To so many fine memories of my brother, Mohsen, for his
uncompromising belief in the power of education.

About the Editor-in-Chief

Hossein Bidgoli, Ph.D., is Professor of Management Information Systems at California State University. Dr. Bidgoli helped set up the first PC lab in the United States. He is the author of 43 textbooks, 27 manuals, and over four dozen technical articles and papers on various aspects of computer applications, e-commerce, and information systems, which have been published and presented throughout the world. Dr. Bidgoli also serves as the editor-in-chief of *Encyclopedia of Information Systems*.

Dr. Bidgoli was selected as the California State University, Bakersfield's 2001–2002 Professor of the Year.

Usability Testing: An Evaluation Process for Internet Communications

Preface

The Internet Encyclopedia is the first comprehensive examination of the core topics in the Internet field. *The Internet Encyclopedia*, a three-volume reference work with 205 chapters and more than 2,600 pages, provides comprehensive coverage of the Internet as a business tool, IT platform, and communications and commerce medium. The audience includes the libraries of two-year and four-year colleges and universities with MIS, IT, IS, data processing, computer science, and business departments; public and private libraries; and corporate libraries throughout the world. It is the only comprehensive source for reference material for educators and practitioners in the Internet field.

Education, libraries, health, medical, biotechnology, military, law enforcement, accounting, law, justice, manufacturing, financial services, insurance, communications, transportation, aerospace, energy, and utilities are among the fields and industries expected to become increasingly dependent upon the Internet and Web technologies. Companies in these areas are actively researching the many issues surrounding the design, utilization, and implementation of these technologies.

This definitive three-volume encyclopedia offers coverage of both established and cutting-edge theories and developments of the Internet as a technical tool and business/communications medium. The encyclopedia contains chapters from global experts in academia and industry. It offers the following unique features:

1) Each chapter follows a format which includes title and author, chapter outline, introduction, body, conclusion, glossary, cross references, and references. This unique format enables the readers to pick and choose among various sections of a chapter. It also creates consistency throughout the entire series.
2) The encyclopedia has been written by more than 240 experts and reviewed by more than 840 academics and practitioners chosen from around the world. This diverse collection of expertise has created the most definitive coverage of established and cutting edge theories and applications in this fast-growing field.
3) Each chapter has been rigorously peer reviewed. This review process assures the accuracy and completeness of each topic.
4) Each chapter provides extensive online and offline references for additional readings. This will enable readers to further enrich their understanding of a given topic.
5) More than 1,000 illustrations and tables throughout the series highlight complex topics and assist further understanding.
6) Each chapter provides extensive cross references. This helps the readers identify other chapters within the encyclopedia related to a particular topic, which provides a one-stop knowledge base for a given topic.
7) More than 2,500 glossary items define new terms and buzzwords throughout the series, which assists readers in understanding concepts and applications.
8) The encyclopedia includes a complete table of contents and index sections for easy access to various parts of the series.
9) The series emphasizes both technical and managerial issues. This approach provides researchers, educators, students, and practitioners with a balanced understanding of the topics and the necessary background to deal with problems related to Internet-based systems design, implementation, utilization, and management.
10) The series has been designed based on the current core course materials in several leading universities around the world and current practices in leading computer- and Internet-related corporations. This format should appeal to a diverse group of educators, practitioners, and researchers in the Internet field.

We chose to concentrate on fields and supporting technologies that have widespread applications in the academic and business worlds. To develop this encyclopedia, we carefully reviewed current academic research in the Internet field at leading universities and research institutions around the world. Management information systems, decision support systems (DSS), supply chain management, electronic commence, network design and management, and computer information systems (CIS) curricula recommended by the Association of Information Technology Professionals (AITP) and the Association for Computing Management (ACM) were carefully investigated. We also researched the current practices in the Internet field used by leading IT corporations. Our work enabled us to define the boundaries and contents of this project.

TOPIC CATEGORIES

Based on our research we identified 11 major topic areas for the encyclopedia:

- Foundation;
- Infrastructure;
- Legal, social, organizational, international, and taxation issues;
- Security issues and measures;
- Web design and programming;
- Design, implementation, and management;
- Electronic commerce;
- Marketing and advertising on the Web;

- Supply chain management;
- Wireless Internet and e-commerce; and
- Applications.

Although these 11 categories of topics are interrelated, each addresses one major dimension of the Internet-related fields. The chapters in each category are also interrelated and complementary, enabling readers to compare, contrast, and draw conclusions that might not otherwise be possible.

Although the entries have been arranged alphabetically, the light they shed knows no bounds. The encyclopedia provides unmatched coverage of fundamental topics and issues for successful design, implementation, and utilization of Internet-based systems. Its chapters can serve as material for a wide spectrum of courses, such as the following:

- Web technology fundamentals;
- E-commerce;
- Security issues and measures for computers, networks, and online transactions;
- Legal, social, organizational, and taxation issues raised by the Internet and Web technology;
- Wireless Internet and e-commerce;
- Supply chain management;
- Web design and programming;
- Marketing and advertising on the Web; and
- The Internet and electronic commerce applications.

Successful design, implementation, and utilization of Internet-based systems require a thorough knowledge of several technologies, theories, and supporting disciplines. Internet and Web technologies researchers and practitioners have had to consult many resources to find answers. Some of these sources concentrate on technologies and infrastructures, some on social and legal issues, and some on applications of Internet-based systems. This encyclopedia provides all of this relevant information in a comprehensive three-volume set with a lively format.

Each volume incorporates core Internet topics, practical applications, and coverage of the emerging issues in the Internet and Web technologies field. Written by scholars and practitioners from around the world, the chapters fall into the 11 major subject areas mentioned previously.

Foundation

Chapters in this group examine a broad range of topics. Theories and concepts that have a direct or indirect effect on the understanding, role, and the impact of the Internet in public and private organizations are presented. They also highlight some of the current issues in the Internet field. These articles explore historical issues and basic concepts as well as economic and value chain concepts. They address fundamentals of Web-based systems as well as Web search issues and technologies. As a group they provide a solid foundation for the study of the Internet and Web-based systems.

Infrastructure

Chapters in this group explore the hardware, software, operating systems, standards, protocols, network systems, and technologies used for design and implementation of the Internet and Web-based systems. Thorough discussions of TCP/IP, compression technologies, and various types of networks systems including LANs, MANS, and WANs are presented.

Legal, Social, Organizational, International, and Taxation Issues

These chapters look at important issues (positive and negative) in the Internet field. The coverage includes copyright, patent and trademark laws, privacy and ethical issues, and various types of cyberthreats from hackers and computer criminals. They also investigate international and taxation issues, organizational issues, and social issues of the Internet and Web-based systems.

Security Issues and Measures

Chapters in this group provide a comprehensive discussion of security issues, threats, and measures for computers, network systems, and online transactions. These chapters collectively identify major vulnerabilities and then provide suggestions and solutions that could significantly enhance the security of computer networks and online transactions.

Web Design and Programming

The chapters in this group review major programming languages, concepts, and techniques used for designing programs, Web sites, and virtual storefronts in the e-commerce environment. They also discuss tools and techniques for Web content management.

Design, Implementation, and Management

The chapters in this group address a host of issues, concepts, theories and techniques that are used for design, implementation, and management of the Internet and Web-based systems. These chapters address conceptual issues, fundamentals, and cost benefits and returns on investment for Internet and e-business projects. They also present project management and control tools and techniques for the management of Internet and Web-based systems.

Electronic Commerce

These chapters present a thorough discussion of electronic commerce fundamentals, taxonomies, and applications. They also discuss supporting technologies and applications of e-commerce inclining intranets, extranets, online auctions, and Web services. These chapters clearly demonstrate the successful applications of the Internet and Web technologies in private and public sectors.

Marketing and Advertising on the Web

The chapters in this group explore concepts, theories, and technologies used for effective marketing and advertising on the Web. These chapters examine both qualitative and quantitative techniques. They also investigate the emerging technologies for mass personalization and customization in the Web environment.

Supply Chain Management

The chapters in this group discuss the fundamentals concepts and theories of value chain and supply chain management. The chapters examine the major role that the Internet and Web technologies play in an efficient and effective supply chain management program.

Wireless Internet and E-commerce

These chapters look at the fundamental concepts and technologies of wireless networks and wireless computing as they relate to the Internet and e-commerce operations. They also discuss mobile commerce and wireless marketing as two of the growing fields within the e-commerce environment.

Applications

The Internet and Web-based systems are everywhere. In most cases they have improved the efficiency and effectiveness of managers and decision makers. Chapters in this group highlight applications of the Internet in several fields, such as accounting, manufacturing, education, and human resources management, and their unique applications in a broad section of the service industries including law, law enforcement, medical delivery, health insurance and managed care, library management, nonprofit organizations, banking, online communities, dispute resolution, news services, public relations, publishing, religion, politics, and real estate. Although these disciplines are different in scope, they all utilize the Internet to improve productivity and in many cases to increase customer service in a dynamic business environment.

Specialists have written the collection for experienced and not-so-experienced readers. It is to these contributors that I am especially grateful. This remarkable collection of scholars and practitioners has distilled their knowledge into a fascinating and enlightening one-stop knowledge base in Internet-based systems that "talk" to readers. This has been a massive effort but one of the most rewarding experiences I have ever undertaken. So many people have played a role that it is difficult to know where to begin.

I should like to thank the members of the editorial board for participating in the project and for their expert advice on the selection of topics, recommendations for authors, and review of the materials. Many thanks to the more than 840 reviewers who devoted their times by proving advice to me and the authors on improving the coverage, accuracy, and comprehensiveness of these materials.

I thank my senior editor at John Wiley & Sons, Matthew Holt, who initiated the idea of the encyclopedia back in spring of 2001. Through a dozen drafts and many reviews, the project got off the ground and then was managed flawlessly by Matthew and his professional team. Matthew and his team made many recommendations for keeping the project focused and maintaining its lively coverage. Tamara Hummel, our superb editorial coordinator, exchanged several hundred e-mail messages with me and many of our authors to keep the project on schedule. I am grateful to all her support. When it came to the production phase, the superb Wiley production team took over. Particularly I want to thank Deborah DeBlasi, our senior production editor at John Wiley & Sons, and Nancy J. Hulan, our project manager at TechBooks. I am grateful to all their hard work.

Last, but not least, I want to thank my wonderful wife Nooshin and my two lovely children Mohsen and Morvareed for being so patient during this venture. They provided a pleasant environment that expedited the completion of this project. Nooshin was also a great help in designing and maintaining the author and reviewer databases. Her efforts are greatly appreciated. Also, my two sisters Azam and Akram provided moral support throughout my life. To this family, any expression of thanks is insufficient.

Guide to the Internet Encyclopedia

The Internet Encyclopedia is a comprehensive summary of the relatively new and very important field of the Internet. This reference work consists of three separate volumes and 205 chapters on various aspects of this field. Each chapter in the encyclopedia provides a comprehensive overview of the selected topic intended to inform a board spectrum of readers ranging from computer professionals and academicians to students to the general business community.

In order that you, the reader, will derive the greatest possible benefit from *The Internet Encyclopedia,* we have provided this Guide. It explains how the information within the encyclopedia can be located.

ORGANIZATION

The Internet Encyclopedia is organized to provide maximum ease of use for its readers. All of the chapters are arranged in alphabetical sequence by title. Chapters titles that begin with the letters A to F are in Volume 1, chapter titles from G to O are in Volume 2, and chapter titles from P to Z are in Volume 3. So that they can be easily located, chapter titles generally begin with the key word or phrase indicating the topic, with any descriptive terms following. For example, "Virtual Reality on the Internet: Collaborative Virtual Reality" is the chapter title rather than "Collaborative Virtual Reality."

Table of Contents

A complete table of contents for the entire encyclopedia appears in the front of each volume. This list of titles represents topics that have been carefully selected by the editor-in-chief, Dr. Hossein Bidgoli, and his colleagues on the Editorial Board.

Following this list of chapters by title is a second complete list, in which the chapters are grouped according to subject area. The encyclopedia provides coverage of 11 specific subject areas, such as E-commerce and Supply Chain Management. Please see the Preface for a more detailed description of these subject areas.

Index

The Subject Index is located at the end of Volume 3. This index is the most convenient way to locate a desired topic within the encyclopedia. The subjects in the index are listed alphabetically and indicate the volume and page number where information on this topic can be found.

Chapters

Each chapter in *The Internet Encyclopedia* begins on a new page, so that the reader may quickly locate it. The author's name and affiliation are displayed at the beginning of the article.

All chapters in the encyclopedia are organized according to a standard format, as follows:

- Title and author,
- Outline,
- Introduction,
- Body,
- Conclusion,
- Glossary,
- Cross References, and
- References.

Outline

Each chapter begins with an outline indicating the content to come. This outline provides a brief overview of the chapter so that the reader can get a sense of the information contained there without having to leaf through the pages. It also serves to highlight important subtopics that will be discussed within the chapter. For example, the chapter "Computer Literacy" includes sections entitled Defining a Computer, Categories of Computers According to Their Power, and Classes of Data Processing Systems. The outline is intended as an overview and thus lists only the major headings of the chapter. In addition, lower-level headings will be found within the chapter.

Introduction

The text of each chapter begins with an introductory section that defines the topic under discussion and summarizes the content. By reading this section the readers get a general idea about the content of a specific chapter.

Body

The body of each chapter discusses the items that were listed in the outline section.

Conclusion

The conclusion section provides a summary of the materials discussed in each chapter. This section imparts to the readers the most important issues and concepts discussed within each chapter.

Glossary

The glossary contains terms that are important to an understanding of the chapter and that may be unfamiliar to the reader. Each term is defined in the context of the particular chapter in which it is used. Thus the same term may be defined in two or more chapters with the detail of the definition varying slightly from one to another. The encyclopedia includes approximately 2,500 glossary terms.

For example, the article "Computer Literacy" includes the following glossary entries:

Computer A machine that accepts data as input, processes the data without human interference using a set of stored instructions, and outputs information. Instructions are step-by-step directions given to a computer for performing specific tasks.

Computer generations Different classes of computer technology identified by a distinct architecture and technology; the first generation was vacuum tubes, the second transistors, the third integrated circuits, the fourth very-large-scale integration, and the fifth gallium arsenide and parallel processing.

Cross References

All the chapters in the encyclopedia have cross references to other chapters. These appear at the end of the chapter, following the text and preceding the references. The cross references indicate related chapters which can be consulted for further information on the same topic. The encyclopedia contains more than 2,000 cross references in all. For example, the chapter "Java" has the following cross references:

JavaBeans and Software Architecture; Software Design and Implementation in the Web Environment.

References

The reference section appears as the last element in a chapter. It lists recent secondary sources to aid the reader in locating more detailed or technical information. Review articles and research papers that are important to an understanding of the topic are also listed. The references in this encyclopedia are for the benefit of the reader, to provide direction for further research on the given topic. Thus they typically consist of one to two dozen entries. They are not intended to represent a complete listing of all materials consulted by the author in preparing the chapter. In addition, some chapters contain a Further Reading section, which includes additional sources readers may wish to consult.

G

Game Design: Games for the World Wide Web

Bruce R. Maxim, *University of Michigan–Dearborn*

INTRODUCTION

Programming computers to play games attracted the interest of such computer scientists as Babbage, Turing, and Shannon long before the first personal computers (PCs) came into existence. When personal computers and dedicated game consoles became widely available, in the 1970s, large numbers of computer game titles appeared in the marketplace almost immediately. Some people have argued that the computational expectations of modern computer game players pushed PC hardware manufacturers to increase the multimedia processing power of the home computer. The advent of the Internet and its rapid spread to homes throughout the world similarly has attracted the attention of game designers seeking to create multiplayer games among widely dispersed users. Creating games intended to run on the World Wide Web requires a good understanding of the principles used to design games for stand-alone computers, as well as knowledge about network architecture and client/server computing. This chapter discusses some of the design principles and challenges posed by developing games for the World Wide Web.

ECONOMIC IMPACT OF COMPUTER GAME INDUSTRY

The computer game industry has had gross sales in excess of 7 billion dollars since 1998 (Sawyer, Dunne, & Berg, 1998). Some industry analysts have predicted that sometime during the next ten years computer game play will be the most popular means of family entertainment. Indeed, by some estimates, computer game sales may have exceeded motion picture revenues for the year 2001. A recent survey showed that the average age of computer game buyers is about 31 years old (WINNY, 2000). Computer game development is serious business. Major game development projects often have production budgets exceeding 2 million dollars for a single title and sequels abound.

The Internet has the potential to allow game developers to increase their share of the entertainment market as the number of households having access to the World Wide Web continues to grow. Users of the World Wide Web can download commercial games to play on their personal computers, participate in multiplayer games online, and find support communities for their favorite games. There are several online game services that derive their sole income from providing access to Internet games for a fee (Morrison, 1996). Many of the console game manufacturers have promised some type of Internet connectivity in their new product lines. A number of successful educational computer games are being ported to the Internet.

A recent survey of information systems managers found that 90% of them have access to games at work and that 58% play games at work several times a week (WINNY, 2000). Easy access to the Internet has encouraged software piracy by some people. In addition to lost worker productivity, chief information officers are finding that their corporate servers are being used by some employees as repositories for the exchange of pirated software, which exposes the company to prosecution for distributing unlicensed copies of software. Many people feel that downloading software from the Internet is a major source of computer viruses in the work place. Computer viruses have a reputation for destroying information stored on computers, and a significant amount of time is often required to remove them and have their damage repaired.

There is some evidence that computer game playing can be psychologically addictive, encourages violent behavior among young children, and can cause repetitive stress injuries. There is also some evidence that playing computer games can increase hand–eye coordination, raise a person's self-esteem, and help children learn to deal with the complexities found in real-life situations (WINNY, 2000).

ELEMENTS OF COMPUTER GAMES

Not every game lends itself easily to online play. Multiplayer games in which players take turns moving and single-player games in which players complete against a computer opponent possessing artificial intelligence seem to be the easiest to adapt to Internet play. One reason for choosing to play a game on the Internet is to experience the interaction with game players around the world. The key to developing a good game is to give players interesting challenges to overcome. The solutions to these challenges should be intuitive to the players and should gradually increase in difficulty. This allows a game to be learned as the player's skill increases. A game that produces random results for a given input may not be perceived as an entertaining game.

Genre

The term genre, as used in this chapter, describes a game type. There are many types of computer games. Use of the term genre is a bit controversial among game designers. Some game designers do not believe it is possible to classify every game as belonging to a single genre. Games from the same genre tend to share many attributes (role of the player, use of animation, user interface style, etc.). Although there is no single agreed-upon list of genre names, a list proposed by LaMothe (1999) appears in Table 1.

Story Line

Most games use some sort of story line to enhance the game. The story line may provide background to give players contexts for their actions (e.g., shooters) or it may actually serve as a script (e.g., role-playing games or interactive fiction) to govern the interactive flow of the game (Sawyer et al., 1998). Linear story lines have only one possible path to a successful outcome. Nonlinear story lines allow players to choose different routes to follow during the course of game play and may even have different endings, based on the decisions made by each player. It is usually good to make the player feel that his or her actions during the game affect the game's (and the story's) ultimate outcome.

Puzzles

In stand-alone games, people are more likely to evaluate a game according to the quality of its story line and graphics rather than the cleverness of its puzzles. However, ingenious puzzles are the heart of interactive fiction or role-playing games. Good puzzles can enhance the story line for any game and can assist with character development. Good puzzles can make a good game great, by giving players small challenges to keep them interested in the game while working toward game completion. Bad puzzles can interfere with the player's progress toward goals and can prevent players from immersing themselves in the story.

Several types of puzzles can be found in computer games. Puzzles may require players to push buttons to copy sequences or discover patterns. Players may be required to start or stop sequences of actions within a specified time period. A game may require users to construct a puzzle solution by combining clues or following a trail of evidence like a detective. Sometimes puzzles may take the form of word searches, magic squares, or riddles. These types of puzzles challenge players, and their performance is likely to improve with practice. This keeps players coming back to play again. Puzzles that rely solely on brute force solutions or excessive trial and error tend to discourage players from returning to play again. Puzzles with random results that depend solely on luck and little skill can also make players lose interest in a game.

User Interface

Players expect games to have graphical user interfaces, even if the game does not involve direct manipulation of game objects (Brown, 2000). Most games found on the Internet are designed to run either from inside a Web browser window or from a dedicated game server. Games designed to run inside a browser window allow the game designer to make use of a user platform that is relatively machine independent with regard to displaying game graphics and animation. Games designed to run from a dedicated server often require a platform-dependent client program to be running on each player's machine. The client program would typically handle user input and display-of-game information sent by the server.

