified desktop **1300** for the unified system **1100**. The unified desktop **1300** is a single logical display that spans both the user interface **1308** associated with the device **100** and the user interface **1304** associated with the computer system **1104**. The unified desktop **1300** can emulate a personal computer environment where windows and applications may be executed and information may be displayed on the unified desktop **1300** for the user.

The unified system **1100** can receive a user interface event, which may be a user interface input into the first user interface **1308** associated with the device **100**, in step **7108**. The user interface input can be a selection of a triad control button **6008** or other control button(s) associated with the device **100** or computer system **1104**. The buttons may provide the ability to display an application manager interface **7212**, in step **7112**. Thus, in response to receiving the user interface input the unified system **1100** can display a first application manager interface **7212** on the device **100**. Optionally, a second user interface input may be received, in step **7116**. The second user interface input may be an input into the second user interface **1304** of the computer system **1104**. In response to the second user interface input, a second application manager interface **7216** may be shown on the computer system interface **1304**. It should be noted that it is possible for one user interface input to force the display of both application manager interface **7212** and application manager interface **7216** with a single input or interaction.

As shown in FIG. **73**, the application manager interfaces **7212** and **7216** may display at least one or more of the active windows **7304**, **7308**, **7312**, **7316**, and/or **7320** on either the first user interface **1304** or the second user interface **1308**. As explained previously herein, the application manager interface **7212**, **7216** may be used to reorder the display of windows in either the device user interface **1308** or the computer system display **1304**. For example, as shown in FIG. **74**, with a user interface input **7404**, **7408**, window **7308** may be brought to the foreground in front of window **7304**, which changes the display **1304**, as shown in FIG. **73**, to what is shown in FIG. **74**. Thus, the unified system **1100** can receive a third user interface input to reorder one or more application representations or thumbnails **7324-7364**, such as window **7308** and/or window **7304**, in the first application interface **7212** and/or the second application interface **7216**, in step **7124**.

The third user interface input **7404**, **7408** can be a drag and drop or a flick gesture as described in conjunction with FIGS. **4**A through **4**H. For example, arrow **7408** can represent a switch in the orientation of the thumbnails or representations **7356** and **7360** that are associated with windows **7304** and **7308**, respectively, in the application manager interface(s) **7212**, **7216**. In this case, window representation **7360** is moved in front of window representation **7356**. This

user interface input **7408** can change the display of the application windows **7304** and **7308** in display **1304** in the computer system **1104**.

Any change in one of the application manager interfaces **7212** and/or **7216** can change the other representations **7324-7364** in the other application manager interface **7212** and/or **7216**. For example, the change **7408** can also change the representation of windows **7332** and **7336**. Likewise, a reorientation **7404** in the other application manager interface **7216** can change the window representations for **7308** and **7304** and the representation of the windows in application manager interface **7212**.

In embodiments, the third user interface can be an input into the touch sensitive display **1308**. Thus, a drag and drop or flick gesture may move the windows in the first user interface **1308** and change the representation of the windows in the application manager interface **7212**, **7216**. The third user interface input may also be a gesture in a gesture capture region **120**, **124** as explained herein. Likewise, changes in the user interface **1304** can also change the application manager interface **7212**, **7216**. For example, window six may receive focus by a user clicking on the window **7308** with a device (e.g. mouse) and bringing the window **7308** into the foreground over windows **7304** and **7312**. This change in focus may also change the order or representation of the windows in application manager interfaces **7212** and **7216**.

The applications in the unified desktop **1300** may have different types that are based on where the windows **7308-7320** are displayed. For example, applications displayed in user interface **1304** may be device focused applications. In contrast, applications displayed on user interface **1308** may be considered computer system focused applications. A device focused application can be an application that is executed on the device **100**. A computer system focused application can be an application that may be executed in either the computer system **1104** or the device **100** but is displayed on the computer system interface **1304**.

A third user interface input that changes the representation of the application manager interface **7212**, **7216** may attempt to change a computer system focused application to a device focused application. The third user interface input may attempt to change the computer system focused application to a device focused application and may be prevented by the unified desktop **1300**. Thus, the unified desktop **1300** does not move the window as specified by the user interface input and may return an error message to the user in one or more of the displays **1304**, **1308**.

A fourth user input may be received that changes a computer system focused application to a device focused application. In this situation, a window may be moved from the computer system display **1304** to the device display **1308**. For example, as shown in FIG. **75**, the window **6 7308** may be moved from the computer system display **1304** to the device display **1308**. The application manager interface **7216** on the computer system **1104** may be updated to show that window **7308** is now on the device interface **1308** and not on the computer system interface **1304**. The change may also be shown in the device **100** application manager interface **7212**. The fourth user interface input that makes the change in the application window **7308** can be a drag and drop, from one interface **1304** to the other interface **1308**, may be a change in one or more of the application manager interfaces **7216** or **7212**, or some other input that changes the positioning of window **7308**.

A fifth user interface input may be received that reorders the window stack of the device **100** as represented in one or more of the application manager interfaces **7212**, **7216**. For example, as shown in FIG. **76**, a change may be made that repositions window **1 7320** and window **2 7316**. The change may be made in one of the application manager interfaces **7212**, **7216**. For example, a drag and drop or a flick gesture of the thumbnail **7316** or **7320** may be done in the application manager interface **7216** to change the position of the windows on the device **100**. The change may then be shown in application manager interface **7212**. This process may also be completed in the device **100** application manager interface **7212** and then shown in the application manager interface **7216**.

An embodiment of a method **7700** for providing application manager interfaces within the unified desktop is shown in FIG. **77**. While a general order for the steps of the method **7700** is shown in FIG. **77**. Generally, the method **7700** starts with a start operation **7704** and ends with an end operation **7728**. The method **7700** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **77**. The method **7700** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **7700** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-76** and. The method **7700** may be described with particular attention paid to FIGS. **60** through **76**.

A method **7700** may also be provided where the first application manager interface **7316** is displayed, in step **7712**, in the first user interface **1308** presented on the device **100** after receiving a first user interface input, in step **7708**, into either the first user interface **1308** or the second user interface **1304** associated with the computer system **1104**, in step **7708**. Optionally, a second user interface input may be received in either the first or second user interfaces **1304**, **1308** associated with either the device **100** or the computer system **1104**, in step **7716**. The second user interface input may cause the unified desktop **1300** to display the second application manager interface **7216** in the computer system display **1304**, in step **7720**. However, in this process **7700**, a third user interface input may reorder one or more thumbnails **7304-7320** in the second application manager user interface **7216**, in step **7724**.

The third user interface input may not affect one or more application windows associated with the reordered thumbnails in the application manager user interface **7216**. For example, as shown in FIG. **78**, the thumbnail **7332** may be moved to a different orientation in the application manager interface **7216** compared to window representation **7308**. However, within the user interface **1304** no change is made as compared to the original user interface shown in FIG. **73**. Thus, it is possible to reorder thumbnails **7324-7364** of the windows **7304-7320** in the application manager interfaces **7216** and **7212** without changing the orientation of the windows **7304-7320** in the user interfaces **1304** and **1308**.

However, reordering thumbnails **7324-7364** in one user application manager interface **7216** or **7212** can reorder those same thumbnails **7324-7364** in the other application manager interface **7212** or **7216**. In this way, the thumbnails **7344-7364** in the first application manager interface **7212** and the thumbnails **7324-7340** in the second application manager interface **7216** stay the same or similar.

Further, the application manager interfaces **7212** and **7216** may display thumbnails or representations for all executing applications. However, the display area for the application manager interfaces **7212** and **7216** may not be large enough

to display all of the thumbnails at the same time but may present a navigable user interface **7212** and **7216**. Thus, by using a swipe, drag and drop, or other gesture or another user interface input described herein, the user may scroll through the thumbnails **7324-7364** in those application manager interfaces **7212** and **7216**.