Games that involve graphical simulations of real-world actions need to have believable behavior, but designers need to remember that they do not need to build a perfect physical model to create fun games. Most physical actions can be approximated assuming simple Newtonian physics and rigid body elastic collisions. In many games, designers may be able to simplify the detection of collisions between screen objects by focusing on an object's center of mass and surrounding it with a rectangular bounding box. In a two-dimensional (2D) graphical system, object collisions are indicated any time the bounding box surrounding one object enters the area surrounded by the bounding box on another object. This allows the game program to speed up the graphical display of the effects of object interactions. Using discrete-simulation (constant step) techniques can

Table 1 Selected Game Genres

GENRE	EXAMPLE	CHARACTERISTICS
Interactive Fiction	Tomb Raider	May be either text based or involve 3D graphics; games are scripted to show that the solution of each puzzle leads players down predetermined paths until the game ends or the user quits
Fighting Games	WWF Warzone	Usually involves one or two players locked in mortal combat; requires fast computer response time and usually contains realistic graphics to depict violent actions
Puzzle and Card Games	Tetris	Classic turn-based board games, card games, or puzzles played by one or more players using a computer keyboard or mouse for input and 2D graphics displays
Role-Playing Games	Ever Quest	One or more players assume the roles of characters who are allowed to interact with each other and with objects in the environment; artificial intelligence techniques are employed to create computer-controlled nonplayer characters who interact with the human-controlled characters; combat between players and solution of puzzles is often part of the game; often players are required use their own judgment to equip themselves prior to beginning a grand quest
God Games	Roller Coaster Tycoon	Often implemented as turn based, graphical simulations in which the player has a chance to set the parameters for simulation and where computer animation is used to display the impact of these decisions over a compressed time period
Simulations	Microsoft Flight Simulator	Driving- or flight-simulator-type games; often makes use of 3D graphics and requires moderately fast real-time display of the response to player actions
Arcade Games and Shooters	Pac Man	Computer versions of classic arcade games; usually involve 2D graphics and have one or two players shoot at objects or each other with laser-type weapons
Sports Games	Madden NFL	Graphical simulations of individual or team-based sporting events; computer uses artificial intelligence to control most players in team sports; make heavy use of multimedia in user interface designs
Military/Strategy Games	Final Fantasy	Similar to god games or interactive fiction with 2D graphical output; may involve more than one player

also help with synchronization of simultaneous events. In discrete simulation, the effects of simultaneous events in a given time unit are modeled offline and displayed for the user as if they occurred at the same time (LaMothe, 1998).

User interaction devices for Internet games tend to be limited to the mouse and the keyboard, because these represent the base-level devices in the Unix world, where a majority of the World Wide Web servers live. For multiplayer games, text and voice communication between players seems to be an important social aspect of games (Munkki, 1997). This communication may take the form of requests for technical support or it may simply be "trash talking." Although text communication only requires the use of the keyboard, voice communication requires the presence of a microphone and speakers on each player's machine.

Besides graphics and computer animation, multimedia elements that have become part of computer games include sound, music, and video. Sound and music can enhance the story line of a game in the same way they do movies. Typically, making use of most multimedia formats in a browser window requires the user to download and install a plug-in on his or her local machine for each media type used. One of the challenging aspects of working with both video and sound in computer games is synchronizing video stream with audio stream so that they seem to be taking place at the same time. The network bandwidth required for streaming either video or audio is substantial for local area networks. The latency or lag time associated with the Internet further complicates the task of media synchronization (Ng, 1997a,b).

Artificial Intelligence

Developing computer opponents for turn-based games was one of the earliest applications of artificial intelligence (AI) by computer scientists. Many of these early computer opponents make use of a static evaluation function that takes a proposed game state as input and returns a numeric value indicating the value of the position of the state. By applying the static evaluation function to each new game state that is reachable from the current game

Table 2 State Transition Table for Robot Guard

CURRENT GAME STATE	EVENT TRIGGER	RESULTING GAME STATE
Move East	Alarm Silent	Move East
Move East	Path Blocked	Move West
Move East	Alarm Activated	Attack Intruder
Attack Intruder	Alarm Activated	Attack Intruder
Attack Intruder	Alarm Silent	Move East
Move West	Alarm Silent	Move West
Move West	Path Blocked	Move East
Move West	Alarm Activated	Attack Intruder

state, the computer opponent can select the alternative with the best numeric value. The performance of computer opponents can be improved by looking ahead two or more moves before applying the static evaluation function. An algorithm like minimax is used to combine the results of the "look ahead" moves (recognizing the fact that each player will be looking for the best move possible).

Another task confronting opponents in combat or sports games is path finding through the game objects displayed on the screen. Nothing exposes weaknesses faster than when a computer opponent allows itself to take the long way around an obstacle when an obviously shorter path is available. Heuristic search techniques like A* (pronounced A star) can be used to avoid time-consuming trial and error searching for paths between game positions (LaMothe, 1999). Sometimes the positions of objects for a particular game state are known in advance and all routes can be precomputed and stored in the game database. This is not an AI technique, but it definitely is one way to speed up game play.

Pursuit of opponents and running away from opponents can often be handled by heuristic techniques based on the distances between player pieces on the game map. If the distance is getting bigger, a pursuit heuristic might be to alter direction to make the distance smaller. If the distance is getting smaller, an evasion heuristic might call for a computer-controlled object to do whatever is needed to increase the distance from the pursuing piece. This type of heuristic is fairly effective for simple objects such as rocks or missiles. For slightly more intelligent objects (such as birds or spaceships), some random behavior might be added every few moves to make the computer-controlled pieces seem more realistic. Movement patterns might also be used to govern the behavior of patrolling guards or prowling animals (LaMothe, 1999).

For important game elements, such as computer-controlled characters in role-playing games or interactive fiction, more advanced AI techniques might be used. Finite-state machines or production systems are good for modeling event-driven computing systems. Finite-state machines only require knowledge of the current game state and the most recent user input or game event to determine the next state of computation. This requires careful analysis of the system states and their relationships, but it can be a very effective way to make a computer-controlled character appear to react intelligently to each game situation. Finite-state machines can be represented graphically or by using state transition tables. Table 2 contains a state transition table that might be used for a robot guard in a combat game. One way to avoid repetitive behavior is to give a computer-controlled character some means of remembering previous actions and allowing them to vary them from time to time (LaMothe, 1999).

Many people would insist that an intelligent computer system should be capable of learning from its mistakes. Neural networks and genetic algorithms used in computer games allow computer opponents to improve their performance based on past game experiences. Even early checkers-playing programs made use of numerical learning techniques similar to these approaches to improve game play.

ROLE OF THE WORLD WIDE WEB IN COMPUTER GAME PRODUCTION

Game Archives

Using any Internet search engine and typing in the search string "computer games," one is likely to find several million hits. Some sites may simply allow visitors to download games to be installed on their personal computers. Some of these games may be freeware, given away by developers, or they may be shareware, in which developers trust users to send voluntary donations to offset development costs. These games may be free demonstration versions of games that can purchased either online or in local retail stores. Some of these sites also provide support resources for both game players and game developers. Some of these sites may provide visitors with opportunities to play games online without needing to install them on their own personal computers.

User Support Communities

Many companies make Web-based user support resources available to registered owners of their products. Game companies are no exception. Online registration of products is an option commonly included during the installation of many computer games. Game owners are often put on electronic company mailing lists and are promised notification regarding software bug fixes (patches) and new product releases. Software companies may also provide access to technical support to assist users with game installation problems or help them download software patches and missing or updated device drivers. Some games may use the Internet to automatically download and install new versions of game components on the user's machine. Many game companies may also provide online bulletin boards to allow users to share game-playing tips with other players or contact technical support representatives for instant responses to questions. Some multiplayer games make use of the Internet to provide communication between players during actual game play. Game manufacturers are finding that adding online communications components to their games is becoming important for success in the market place (Bernier, 2000). Many games are so popular that the users themselves set up Web sites to share reviews of new games and provide game cheats that show scripted solutions for beating complicated game puzzles. Simply typing the name of a popular game (e.g., Tomb Raider) into a search engine is likely to yield thousands of hits.

Developer Resources

Most game developers insist that knowing their potential users is the key to the success of any game. Communication between geographically widely distributed developer and game users can be easily supported by the World Wide Web. Online entertainment requires interactive participation by its users. Games must evolve, and developers need to filter user feedback into the design of their improved game. The process is very much like user-centered software design. The production value realized by developers of online games and Internet development processes involves game design quality improvement, evolution of multiplayer game technologies, creation of communications mechanisms, and increasing media density or fidelity in the game (Palumbo, 1998). Some companies underestimated expected customer support demands during the launch of a game and found that games sales exceeded the established customer support system. Companies can reduce or eliminate many support problems by having the foresight to create a Web site dedicated to late-breaking game news and user communication (Firor, 2002).

Beta testing is a type of testing where the preliminary release of a software product is made available to a subset of its intended users, who then make use of the product in their own personal computing environments. The beta testers ideally report problems and make suggestions to the software developers prior to product launch. This early user feedback has proved to be an effective means of reducing the number of bugs found after product launch. The use of the Internet can facilitate the distribution of the beta versions of the software, as well as the collection of user reactions to it.

There are several Web sites dedicated to communication between game developers themselves (e.g., Gamasutra). These Web sites allow experts to share technical tips among themselves. Many times, developers will share with the Web audience the lessons learned while developing successful (or unsuccessful) products. The commercial game development community is widely scattered and very volatile. Many companies make use of contract employees on a project-by-project basis. Some Web sites allow visitors to post employment ads and resumes to enable potential employers and employees to find one another as new game development projects are undertaken.

The World Wide Web can also provide sources for software development tools and training for developers. The training may take the form of short, free tutorials or full, semester-long, online courses. These courses may be offered by universities or by commercial companies (e.g., http://www.gameinstitute.com). Java is a popular development language for networked games and is distributed free of charge over the Internet. There are companies (e.g., Mpath) that provide dedicated game service over the Internet (Morrison, 1996). This service is usually provided on a pay-to-play basis to support multiplayer game play. Some companies may license the use of their online game engines or servers to other developers to improve their revenue stream.

Online Games

Online games can be delivered via the Internet or through dedicated game servers on wide area networks with locally installed client software on a player's personal computer. Single-player games are often accessed directly from a Web site and a player communicates with a game from inside his or her Web browser. Game play for single-user games using a Web browser interface is much like game play for single-user games designed for stand-alone PCs, because the game logic may in fact be running on the local PC and not on the server. To display multimedia content, a user is usually required to have the appropriate media plug-ins installed on his or her personal computer. Standard Web technologies (HTML, Javascript, common gateway interface scripts, or Java) might be used to deliver the game output to the Web browser and to process the player's input. To communicate with a dedicated game server, the client program may be implemented using any programming language capable of supporting socket programming. Socket programming is a technique for allowing the exchange of information between two programs running on the same computer network. Browser interfaces to online games have the advantage of allowing for multiplatform game implementation with very little additional effort on the part of the developers.

When people think of online games, they often envision multiplayer games, with several players distributed at distant locations on a local area network or globally connected by the World Wide Web. There are two big problems confronting designers of multiplayer games. The first is difficulty in synchronizing game-state information when multiple instances of the game client software are running simultaneously. The second difficulty is related to the first in that the latency (or response time lags) that occurs as the user inputs and the resulting game consequences need to be shared with players using client software running on independent machines connected by a relatively slow network (the Internet). The types of multiplayer games that are implemented most easily on the Internet are turn-based games or event-based games, because in these, the lags in response times inherent in Internet applications are most easily hidden (Morrison, 1996).

Interactivity and social diversity are two of the most powerful elements of the Internet (Palumbo, 1998). The Internet gives designers a chance to build community followings for their games. This was not done easily before the advent of online games. For some games (e.g., Quake or Diablo), players created their own communities (Min, 2000). Some games (e.g., Fireteam) are based on players recruiting teams to play against similarly recruited teams across the Internet. Many teams stay together for long periods of time and enjoy their inclusion in a cohesive group. Teams may create their own Web sites to coordinate their efforts.

The World Wide Web provides a number of resources and opportunities to both game developers and game players during all phases of the software development cycle. Software can be delivered directly to game players. Games can be played over the Internet. Developers can communicate with each other and their potential user groups during the game development process. Users can make use of the Internet to form their own support groups.

DESIGNING COMPUTER GAMES

Brainstorming

Sometimes the toughest part of building a game is coming up with an idea. Game ideas may come from popular books, movies, sport contests, or board games. Designers often choose one of three possible starting points: genre, technology, or story line (Rouse, 2001). Choosing a genre, many times, determines the type of technology that will be used in the game. The technology used to implement a game may also determine the type of genre that can be used most effectively for a particular game. Often designers choose game technologies because they already exist or because the particular technologies are what the target audience for the game expects.

As with all software engineering endeavors, in game design it is very important to understand the desires of the prospective users. Failing to appreciate the cultural biases of potential players may result in designing a game that sells well in one country and poorly in another. Poor-quality artwork and mediocre animation sequences can cause a game to be rejected by potential purchasers. Poor game play, often caused by the use of inconsistent and unintuitive user interfaces, can also cause a game to fail in the market place. In commercial game sales, the first game of its kind to reach the marketplace and deliver all its promises is usually the big winner financially. Many failed games have been based on obsolete technology or were delivered too late to the marketplace to beat the competition.

Documents

Modern game designers are finding that it is important to treat computer game design in the same way other software engineers approach projects involving large numbers of people and significant investments of time. Game developers are likely to use evolutionary software process models (e.g., rapid prototyping) to mange their development risks and reduce their project completion times. This means that the game may be built incrementally, starting with a small version of the game and adding features to each increment. Each increment will have defined requirements, design goals, and project and testing goals. This requires that formal project documents be developed early in the project and revised often.

The first project document developed for a game is sometimes called a game treatment. The purpose of the game treatment is to sell the game idea to potential investors or to a development team considering which project to undertake next (Lewindowski, 1999). The most important point to convey is what it is like to actually play the game. The player's role and allowed actions in the game should be described, as well as the behavior of computer-controlled characters and objects. The intended audience for the game also needs to be identified. The game story line should be summarized, along with the major and minor goals to be achieved by players. The proposed game-delivery platforms (hardware and software) should be described. The technology (production tools) required to implement the game should be described as well. The introduction of multimedia elements, such as 3D graphics or CD-quality music, increases the complexity of the development task, as do plans to make use of client/server technology to allow multiplayer, networked game play. It is very important to ensure that the proposed game-playing environment be readily accessible to the intended game audience.

The game treatment must be written in sufficient detail to allow potential investors or collaborators to decide whether or not to move forward with this project. The game treatment plays a role similar to a feasibility document in a software engineering project. Many games are developed using a rapid prototyping process. This means that the game treatment will be used as the initial-requirements definition for the game. Prior to accepting the game as defined in the game treatment, the developers and investors discuss the risks involved. Risks are threats to successful completion of the software development project. Several types of risks need to be considered. Business risks are concerned with the marketing and profitability of a product. Technical risks are concerned with the implementation of the software product. Project risks are concerned with threats to the project budget and development schedule. The game treatment may be modified or rejected based on consideration of each of these risks.

All software projects need to have written design documents to work from before any programming work begins, and games are no exception. The design document created for evolutionary process models used for software projects such as computer game programming or Web site design will most likely to be a dynamic living document that changes with the project as implementation proceeds. So it is not necessary to specify every detail of every game algorithm or data structure before programming activities begin. However, to avoid unnecessary rework of software products, a clear understanding of the game's overall direction must be held by all development team members as they begin working on the project.

For games that have more than a single action screen, a storyboard is often developed. Animators and movie writers use storyboards to provide a visual layout of the key scenes that will be shown to the audience. Game designers make use of storyboards to show a sequence of 6–12 key scenes from the game, along with notes describing the multimedia elements and game actions that will accompany each scene.

A flowchart may be used to show how the linear sequence of screens displayed in the storyboard may be interrupted by user actions or computer-generated game events during the course of game play. Users find games to be more interesting if they are able to vary the plot sequence of the game each time they play. The flowchart defines those places in the game that plot may be varied without destroying the story line completely.

If games have complex characters, a character bible is created, containing every observable fact and describing each character the player will interact with during the game. Sometimes bibliographies are written for each character so that as a game unfolds, a game designer will not make mistakes when displaying these characters and their actions to game players. This helps the user become more immersed in the game as fantasy. Memorable characters can lead to game sequels or can become marketing icons in their own right.

A game script, which is not likely as books or movies to be linear in nature, would be difficult to describe without the tools mentioned previously. Two important elements of the game script include level designs and puzzle details. Game levels are added to give players a sense of goals completion on their way to finishing the game. Level design has become an important specialization in game development. From an economic standpoint, adding levels to an existing game is far less costly than designing a new game.

User interface design takes on a high level of importance in game development projects. One representation of the user interface design consists of the screen displays seen by the user at any given point of the game. A second dimension of the user interface design is creating a flow diagram containing enough detail so that all user actions that trigger game events and their consequences are included. Software engineers call this type of diagram a state transition diagram. Often the user interface is developed as a working prototype for the game. Web page development tools can be particularly helpful in this regard. It is often easy to link Web pages containing the multimedia elements experienced by the user in the nonlinear order they would experience during the course of the game. Animation sequences can be added as they are created. If the game is to be implemented as an Internet game, the amount of throwaway code is minimized.

Game development projects often involve many developers independently producing code simultaneously for different parts of the game system. It is essential to develop a project management plan early in the design cycle to avoid production delays and unnecessary reworking. The project plan needs to clearly identify the people required to complete the game project and the skills that should be possessed by each team member. The hardware, software tools, and consumable materials required for development need to be identified so they can be utilized in a timely manner during game implementation. Once the people and resources required to complete the project are identified, it should be possible to begin to build a budget and a schedule for the project. Software engineers have techniques at their disposal that allow them to accurately predict the cost and duration of software development projects. It is important to utilize these techniques when building a project plan for a game, because games are costly to develop and missing delivery deadlines can be detrimental to a game's success. For example, failing to complete a game tied to a popular movie in time for it to be sold during the Christmas shopping season can make the game an economic failure. Wise game developers will also take the time to analyze their development risks and identify ways of preventing these risks from becoming threats to the completion of the game project. Some of these risks include marketing concerns, technology availability, programming skills, funding, and resource issues.

CREATING GAME CONTENT

Platforms

Online computer games (either single or multiplayer) by definition rely on network communication in one form or another. There are two common models for network communication, peer to peer and client/server. Hybrid models combining the benefits of both also exist (Ng, 1997b). With the client/server communication model, the game logic and database operations tend to be executed on the server machine. The player's machine often only needs to be running a client program that is capable of displaying the current game state based on data sent by the server and of collecting player input to send to the server as needed. Modem-to-modem communication might be thought of as a special case of peer-to-peer networking. In peer-to-peer networking, each player's machine needs to be running its own copy of a game program that is capable of handling both the game logic and the input/output operations required to play the game. Some hybrid models make use of peer-to-peer networking communication, but one of the machines is given the additional task of routing messages among all the game players.

The target delivery platform has great impact on the type of game content that can reasonably be included in a particular game. A game designed for a single player using the client/server communications model may be limited only by the speed of the network connection to the game server. Consequently, for a single user online, a game designer may need only to decide which operating systems and which processor types he or she is interested in supporting. The Windows- and Unix-type operating systems are the most popular target platforms in terms of numbers of users in 2002. Windows operating systems are designed to run on machines that make use of Intel-type processors. Unix operating systems are available for almost every personal computer processor and have nearly identical resources in each implementation. Each operating system tends to support graphics programming in different ways, because the graphic libraries are based on different standards. Each program will need to be recompiled to run on each type of processor, because each processor requires programs to be written using its own unique machine language. Similarly, each operating system supports different types of multimedia. So even if a designer is relying on browser technology that tends to be machine independent, he or she still needs to be aware of which media types will be supported by an operating system and which will not.

The choice of server technology can also be important. Dedicated game servers may give game designers the most control over the delivery of the game content.

They may also make it easier to control access to a game and charge users for its use. If a dedicated game server is not accessible from the Internet, it is harder for users to access without incurring long-distance phone charges. Once game players are connected via the Internet to multiple game servers, the problems of communication latency will begin to appear. This can make it tough to synchronize the display of action sequences that appear to all users at the same time, or even to process user input in a timely manner.

Compilers and Game Engines

Most multimedia games are not developed from scratch. Developers usually rely on a development library that contains tools needed to create graphical user interfaces and manipulate multimedia game objects. Most games written for the PCs are written using Microsoft's Visual C++ programming language and make use of Microsoft's DirectX game-development library. One of the components of DirectX (called DirectPlay) supports peer-to-peer network communication over the Internet. DirectX is not a complete game-development library. To make game programming more efficient, many developers create game engines that contain complete subsystems (like game AI or sprite animation and collision detection or level design templates) out of development library components provided in such products as DirectX. The Microsoft .NET software development tools may make it easier to unify network and desktop computing resources for users of Microsoft products.

DirectX is not a platform or machine-independent software product. Because Unix is such a popular Web-development platform, there is a great deal of interest in using open-systems software products (such as Linux, OpenGL, and gcc) for game development. Indeed, many console games are written using these technologies, so there is a great deal of interest in adding networking to existing console games.

The use of software libraries for game physics and 3D models is a new area of interest for game developers. The use of libraries has not been popular among game developers in the past, because it was felt that their use would reduce the entertainment value of games by making them appear to be shallow copies of one another. Three-dimensional-game architectures, DVD playback systems, and sound systems are changing so rapidly these days that developers cannot afford to develop game software completely from scratch within the desired eight-month development cycle. Consequently, game developers are beginning to view the use of libraries more favorably.

Technologies used for Web-based computing have also been used to implement online games. Web-based computing depends on each computer having a fairly standard Web browser as its primary user interface. This tends to have the advantage of allowing games developed using one operating system or hardware platform to be used on others. Java has been used to implement both single and multiplayer multimedia action games. Javascript and Flash can be used to implement single-player games that have modest graphics and user input requirements. C++ and Perl are popular languages for implementing CGI programming. CGI programming has the advantage of allowing programs to run on the server machine and requiring the client machine to have only a Web browser running on it. This, of course, makes it possible for players to access game programs from several different types of machines.

Multimedia Tools

Computer games typically include three types of multimedia content: visual (pictures, animation, and video), aural (recorded or generated sounds and music), and textual. Multimedia game content is usually created using specialized tools (scanners, digitizers, synthesizers, etc.) as part of the development process. Artwork is often created using computer-based drawing tools or photographs to allow more realistic images to be included in the game display in a shorter time period. Real-time animation sequences may take too long for the computer to generate during game play, and it may be better to display them as prerecorded videos. Designers often need to choose between the level of player control and the amount of time it takes to create the animation dynamically and display it during the game. With sound the opposite may be true; it is sometimes faster to synthesize speech or music rather than record it (even though the fidelity may not be as good).

When a game is to be played over the Internet, designers may find themselves with fewer options for art, video, and sounds. Web browsers may only support the display of .gif or .jpg graphics files and only .au files for sounds. Requiring players to have multimedia plug-ins (e.g., Quicktime video or Microsoft's MediaPlayer) installed on their local machines can mitigate some of these media format limitations.

In many multimedia-computing applications, elements such as sound and music are digitized and stored in separate files. It can be challenging to combine and synchronize the two media streams so that the viewer sees a coherent presentation. Coordinating real-time multimedia streams is not easy and can take a lot of bandwidth. Some of the challenges are related to communications and processing delays that become even more obvious when the Internet is involved. Some techniques for synchronization involve interleaving the data streams, and some may involve embedding time codes to be used by the media player to combine the streams at the appropriate time. The use of technologies such as Quicktime and Realmedia can make the developer's task much simpler.

MULTIPLAYER GAMES AND NETWORKING

There are several attractions to using the Internet to play games. The Internet can make games available to large numbers of users on a round-the-clock basis. The Internet can provide users with the opportunity to build global support communities for particular games and allow direct marketing of game-related items to consumers. (Ng, 1997a). It is harder to add Internet capability to a game after it is written than during the design phase

(Lincroft, 1990). There are several networking issues that must be taken into a count when a multiplayer game is being designed.

Session-Oriented Multiplayer Games

Not every multiplayer game is amenable to delivery on the Internet. In many ways, turn-based games are easier to deploy than fighting games because of inherent latency problems with Internet communications. Even for turn-based games, designers need to decide whether new players can drop in at any time or whether they can join only at fixed points in the game. In session-oriented multiplayer games, new players can join the game only when a new round or a new level of play begins. Sometimes this decision is related to whether the online game is designed to be short in duration or whether it will be a persistent game, which never ends and in which players drop in and out. Designers need to consider what will happen to the lost entities created as players or servers drop out of games. Should an AI take over for a lost entity? Can a backup server replace a lost network connection? In games that last longer than 3 hr, it is important for users to be able to save incomplete games or characters they developed (Ng, 1997a). Whether a game should be saved on the server or on a client machine may depend on the size of the game-state information structure.

Synchronization Problems

With networked game communications, the key problem is synchronizing the sharing of game-state information among several users in a timely manner. One solution is to use state synchronization, which requires each player's game instance to send a copy of its current state information to each of the other game instances. This requires a lot of bandwidth and takes a lot of time in the peer-to-peer model. A second solution is to use input synchronization. This requires each game instance to communicate its player's input to each of the other game instances. This reduces the amount of bandwidth required. If a game includes random events that do not depend on user inputs, the input synchronization system can fall apart. When random events are allowed in game play, a combination of these two synchronization techniques may need to be used. This means that a game instance may need to share information on its user's input as well as on changes in its game-state information with each other game instance following a random event (Morrison, 1996).

Information-Sharing Concerns

The problem of sharing information in a timely manner among widely scattered Internet users has two other dimensions: bandwidth and latency. Bandwidth issues can be dealt with after a game is written by using such techniques as data compression or by limiting the number of game players. Latency must be addressed during the design. If peer-to-peer networking is used for a multiplayer game, it is sometimes wise to make one of the peer machines take on the added responsibility of relaying messages to all game players, much like a server would do in the client/server model. Intelligent routing schemes might also need to be used. It is doesn't matter whether each player in a multiplayer game has exactly the same view of the game state or not. The only thing that matters is that players do not miss seeing important events (e.g., when one player shoots at another). In modern operating systems, it is possible to separate game communication from graphics displays (renderings) by using separate threads for communication and rendering (Ng, 1997b).

Dead reckoning is used to render game objects based on their last known information (e.g., heading and velocity). This reduces the amount of information that must be shared among players. This also helps deal with unreliable network connections. If a connection is lost, dead reckoning can be used to predict the game-state changes until the connection is restored. This assumes that no major changes take place during the time the connection is missing. Sometimes it is wise to build in delays to the time required to process each user input, so that when delays occur, the users do not notice them as much (Munkki, 1997). In the real world, humans cannot see objects beyond the horizon or in the next room. It is not necessary to render these objects until the player could reasonably expect to see them. Sometimes the client needs to keep two copies of the game state. One copy contains changes based on the actual actions taken by all players, and one copy contains changes made by dead reckoning. When information is received indicating that the copies are no longer acceptably in synch, the state discrepancies need to be fixed by the client when it is convenient (Lincroft, 1999). Sometimes these discrepancies can be hidden from the player by scheduling game-state changes two or three virtual time periods in the game's future story line and waiting to render them on the screen until their correctness is verified.

Network Protocol Trade-offs

Sometimes designers need to consider carefully which networking protocols provide the best means of communicating among game clients. Much of the time, Internet communication is done using the TCP protocol, which is reliable, stream oriented, connection persistent, and slow. Part of the reason it is slow is that although data packets are always delivered, the packets must be assembled before the message can be delivered. The UDP/IP protocol is unreliable and has small packets and very low overhead. The UDP/IP protocol can be much faster than TCP, but the programmer has the responsibility of checking information to see that it is received in the proper order (Bernier, 2000). Simply using faster network connections (e.g., Internet2) does not eliminate the need to consider these trade-offs between TCP and UDP/IP.

CONCLUSION

Two computing applications that involve extremely large numbers of users are computer games and Web-based applications. It is only natural to want to consider using the Internet to support the development and delivery of computer games. As high-speed Internet connections (e.g., DSL, cable modems, Internet2) become more widely available and affordable to home users, interest in developing online games will continue to increase. It is important to remember that the computer game industry, which is only 30 years old, has already grown to a multibillion-dollar-a-year industry. Its growth was accelerated by the advent of the affordable home computer. The Internet is fewer than 10 years old and has grown at an even faster rate. As game developers have better and faster network technologies (e.g., Internet2) to exploit, the quality of online multiplayer games is likely become closer to that of today's console games. It is important to note that new techniques for event synchronization will also be required, because part of the problem is displaying games simultaneously to several users (not just bandwidth and latency issues).

GLOSSARY

Bandwidth The potential amount of information able to flow simultaneously through a computer network.

CGI Common gateway interface; a protocol for allowing remote users to run computer programs on a machine housing a Web server.

Client/Server Computing A type of networked computing in which one computer (the client) requests data and/or services from another computer (the server).

Demos An executable subset of a larger program, intended to give users an idea of what it is like to use the full product.

DirectX Microsoft game-development-tool library.

First-Person Game A game that displays the screen view as seen through the eyes of the game's main character.

Flash A popular Internet multimedia animation language distributed by Macromedia; requires a browser plug-in to be installed on a client machine.

Freeware Software distributed free of charge by its author.

Game Engine The core code that handles the basic functionality of a game and that may be customized to deliver several variations of a particular game genre.

gcc A free C/C++ complier distributed by the Open Systems Software Group.

Javascript An Internet scripting language supported by most popular Web browsers.

Latency The delay that occurs between the time a network signal is sent and the time the signal is received and acted on.

Linux Freeware version of the Unix operating system; versions are available for most PC hardware platforms.

NPC A nonplayer character controlled by a computer program, usually in a role-playing game.

OpenGL Standard graphics library developed by Silicon Graphic.

Rendering The task of drawing an on screen graphical representation of a data object.

RPG Role-playing game; players in this type of game assume the roles of characters in a story and are allowed to interact with other players, nonplayer characters, and game objects.

Shareware Software distributed by its author on a trial basis with the expectation that users will send payment if they find it worthwhile.

Sprite An animated graphical game object typically capable of independent motion on the game display screen.

Third-Person Game A game that displays the main character interacting with the game environment as if the game player were watching a movie from the perspective of an onlooker.

Thread A separately executing process in a multiprogramming execution environment.

Unix A popular computer operating system often used by Web programmers and Internet server administrators.

Gender and Internet Usage

Ruby Roy Dholakia, *University of Rhode Island*
Nikhilesh Dholakia, *University of Rhode Island*
Nir Kshetri, *University of North Carolina*

INTRODUCTION

Modern information and communications technologies (ICTs) such as the Internet arguably have the potential to offer greater benefits to women than men (Carter & Grieco, 2000; United Nations Conference on Trade and Development [UNCTAD], 2002). For instance, new ICT applications such as changing a health service appointment electronically can "return" the time lost by single mothers under conventional arrangements that require travel to a clinic for such tasks (Carter & Grieco, 1998). In reality, however, a significant gender bias toward men exists in the adoption of modern ICTs, including the Internet. For instance, the user survey conducted by Graphic, Visualization, & Usability Center (GVU) in 1998 found that 66.4% of the Internet users in the world were men and 33.6% were women (GVU Center, 1998). In 2000, the bias still persisted in most parts of the world, with the exception of the United States and Canada. Understanding of the Internet's evolution over time and space, therefore, is incomplete unless we understand the role and influence of gender in the processes of Internet adoption and usage.

Most available statistics on Internet usage tend to use the terms *gender* and *sex* interchangeably, even though sex is a biological characteristic and gender is the "social constructed roles ascribed to males and females. These roles, which are learned, change over time and vary widely within and between cultures" (United Nations definition, World Bank, 2002). Although the current reporting of data on the Internet and gender does not adequately capture the cultural and changing differences in gender roles, the data do provide a view of some of the differences in ways men and women use the Internet. They underscore the importance of "gender and Internet usage" as a topic and the need for an explanation of phenomena such as the following (based on a variety of sources, including Brisco, 2002; Hafkin, 2001; UNCTAD, 2002):

- In the United States and Canada, proportions of Internet users seem to parallel gender proportions in the population, but in other advanced economies, such as Sweden and Japan, men still account for a larger portion of the Internet-using population.
- In some countries, women Internet users have increased dramatically. For example, between 1999 and 2000, the proportion of women Net users jumped from 33% to 42% in Mexico and from 25% to 43% in Brazil.
- While women represent nearly 50% of the labor force in Asia and own more than one third of small and medium-sized businesses in the region, in 2000 they accounted for only 22% of Internet users on average.
- In Africa, women's participation in Internet usage continues to be low, ranging from 12% in Senegal to 38% in Zambia.

In this chapter, we address the following questions:

- What is the nature of gender bias in Internet adoption and usage?
- Is the bias changing over time and space?
- How can the bias be profiled and expressed effectively?
- What factors explain the variation of the bias within and across countries?
- Why do men and women tend to use the Internet for different purposes?

We use country-level Internet usage data obtained from various sources to address these questions. These multiple sources have used a variety of methods to collect, analyze, and represent data and such heterogeneity in data imposes several limitations on their use and interpretation. Lacking a single, comprehensive study based on a consistent approach to the collection of data globally, we have relied on available heterogeneous data to examine the gender relationships. The remainder of the chapter (a) examines the nature of gender bias in the adoption of the Internet, (b) discusses various possible sources of the bias, and (c) provides some conclusions. In this chapter, we use the terms gender and sex interchangeably, to reflect the availability of data.

Table 1 Gender Distribution of Internet Users Worldwide

REGION/COUNTRY	INTERNET USERS M:F (RATIO 2000)	GDP PER CAPITAL ($, 2001)	SOURCE
Western Europe	58:42	22,311	Jupiter MMXI (2002)
Denmark	64:36	31,090	Pastore (2001)
Germany	60:40	23,700	Stewart (2002)**
Ireland	60:40	23,060	Jupiter MMXI (2002)
Italy	70:30	24,340	Jupiter MMXI (2002)
Spain	56:44	20,150	Pastore (2001)
Sweden	61:39	25,400	Jupiter MMXI (2002)
United Kingdom	57:43	24,460	Jupiter MMXI (2002)
USA	50:50	34,870	Nua Internet Surveys (2000)
Latin America	60:40	4,896	E-Marketer (2001b)
Argentina	57:43	6,960	E-Marketer (2001b)
Brazil	57:43	3,060	E-Marketer (2001b)
Mexico	58:42	5,540	E-Marketer (2001b)
Asia	78:22	1,925	Hafkins &Tagger (2001)
China	70:30	890	China Internet Network Information Center (2001)
India	77:23	460	E-Marketer (2001a)
Japan	67:33	35,990	Hafkins & Tagger (2001)
Korea	53:47	9,400	Deok-hyun (2001)
Singapore	57:43	24,740	Pastore (2001)
Oceania	54:46	19,080	Pastore (2001)
Australia	55:45	25,780	Pastore (2001)
New Zealand	52:48	12,380	Pastore (2001)
Middle East	94:6	4,089	Hafkins & Tagger (2001)

Note. GDP = gross domestic product. GDP data are from United Nations Development Program (2000), World Bank (2003), and authors' calculation.
**Data for January 2002.

NATURE OF GENDER BIAS IN INTERNET ADOPTION

Global Variation

Precise data on Internet usage by gender are extremely difficult to obtain, especially from developing countries, and the available data lack reliability and comparability (UNCTAD, 2002). Nonetheless, statistics on Internet access and use across countries (Table 1) reveal gender as one of the most important factors influencing Internet adoption and usage. The degree of gender bias in the adoption of the Internet varies widely across the world. As Table 1 indicates, among Internet users, the male–female ratio ranges from 94:6 in the Middle East to 78:22 in Asia, 75:25 in Western Europe, 62:38 in Latin America, and finally 50:50 in United States. There is great variability even within a region. In Western Europe, for instance, the male–female ratio in Internet use varies from 70:30 in Italy to 55:45 in Germany.

In general, the proportion of female Internet users tends to be higher in countries with higher per capita incomes. For instance, countries in Western Europe and Oceania had higher proportions of female Internet users than lower income countries in Asia and Latin America. In the developing countries, women usually account for much smaller proportion of the total Internet population (Table 1). Adoption of any technology, including the Internet, requires investments in fixed capital as well as recurring variable costs. A lower income level implies that users have to invest a higher proportion of their income in acquiring and using a technology. (In developing countries, Internet availability in public venues such as Internet cafes obviates the need for fixed investments by individuals. There are, however, serious gender barriers that prevent women from going to such public locations and using the Internet. Therefore, for women, lack of funds to buy a computer continues to be a barrier.) The total perceived sacrifice in adopting the technology thus is higher for individuals with lower income levels. Women's per capita GDP (gross domestic product) worldwide is lower than that of men (see Table 4, later in this chapter) and women's per capita GDP as a proportion of men's per capita GDP varies widely across the world. The income disparity across sexes thus explains some of the gender disparities and global variations in Internet adoption and usage.

The proportion of female users is also higher among countries with longer history of Internet usage. For instance, in the early 2002, female Internet users were 46% in Sweden, 42% in Britain, and 39% in Germany and France. This proportion drops to 31% in Italy and 29% in Spain ("Men Still Dominate," 2002a). Similarly, Brazil and Mexico—early-adopting Latin American nations—

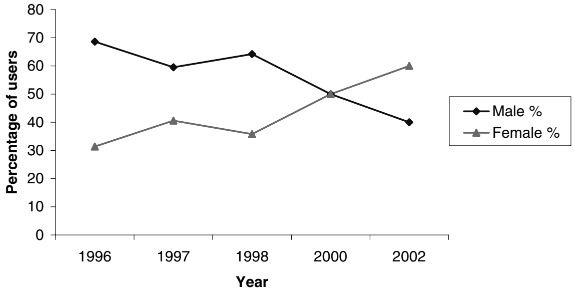

Figure 1: Gender distribution of Internet users in USA.

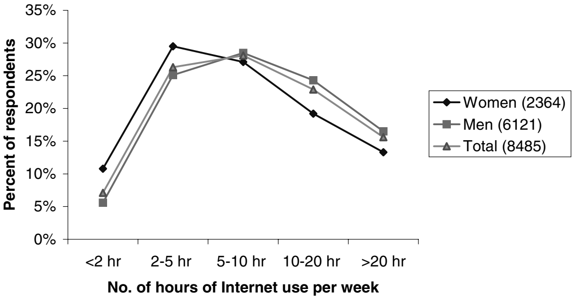

Figure 2: Gender and Internet usage in Quebec, Canada (1997).

had higher proportion of female Internet users than other Latin American nations.

The gender gap in Internet adoption has been diminishing over time. Some statistics suggest that the gender gap may even be reversed in the United States and Canada but not in other countries. As presented in Figure 1, the gender bias in Internet adoption in the United States disappeared in 2000 and also started showing a reverse trend after that—with more women than men online.

Width and Depth of Internet Adoption

Despite some evidence of the narrowing and even reversing gender bias (Figure 1; Rainie, 2002), further analysis indicates that the bias still persists in terms of the width and depth of adoption—even in countries where the gender gap has seemingly disappeared. The concepts of width and the depth of technology adoption help extend the analysis of gender bias in Internet adoption. Gatignon and Robertson (1991) defined the width of adoption as the "number of people within the adoption unit who use the product, or the number of different uses of the product" and the depth as "the amount of usage or the purchase of related products" (p. 468). Thus, higher width of Internet usage is associated with greater number of individuals within a household using the Internet, as well as greater number of different uses of Internet by a specific member of that household. For instance, a possible measure of the width of Internet adoption may be the number of activities or applications (e.g., education, communication, information search, entertainment, etc.) for which Internet is used.

For a multifunctional technology such as the Internet, "depth" can have at least two measures: one related to the usage of the technology for performing a particular function (functional depth) and the other related to the total usage of the technology (overall depth). In case of Internet, for instance, a possible measure of functional depth of "Internet adoption for shopping" could be the number of times per month an individual uses the Internet for shopping or the total time per month spent shopping online. Total or overall depth of adoption of the Internet, on the other hand, could be measured by the total time spent using the Internet per month.

It is not surprising to find that men still outpace women on the Internet in terms of various usage measures ("Demographics: European Women Surf," 2002), and this bias is evident even in countries where the overall ratio of Internet users has become gender-neutral. In 1997, a study conducted in Quebec, Canada, indicated that men were heavier users of the Internet than women (Figure 2). The study indicated that men spent 16% more time online than women, viewed more pages, and went online more often. As a result, Internet adoption tends to be much deeper for men than for women. This was also evident in a December 2000 U.S. study indicating that men went online 20 times, spent 10 hours and 24 minutes online, and viewed 760 pages per month. The corresponding figures for women were 18 sessions, 8 hours and 56 minutes, and 580 pages (Nua Internet Surveys, 2001). Similarly, in Asia male Internet users in 2001 spent 14.5 hours per month online compared with 12 hours spent by women (Nua Internet Surveys, 2002b; Silicon.com, 2001).

The functional depth of Internet adoption depends on the type of usage. For instance, compared with Spanish men, Spanish women tend to favor instant messaging sites and file sharing. In Asia, the functional depth of Internet adoption for visiting sports sites is higher for men than women. In Hong Kong, for instance, 10% more men visit soccer-related sites than women (Nua Internet Surveys, 2002a).

Visits to various Web sites also show significant gender differences in the United States and Canada, as well as rest of the world (Table 2). Only in the case of Yahoo! did more U.S. and Canadian women than men visit a site; the differences are more pronounced in the rest of the world ("Demographics: European Women Surf," 2002b).

A survey conducted in 2001 indicated that although 100% of the female respondents using a computer in Rhode Island used e-mail applications, there were variations in usage locations (Dholakia, Dholakia, Mundorf, & Xiao, 2002). Men, more than women, used e-mail both at home and work; women tended to e-mail mostly at work. For online shopping, the difference was even more pronounced, with more men reporting being Internet shoppers and conducting shopping transactions from home as well as work (Table 3). When we examined shopping sites such as eBay and Amazon.com, men used these sites more than women in all parts of the world, including the United States and Canada. The only exception, Amazon.com, was used by more women than men, but only in the United States and Canada (see Table 2).

Other studies report similar gender bias within the United States. Unilever (2001) suggested that online shoppers are more likely to be men than women; men dominate

all shopping categories except health and apparel (Ebates.com, 2000). Men not only report more incidences of Internet shopping, they also tend to be "heavy buyers," spending over $500 more online than women (48%) (Bhatnagar, Misra, & Roy, 2000). Men also exhibit considerable variation in Internet shopping behaviors, whereas women tend to stick to "click-and-mortar" behavior patterns—"shopping" online but buying offline ("What Kind of Dot-Shopper Are You?," 2000).

The functional depth of Internet adoption varies across age groups within as well as across countries. Among Internet users in the age group 18 to 24 years in the United States, women prefer to visit news and entertainment sites, whereas men prefer search engines and sports sites (Nua Internet Surveys, 2002b). Similarly, a survey conducted in the United Kingdom indicated that about 80% of men aged 55 and older used the Internet for searching information or for pursuing their hobbies, whereas 86% of women in the same age range preferred to use the Internet to communicate with friends and family (Nua Internet Surveys, 2002c).

Similarly, gender composition of the online registrants at a local U.S. newspaper indicated that, for all age groups over 25, more men than women tend to register online (Figure 3).