In the unified desktop **1300**, a first application window **7304** may be displayed on the first user interface **1304**. Likewise, a second application **7316** may be displayed in the second user interface **1308**. As explained previously, the second application **7316** may be a device focused application while the first application **7304** may be computer system focused application. The device focused application **7316** shown in the second user interface **1308** and the computer system focused applications **7304-7312** in the first user interface **1304** can be displayed differently in the application manager user interfaces **7216**, **7216**. For example, the set of application representations **7332-7340** and **7356-7364** are associated with the computer system applications **7304-7312** on the first user interface **1304**. These thumbnails **7332-7340** and **7356-7364** show a darkened dotted box, which delineates the thumbnails as being computer system applications and/or displayed on the first user interface **1304**. Other visual indicia may be used besides the dotted black line as the dotted black line is only provided as an example of how different types of thumbnails may be displayed differently.

Further, the computer system thumbnails **7332-7340** and **7356-7364** may be differently positioned than the thumbnails representing device focused application. For example, in the first application manager user interface **7212**, the thumbnails **7332-7340** and **7356-7364** are shown to the right on a second user interface **114** of the device display **1308**. The thumbnails **7344-7352** for the device focused applications may be displayed to the left or on a first user interface **110** of the device display **1308**.

Likewise, the thumbnails **7324-7328** for device focused applications may be shown at the top of the second application manager user interface **7216** and separated by a line **7804**. The computer system application thumbnails **7332-7340** may be shown at the bottom or below the line **7804** of the second application user interface **7216**.

The second application **7316** may be an Android application. The first application **7304** may be an Android application and/or a personal computer productivity application. An Android application could be any application that executes in the Android or Android-similar computer system **1104** or operating system. A personal computer productivity application can be any application that typically executes on a personal computer **1104**.

An embodiment of a method **7900** for providing application manager interfaces within the unified desktop is shown in FIG. **79**. A general order for the steps of the method **7900** is shown in FIG. **79**. Generally, the method **7900** starts with a start operation **7904** and ends with an end operation **7928**. The method **7900** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **79**. The method **7900** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **7900** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-78** and **81-82**. The method **7900** may be described with particular attention paid to FIGS. **60** through **78**.

Another method **7900** may provide for a device **100** and a computer system **1104** that are docked to form a unified system **1100**. A unified desktop **1300** may be generated to for the unified system **1100** that provides for the first user interface **1308** and a second user interface **1304** being part of the unified desktop **1300**, where the unified desktop **1300** emulates a personal computer environment. Thus, the unified system **1100** can receive an indication that the device **100** is docked with the computer system **1104**, in step **7908**. The unified system **1100** can then generate the unified desktop **1300**, in step **7912**.

Thereinafter, the unified desktop **1300** may receive a first input as a user interface event that moves the display window associated with an application from the device user interface **1308** to the computer system user interface **1304**, in step **7916**. As explained previously, applications displayed on the display **1308** are device focused applications. When moving a device focused application to the computer system user interface **1304**, the unified system **1100** must determine if that application being executed on a device **100** is associated with a big brother application normally associated with the computer system **1104**, in step **7920**.

A big brother application is an application that is normally executed in the computer system **1104** that has functionality similar to at least one application executed by the device **100**. For example, a Twitter application run in an Android environment on the device **100** may have a big brother application for Twitter that is typically run in a computer system environment on the personal computer **1104**. Thus, the big brother application is the application on the computer system **1104** that is associated with the application executed on the device **100**.

These big brother applications may be associated with the device applications to provide a seamless transition when moving application windows in the unified system **1100**. If the device application is associated with a big brother application, the device **100** may send a directive to the computer system **1104** to begin execution of the big brother application, in step **7924**. The directives are sent as explained herein to execute different functions in the unified system **1100**.