SOURCES OF GENDER BIAS IN INTERNET ADOPTION

Because the adoption of the Internet is a relatively new phenomenon, there are limited data on changes over time, particularly for countries outside the United States. Based on available data, it is likely that the gender bias will largely disappear over time. For instance, data from online registrants at a newspaper site in the United States in 2002 (see Figure 3), clearly show the narrowing gender gap at younger ages until the pattern reverses itself for the 13–24 age group. For this egalitarian pattern to emerge for all age and income groups and across all countries, several forces must operate in a convergent manner. Figure 4 provides an overall framework that offers a perspective on various factors that contribute to the gender bias in the adoption of modern ICTs such as the Internet.

There are several variables at the macro level that influence the overall environment in which decisions are made regarding technology—decisions regarding who designs the technology, what features are included in the design—that influence the usefulness and adoption patterns of technology. There also are several factors at the micro level that influence evaluation and adoption of specific technologies. A complex interplay between these forces shape the gender–technology interactions and lead to gender symmetry or asymmetry in the overall adoption of a specific technology like the Internet as well as the width and depth of adoption.

Sociocultural Factors

Culture can be viewed as one of the components of external variables in the technology acceptance model (TAM) proposed by Davis (1989). Although men and women everywhere differ behaviorally in some ways, they do not always differ in the same ways or to the same degree across countries. Cultural factors explain a significant

Table 3 Location (Home or Workplace) of Internet Use in Rhode Island, USA

	MALE ($n = 80$) (%)			FEMALE ($n = 56$) (%)		
Application Used	None	At least in one locations	Both locations	None	At least in one locations	Both locations
E-mail	2.5	17.7	79.7	0	26.8	73.2

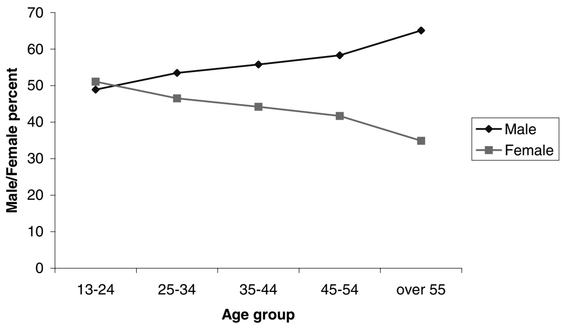

Figure 3: Gender distribution of online registration at a U.S. newspaper site.

proportion of such variations (Segall, Dalon, Berry, & Poortinga, 1990). Such differences are likely to result in gender bias in Internet adoption in several ways. First, cultural factors determine the level of involvement of men and women in technology-related decisions. Second, culture is one of the important factors in determining the likelihood of learning the skills required for Internet use. Third, culture influences the adoption of a technology by making the alternative technologies more or less attractive in performing a function. We describe each of these factors in the following paragraphs.

Women's Involvement in Decision Making

Cultural factors influence women's involvement in decision making at various levels: household, organization, and national levels. Rahman and Kumar (1998) found limited participation of women in technology adoption decisions in Bangladesh. Truman and Baroudi's (1994) analysis indicated that women receive lower salaries than men even after controlling for job level, age, education, and work experience. These same factors constitute some of the causes of women's underrepresentation in the information-systems-related occupations in the United States (in 1991, 33.7% of system analysts and 34 % of U.S. programmers were women; Truman & Baroudi, 1994). The data from United Kingdom show similar relationships. In 1991, British women accounted for only 10% of the professional membership of the British Computer Society, 3% of the data processing managers, 20% of senior system analysts, and 25% of programmers (Beech, 1991). Women are also underrepresented in national-level decision making. As Table 4 indicates, women's proportion of seats in parliaments varies from 3.5% in Arab states to 21.2% in East Asia. The differences in women's involvement in decision making may be both a cause and an effect of differences in terms of job preferences, educational specializations and Internet usage.

Adoption of Technology: Width & Depth

Figure 4: Gender-culture-technology interaction.

Influence of Culture on Attitudes Toward Acquiring Technology-Related Skills

Sociocultural factors influence the perceived benefits of acquiring technology-related skills. In general, women tend to face higher barriers than men in accessing education and training required to use ICTs (UNCTAD, 2002). Moreover, such barriers vary widely across cultures. Consider, for instance, two countries at about the same level of economic development, India and Egypt. In India, it is easier for parents to find better husbands for their daughters if the daughters are educated, hence they emphasize girls' education (Kumar, 1991). Egyptians, on the other hand, do not give importance to women's education because Egyptian men seek less educated wives (Mianai, 1981).

Availability of skills required to use a technology influences perceived ease of use and perceived usefulness of the technology and hence attitude toward its adoption. In the case of the Internet, for instance, a potential adopter must have a computer and English language skills. In some cases, the required skills may be learned only for the purpose of using the technology, whereas in other cases they are learned for some other (more general) purposes. For instance, it is unlikely that a potential adopter would learn English and acquire computer skills solely for the purpose of using the Internet. Thus, additional perceived benefits of learning the skills influence the attitude toward learning them (Fishbein, 1967) and hence adopting the technology. Because of job-related reasons, men in many countries may learn some English, and this skill also incidentally helps in using the Internet.

Features Included in the Internet

It is not surprising that because of these sociocultural influences, the features included in the design of a technology tend to favor men over women. Features unappealing to women users are likely to exist for several reasons. First, women are highly underrepresented in administration, managerial, and technical jobs in most of

Table 4 Gender-Related Indicators Influencing Internet Use

Note. F = female; GDP = gross domestic product; M = male.

the countries. For instance, whereas the proportion of women administrators and managers in the United States is 44.4%, women are virtually nonexistent in such jobs in many of the countries (United Nations Development Program, 2000). Such lack of top-level representation is compounded by manufacturers' unawareness of women's needs. Even when market research data are available, designers tend to ignore such evidence of actual needs and rely instead on speculative ideal types or stereotypes of women users (Cockburn & Dilic, 1994). Moyal (1992) argued as follows:

> It is the male engineer, technician, manager, strategic planner and policy-maker who have devised and installed the telegraph, the telephone, radio and television broadcasting stations, the communications satellite, and the advanced digital and mobile communication infrastructures and networks that link and continue to upgrade our spiraling telecommunication world.

In the case of the Internet, several technology-related factors tend to favor male users, including the following (Abernathy, 1999; Biersdorfer, 2001; Herring, 1999; Marketing to Women, 2001):

- Stereotyped views of female users;
- Male-oriented aggressive formats of computer games;
- Largely male-oriented online discussion groups, lacking elements of civility and online etiquette that women desire; and
- Prevalence of Internet pornography.

Features designed into a technology influence perceived usefulness and perceived ease of use (Davis, 1989), the major predictors of the likelihood of the adoption of a technology. Lack of features that appeal to women means lower perceived usefulness and perceived ease of use for female users, leading to lower width and lower overall depth of Internet adoption among women. If more features that appeal to women are included, then women's likelihood of adoption as well as the width and the depth of adoption are likely to increase.

Attractiveness of Alternative Technologies

Cultural factors could influence the propensity to adopt a given technology in performing a certain function by making the "alternative technology" less or more attractive. For example, consider two relatively affluent Middle Eastern countries, Saudi Arabia and Kuwait. Whereas the proportion of female Internet users in the Arab states is estimated to be between 4% (Internet.com, 2001) to 6% (Hafkin & Tagger, 2001), the proportion is more than 66% in Saudi Arabia ("How women beat the rules," 1999; "International Online," 2000) and more than 50% in Kuwait (Wheeler, 1998). The rapid increase in the number of female Internet users in Saudi Arabia is driven mainly by women's use of the Internet for business and personal reasons. In Muslim countries such as Saudi Arabia, women are not allowed to drive cars. Also, open and public interactions between men and women are highly constrained outside of marriage and family in Muslim societies. The Internet helps overcome such barriers. Wheeler (1998), for example, reported that several people in Kuwait had fallen in love and subsequently married through use of Internet relay chat technology. The Internet proved to be much better than the existing alternatives for women in the Middle Eastern cultural settings, given the social norms against women driving cars and the restricted public intermingling of the two sexes.

Gender-Related Factors

As social products, any technology including the Internet is not culturally neutral or value-free. The degree of compatibility between the values and norms of the technology and those of a potential adopter largely determine the adoption patterns of the technology (Rogers, 1983). The

Table 5 Summary of the Nature of Gender Bias in Terms of Several Indicators

INDICATOR	RESEARCH FINDINGS	REMARKS
Proportion of female Internet users	Lower than the proportion of male Internet users in most markets Tends to increase with the maturity of the Internet market.	Has reversed in the United States and Canada; female users outnumber male users in these countries
Width of adoption	Tends to be higher for men.	Men tend to use Internet for more applications than women.
Functional depth of adoption	Depends upon the type of Internet application	For instance, in the United States, Internet adoption for visiting news and entertainment sites is deeper for women and that for visiting search engines and sports sites is deeper for men
Overall depth of adoption	Tends to be higher for men	Men tend to spend more time online than women and to visit more pages

Sources: Nua Internet Surveys (2000); Graphic, Visualization, & Usability Center Center (1998); O'Leary (2000).

"values" of most of the ICT products and services, including the Internet, tend to be more masculine than feminine, which partly explains the existing gender-related digital divide (Herring, 2000).

Men and women are also "specialized" for different tasks. In the United States, for instance, "going shopping" is associated with women whereas men "work" (Firat & Dholakia, 1998). These specializations partly explain why American women still assume major responsibility for shopping (Dholakia, 1999) and why 70% of women make most of the household and purchase decisions (Hawfield & Lyons, 1998). These gender-related stereotypes persist, even among young adults (Dholakia & Chiang, 2003). Such differences in specialization tend to result in gendered adoption patterns and gendered width and depth of applications of a given technology. As Internet applications have expanded to include roles and responsibilities that have traditionally fallen on women—including greater range of shopping and family communications—the proportion of women users on the Net has increased.

Attitude Toward Risk and Attitude Toward Technology

Men and women differ significantly in terms of attitude toward risk (Slovic, 1966) and toward technology in general (Brunner & Bennett, 1998). Because so-called innovators of a new technology have more favorable attitudes toward risk (Gatignon & Robertson, 1991), women's risk-averse behavior is likely to result in lower rates of technology adoption. Men and women also differ in terms of their attitudes toward technology. In an experiment with school children, Brunner and Bennett (1998) found that girls were more ambivalent about technologies, were more likely to get bored with a bad technology experience, and were less likely to fix a technology if it breaks, compared with boys in the same age group. Venkatesh and Morri (2000) reported gender differences in the importance assigned to various factors for the adoption of ICT, and Gefen and Straub (1997) reported gender differences in the perception and use of e-mail.

CONCLUSION

In summary, men and women have different "cultures," are "specialized" in different tasks, and have different preferences. Such differences tend to interact with the features found in the Internet and other modern ICTs in ways that intensify their perceived usefulness and the perceived ease of use in favor of men rather than women. Table 5 summarizes the existing gender bias in Internet use in terms of several indicators.

Several limitations characterize the data used for the analysis and interpretation of gender differences in Internet use. First and foremost, our analysis has used a variety of sources, each of which has employed its own methodology of collecting, analyzing, and reporting data. Next, the data use *sex* and *gender* interchangeably such that it is difficult to capture sociocultural differences in the "meanings, roles, values, and status" assigned to the words *male* and *female*. Keeping these limitations in mind, the analysis presented in this chapter seems to support the following conclusions:

- There is a gender gap measured by the proportion of male and female Internet users.
- This gap is decreasing and has even reversed in overall terms in the United States and Canada.
- When the gap is examined in terms of additional constructs (width and depth of adoption), differences in male–female uses of the Internet persist even in countries when the overall gap has reversed. RISQ analysis of Canada (Figure 2) shows time use differences. Tables 2 and 3 show application differences.

Several factors contributing to gender bias in the adoption of the Internet have been discussed in this chapter. Drawing on a general model of gender–technology–

culture interaction, we first reviewed the sociocultural factors that contribute to the Internet being less compatible with the culture and values of women than those of men. Limited involvement of women in technology-related decisions may be both a cause and effect of differences at several levels. With lower preference for disciplines that demand higher intensity of Internet use such as science, engineering, and technology, features included in the Internet and related technologies tend to favor men over women. The two genders also differ in their attitudes toward acquiring required skills, and in valuing alternative technologies. These factors partly explain a lower rate of Internet adoption among women.

Second, we reviewed gender-related factors that influence men's and women's attitudes toward risk and attitudes toward technology in general. Greater risk aversion and a generally more unfavorable attitude toward technology-related problems tend to result in lower adoption rates among women. Because men and women differ in terms of their specializations, the functional depth corresponding to an application (e.g., shopping) tends to be different for the two genders. It is not surprising that men report greater purchases of technical products online and women purchase more apparel. When an application is consistent with gender specialization, such as a woman's greater role in maintaining and enhancing the family's social interaction and communication patterns, then almost universal use by women can be expected, as is becoming evident to some extent with respect to e-mail. Finally, the adoption of the Internet, like all other ICTs, is a function of the income level of the potential adopters. Women's lower per capita income and lower literacy rate partly explain the existing gender bias in terms of the adoption of the Internet.

Managerial and Policy Implications

It is likely that with the passage of time many of these gender differences will diminish. To the extent that sociocultural and gender-related factors act as barriers to the design and use of technology such as Internet, these sources of gender bias can be tackled if appropriate measures are taken at various levels. Because men and women have different "cultures," specializations, and preferences, the prevalent "one-size-fits-both-genders" approach is less likely to work in the design of a technology such as the Internet. Research is needed to understand women's needs in better ways and technology designers should be induced to incorporate features that meet such needs.

At the policy level, greater emphasis is needed on women's education—especially in science, engineering, technology, and administration fields. Women's representation in ICTs is strong in Singapore because of the government's "concerted" state directed ICT training—58% of analyst programmers and 52% of analyst designers in 1987 were women (Webster, 1996). Women educated in such fields are likely to have the skills and propensity to adopt modern ICTs. Women's enrollments in such disciplines would have doubly greater social benefits since women trained in ICTs are likely to be the future designers and incorporate features that are likely to favor women's adoption. The emphasis must be accompanied by new ways of imparting the education, however (Shaffner, 1993, p. 97):

> The whole idea of sitting at a desk in an office and using a computer would have to change. It would have to be more like something that you could do in an environment where you could have children, babies, lovers, and community.

Policies are also needed to impart ICT skills to a broader group of women and enhance existing skills. These include ICT awareness programs, ICT-related training opportunities for women in workforce, and acquisitions of the right and sufficient ICT skills (UNCTAD, 2002). Finally, the extent to which the gender-related digital divide can be bridged depends on women's access to and involvement in technology-related decisions at the household, organizational, national, and international levels.

ACKNOWLEDGMENT

The authors are grateful to multiple reviewers of *The Internet Encyclopedia* for detailed and valuable comments on earlier versions of this chapter. Support for the research from RITIM (Research Institute for Telecommunications and Information Marketing) at The University of Rhode Island is gratefully acknowledged.

GLOSSARY

Adoption of an innovation A micro process that focuses on the stages through which an individual passes when deciding to accept or reject an innovation.

Depth of adoption of a technology The variety and extent of usage of the acquired technology or the purchase of related products.

Functional depth of adoption of a technology The frequency that a multifunctional technology such as the Internet will be used for a particular function (e.g., for shopping).

Gender The "social constructed roles ascribed to males and females. These roles, which are learned, change over time and vary widely within and between cultures" (United Nations definition). Although *sex* and *gender* are often used interchangeably, sex is a biological variable and gender a social construct. The adjectival and noun forms of *male* and *female* are typically employed in a biological sense, whereas the adjectives *masculine* and *feminine* are typically employed in a gendered, social sense.

Gender-related development index (GDI) A composite index measuring average achievement in the three basic dimensions captured in the human development index—a long and healthy life, knowledge, and a decent standard of living—adjusted to account for inequalities between men and women.

Gross domestic product (GDP) The sum of the total value of consumption expenditure, total value of investment expenditure, and government purchases of goods and services.

Information and communications technologies (ICTs) Technologies that facilitate the capturing, processing, storage, and transfer of information.

Internet The "global information system that (i) is logically linked together by a globally unique address space based on the Internet Protocol (IP) or its subsequent extensions/follow-ons; (ii) is able to support communications using the Transmission Control Protocol/Internet Protocol (TCP/IP) suite or its subsequent extensions/follow-ons, and/or other IP-compatible protocols; and (iii) provides, uses or makes accessible, either publicly or privately, high level services layered on the communications and related infrastructure described herein" (The Federal Networking Council, 1995).

Total or overall depth of adoption of a technology A measure that can be determined by the total time spent using the technology in a given period of time (e.g., per month).

Width of adoption of a technology The number of people within an adoption unit who use the product, or the number of different uses of the product.

Geographic Information Systems (GIS) and the Internet

Haluk Cetin, *Murray State University*

INTRODUCTION

A geographic information system (GIS) consists of hardware, software, and users to support the capture, storage, retrieval, update, management, manipulation, analysis, display, and modeling of geospatial data. Before GIS, researchers used films and mylars to manually overlay spatial information. The integration of spatial information with nonspatial attributes (variable) is a critical component of a GIS. Many large complex tasks are accomplished much more quickly by a GIS than by a human working alone. A GIS is a "smart map" system linking databases to digital maps. Several names, such as spatial information system, land information system, natural resource management information system, planning information system, and environmental information system, have been used for GIS, giving a "high-tech" feel to spatial information (Goodchild & Kemp, 1992).

GIS and related technologies are becoming more available to many users in different disciplines through the World Wide Web. GIS and related technologies will help greatly in the management and analysis of worldwide data and allow better understanding of environmental and other processes around the world.

Desktop GIS has been the system of choice, but it has many limitations including high cost, high learning curve, and limited public access of data. On the other hand, an Internet-GIS (i-GIS), which focuses on distributed geographic information services for the decentralization of geographic information management, has many advantages including decentralized data storage, wider user access, and convenience (Plewe, 1997; Tsou & Buttenfield, 2002). The advent of the Internet and computer technology has made it possible to share and analyze data through World Wide Web–based management systems. The Internet and GIS have been used to download, preprocess, review, modify, and analyze up-to-date geographic data since the early 1990s. Although today's Web-based systems offer an excellent opportunity to use GIS beyond the home and office, existing i-GIS map servers do not provide the complex analytical functionality required by many users.

Internet-GIS is becoming one of the most rapidly evolving fields in e-commerce. For organizations and institutions, i-GIS will provide easy access to GIS data with decentralized databases.

Future GISs, including automated processing at offices and homes, will likely be a part of our daily lives. When you walk into your house, the system will know where you are and what kinds of things you might want to do, such as turning on specific appliances or planning a trip using virtual environments.

A BRIEF HISTORY OF GEOGRAPHIC INFORMATION SYSTEMS

GIS technology, which began in the 1960s, has been one of the most rapidly evolving fields during the past two decades. The Canada Geographic Information System (CGIS) and the Urban and Regional Information Systems Association (URISA) were developed in 1963, the latter a nonprofit association using GIS technology in public works and services and local and state planning agencies. The Harvard Laboratory for Computer Graphics established in 1964 pioneered many aspects of GIS. In 1965, Synagraphic Mapping System (SYMAP), an automated computer mapping application system, was developed at the Northwestern Technology Institute and at the Harvard

Laboratory for Computer Graphics. In 1967, the United States Central Intelligence Agency (CIA) developed an Automatic Mapping System (AUTOMAP), a map compilation system at the global level. The establishment of several companies, including the Environmental Systems Research Institute (ESRI) and Intergraph Corporation in the United States and Laser-Scan in the United Kingdom, initiated worldwide commercial applications. In the 1970s, several GIS programs and systems were established and the first Landsat Multispectral Scanner (MSS) satellite (originally known as ERTS-1) was launched. In 1977, the U.S. Geological Survey developed one of the first spatial data formats, the digital line graph (DLG). The establishment of other companies, such as ERDAS, which was founded in 1978, and the first vector based GIS data structure, ODYSSEY GIS, which was developed at the Harvard Lab, provided major advances. In 1981, ESRI introduced one of the earliest commercial GIS software packages, Arc/Info, which has become by far the most widely used GIS software including topological consistency in GIS data sets. During the same year, the global positioning system (GPS) project became operational. In 1982, the development of the Geographic Resources Analysis Support System (GRASS), an open source/free raster–based GIS software, was begun at the U.S. Army Construction Engineering Research Laboratories, a branch of the U.S. Army Corp of Engineers. During the late 1980s, several GIS companies such as MapInfo (1986), SPOT satellite program (1986), Idrisi project (1987); a GIS journal; the International Journal of Geographical Information Systems (1987); a GIS conference; the first GIS/Land Information Systems (LIS) conference (1988); and data formats such as the first public release of the U.S. Bureau of Census TIGER (topologically integrated geographic encoding and referencing) digital data were created. The U.S. Geological Survey defined one of the latest spatial data formats, the Spatial Data Transfer Standard (SDTS), in 1992 (Federal Information Processing Standard 173). During the 1990s, GIS became one of the most rapidly evolving information technology (IT) fields. Today GIS is being used in many disciplines including the hard sciences; the engineering, medical, and social science fields; at every level of government including the local, state, and national levels; and in business and industry.

One of the important issues in GIS is meta-data standards, which describe the origin, content, quality, condition, and other characteristics of geospatial data. The Federal Geographic Data Committee (FGDC) coordinates the development of the National Spatial Data Infrastructure (NSDI). According to the FGDC, "the NSDI encompasses policies, standards, and procedures for organizations to cooperatively produce and share geographic data. The 17 federal agencies that make up the FGDC are developing the NSDI in cooperation with organizations from state, local and tribal governments, the academic community, and the private sector." The FGDC approved the Content Standard for Digital Geospatial Metadata (FGDC-STD-001–1998) in June 1998 (http://www.fgdc.gov/metadata/metadata.html). The FGDC has created a Web-based FGDC Metadata Entry System (http://130.11.52.178/metaover.html) "to stimulate the creation of basic FGDC-compliant meta-data records for the cataloging of spatial data sets." Also, the NSDI/FGDC National Geospatial Data Clearinghouse Information Resource Web site (NSDI/FGDC, 1998) node has been created to provide links to spatial data. The Clearinghouse Activity is a decentralized system of servers located on the Internet which contain field-level descriptions of available geospatial data.

DESKTOP GEOGRAPHIC INFORMATION SYSTEMS

There are several definitions of GIS (Chrisman, 1997). GISs are a form of information system applied to geographic data and consist of several interconnected subsystems including data storage, management, and processing; data analysis and manipulation; and output subsystems used to capture, store, retrieve, update, process, analyze, model, and display spatially referenced (georeferenced) data systematically. A GIS is different from a database management system (DBMS) in terms of capability. DBMSs store and process mostly nonspatial data. On the other hand, a GIS, which may also include relational database management systems (RDBMS), not only processes geospatial data but also link nonspatial (or attribute) information to spatial data. A GIS enables institutions and managers to manipulate geographic data more efficiently and to make informed decisions for planning purposes.

Contributing Technologies and Disciplines

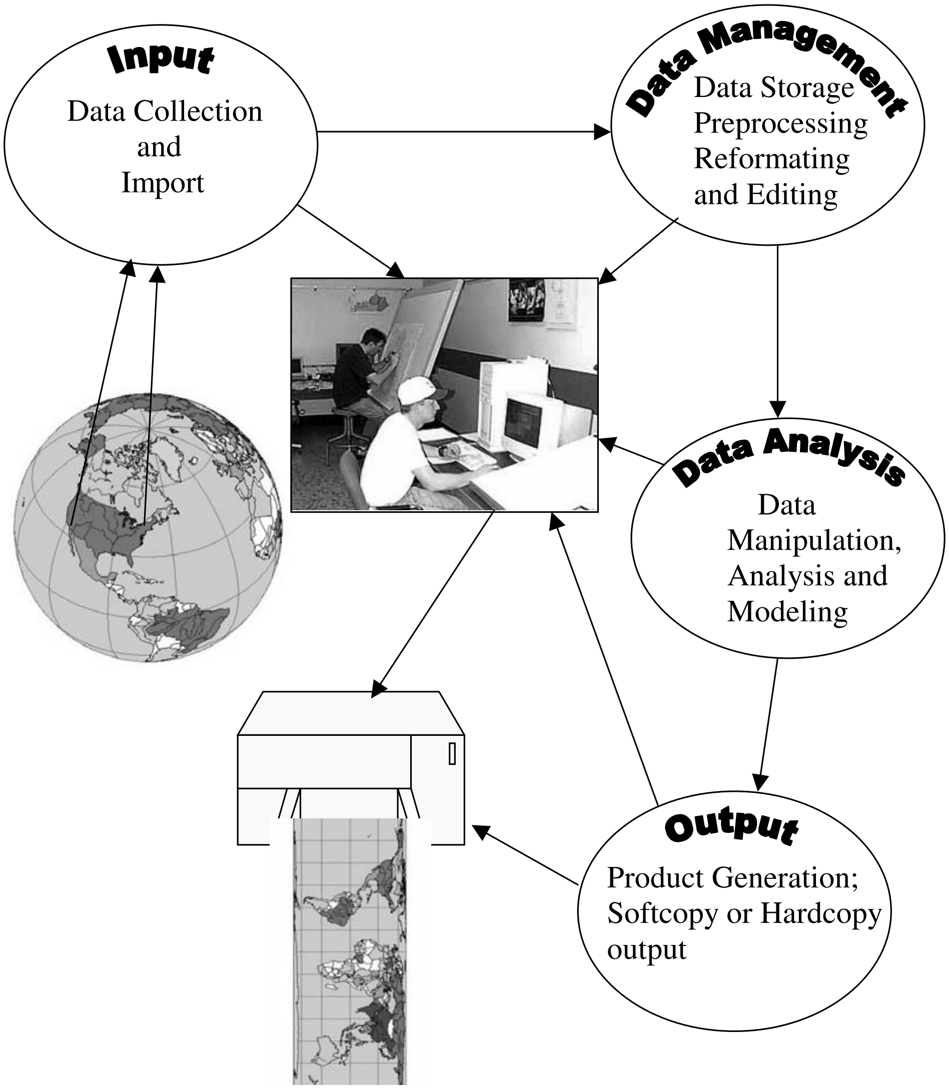
GIS represents a convergence of numerous disciplines and technologies. A GIS has the potential to offer a technology that can be used by diverse disciplines emphasizing spatial data collection, analysis, manipulation and integration, analysis, and modeling. Several disciplines including artificial intelligence (AI), civil engineering, computer science and engineering, earth sciences, electronic engineering, geodesy, geography, mathematics, photogrammetry, remote sensing, and semiotics have contributed to the technology used in today's GIS.

Components of a GIS

A GIS is an integrated system consisting of hardware, software, data, and users (Aronoff, 1995; Bolstad, 2002; Figure 1). GIS hardware includes computers, input devices, data storage, display, and output systems. GIS software is the main part of the system and provides for spatial data management, manipulation, analysis, display, and output. Data input devices include digitizers, scanners (flat-bed or drum), and imaging systems such as digital cameras. Data storage units are tape and disk drives (hard disk and floppy), CD/DVD drives, and other optical and magnetic storage devices. GIS display and output devices are monitors, projectors, printers, and plotters. GIS output can be in hard-copy (paper maps, tables, etc.) or softcopy format (digital data and images).

GIS Data Structures

There are two major data structures used in GISs, vector- and raster-based (Goodchild & Kemp, 1992). Each data



Input
Data Collection and Import
Data Management
Data Storage
Preprocessing
Reformatting and Editing
Data Analysis
Data Manipulation, Analysis and Modeling
Output
Product Generation; Softcopy or Hardcopy output

Figure 1: Components of geographic information systems.

structure has advantages and disadvantages (Figure 2a and 2b). A vector-based GIS is more useful when point (a location), line (roads or rivers), and polygon (fields or parcels) types of data are used (Figure 2a). The raster data model is more suitable for image-based data, such as aerial photos or satellite images (Figure 3). Raster data usually consist of rectangular grid cells (or pixels). Raster data can be manipulated quickly by a computer, but they often take up substantial disk space and are less detailed. Most modern GISs include the two data structures because both are used for most projects (Figure 4).

A GIS incorporates data from different sources and has many functions, including data browsing, retrieving, updating, displaying and querying, mapmaking, address matching and route finding, modeling, and terrain and statistical analysis. A GIS uses map mathematics to deal with many tasks including data conversions, data overlays, and buffers (DeMers, 2000).

GIS has applications in almost every discipline requiring some spatial data handling. Integration of a GIS technology with other systems such as GPS allows locations to be found quickly as in the case of 911 emergency response systems (Xue, Cracknell, & Guo, 2002). These applications are discussed in detail in the next section.

APPLICATIONS OF GIS

The following are some examples of GIS applications in several fields. There are also many GIS applications in the various subcategories, which are not discussed here.

Agriculture Applications

Farmers who have large fields can manage farm data easily with a GIS. They can create base maps that include roads, houses, barns, and farm field boundaries and

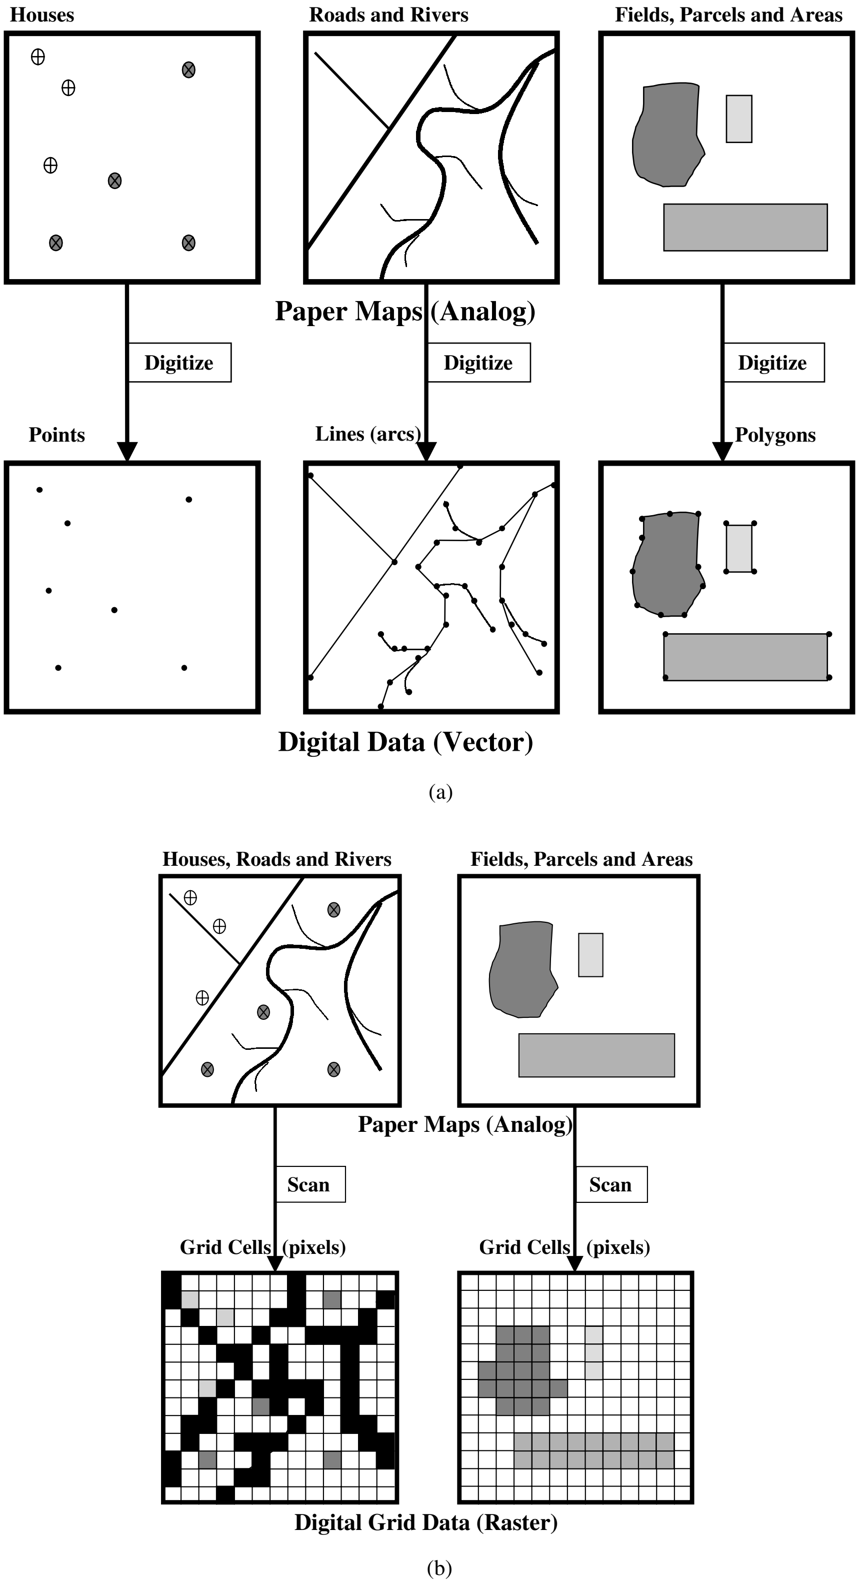


Figure 2: Geographic information system data structures: (a) vector data model and (b) raster data model.

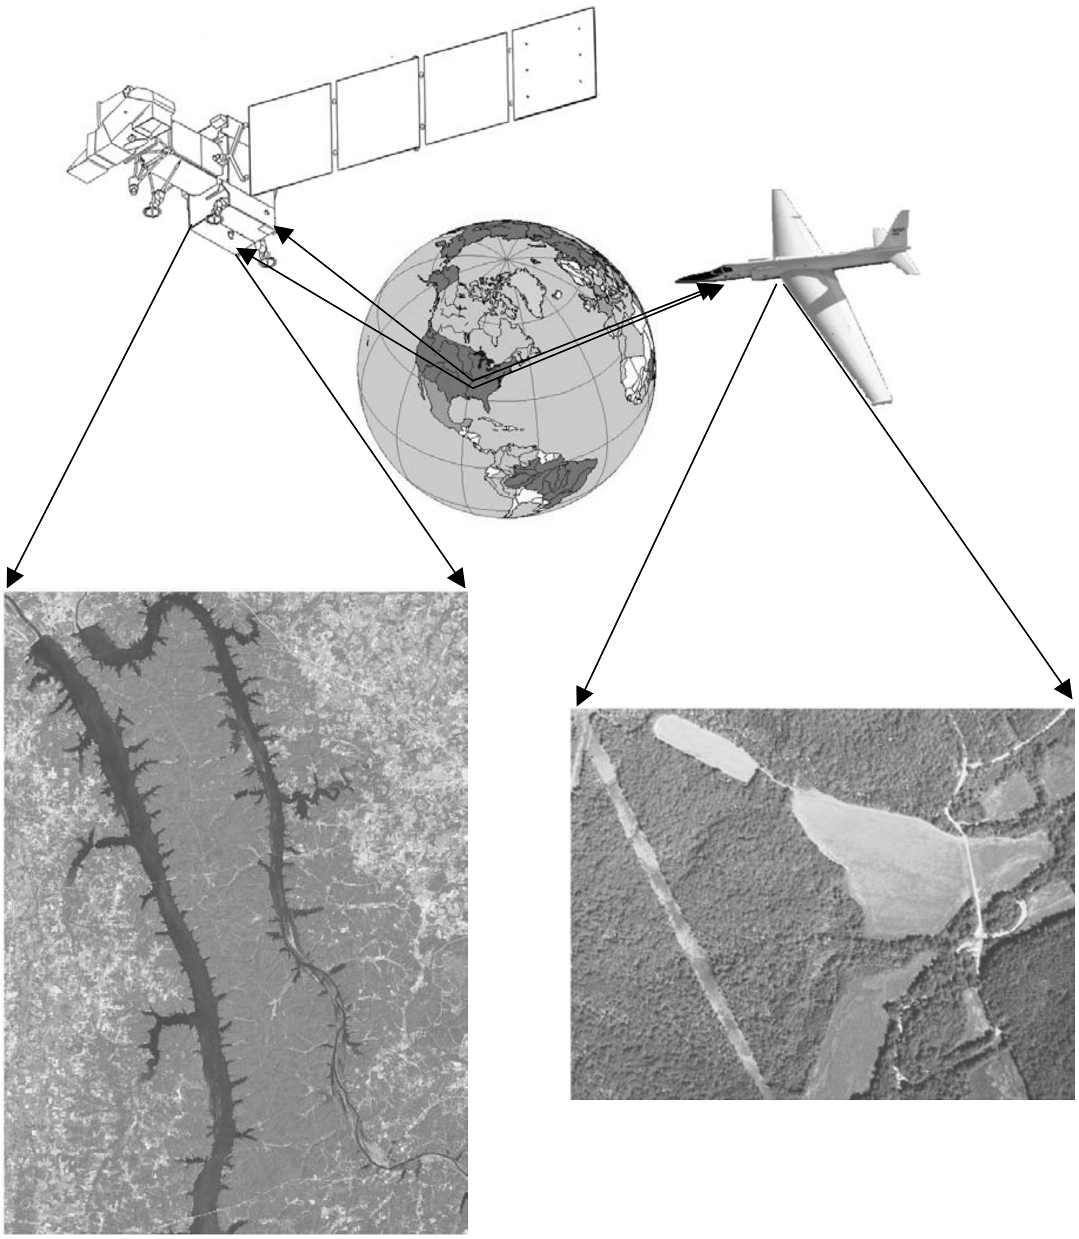

Figure 3: Satellite and airborne remotely sensed data suitable for raster data model (satellite and aircraft images are courtesy of NASA).

overlay them with maps that include drainage systems, soils, land use, pest and disease maps, and topography (elevation, slope, and aspect). The GIS may be used to improve management efficiency and the decision-making process. Many companies and research institutions are developing precision agriculture systems (PAS) using GIS and differential GPS to plan fertilizer, pesticide and herbicide, and irrigation applications at an optimum level to improve crop yield. GIS allows farmers access up-to-date farm data to increase production and reduce costs.

There are several GIS based PASs that allow farmers to use field data such as soil moisture, soil types, and nutrient information to develop prescriptions to apply specific amounts of fertilizer, seed, or other products. For example, seed population maps (seed prescription) can be created using soil moisture capacity of a farm field where different soil moisture conditions may exist. Many studies have shown that variable rate seeding improves yield. Higher rate seeding is applied to areas with higher soil moisture capacity, and lower rate seeding is applied to areas with lower soil moisture capacity. Similarly, variable rate nitrogen for corn or wheat can be applied to areas with differing nutrient deficiencies. A GIS also enables farmers to make quick informed decisions regarding crop

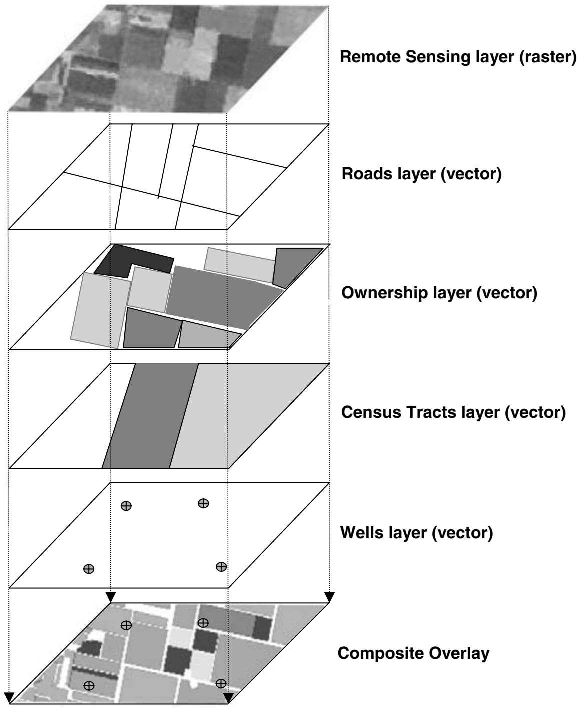

Figure 4: An integrated geographic information systems database.

stress due to disease (fungus, etc.), pest infestation, or water or salinity stress.

Today farmers have greater access to GIS data such as soil type, satellite and aircraft imagery, topography and geomorphology, and moisture condition. Farmers can access the Internet and obtain current satellite imagery, disease and pest infestations, and weather data to improve the management of their farms.

A farmer does not need to own a GIS to map his or her farm. Some companies have developed Internet map servers (IMS) to let farmers manage data. Currently, these IMSs do not provide the full capabilities of a GIS. In the near future, such software will allow the creation of farm maps with a minimum knowledge of GIS and without owning a GIS.

Archaeological and Geological Applications

GIS helps archaeologists examine archaeological sites interactively and model the sites for different scenarios using various human and natural activities that affected the sites. Some sites may include several historical events. GIS is a dynamic system and allows the construction of layers that represent these time periods. These layers can then be studied to reconstruct the history of the site.

GIS has many applications in geology. GIS provides the framework to input, develop, interpret, and analyze complex spatial and tabular datasets used for many mining and petroleum operations. Mineral and petroleum exploration, geological and hydrogeological mapping, karst modeling, earthquake and other natural disaster mapping, and resource assessments are just a few examples of applications in geology. The USGS (http://www.usgs.gov) provides many examples of GIS in geosciences.

A GIS is a powerful tool when integrated with other systems such as GPS technology for geological applications. In the past, geological mapping was labor intensive and time-consuming. The use of GPS with GIS and other technologies such as remote sensing has helped geologists to be more efficient and accurate in mapping as well.

Education and Research Applications

GIS has been one of the fastest growing technologies used in classrooms and research. A GIS is capable of performing analyses of geospatial or attribute data and provides powerful tools for almost any academic discipline. Libraries that provide tools for exploring information and museums that have systems that analyze historical and spatial data use dynamic GIS images. GIS helps students and teachers learn geography-related issues in an interactive way.

The software, hardware, and spatial data required for GIS analyses are readily available to K–12 schools and to universities through the Internet. The traditionally complex character of GIS is no longer a problem because there are several i-GIS application modules available for free or at a low cost, allowing K–12 students to access and process free data over the Internet. These modules minimize the initial learning curve and allow the use of a customized local data set. As a result, students can gain fundamental experience in the analysis of spatial data with the help of remote sensing, GPS, desktop GIS, and Internet-based mapping.

Another application of GIS is in educational administration. Several school districts have developed school attendance decision support systems designed to manage a rapidly growing student population. Students are assigned a specific school based on the location of their home, for example.

Many disciplines and technologies contribute to research in GIS. Software or system designers and engineers, database managers, geographers, cartographers, and scientists create software and algorithms that are used in many GISs. Research universities and private companies have developed GISs and GIS modules that provide new functions for existing information systems. Spatial decision support system (SDSS) models that can be used easily without extensive training have also been developed. There are many differences between GIS and SDSS. GIS sites usually require technical analysts to set up databases and use complex functions, whereas SDSS sites generally require one or two business analysts who want to make spatial decisions with limited GIS capabilities (Daniel, 1992). Some of these models are available on various Web sites.