Thereinafter, the computer system **1104** may receive, from the device **100**, state information, in step **7928**. State information can be information that describes the current state of the application was when it was executing on the device **100**. For example, the state information can have a configuration of the display or any information that is being stored in memory that will be needed by the computer system **1104** to continue execution of the application. The state information is extracted at the point that the application was moved to the computer system display **1304**. Examples of state information for a web browser application may be the current site or URL that had been navigated to for the web browser. Further, any information currently entered into a user interface associated with the web browser may also be provided to the computer system **1104**. Other applications may have different, less, or more state information transferred from the device **100** to the computer system **1104**.

Once the state information is received or at some point after the determination is made that a big brother application is associated with the device application, the computer system **1104** can re-execute the device application as a big brother application, in step **7932**. Thus, the big brother application is executed and emulates the application from the device **100** and provides the appearance that the application window was seamlessly moved from the device **100** to the computer system **1104**.

The input that causes the big brother application to execute may be the docking of the device **100**. Thus as explained herein before, the docking of the device **100** may cause one or more windows to move from the device display **1308** to the computer system display **1304**. In other embodiments, the first input that moves the window may be a user interface interaction, such as a drag and drop or other type of user interface interaction, which moves the display from the first user interface **1308** to the second user interface **1304**.

The directive sent from the device **100** to the computer system **1104** may be a command from the device **100** to the computer system **1104** to execute the big brother application. As explained with the device **100** being master and the computer system **1104** being subordinate to the device **100** during execution of the unified system **1100**, the device **100** can command the computer system **1104** to complete certain functions. In this case, the device **100** may command the computer system **1104** to execute the big brother application. The state information may follow the directive in a second message after the directive has been sent. In this way, the computer system **1104** may begin executing the big brother application, at least in a general sense, before receiving the state information to configure the big brother application into a common state as was shown on the device **100** before the window was moved.

Examples of the execution of big brother applications are shown in FIGS. **80** and **81**. In this example, at least two applications **8004** and **8008** are being executed on the device **100** and shown in the device display **1308**. There are no current executing applications shown in the computer system display **1304**. At some point, due to a user interface input or other event, the applications **8004**, **8008**, being executed on the device **100**, are moved to the computer system display **1304**, as shown in FIG. **81**. While the two application windows **8004**, **8008** may be similar to what was shown in the device **100**, the application windows **8004**, **8008** are executed in big brother applications on the computer system **1104**. For example, the web browser function **8008** being executed in the device **100** is now being executed in a computer system web browser application. Likewise, the Twitter application **8004** executed in the device **100** is now being executed as a Twitter application on the computer system after being moved to the computer system display **1308**.

An embodiment of a method **8200** for providing the unified desktop is shown in FIG. **82**. A general order for the steps of the method **8200** is shown in FIG. **82**. Generally, the method **8200** starts with a start operation **8204** and ends with an end operation **8228**. The method **8200** can include more or fewer steps or can arrange the order of the steps differently than those shown in FIG. **82**. The method **8200** can be executed as a set of computer-executable instructions executed by a computer system and encoded or stored on a computer readable medium. Hereinafter, the method **8200** shall be explained with reference to the systems, components, modules, software, data structures, user interfaces, etc. described in conjunction with FIGS. **1-81**. The method **8200** may be described with particular attention paid to FIGS. **60** through **81**.

Method **8200** may begin when the indication is received by the device **100** or computer system **1104** that the device **100** is docked with the computer system **1104**, in step **8208**. Thus, the device **100** and computer system **1104** are provided and then docked to form a unified system **1100**. The unified system **1100** can then generate the unified desktop **1300**, in step **8212**. The unified desktop **1300** is a common display that covers both the display **1308** of the device **100** and the display **1304** of the computer system **1104**. This unified desktop **1300** emulates a personal computer environment.

Thereinafter, a user interface event or other input may be received that moves the display of an application from the device user interface **1308** to the computer system interface **1304** (see FIGS. **79-81**). The application display may be associated with an application that was originally executed on the device **100**. The device **100** must then determine, for the unified system **1100**, whether the application is associated with the big brother application.