Several GIS models can be purchased from GIS companies, but other models are available free of charge via the Internet. Some of the models and modules available on the Internet are related to hydrology and soils (e.g., SWAT, 2001) archaeological (e.g., Mn/Model, 1997), and emergency response (E-911). More research is being done to integrate traditional GIS with the Internet to provide data more rapidly. As stated earlier, IMS is one of the current technologies integrating GIS and the Internet.

Emergency 911 Systems and Health Applications

GIS allows 911 operators to access many databases quickly and efficiently, such as the transportation network, housing, the nearest water source, and location information for the nearest hospitals or other medical facilities. When integrated with GPS technology, a GIS allows 911 operators to track emergency vehicle locations and determine the best route. An emergency management GIS system can find the closest response units to the location of an incident and direct them to the nearest emergency medical facility saving critical time by analyzing traffic conditions and other factors.

Several health organizations and federal agencies such as the National Institutes of Health (NIH) and the National Cancer Institute (NCI) provide statistics, epidemiology, and cancer information and data over the Internet. NCI has created a cancer mortality map and graph Web site (http://www3.cancer.gov/atlasplus/), which provides interactive maps, graphs, and tables showing geographic patterns of cancer death rates for more than 40 cancers for the 1950–1994 time period. The cancer data provided at the Web site have been used to analyze spatial relationships between cancer mortality rates and environment using GIS (Ozkirim & Cetin, 2001).

Environmental Management, Forestry, and Conservation Applications

GIS has been adapted and used to assist government agencies, companies, and universities in natural resource management, environmental impact assessment, waste management, site remediation, and forest and fire management. GIS provides natural resource managers powerful analysis and decision-making tools for long-term forecasting. Diverse ecosystems can be analyzed and modeled by combining spatial, spectral, and temporal data through visualization analysis. Foresters, for example, can make long-term forecasts for forest inventory, wildlife habitat management, and fire prevention and management. GIS has been adapted by many coastal and marine researchers to create and manage large coastal ecosystem databases.

The U.S. Environmental Protection Agency (EPA) focuses on assisting businesses and communities with compliance training and guidance and is responsible for enforcing and ensuring compliance with environmental regulations. EPA has created many environmental data sets and uses GIS to regulate and monitor emissions from power plants, factories, and motor vehicles. The EnviroMapper Web site, for example, is one of EPA's Internet sites providing various types of environmental information, including air releases, drinking water, toxic releases, hazardous wastes, water discharge permits, and Superfund sites (http://www.epa.gov/enviro/html/em/). Users can create maps (dynamically) at the national, state, and county levels and link them to environmental text reports.

GIS is also used to monitor environmental problems in watersheds such as chemical or oil spills and wastewater. GIS is a powerful tool for understanding environmental issues and changes.

Remotely sensed data (Figure 3) have become a primary input to GISs used to model the earth and its resources at local, regional, and global scales. Large-scale monitoring and mapping has become possible with the advent of new high-spectral, spatial, and temporal resolution satellite sensors. The integration of remotely sensed imagery with other GIS data allows a synergistic processing of multisource spatial and spectral data for environmental applications.

The United Nations Environment Program has established a GIS-based interactive environmental Web site (http://www.unep.net) providing worldwide environmental data and a forum for technical peer review. The site can be used to create environmental maps with statistical and other up-to-date attribute information for any location or region in the world.

The USGS provides many GIS data including digital raster graphics (topographic maps in digital form), digital orthophotos, DLGs, and Digital Elevation Models that are used in environmental applications. The USGS has created several Web sites to query the data over the Internet (i.e., http://edc.usgs.gov/ and http://edcsns17.cr.usgs.gov/EarthExplorer/).

Federal, State, and Local Government Applications

Many federal agencies use GIS to create national and worldwide databases. The USGS is one of the agencies that pioneered its use. The USGS has developed many GIS formats and data sets that are used by the public, by industry, and by federal, state and local governments. One of the enhanced USGS sites, SDDS uses an IMS to serve the National Elevation Dataset (NED) at http://seamless.usgs.gov/viewer.htm. The U.S. Bureau of Census has created several data formats and data sets such as census data and the TIGER digital data. The Federal Emergency Management Agency (FEMA) has also created many GIS data sets and modules such as flood risk maps, National Hazard Loss Estimation Methodology (HAZUS), and other emergency-related data sets. FEMA has established an Internet-based GIS "Flood Map Store" to allow the public to access flood maps.

State and local governments use GIS for regional and urban planning and development, policy analysis, cultural and resource management, social and demographic studies, transportation, education, environmental health, assessment and waste management, and public utilities. For example, GIS is used to incorporate up-to-date data and sometimes real-time information for public utilities and wastewater and storm-water management.

There are numerous local government applications of GIS including emergency response and management, facilities or properties mapping, site location, building and site permits, land use, land regulation, street planning, election management, and emergency transportation routing. For example, law enforcement and public safety agencies collect large amounts of data including those regarding crimes, citations, arrests, field interviews, chronology, and other law enforcement information. Law enforcement agencies use GIS to create crime location and trend maps. It provides a powerful decision-making tool for police and federal and private investigators by allowing them to analyze crime data graphically in a spatial context. A GIS also allows government lawyers and prosecutors to improve case preparation and presentation and create interactive maps and models for cases including spatial evidence data linked to images, documents, witnesses, and other evidences.

Commercial Applications

Most business data are spatially georeferenced. GIS can be used to determine a business location based on crime data, environmental factors, location of customers and competitors, and transportation infrastructure. GIS can also be used to manage and analyze information about sales, customer (demographic) profiles, markets, distribution networks, inventories, status of processing facilities, service boundaries, and delivery routes. For example, GIS can assist the food processing industry by providing accurate spatial and attribute information about raw materials and inventories and distribution networks.

Companies providing pesticides, fertilizers, seeds, equipment, and services to farmers can benefit from a GIS by analyzing short- or long-term trends and strategies for product distributions. They can use GIS to monitor customer demand based on conditions such as weather to deliver products efficiently.

GIS technology enables pipeline companies and operators to integrate geospatial-based data to monitor and manage pipelines with efficiency and integrity. Applications include demographic analysis, marketing, customer segments, and optimal site locations for pipes and pumping stations. GIS technology enables pipeline companies to integrate geography-based data with other data such as customer, operations, and marketing for planning and problem-solving purposes. Many pipeline companies use GIS to monitor, analyze and evaluate pipeline performances. Pipeline companies can reduce design costs for locating potential pumping stations and pipelines by analyzing spatial data, geology, soils, land ownership, customer, topography, and the transportation network. The companies can also optimize the routing of service vehicles to save time and cost.

Similarly, GIS technology enables electric power companies to monitor, analyze and evaluate power grids. They can use GIS to integrate spatial data with operations, customer demand, and other data to optimize services to customers. When there is a high demand for electricity, companies can analyze and find the least expensive source of electricity from other power companies. Most power companies also use GIS to locate new potential power grids and towers.

Factories and public service companies utilize GIS to monitor raw material input, production, and output. GIS allows companies to analyze production to make long-term predictions. System designers use GIS because its modules or user interfaces can be changed at a low cost compared with factory machinery.

Military and Defense Applications

Defense organizations and military forces use GIS to improve decision support systems. Most military aircraft and ships use GIS and related technologies such as GPS and artificial intelligence systems. At a command control, most decisions are geographical (spatial). A military commander can make up-to-date operational, logistical, tactical, or administrative decisions with a GIS. In the past, most battle decisions were based on paper maps and pushpins. A GIS can provide rapid access to up-to-date spatial data and tools to field commanders or command controls to make quick decisions and can be used to create virtual battlefields. A GIS can also be used to provide logistics to troops or transportation units and handle base management. The use of spatial data standards with a GIS provides interoperability among many branches of military and contractors providing support to the military.

GIS is becoming an integral component in the intelligence field. Up-to-date information, which can be easily provided by a GIS, is important for the field. The CIA was one of the first agencies to use GIS. The National Imagery and Mapping Agency aids the intelligence community by providing many types of geospatial data and maps to the military using GIS.

Real Estate, Financial, Insurance and Business Applications

GIS allows realtors to build spatial databases so that customers can access real estate data quickly. Customers can visit several places in a short period of time using virtual GIS by displaying maps or aerial images of property locations, property photos, and videos. Customers can query data layers including proximity to schools, libraries, fire stations, police stations, highways, dump and toxic waste sites, mines, parks, entertainment facilities, or shopping centers. Title companies, among the first GIS users in the business sector, use GIS to search titles, access parcel ownership data, and make maps in a short period of time. Many title companies, multiple listing services, and the real estate industry have begun to implement Internet-based GIS marketing tools to provide free public access to ownership, locational, and physical data.

Financial institutions use GIS to analyze customers' financial behavior and needs. GIS allows the use of many databases including demographic, real estate, transportation, and other spatial data to establish market share, marketing targets, market penetration, and advertisement strategies. GIS can provide companies cost-effective ways to examine purchasing, travel, and other customer habits. Many investment companies are adopting GIS, which is well suited to analyze competitor information, visualize market situations, and analyze portfolios. GIS is used to find better locations for new bank branches and to analyze how these new branches affect existing branch locations. Many banks and credit card companies use i-GIS or IMS to provide customers with locator tools and interactive maps showing the nearest ATM or branch and the best route to an ATM location.

GIS allows surveyors to improve their tasks and to access many diverse data. Most surveyors are moving from computer aided design–based (CAD) systems to GIS, which provides tools to manage and analyze diverse data and integrate with GPS technology.

Journalists can access GIS and use demographic (census) data, crime locations, crime statistics, and traffic accidents to map many complex scenarios quickly and accurately. GIS provides reporters with more powerful tools, faster data access, and more dynamic mapping capabilities to complete tasks in a short period of time. Reporters can download the data using wireless connections to the Internet at the scene or before they arrive. With the availability of more powerful i-GIS, journalists will be able to analyze, model, and map areas of interest more efficiently in the field.

Several insurance companies use GIS and diverse data such as demographics, proximity to fire stations, and crime and environmental data to analyze property locations and surrounding areas for making accurate predictions and quick decisions.

Telecommunications and Transportation Applications

GIS applications in telecommunications include multiple market and demographic analysis, target marketing, customer segments for communication products and optimal site locations for cable and cellular towers. GIS technology enables telecommunication companies to integrate geospatial data with other data such as customers, operations, and marketing for planning and problem-solving purposes. Many local and long-distance telephone companies use GIS to monitor, evaluate, and analyze network performance and problems. Telecommunications companies can manage and route service vehicles using GIS, optimizing the routing of service vehicles to save time and cost. Call center operators can use GIS to access information about customers and the status of their networks such as equipment or signal quality. GIS provides support tools that can work in a complex environment, which many telecommunications companies require. Many cellular companies use spatial data (land ownership, customer locations, topography, and transportation network) to locate potential antenna sites to reduce design costs.

Airlines and bus companies can map everything from customer data to traffic statistics. Based on weather patterns, an airline company can use GIS to rearrange flights, match customers to particular airplanes, and track the status of airplanes. Bus companies can find the best routes by integrating GIS technology with GPS. By using GPS technology, the companies can track their fleet and analyze customer demand to use their buses more efficiently. Bus drivers can use GPS to find locations. GPS can be useful in rural areas where road signs may not be adequate.

GIS can be used to create worldwide transportation databases to handle daily changes such as monitoring rail systems and road conditions, redirecting ground and air traffic (intelligent transportation system), and maintaining transportation networks. GIS has been successfully used by railroad companies to handle commodity flow analysis, facilities management, emergency response and risk management, capacity planning, and passenger information. Complex road maps can be created using a GIS. Many companies and agencies use GIS for road construction, design, operations, and maintenance.

Integration of GIS technology with GPS allows trucking companies to reach locations quickly. Many companies using the two systems track fleet vehicles and find the best route to deliver goods and services for optimum deployment and cost savings. Moreover, these companies also use GIS for depot and warehouse operations.

Public Participation GIS (PPGIS)

A National Center for Geographic Information and Analysis (NCGIA) workshop was held in Orono, Maine, to explore public participation in GIS (PPGIS) in 1996. The workshop defined the characteristics of an alternative GIS called GIS/2 (http://ncgia.spatial.maine.edu/ppgis/ppgishom.html). In 1998, a specialist meeting called Empowerment, Marginalization and Public Participation GIS (PPGIS) was held in Santa Barbara, California (http://www.ncgia.ucsb.edu/varenius/ppgis/ncgia.html). The PPGIS term was used to include topics related to community interests and GIS technology. This initiative included several topics such as implementations of PPGIS, effects of the use of GIS on local politics, GIS in local surveillance, and the impacts and implications of spatial information on communities. PPGIS sessions were held at the 96th Annual Association of American Geographers (AAG) meeting in Pittsburgh in 2000.

The first "Annual Public Participation GIS Conference" was organized by URISA and held at Rutgers University, New Brunswick, New Jersey, in July 2002 (http://www.urisa.org/ppgis.htm). The conference brought together participants that included citizens and citizens groups, public officials, administrators, technicians, planners, librarians, policy scientists, and researchers. Several issues, including the value of GIS technology in empowering citizen organizations and communities, urban neighborhoods, indigenous peoples, developing nations, environmental organizations, and virtual communities, were discussed at the meeting.

PPGIS is a distributed, Internet-based GIS and has enabled many communities to access and distribute local knowledge among the community. PPGIS is intended for a broad audience of students, academics, planners, policy makers, and GIS practitioners. Several PPGIS projects have been implemented within the context of an academic debate over GIS and society (Weiner, Harris, & Craig, 2001). Users of community GISs do not require any software beyond an ordinary Web-browser, making the involvement of the community all the more possible.

DESKTOP GIS VERSUS INTERNET OR INTRANET GIS

Although desktop GIS has been a choice for many institutions requiring analysis of complex geographic databases, it has many limitations including cost and public access issues. Before the introduction of i-GIS, many companies, educational institutions, and local, state, and federal agencies started to use intranet GIS to overcome some of the limitations of a traditional GIS; however, an intranet-based GIS does not usually allow full public access. On the other hand, i-GIS has many advantages, including decentralized data storage and data maintenance, wider data access, and convenience. Web-based systems offer many opportunities to go beyond the home or office. Existing i-GIS map servers do not facilitate analysis of complex geographic databases, however, because some technological (e.g., software and bandwidth and speed) issues and specific user requirements. Today's Web based IMS systems offer data browsing, retrieving, updating, displaying and querying, mapmaking, address matching, and route finding. Most of them and probably new ones will be able to facilitate analysis of complex geographic databases in the near future when some of the technological limitations that exist today are overcome.

GIS DATA USERS AND THE INTERNET

GIS has been used at local, state, and national levels. The power of a GIS is highly correlated with its accessibility. A desktop GIS is mostly used by experts. Therefore, a desktop system is generally limited to a smaller group of people. A Web-based GIS can be accessed by millions of people using the Internet. Most people do not need to know all the aspects of GIS. Many probably do not realize that they are using an i-GIS (e.g., a map server such as MapQuest [http://www.mapquest.com/] or MapBlast! [http://www.mapblast.com/] providing maps and driving directions) when they request a best route for a destination.

Most GIS data are dynamic, therefore regular updating of data is required in most instances. When a user desires a best route, a map server should not contain outdated data. If a bridge is out, a GIS cannot generate alternate routing unless its database is updated promptly.

During the early days of GIS, data were created and used predominantly by federal agencies. The U.S. Geological Survey (http://www.usgs.gov/), the U.S. Census Bureau (http://www.census.gov/), the Central Intelligence Agency (http://www.cia.gov/), and the National Imagery and Mapping Agency (http://www.nima.mil/) have generated many data formats and databases. During the 1970s and 1980s, GIS data were mostly available on magnetic tapes or floppy disks, which were delivered in days or weeks and were costly. The Internet was used to transfer data to private users, but during the late 1980s and early 1990s the main users of GIS data and the Internet were government agencies and research universities. With the introduction of the Web in the early 1990s, many institutions started to provide data to the public over the Internet. During the past decade, local and state governments, as well as the private sector, helped create many datasets that were available to the public. GIS became a part of our daily life and a multibillion dollar industry in the late 1990s. Most of the GIS data were provided free via the Internet. The USGS stopped serving some of the data that were originally provided from its Web site and transferred some datasets to private companies. These companies provided GIS data free or charged minimal fees for faster service (i.e., faster Internet connections or delivery) because their sites were financially supported by advertisements. When advertising companies started to cut their advertisement spending, GIS data providers started to charge more for their services.

INTERNET VERSUS INTRANET GIS

The term intranet is usually used to describe applications and protocols of the Internet used to share and move information within an organization's boundaries. Intranet systems have been used to serve and share GIS data within institutions because data could not be made public because of security issues and other technical limitations of the Internet. Many large corporations have Intranets for their employees. Intranets may be connected to the outside world via a firewall, which allows a protected gateway between an organization's internal network and the Internet. An Intranet typically has several advantages over the Internet:

- *Secure connections:* Intranet provides private internal networks such as local area network (LAN) or wide area network (WAN), which are protected from outside Internet users by a firewall.
- *Easier control:* Intranet is much easier to handle in terms of protocols and connections.
- *Higher data transfer speed per unit (bandwidth) cost:* Intranet provides higher and broader bandwidth per unit cost than the Internet.

For large companies that have offices in various cities or states, Intranet services may not be sufficient. Several network providers offer virtual private network (VPN) services, which are used on the public or open Internet, to companies that have more than one business location. These companies use point-to-point tunneling protocol (PPTP) to make secure connections between VPN nodes. Because the Internet is an "unsecure" open network, the PPTP is used to transmit data from one VPN node to another securely.

As stated previously, GIS data are dynamic and must be updated regularly. Several county and city agencies started to update and share their data with local and state agencies via the Internet in the mid-to-late 1990s. To use a GIS over the Internet, RDBMS with object-oriented extensions, software systems with cross-platform portability, client-server architecture, and other technologies had to be developed.

With the growth of the Internet, the distribution and viewing of data online are now an integral part of many projects. The integration of GIS with the Internet is an inevitable trend that is becoming a reality. Several companies have developed ActiveX-based distributed applications in addition to the standard IMS-based systems. The ActiveX-based systems are similar to the IMS-based systems but use a Web browser. A user connects to a Web server having "desktop" GIS software using a browser and loads the ActiveX component to run a GIS mapping application software remotely. Using the ActiveX component has many advantages including the use of data on a local computer without using remote disk mount utilities, which can be difficult to maintain. This technique is ideal for local or state governments that may require quick access to data (i.e., ownership or parcel data).

Desktop GISs are not appropriate for modern distributed network environments because of their closed architecture. Distributed GIS services can provide many

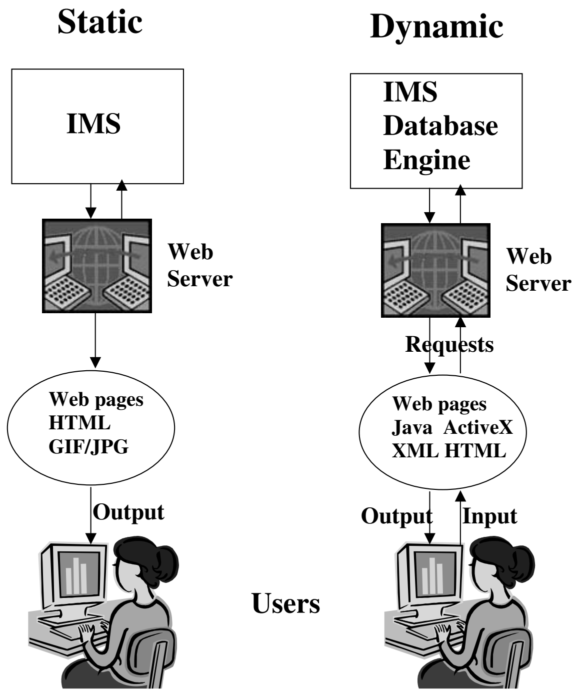

Figure 5: Static and dynamic Internet Map Servers.

capabilities and functions for data storage and management (Brown, 1999; Huang, Jiang, & Li, 2001; Huang & Worboys, 2001; Tsou & Buttenfield, 2002). In addition to the ActiveX-based systems, there are also other technologies, such as Java/VRML (virtual reality modeling language), common gateway interface (CGI), extensible markup language (XML), .NET, and other services used to support the development of i-GIS.

INTERNET MAP SERVERS

It is expensive to maintain and update large GIS databases. One of the goals of IMSs is to access large spatial databases in real time and to provide the data to the public. Most IMSs have been used to browse, display, query, and retrieve spatial and attribute data. Some IMSs can also be used to update GIS data. There are several commercially available IMS software packages (see references for their URL), which offer several GIS functions including routing, regional, and local- or street-level mapping, and simple querying and analysis (Jankowski, Stasik & Jankowska, 2001; Limp, 2001, 2002).

IMSs can be classified into two major groups, static and dynamic (Figure 5). A static IMS provides maps in GIF, JPEG, or other image formats. Map images (usually in the form of a digital raster graphics in TIFF format) are created using desktop GIS software or scanned from existing hard-copy maps in advance and served over the Internet using a Web server and basic Web browser formats (e.g., HTML code). Dynamic systems usually update map images based on users' requests or based on current data to be made available to the users (Figure 6). Only dynamic IMSs provide the functionality of local standalone GIS databases. Some dynamic systems allow users to create their own maps or perform limited geographic analysis. Several local and state governments provide data including parcel tax data, current conditions (roads, crime events, and patterns), environmental conditions such as lake or river levels and fire information, and other maps to the public using IMSs (Table 1).

Today there are many commercial Web-based IMS systems such as AltaMap (GeoMicro), ArcIMS, ArcView Internet Server, Autodesk MapGuide, BeyondGeo, Demis Map Server, EarthKey, FreshMaps, GEO-Data Explorer (GEODE), GenaWare, GeoServ.org, InterroMAP, MapInfo MapXtreme, MapObjects IMS, Maptitude for the Web, Map-TV, Oracle, VectorEyes, Web Mapper, and WebView. Some IMSs are available free of charge: ALOV Map, GeoTools, Imapper, Jshape, MapCiti, MapIt!, and Mapserver (see their URLs in the Further Reading section). Currently, most of these IMSs have some technological limitations. In the future, new IMSs will be able to overcome some or most limitations to facilitate analysis of complex geographic databases remotely via the Internet.

THE FUTURE OF INTERNET GIS (I-GIS)

One of the difficulties of offering distance-learning courses, particularly IT courses via the Internet, is the availability of software used over the Internet (e.g., the ability to use software like Excel or Wordperfect on a different (remote) computer using a Web browser). Much research is being conducted to integrate desktop and Internet-based software packages. Geographic information science (GISc) is one of the fields that will benefit the most.

Integration of desktop GIS and i-GIS is still an evolving issue. More and more companies have offered i-GIS packages over the last several years, and shareware software packages are being circulated. These new developments will bring several other issues including data and computer security, meta-data, and data format issues to the forefront.

A standard language for i-GIS is necessary to have systems compatible across the Internet. The Open GIS Consortium (OGC), an international industry consortium of several hundred companies, government agencies, and universities participating in a consensus process, has been established to develop publicly available geoprocessing specifications and to deliver spatial interface specifications that are openly available for global use (http://www.opengis.org/). OGC's OpenGIS specifications for interfaces and protocols, the foundation for "interoperable" geoprocessing, have become widely used. Development of XML in 1996, which has been a W3C standard since February 1998, provided a tool for OGC to develop a geography markup language (GML), a new common geospatial data format. OGC specified GML, an XML extension for encoding the transport and storage of geographic information, including both the geometry and properties of geographic features in 1999. GML, which is based on OGC's abstract model of geography, is becoming a standard for i-GIS. The GML 2.5 version, which was approved in September 2001, incorporated various schema revisions. The latest version, GML 3.0, is currently in progress.

Note. All sites retrieved October 22, 2002.

Internet-GIS is becoming one of the most rapidly evolving fields in e-commerce. GIS applications in wireless e-commerce integrating GPS and GIS technologies to direct customers to the nearest locations such as restaurants, gas stations, and hotels and to track vehicles for automatic vehicle location are now available. For institutions, i-GIS will provide easy access to GIS data without duplication (decentralized database). For developers, i-GIS will facilitate a new challenge as well as an opportunity to increase their market share. Users will become proficient at bringing GIS to the Web and become experts in data import and export, query, manipulation, analysis, output, and synthesis. More important, users may become project managers who will realize the value of i-GIS for quick decision making.

Existing i-GIS map servers are presently not able to fully analyze complex geographic databases. In the near future, we will be able to use a GIS from wherever we are, at home or in a different city. Still, it is likely that a Web-based i-GIS will never be "complete." Upgrades, patches, updates, and changes will always be necessary. As our collective experience and understanding of the technology grows daily, we will never be satisfied with the current technology and will look for better alternatives.

CONCLUSION

Today GIS is being used in almost every field that emphasizes spatial data collection, analysis, manipulation and integration, analysis, and modeling. Desktop GIS has been the system of choice for many institutions requiring analysis of complex geographic databases. Nonetheless, it has many limitations including startup cost, learning curve, management difficulty, and public access issues. On the other hand, i-GIS, using decentralized data storage, provides easy access to GIS data without duplication. With the growth of the Internet, distribution and viewing of data are now an integral part of many projects. The integration of GIS with the Internet is still an evolving issue and an inevitable trend that is becoming a reality. Although today's i-GISs do not offer the full capabilities of a desktop GIS, partly because of software limitations and the bandwith and speed available to most Web users, future i-GISs will include automated GIS processing and will be a part of our daily lives.

ACKNOWLEDGMENTS

The author thanks Drs. Thomas C. Kind, Burl I. Naugle, George W. Kipphut, Peter W. Whaley, and Ms. Lynn V. Leasure for reviewing this manuscript. The U.S. physical map (Figure 6) was created by Mr. Kevin Sturgill.

GLOSSARY

ActiveX ActiveX, which includes both client and server technologies, is a set of technologies enabling interactive content for the World Wide Web.

Attribute Nonspatial information associated with a geospatial feature.

Digital line graph (DLG) A vector data format defined by the U.S. Geological Survey.

Digital Raster Graphics (DRG) A raster data format defined by the U.S. Geological Survey.

Geospatial data Information (derived from mapping, surveying, or remote sensing technologies) that identifies the geographic location and characteristics of natural or artificial features and boundaries on Earth.

Graphic interchange format (GIF) An image format.

Geography markup language (GML) A new common geospatial data format.

Global positioning system (GPS) A satellite navigation system providing specially coded satellite signals that can be processed using a GPS receiver to compute position. At least three GPS satellite signals are used to compute positions in two dimensions and four GPS satellite signals are needed to compute positions in three dimensions. In the United States, GPS is funded and controlled by the U.S. Department of Defense.

Hypertext markup language (HTML) A language used to create Web documents.

Internet map server (IMS) Internet-based mapping system providing maps online and a technology integrating GIS and the Internet.

Joint Photographic Experts Group (JPEG) An image format.

Pixel A two-dimensional picture element (cell). The smallest element of a digital image.

Raster An equally spaced, two-dimensional rectangular grid (a regular or nearly regular, tessellation of a surface) pattern of quantized sample values. It is often called an image-based data structure.

Spatial data transfer standard (SDTS) A spatial data format defined by the Department of Commerce in 1992 (Federal Information Processing Standard 173).

Tagged image file format (TIFF) An image format.

Uniform resource locator (URL) A unique address on the Internet.

Vector A mathematical term for a directed line segment. A data model using sets of coordinates and attributes to define discrete features, points, lines, or polygons.

Extensible markup language (XML) It describes a class of data objects called XML documents and the behavior of computer programs processing them. XML is designed to describe data, whereas HTML is designed to display data.

Global Diffusion of the Internet

Nikhilesh Dholakia, *University of Rhode Island*
Ruby Roy Dholakia, *University of Rhode Island*
Nir Kshetri, *University of North Carolina*

INTRODUCTION

Since the 1970s, the number of countries connected to the Internet has increased steeply from 60 in 1993 to 214 in 2000 (see Figure 1). Despite this growth, the Internet has a highly asymmetric global distribution (see, e.g., Kshetri, 2001). There were 40 million people worldwide using the Internet regularly in 1995 (Media Metrix, 2000). This jumped to 131 million by the end of 1999 (Pastore, 2000) and to 606 million by September 2002. An estimate by the Angus Reid Group (2000) suggests that that there will be one billion Internet users by 2005.

The Internet is the fastest diffusing information and communication technology (ICT) innovation to date. For instance, it took just 10 years for the Web-based Internet to reach 50% of American homes, compared to 52 years taken by electricity and 71 years by the telephone (Thierer, 2000). It took only 3 years for the Internet to reach 50 million users. By contrast, it took 38 years for radio and 13 years for television to have 50 million users (Bell & Tang, 1998). During 1999, the number of Internet users increased by 1 million every month (McLaren, 1999).

The global distribution of Internet penetration and use, however, is far from uniform (see Figures 2 and 3). Developed countries account for a disproportionately high number of Internet users worldwide: 61.7% of the world's Internet users live in North America and Europe, for instance, but they account for less than 20% of the world's population. As of May 2002, less than 0.1% of Africans had access to the Internet compared to 52.2% of North Americans. Similarly, as of 2000, developing countries with 84% of the world's population had less than 6% of world's Internet users (Cyber citizenship gains in developing world, 2000). The discrepancy is even steeper for the number of Internet hosts worldwide: North America and Europe account for almost 90% of Internet hosts, whereas Asia and the Pacific, with over 60% of the world's population and 31% of the world's Internet users, contribute only 8% of the total number of Internet hosts worldwide.

There are, however, some encouraging signs. For instance, Internet users worldwide grew by 30% in 2001 and one-third of the new users were from developing countries (United Nations Conference on Trade and Development [UNCTAD], 2002).

Because the Internet is a "new product," an analysis of the pattern of its spread worldwide and within a given country from the perspective of the innovation diffusion and adoption literature could provide valuable insights into the factors driving the diffusion dynamics (Takacs & Freiden, 1998). The diffusion and adoption patterns of an innovation are functions of several elements including characteristics of the *innovation* itself, the *channel of communication*, the nature of the *social system*, and *time* (Rogers, 1983).

Because social systems around the world differ in several dimensions, diffusion patterns of the Internet vary widely across countries. In this chapter, some of the key differences in Internet diffusion patterns around the world are highlighted.

We examine the global diffusion of the Internet and the factors influencing its diffusion dynamics. The remainder of the chapter (a) provides a brief historical overview of global Internet diffusion, (b) discusses the global diffusion patterns of the Internet, (c) integrates theories from diverse perspectives that help explain the diffusion and adoption phenomena, (d) discusses the factors that are likely to shape the global diffusion of the Internet, and (e) provides some conclusions.

INTERNET DIFFUSION: HISTORICAL OVERVIEW

The Internet passed through various stages to arrive at the present situation. The first wide area network (WAN)

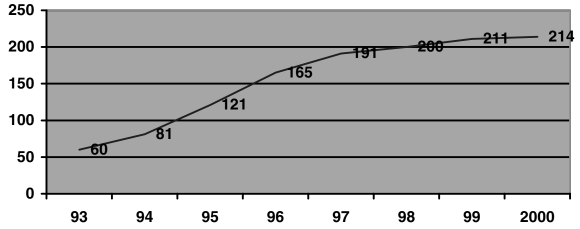

Figure 1: Number of countries connected to the Internet. Source: International Telecommunications Union (2001b).

was developed in 1965. It took another 4 years for the first two hosts in the ARPANET to be connected. The graphical format of the Internet as we know it now emerged in the 1990s.

Internet Diffusion Prior to 1980

Drawing primarily from Leiner et al. (2002), we trace the early history of Internet diffusion in this section. President Eisenhower's request for funds to create the Advanced Research Projects Agency (ARPA) within the U.S. Department of Defense in 1958 laid the foundation for the Internet. The packet switching theory first published by Leonard Kleinrock of MIT in 1961 was a major step toward computer networking. In August 1962, J.C.R. Licklider, also of MIT, proposed the "Galactic Network" concept. The Galactic Network concept provided a remarkably prescient view of the contemporary Internet—it envisioned a set of globally interconnected computers through which data and programs could be accessed from any site. In October 1962, Licklider became the head of the computer research program at the Defense Advanced Research Projects Agency (DARPA). He also convinced his successors at DARPA of the importance of the networking concept. Under a military contract, Paul Baran of Rand Corporation wrote key memoranda in the early 1960s outlining the "survivability" of a distributed, packet-switched network, even under conditions of a major nuclear attack. As Rand Corporation states in its historical notes

> All of the nodes in this unusual network would have equal status; be autonomous; and be capable of receiving, routing, and transmitting information. Under Baran's concept of distributed communications—now called packet switching—each message would be broken into a series of short, fixed-length pieces, and each would be sent as an individually addressed packet that would find its own way through the network by whatever route happened to become available, jumping from node to node until it reached the final destination. If parts of the network were destroyed, the self-sufficiency of each node plus the data within the packet allowed the node to seek alternative ways of moving the packet along. (RAND's History, n.d.)

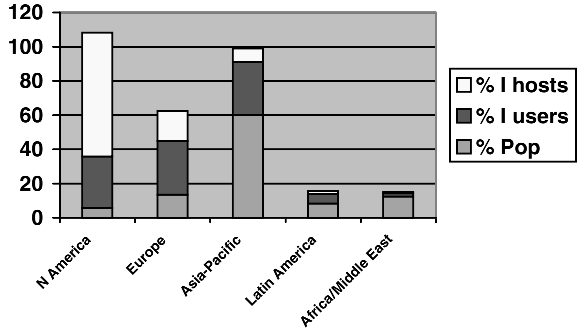

Figure 2: Uneven distribution of the Internet worldwide. Sources: Kshetri and Dholakia (2002), Nua Internet Surveys (2002), and authors' research.

Next, it was necessary to make the computers "talk" to each other. In 1965, MIT researchers Thomas Merrill and Lawrence G. Roberts were able to connect the TX-2 computer in Massachusetts to the Q-32 in California. This was the first wide area computer network. In 1966 Lawrence G. Roberts, who had joined DARPA, put together his plan for the ARPANET. Kleinrock's Network Measurement Center at UCLA was selected to be the first node on the ARPANET in September 1969. In October 1969, the Stanford Research Institute (SRI), about 350 miles to the north of UCLA, provided a second node and the first host-to-host message was sent from Kleinrock's laboratory to SRI. Two more nodes were added at the University of California at Santa Barbara and the University of Utah. Four host computers were connected together into the initial ARPANET, the forerunner of today's Internet, by the end of 1969. It is interesting to note that independent of the U.S. efforts, Donald Davies of the National Physical Laboratory (NPL) in U.K. proposed development of a nationwide packet communications network, based on a packet size of 1,024 bits—the same packet size that Paul Baran had proposed in the U.S.

The number of computers connected to the ARPANET grew rapidly after 1970 (see Table 1). In December 1970, the Network Working Group (NWG) finished the initial ARPANET host-to-host protocol, called the network control protocol (NCP). As the ARPANET sites completed implementing NCP during the period 1971–1972, the network users finally could begin to develop applications. In 1972, electronic mail was introduced. Bolt, Beranek, and Newman (BBN), a consulting firm started by MIT professors Richard Bolt and Leo Beranek and their student Robert Newman, sent the first person-to-person email using the @ symbol in the address. To meet the needs of an open-architecture network environment, Bob Kahn and Vint Cerf developed the transmission control protocol/Internet protocol (TCP/IP) in 1973. TCP/IP proved remarkably resilient and enduring as a means of managing data communication networks.

Starting from the mid-1970s, computer networks grew rapidly. ARPANET expanded internationally by connecting to the University College of London (England) and NORSAR (Norway) in 1973. Most of the early networks, however, were closed communities of scholars. There was virtually no pressure for the individual networks to be compatible and hence they were not.

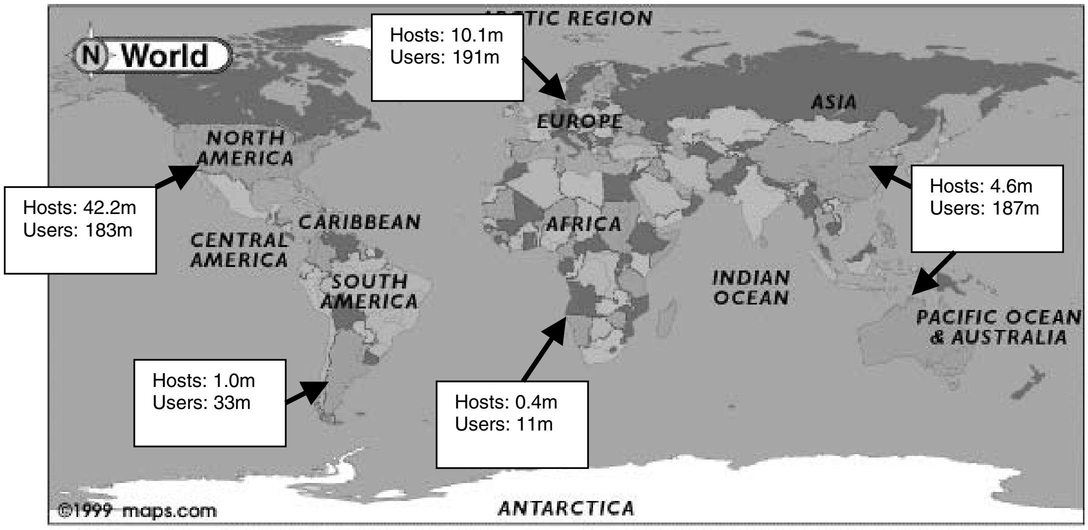

Figure 3: Global distribution of Internet hosts and Internet users. Note: Internet user data are for September 2002 and Internet host data are for the year 1999.

Internet Diffusion During 1980–1990

Various developments in the 1980s facilitated the diffusion of the Internet. The number of Internet hosts grew 500-fold in this period, from 200 in 1980 to 100,000 in 1989 (Table 1). In 1980, Tim Berners-Lee wrote the program known as "Enquire Within," which was a predecessor to the World Wide Web (WWW). Other developments include IBM's announcement of the first personal computer in 1981 and the foundation of Cisco Systems in 1983.

The ARPANET host protocol changed from NCP to TCP/IP on January 1, 1983, to meet the needs of an open-architecture network. In November of 1983, the domain name systems (DNS), such as .edu, .gov, .com, .mil, .org, .net, and .int were created. The first "dot-com" in the world was Symbolic.com. It became the first registered domain on March 1, 1985. In 1985, the National Science Foundation (NSF) also decided that TCP/IP would be mandatory for the NSFNET backbone.

Table 1 Growth in the Number of Internet Hosts

Year	No. of Hosts	No. of Hosts (in millions)	Remarks
1965	2	—	TX-2 and Q-32 connection.
1970	4	—	ARPANET project had a backbone of four computers.
1972		—	E-mail introduced
1973		—	TCP/IP developed
1975	100	—	
1980	200	—	"Enquire Within," predecessor of WWW, developed
1985	2,000	—	TCP/IP mandatory for NSFNET
1986	5,000	—	
1987	10,000	—	
1989	100,000	0.1	
1990	200,000	0.2	NSFNET succeeded ARPANET
1993	2,700,000	2.7	Mosaic Web Browser developed
1994	5,800,000	5.8	
1995	14,000,000	14.0	Windows 95
1996	22,000,000	22.0	
1997	30,000,000	30.0	
1998	43,000,000	43.0	
1999	72,000,000	72.0	
2000	104,000,000	104.0

Internet Diffusion After 1990

The Internet was opened to the public in the early 1990s. Major technological developments such as Tim Berners-Lee's creation of the World Wide Web (WWW), the development of the Mosaic Web browser in 1993, Sun Microsystems' release of Java, and the release of Windows 1995 further facilitated the diffusion of the Internet (Webopedia 2002). As a result, the Internet grew significantly in the 1990s, in terms of the number of hosts, number of users, and global coverage. The number of Internet hosts increased from 200,000 in 1990 to 104 million in 2000. By 1990, major countries across the world such as Australia (AU), Germany (DE), Israel (IL), Italy (IT), Japan (JP), Mexico (MX), the Netherlands (NL), New Zealand (NZ), Puerto Rico (PR), the United Kingdom (UK), Argentina (AR), Austria (AT), Belgium (BE), Brazil (BR), Chile (CL), Greece (GR), India (IN), Ireland (IE), Korea (KR), Spain (ES), and Switzerland (CH) had country-specific domains and were already connected to the NSFNET (Goldstein, 2000). Several smaller and less developed countries were gradually connected to the Internet.

Future Scenarios

Along with the exponential growth in the number of Internet users worldwide, newer means to access the Internet keep appearing. In particular, Internet access by mobile and broadband technologies is experiencing rapid growth worldwide. For instance, by 2009, cellular phone subscribers in the world are expected to outnumber fixed line subscribers (International Telecommunications Union, 2000). Furthermore, over 25% of e-commerce is predicted to take place over handheld sets by 2005 (Shaffer, 2000).

The number of broadband subscribers worldwide is estimated to exceed 46 million by the end of 2002 (Reports about the death of broadband are premature, 2002). The annual worldwide broadband growth rate for the period 2002–2004 is projected to be in the range of 61% to 150% (Lammers, 2001). Whereas cable modem service is gaining popularity in the U.S., digital subscriber line (DSL) has become the main broadband access technology outside the U.S. Other broadband access technologies such as satellite broadband, fiber-to-the-home, and fixed wireless service accounted for 5% of the worldwide broadband market in 2002 (Study says broadband growth remains robust, 2002).

GLOBAL DIFFUSION OF THE INTERNET

Starting with just a few countries in 1990, the number of countries connected to the Internet crossed 200 by mid-1998 (World Intellectual Property Organization, 2000) and 214 in 2000. The diffusion pattern of the Internet, however, varies widely across the world. Table 2 details the global distribution of the number of Internet users in September 2002. North America, where the Internet originated, has over 182 million users, accounting for 30% of the world's users but only 5.6% of the world's population. Europe, with its early connection to the ARPANET, currently has the highest number of Internet users (more than 190 million). Asia and the Pacific, with over 60% of the world's population, are experiencing some of the most rapid growth in recent years and are expected to double their number of Internet users by 2005.