To begin the determination, the device **100** can search metadata **8300**, shown in FIG. **83**, associated with a big brother application pool to determine if there is an associated big brother application, in step **8220**. A big brother application pool can be a set of one or more applications that are associated with one or more device **100** applications. The computer system applications in the big brother application pool may emulate or have similar features or functions to device applications and present a set of big brother applications.

The metadata **8300** associated with the big brother application pool may be as shown in FIG. **83** in the data structure **8304**. The data structure **8304** shown in FIG. **83** may be any type of database or other data storage technique or structure that allows for the metadata **8300** or information to be searched, stored, and retrieved for use in various functions.

The unified system **1100** can use the big brother application pool metadata **8300** to determine if an application is part of a big brother application pool, in step **8224**. Thus, if the device **100** application is associated with a big brother application, the method **8200** may proceed YES to step **8228** where the big brother application is executed and the application for the device **100** is moved into the big brother application. If there is no big brother application, the method **8200** may proceed NO to execute the application in a freeform window, in step **8232**. A freeform window is a type of logical structure within the unified system **1100** that allows for device applications to be executed in the computer system **1104** environment without having a big brother application.

As shown in the data structure **8304**, the big brother application pool can include two or more big brother applications. The data structure can include more or less data and have more or fewer entries than that shown in FIG. **83**, as represented by ellipses **8348** and **8352** Each big brother application, in the big brother application pool, can be associated with at least one application executed on the device **100**. For example, in row **8308**, device application **1** is associated with big brother application W. Thus, the unified system **1100** can search the metadata within the row **8308** of the associated applications to determine that the device **100** application **1** is associated with big brother application W.

The metadata **8300** can include the association as shown in column **8312**. Column **8312** can have a simple indication as to whether or not there is an association for the device application in column **8316**. The column **8312** can be searched quickly as it is binary, for the unified system **1100** to determine if the device application, shown in column **8316**, has an associated big brother application in column **8320**. If there is an association, a third column **8328** may identify which big brother applications are associated the device application in column **8316**.

The associations between the device applications, in column **8316**, and the big brother applications, shown in

column **8324** may be created automatically or manually. Thus, there may be a simple indication automatically provided to help a user make the association. For example, a simple name of the application may be enough to determine if there is an association between a device application and a big brother application. In other situations, a user or system administrator may be able to make the associations manually by providing the metadata or the association to the data structure **8304**. The user may manually set an association between, for example, application **8332** and big brother application **8336**.

The device **100** may search the metadata within the data structure **8304**. As the device **100** may be master, the device **100** may determine if there is a big brother application. As such, if the device **100** does determine there is a big brother application associated with the device application whose display is moved to the computer system display **1304**, the device **100** can send a directive to the computer system **1104** to execute the big brother application identified or associated with the metadata **8300**, in the data structure **8304**. Thus, the device **100** can read the identifier, in column **8324**, and send that information to the computer system **1104** to execute that big brother application. Further, the device **100** may read the state information included in column **8328** to determine what state information to send to the computer system **1104** to properly execute the window in display **1304**.

An application may be introduced to either a device **100** or the computer system **1104**. When a new application or some other change to the configuration of the device **100** or computer system **1104** is made, a new association between a device application and a big brother application may be made. For example, if application **8340** is recently introduced to the device **100**, the device **100** may automatically determine that there is a big brother application, application **8344** on the computer system **1104** that should be associated as a big brother application. Thus, if a new application is installed, the device **100** may create a new row or item in the data structure **8304** making the association and determining the metadata for the association in the data structure **8304**.

While the exemplary aspects, embodiments, and/or configurations illustrated herein show the various components of the system collocated, certain components of the system can be located remotely, at distant portions of a distributed network, such as a LAN and/or the Internet, or within a dedicated system. Thus, it should be appreciated, that the components of the system can be combined in to one or more devices, such as a tablet-like device, or collocated on a particular node of a distributed network, such as an analog and/or digital telecommunications network, a packet-switch network, or a circuit-switched network. It will be appreciated from the preceding description, and for reasons of computational efficiency, that the components of the system can be arranged at any location within a distributed network of components without affecting the operation of the system. For example, the various components can be located in a switch such as a PBX and media server, gateway, in one or more communications devices, at one or more users' premises, or some combination thereof. Similarly, one or more functional portions of the system could be distributed between a telecommunications device(s) and an associated computing device.

Furthermore, it should be appreciated that the various links connecting the elements can be wired or wireless links, or any combination thereof, or any other known or later developed element(s) that is capable of supplying and/or communicating data to and from the connected elements. These wired or wireless links can also be secure links and may be capable of communicating encrypted information. Transmission media used as links, for example, can be any suitable carrier for electrical signals, including coaxial cables, copper wire and fiber optics, and may take the form of acoustic or light waves, such as those generated during radio-wave and infra-red data communications.

Also, while the flowcharts have been discussed and illustrated in relation to a particular sequence of events, it should be appreciated that changes, additions, and omissions to this sequence can occur without materially affecting the operation of the disclosed embodiments, configuration, and aspects.

In yet another embodiment, the systems and methods of this disclosure can be implemented in conjunction with a special purpose computer, a programmed microprocessor or microcontroller and peripheral integrated circuit element(s), an ASIC or other integrated circuit, a digital signal processor, a hard-wired electronic or logic circuit such as discrete element circuit, a programmable logic device or gate array such as PLD, PLA, FPGA, PAL, special purpose computer, any comparable means, or the like. In general, any device(s) or means capable of implementing the methodology illustrated herein can be used to implement the various aspects of this disclosure. Exemplary hardware that can be used for the disclosed embodiments, configurations and aspects includes computers, handheld devices, telephones (e.g., cellular, Internet enabled, digital, analog, hybrids, and others), and other hardware known in the art. Some of these devices include processors (e.g., a single or multiple microprocessors), memory, nonvolatile storage, input devices, and output devices. Furthermore, alternative software implementations including, but not limited to, distributed processing or component/object distributed processing, parallel processing, or virtual machine processing can also be constructed to implement the methods described herein.

In yet another embodiment, the disclosed methods may be readily implemented in conjunction with software using object or object-oriented software development environments that provide portable source code that can be used on a variety of computer or workstation platforms. Alternatively, the disclosed system may be implemented partially or fully in hardware using standard logic circuits or VLSI design. Whether software or hardware is used to implement the systems in accordance with this disclosure is dependent on the speed and/or efficiency requirements of the system, the particular function, and the particular software or hardware systems or microprocessor or microcomputer systems being utilized.

In yet another embodiment, the disclosed methods may be partially implemented in software that can be stored on a storage medium, executed on programmed general-purpose computer with the cooperation of a controller and memory, a special purpose computer, a microprocessor, or the like. In these instances, the systems and methods of this disclosure can be implemented as program embedded on personal computer such as an applet, JAVA® or CGI script, as a resource residing on a server or computer workstation, as a routine embedded in a dedicated measurement system, system component, or the like. The system can also be implemented by physically incorporating the system and/or method into a software and/or hardware system.

Although the present disclosure describes components and functions implemented in the aspects, embodiments, and/or configurations with reference to particular standards and protocols, the aspects, embodiments, and/or configurations are not limited to such standards and protocols. Other similar standards and protocols not mentioned herein are in

existence and are considered to be included in the present disclosure. Moreover, the standards and protocols mentioned herein and other similar standards and protocols not mentioned herein are periodically superseded by faster or more effective equivalents having essentially the same functions. Such replacement standards and protocols having the same functions are considered equivalents included in the present disclosure.

The present disclosure, in various aspects, embodiments, and/or configurations, includes components, methods, processes, systems and/or apparatus substantially as depicted and described herein, including various aspects, embodiments, configurations embodiments, subcombinations, and/or subsets thereof. Those of skill in the art will understand how to make and use the disclosed aspects, embodiments, and/or configurations after understanding the present disclosure. The present disclosure, in various aspects, embodiments, and/or configurations, includes providing devices and processes in the absence of items not depicted and/or described herein or in various aspects, embodiments, and/or configurations hereof, including in the absence of such items as may have been used in previous devices or processes, e.g., for improving performance, achieving ease and\or reducing cost of implementation.

The foregoing discussion has been presented for purposes of illustration and description. The foregoing is not intended to limit the disclosure to the form or forms disclosed herein. In the foregoing Detailed Description for example, various features of the disclosure are grouped together in one or more aspects, embodiments, and/or configurations for the purpose of streamlining the disclosure. The features of the aspects, embodiments, and/or configurations of the disclosure may be combined in alternate aspects, embodiments, and/or configurations other than those discussed above. This method of disclosure is not to be interpreted as reflecting an intention that the claims require more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive aspects lie in less than all features of a single foregoing disclosed aspect, embodiment, and/or configuration. Thus, the following claims are hereby incorporated into this Detailed Description, with each claim standing on its own as a separate preferred embodiment of the disclosure.

Moreover, though the description has included description of one or more aspects, embodiments, and/or configurations and certain variations and modifications, other variations, combinations, and modifications are within the scope of the disclosure, e.g., as may be within the skill and knowledge of those in the art, after understanding the present disclosure. It is intended to obtain rights which include alternative aspects, embodiments, and/or configurations to the extent permitted, including alternate, interchangeable and/or equivalent structures, functions, ranges or steps to those claimed, whether or not such alternate, interchangeable and/or equivalent structures, functions, ranges or steps are disclosed herein, and without intending to publicly dedicate any patentable subject matter.

What is claimed is:

1. A method, comprising:

providing a device with a first display;

providing a computer system with a second display;

docking the device to the computer system to form a unified system;

generating a unified desktop for the unified system, the unified desktop including at least a first user interface displayed on the first display of the device and a second user interface displayed on the second display of the computer system;

receiving a first user interface input on the first user interface;

in response to receiving the first user interface input, displaying a first application manager interface on the first user interface that includes thumbnails associated with each of at least two application windows displayed on the unified desktop;

receiving a second user interface input on the second user interface;

in response to receiving the second user interface input, displaying a second application manager interface on the second user interface that includes thumbnails associated with each of the at least two application windows displayed on the unified desktop;

receiving a third user interface input in the second application manager interface; and

in response to the third user interface input:

reordering two or more thumbnails in the second application manager interface;

reordering two or more thumbnails in the first application manager interface that correspond to the two or more reordered thumbnails in the second application manager interface; and

changing, in the unified desktop, a display of the two or more application windows associated with the two or more reordered thumbnails.

2. The method of claim **1**, wherein the device further includes a second device display.

3. The method of claim **2**, wherein the device further includes a first screen with the first display and a second screen with the second device display.

4. The method of claim **1**, wherein a display order of the thumbnails in the first application manager interface is similar to a display order of the thumbnails in the second application manager interface.

5. The method of claim **4**, wherein the first application manager interface and the second application manager interface display thumbnails for all executing applications, and wherein the second application manager interface includes a first portion and a second portion, the first portion to display thumbnails of application windows displayed on the first user interface and the second portion to display thumbnails of application windows displayed on the second user interface.

6. The method of claim **5**, wherein a first window of a first application is displayed on the first user interface and a second window of a second application is displayed on the second user interface, and wherein a first thumbnail associated with the first window is displayed in the first portion of the second application manager and a second thumbnail associated with the second window is displayed in the second portion of the second application manager.

7. The method of claim **6**, wherein the first application is a device focus application and the second application is a computer system focus application.

8. The method of claim **7**, wherein both the first application manager interface and the second application manager interface display thumbnails for the first application differently than thumbnails for the second application.

9. The method of claim **8**, wherein the first application is an Android application.

10. The method of claim **8**, wherein the second application is an Android application or a personal computer productivity application.

11. A unified system, comprising:
a device comprising:
a first screen with a first display;
a first memory; and
a first processor;
a computer system comprising:
a second screen with a second display;
a second memory; and
a second processor, wherein the device is docked with the computer system to form the unified system including a first user interface displayed on the first display of the device and a second user interface displayed on the second display of the computer system; and
wherein the unified system is configured to:
display windows associated with open applications on the first and second user interfaces;
receive a first user interface input on the first user interface;
in response to receiving the first user interface input, display a first application manager interface on the first user interface that includes thumbnails associated with windows displayed on the first and second user interfaces;
receive a second user interface input on the second user interface;
in response to receiving the second user interface input, display a second application manager interface on the second user interface that includes thumbnails associated with windows displayed on the first and second user interfaces;
receive a third user interface input in the second application manager interface; and;
in response to the third user interface input:
reorder two or more thumbnails in the second application manager interface;
reorder two or more thumbnails in the first application manager interface that correspond to the two or more thumbnails reordered in the second application manager interface; and
change, in the first and second user interfaces, a display of two or more application windows associated with the two or more reordered thumbnails.

12. The unified system of claim 11, wherein an order of the thumbnails in the first application manager interface is similar to an order of thumbnails in the second application manager interface.

13. The unified system of claim 11, wherein one or more windows of open applications displayed on the first user interface are device-focused and one or more windows of open applications displayed on the second user interface are computer system-focused.

14. The unified system of claim 13, wherein the one or more device-focused applications are Android applications and the one or more computer system-focused are one or more of Android applications and personal computer productivity applications.

15. The unified system of claim 11, wherein the second application manager interface includes a first portion and a second portion, the first portion to display thumbnails of windows displayed on the first user interface and the second portion to display thumbnails of windows displayed on the second user interface.

16. A non-transitory computer readable medium having stored thereon computer-executable instructions that cause a processor to execute a method for providing a unified desktop for a unified system, the computer-executable instructions comprising:
upon docking a device with a computer system, instructions to generate the unified desktop for the unified system, wherein the unified desktop includes a first user interface displayed on a first display of the device and a second user interface displayed on a second display of the computer system;
instructions to receive a first user interface input on the first user interface;
in response to receiving the first user interface input, instructions to display a first application manager interface on the first user interface, the first application manager interface displaying thumbnails that correspond to windows of open applications displayed on the first user interface and the second user interface;
instructions to receive a second user interface input on the second user interface;
in response to receiving the second user interface input, instructions to display a second application manager interface on the second user interface, the second application manager interface displaying thumbnails of the windows of open applications displayed on the first user interface and the second user interface;
instructions to receive a third user interface input in one of the first user interface and the second user interface; and
in response to the third user interface input:
instructions to reorder two or more thumbnails in each of the first and second application manager interfaces; and
instruction to change, in the unified desktop, a display of the two or more windows corresponding to the two or more reordered thumbnails.

17. The non-transitory computer readable medium of claim 16, wherein an order of the thumbnails in the first application manager interface is similar to an order of the thumbnails in the second application manager interface.

18. The non-transitory computer readable medium of claim 16, wherein one or more windows displayed on the first user interface are associated with device-focused applications and one or more windows displayed on the second user interface are associated with computer system-focused applications.

19. The non-transitory computer readable medium of claim 16, wherein visual indicia of the thumbnails in the second application manager interface that correspond to windows displayed on the first user interface is different from visual indicia of the thumbnails in the second application manager interface that correspond to windows displayed on the second user interface.

20. The non-transitory computer readable medium of claim 18, wherein one or more thumbnails of the computer system-focused applications in the first application manager interface and the second application manager interface are grouped together, and wherein one or more thumbnails of the device-focused applications in the first application manager interface and the second application manager interface are also grouped together.