Internet Diffusion in Africa and the Middle East

In the Middle East region, Israel was a pioneer in connecting to the Internet—in 1989, along with selected key European and Asian nations. African and other Middle Eastern nations came to the Net much later. By

Table 2 Geographical Distribution of Internet Users Worldwide (September 2002)

World Region (% of World Population)	Number of Internet Users (% of World Users)	Remarks
North America (5.6% of world population)	182.67 million (30.2% of the total Internet users in the world)	Enjoys many advantages. The place of origin of most Internet technologies.
Europe (13.5% of world population)	190.91 million (31.5% of the total Internet users in the world)	Early connection to ARPANET proved to be of great value.
Asia-Pacific (60.2% of world population)	187.24 million (30.9% of the total Internet users in the world)	Some of the most rapidly growing Internet markets located here.
Latin America (8.3% of world population)	33.35 million (5.5% of the total Internet users in the world)	Except Mexico, Internet entered late, but is growing very fast.
Africa/Middle East (12.4% of world population)	11.43 million (1.9% of the total Internet users in the world)	Israel was a pioneer. Sub-Saharan Africa was very late. South Africa dominates.
World (Total)	605.60 million	Expected to reach a billion or more by the end of the decade.

connecting with the global network in 1993, South Africa and Tunisia became the first African countries to join the Internet (Tripod.com, 2002). By 1998, all African countries except Congo had Internet connection (the State of the Internet in Africa, 2000; Tripod.com, 2002). South Africa dominates this region's Internet market, followed by Israel, Egypt, the United Arab Emirates, and Saudi Arabia (Table 3). In discussing ICTs in Africa, Ya'u (2002) tellingly points out, "Of the 157,325 Internet hosts in Africa, 144,445 are in South Africa, leaving less than 10,000 for the rest of Africa."

According to the State of the Internet Report 2000 of the U.S. Internet Council, Internet diffusion in Africa has been hampered by factors such as poverty, low computer penetration, illiteracy, lack of trained personnel, lack of interest, and a failure to understand the benefits of Internet access (CITI, 2000).

Internet Diffusion in Asia and the Pacific

Internet is growing very rapidly in the Asian–Pacific region. The number of Internet users in this region is expected to increase to 374 million by the end of 2005 (Rao, 1999). Japan, South Korea, Taiwan, and New Zealand dominate the region's Internet market so far (Table 4). China and India, however, are the fastest growing Internet markets in this region (Javalgi & Ramsey, 2001; Kshetri, 2002). Each is expected to have more Internet users than the U.S. by 2010 (Nua Internet Surveys, 1999b).

Internet Diffusion in Europe

Most European countries introduced the Internet much earlier than their counterparts in Asia, Africa, and Latin America. For instance, the University College of London (England) and NORSAR (Norway) were connected to ARPANET as early as in 1973. Similarly, Germany (DE), Italy (IT), the Netherlands (NL), and the United Kingdom (UK) were connected to the NSFNET in 1989 and Austria (AT), Belgium (BE), Greece (GR), Ireland (IE), Spain (ES), and Switzerland (CH) were connected in 1990 (Goldstein, 2000). Germany and the U.K. dominate the Internet market of this region (Table 5) .

Internet Diffusion in Latin America and the Caribbean

Compared to the North American and European economies, the Internet is a relatively new phenomenon

Table 4 Internet Users (IU) and Internet Hosts (IH) in Asia and the Pacific (1999)

in Latin America and the Caribbean. The region, however, is experiencing phenomenal growth in the number of Internet users. A survey conducted by Nazca indicated that use of the Internet tripled in this region between 1995 and 1997 (Tudor, 1999). The networks in most of the Latin American economies were established during 1995–99 (Hahn, 1999). By connecting to NSFNet in 1989, Mexico became the first country in Latin America to connect to the Internet (Goldstein, 2000). As Table 6 indicates, big Latin American economies such as Argentina, Brazil, and Mexico dominate the Internet population in the region.

Internet Diffusion in North America

North America, the original locus of the Internet, accounts for numbers of Internet hosts and Internet users disproportionately higher than in the rest of the world. By 1999, the U.S. had over 98 million Internet users and 40 million hosts (Euromonitor, 2001b). Canada, similarly, had over 11 million Internet users and 1.4 million Internet hosts by 1999 (Euromonitor, 2001b). These numbers have been growing rapidly and reaching saturation levels.

Unconnected Pockets

Most of the countries that connected to the Internet very late, connected in very limited ways, or did not connect at all did so not because of economic reasons but because of *political* or *religious* reasons. Commenting on Internet-free countries in 1996, Maslen (1996) made the following observations:

Table 6 Internet Users (IU) and Internet Hosts (IH) in Latin America and the Caribbean (1999)

Country	IU (1999)	IU per 1000 People (1999)	IH (1999)	IH per 1000 People (1999)
Argentina	520,000	14.2	132,000	3.6

Source: Euromonitor (2001a, 2001b).

In June 1996, just twenty countries remained with absolutely no e-mail or Internet connection: Afghanistan, Bhutan, Burma, Burundi, Congo, Gabon, Guinea Bissau, Iraq, Liberia, Libya, Mauritania, North Korea, Oman, Rio Muni, Rwanda, Somalia, Syria, Western Sahara, Yemen, and Zaire. . . . Of these countries, more than half are in Africa, in most cases only recently (fifty years or less) free from colonial rule. . . . Many of these countries are not wealthy, but there are surprising exceptions. Libya, Western Sahara, Oman and Gabon are relatively affluent, so their abstention from the Internet cannot be explained in purely economic terms.

Politics, economics and international diplomacy have always been involved in the spread of the Internet. Sixteen of these twenty "unwired" countries are Islamic, or have large Islamic populations. . . . At least six Internet-free countries have been involved in destructive internal or external conflicts in the last ten years. . . . Iraq, Libya, North Korea and Somalia (a fifth of the no-Internet countries) have all been on poor (or hostile) diplomatic terms with the United States. . . . [There is also] a definite (two-way) correlation between countries' levels of democracy and Internet connectivity. Sixteen of the twenty unconnected nations possessed very low levels of democracy.

THEORIES OF DIFFUSION AND ADOPTION OF INNOVATIONS

A deeper and richer understanding of the multifaceted and complex processes of diffusion and adoption of the Internet requires an integration of theories from diverse perspectives such as political science and international relations, sociology, marketing, communications, information systems, and geography.

Theoretical and empirical evidence suggests that politics and government policy play important roles in the diffusion of modern ICTs. Diffusion theories that relate diffusion pattern with political structure in a country argue that a technology is not equally compatible with all types of political structures. These theories, for instance, predict that authoritarian governments have relatively less favorable attitudes toward developing interpersonal means of communications such as the telephone and the Internet (e.g., Groth & Hunt, 1985; Kshetri, 2001; Kshetri & Dholakia, 2001). Groth and Hunt (1985), for instance, postulate that Marxist governments allocate a relatively smaller proportion of resources for the development of interpersonal communications. The unfavorable attitude towards the Internet has hampered the growth of Internet in countries with authoritarian regimes such as China, Cuba, and Syria.

Diffusion of innovations also entails "interaction between life-experience and history" (Erben, 1993) and hence theories from sociology may help explain some aspects of the diffusion dynamics. For instance, the cultural imperialism hypothesis (Tomlinson 1991)—western control of mass media combined with human desire to improve their lives leads consumers from developing countries to imitate the developed ones—could help explain the role of global media in the diffusion of modern ICTs in developing countries. Similarly, technology–society compatibility theories (Gatignon & Robertson, 1985; Rogers, 1983) could help explain why a particular technology is more compatible with certain societies than others. Past research has found that "country-level effects" or "societal effects" (Kshetri & Dholakia, 2002; Zaheer & Zaheer, 1997) have a strong influence on the technology adoption behavior of firms and individuals in a country.

Because diffusion of innovation requires an understanding of "people, hardware, software, communication networks and data resources" that collect, transform, and disseminate information (O'Brien, 1996), theories from information systems are well suited for explaining such aspects of the diffusion and adoption phenomena.

Diffusion and adoption of ICTs entail decisions at various levels (individual, organization, national, international) about allocation of scarce resources (Andrews, 2002). Economic theories help explain how individuals, organizations, and governments make decisions regarding the allocation of resources in ICT investment. Basic demand and supply theories are helpful in explaining the varied distribution patterns of the Internet across countries. For instance, income can be expected to be positively associated with the demand for modern ICT products (Gatignon & Robertson, 1985; Rogers, 1983).

Geography and geopolitics are important aspects of international business in general (As-Saber, Liesch, & Dowling, 2000) and global diffusion of innovations in particular. Geopolitical theories help in answering questions such as, "Why are things located where they are? How do different places relate to each other? How have geographic patterns and relationships changed over time?" (Baerwald, 1996, p. 23). Geopolitical variables include population (Cohen, 1963) as well as characteristics of populations such as skills, educational qualifications, productivity, and the cost of labor (As-Saber et al., 2000; Baerwald, 1996). Literacy rates and English language skills are other geopolitical factors likely to influence the diffusion of innovations. Such skills are associated with the availability of information and the proficiency required to use a new technology or the "interrelatedness" among users and producers of the technology (Cassiolato & Baptista, 1996). The diffusion of a technology is negatively related to the disparity between the skills needed to use the technology and the consumer's existing knowledge (Gatignon & Robertson, 1985). High illiteracy rates have hampered the adoption of the Internet in less developed countries. Geopolitical variables such as geographical distance between adopting units (Gatignon & Robertson, 1985) influence the level of terrestrial barriers and hence the diffusion of the Internet. Origination of the Internet in the U.S. is one of the major factors responsible for the disproportionately higher number of Internet users in North America. Furthermore, high-bandwidth backbones were created first in North America, followed by Europe, and the data traffic to other regions was constrained by low-bandwidth connections.

FACTORS IMPACTING THE DIFFUSION OF THE INTERNET

Economic Factors

Economic factors such as income level, availability and price structures of ICT products and services, and bandwidth and supporting infrastructures influence the diffusion of the Internet (Kshetri, 2001). The cost of a PC as a proportion of per capita GDP, for instance, is 5% in high-income countries compared to about 300% in low-income countries (International Telecommunications Union, 2001a). In January 2001, the price of the cheapest Pentium III computer was US $700 (United Nations Development Program [UNDP], 2001b), an amount much higher than the average per capita GDP of most developing countries. Similarly, monthly Internet access charge as a proportion of per capita GDP in 2001 varied from 1.2% in the United States to 118% in Sierra Leone (international Telecommunications Union, 2001a).

Economic factors influence the means used to access the Internet. Many people in developing countries who cannot afford PCs can access the Internet through public kiosks and cafes at much lower rates (e.g., Kirby, 2002). Paging networks are popular in China because of the higher costs of computer and the fixed Internet access (Ebusinessforum.com 2000). In Japan, the popularity of NTT DoCoMo's i-Mode services and the government's effort to lower the cost of data flow over the mobile network accelerated the growth of the mobile Internet (Stout, 2001).

Finally, bandwidth availability is a determinant of Internet adoption and diffusion. In general, it is very low in developing countries. For instance, 50% of the worldwide bandwidth capacity is in North America compared to 3% in the Middle East and Africa (Frontline.net, 2001). Lower bandwidth results in longer times to transfer data and hence low relative advantage of Internet use. Moreover, the lack of intraregional infrastructures in developing nations of Asia, Africa, and Latin America means that even Internet communications with neighboring countries have to be routed through the U.S. or other industrialized countries in Europe, further increasing the costs. When high bandwidth is available and reasonably priced, as in South Korea, it becomes a driver of rapid Internet diffusion.

Sociocultural Factors

The degree of compatibility of the Internet and its various uses with the values and norms of a social system (Rogers, 1983) influences its diffusion patterns in that social system. An examination of the "values" and "culture" inherent in the Internet thus helps predict the degree of acceptance or rejection of the Internet in a society. An important component of this value system is related to skills required to use the Internet. Literacy and computer skills are almost prerequisites for Internet use. A large proportion of the population in developing countries is illiterate and a still higher proportion lacks computer skills.

Some attempts to overcome the literacy and language barriers are under way. One such attempt is the creation of the Simputer (Sterling, 2001), "a small handheld device designed for the rough conditions of rural India. It operates—without a keyboard—through touch, sound, and simple visual icons. It translates English-language Web sites into local Indian languages, reading the content aloud to illiterate users."

Moreover, the Internet tends to favor the English-speaking population because most of the software and interfaces used in the Internet are in English. Also, a large proportion of the WWW content is in the English language. For instance, a survey conducted in 1998 found that about 85% of the texts on the WWW were in English (Nunberg, 2000), which decreased to about 80% in 1999 (Nua Internet Surveys, 1999a).

Internet's asynchronous nature and impersonal style of communication make it incompatible with the cultures of some societies. For instance, in Japan personal correspondence is normally handwritten to show respect and courtesy (James, 1998).

Another component of the Internet's value system has to do with the place of origin of the core technology as well as the bulk of the content. The Internet originated in the U.S. and most of the content available on the WWW originates in the Western countries. Many people in the East tend to doubt the integrity of information originating from the Western world and view the use of English as a vehicle for executing an electronic "Pax Americana" (Shabazz, 1999).

Geopolitical Factors

National institutions can take measures to influence an innovation as well as its diffusion. As discussed in an earlier section, then U.S. President Eisenhower took initiatives to create the Advanced Research Projects Agency (ARPA) within the U.S. Department of Defense in 1958, thereby laying the foundation for the Internet. Similarly, measures taken by the National Science Foundation (NSF) in 1985 to make TCP/IP the mandatory protocol accelerated the diffusion of the Internet.

Political support strongly influences the diffusion of the Internet. Investments in modern ICTs alone will not bridge the digital divide in the absence of such political support (Koss, 2001). Internet diffusion in several countries, especially the developing ones, has been hampered by political factors such as authoritarian governments' concern about the flow of information on the Internet, tariff/nontariff barriers to ICT products, and unfavorable regulatory environments that negatively influence the telecom markets (Kshetri, 2001). The Internet has been described as "the greatest democratizer the world has ever seen" (Pitroda, 1993, p. 66). It is, thus, incompatible with most authoritarian regimes. Threatened by free flow of information on the Internet and the possible negative impact on their "right to rule," authoritarian regimes such as those of Malaysia, China, Singapore, Syria, and Cuba have opted for several mechanisms to control the Internet. For instance, the Chinese government closed 150,000 unlicensed Internet cafes following a deadly fire in a Beijing Internet cafe and the remaining cafes are required to install software that prevents access to up to 500,000 banned pornographic sites or sites with "subversive content" (Behind China's Internet red firewall, 2002). Similarly, a recent study conducted by Harvard Law School found that a central array of proxy servers in Saudi Arabia filters and blocks "sexually explicit" content (Hermida, 2002).

Authoritarian regimes are also slow to enact laws to recognize digital and electronic signatures (DES) (Kshetri and Dholakia, 2001). Many democratic governments lack DES laws as well. By the end of 2000, for instance, only about 45 nations in the world had laws recognizing DES (Stephens, 2001). Lack of DES laws has hampered the use of the Internet for commercial and government services in several countries.

Tariff and nontariff barriers and regulations in telecom markets are hindering e-commerce development in some developing markets. Many developing countries tend to treat ICT products as luxury items and impose import duty, surtax, value added tax, sales tax, etc., making these products expensive and unobtainable (UNCTAD, 2000).

Measures Taken by International Agencies

Several international institutions have launched ICT-led initiatives to accelerate the diffusion of the Internet (Kshetri, 2001; Shadrach, 2002). First, international agencies have helped *introduce* the Internet for the first time in developing countries that lacked the infrastructure for the Internet (Brown, Malecki, & Spector, 1976). In this way, the international agencies are breaking the "hierarchical pattern" (Gatignon & Robertson, 1985, p. 858) of Internet diffusion—a pattern of slow trickle-down of innovations from the rich to the poor. The United Nations Development Program (UNDP) introduced the Internet in more than 15 countries by connecting them to the global network (UNDP, 2001a). Similarly, the World Bank initiated the Information for Development Program (InfoDev) in 1995 to promote projects emphasizing the use of ICTs for economic and social development. This program has a special emphasis on the needs of the poorest in developing countries.

Second, some international agencies are helping to *reduce the gap between skills required for Internet use and existing skill*s of potential users in developing countries. By early 2001, for instance, UNDP had trained over 25,000 organizations and helped create over 40,000 Web sites for governments and civil society stakeholders (UNDP, 2001a).

Third, international institutions are influencing national governments to *increase the level of competition* in the telecom sector, which has resulted in the availability of higher quality ICT products and services at lower prices. In 1997, 60 developing countries made commitments to the World Trade Organization (WTO) to introduce competition in the telecom sector. Similarly, 13 developing countries also signed the Information Technology Agreements (ITA) under the WTO to eliminate customs duties on seven broad categories of ICT products.

Table 7 Internet Penetration and Related Indicators for Selected Economies in the World

	Internet Penetration			Factors Influencing Internet Penetration			
Country	No. of Internet users per 1000 (1999)	No. of Internet hosts per 1000 (1999)	Rank order of Internet penetration (within region)	GNP per capita ($, 2000)	Population ('000), (2000)	Civil Liberty Index (2000)	Literacy rate (%, 2000)
Africa and Middle East							
Israel	155.1	23.5	1	16,310	5,842	2	95.7
United Arab Emirates	146.0	14.6	2	17,276	2,369	5	74.6
South Africa	47.6	4.2	3	3,020	43,421	2	84.6
Sierra Leone	1.5	0.0	4	130	5,233	5	31
Asia-Pacific							
Singapore	340.7	21.0	1	24,740	4,152	5	91.8
Australia	267.3	50.8	2	20,530	19,165	1	99
Japan	162.1	18.5	3	34,210	126,550	2	99
China	5.5	0.0	4	840	1,261,832	6	82.8
Pakistan	0.7	0.0	5	470	141,554	5	44
Europe							
Finland	404.4	93.5	1	24,900	5,167	1	99
Slovenia	246.4	13.2	2	10,070	1,928	2	99.6
Portugal	81.0	7.1	3	11,060	10,048	1	91.4
Romania	17.2	1.7	4	1,670	22,411	2	97.9
Latin America and Caribbean							
Uruguay	96.9	6.9	1	6,090	3,334	2	97.6
Argentina	14.2	3.6	2	7,440	36,955	3	96.7
Bolivia	5.3	0.1	3	1,000	8,153	3	84.4
Cuba	4.5	0.0	4	1,700 (ppp)	11,142	7	96.4
North America							
USA	351.7	145.6	1	34,260	275,563	1	99
Mexico	21.6	2.0	2	5,080	100,350	4	90.8

Notes: 1. ppp stands for purchasing power parity. 2. Civil liberty index: 1 represents most free and 7 represents least free.
Sources: http://www.lyd.org/english/economic_freedom/percapita_income_troughout.pdf, http://www.odci.gov/cia/publications/factbook/geos/cu.html#Econ, European Marketing Data and Statistics, Freedom House, International Marketing Data and Statistics.

Fourth, international institutions are facilitating Internet *adoption by small and medium-sized enterprises* (SMEs), which otherwise may be reluctant to adopt the Internet. The United Nations Conference on Trade and Development (UNCTAD) launched the Global Trade Point Network (GTPN) in 1992. Its objective is to facilitate Internet adoption by SMEs, especially for accessing global markets. As of 2000, its electronic trading opportunity (ETO) system connected more than 20,000 trade organizations worldwide.

Fifth, international institutions are *influencing national laws, regulations and policies*, and are making them more conducive to the use of the Internet for various purposes. The UN Commission on International Trade Law (UNCITRAL) undertook a major initiative leading to the adoption of the Model Law on E-Commerce. Many countries around the world have enacted new Internet laws by taking the UNCITRAL model law as the guideline. The World Intellectual Property Organization (WIPO) member states also approved the establishment of WIPOnet, which provides basic, secure Internet connectivity and services to intellectual property offices. Similarly, the International Chamber of Commerce (ICC) has developed a model contract for privacy and transborder data flows. The Organization for Economic Cooperation and Development (OECD), in a similar vein, has developed action plans to address issues related to authentication, certification, consumer protection, and privacy in the use of the Internet (Kshetri, 2001).

The differences in social systems across the world have been selectively summarized in Table 7 to show the influence of several factors shaping the diffusion dynamics of the Internet. It is quickly evident that countries with the lowest Internet penetration levels also have the highest restrictions on civil liberties (e.g., Sierra Leone, Pakistan, and Cuba). It is possible to overcome some of the barriers to Internet penetration created by restricted civil liberties through high literacy levels, as in the case of China and Singapore. In addition to an open society and high literacy, economic resources are also necessary. Countries with the highest Internet penetration levels also have the highest levels of per capita income (e.g., USA, Finland). Finally, sociocultural factors such as English language skills explain some of the differences in Internet penetration between Australia and Japan.

CONCLUSION

In this chapter, we provided an overview of the global diffusion of the Internet and examined the factors that have shaped and are continuing to shape the diffusion dynamics of the Internet. The diffusion pattern of an innovation such as the Internet is a function of economic, political, cultural, and geographical factors. Because social systems across the world differ significantly in terms of these factors, diffusion patterns of the Internet also vary widely across nations. Low levels of income, authoritarian governments' distaste toward the Internet, sociocultural environments that are incompatible with the Internet, and terrain barriers have hampered the rapid diffusion of the Internet in developing countries. As a result, developing countries account for a disproportionately low number of Internet users and Internet hosts worldwide. Enlightened public policies, forward-looking corporate strategies, and concerted efforts by international agencies are of value in extending the reach of the Internet to all parts and all citizens of the globe.

ACKNOWLEDGMENT

The authors are grateful to multiple reviewers of *The Internet Encyclopedia* for detailed and valuable comments on earlier versions of this chapter.

GLOSSARY

Adoption of an innovation A micro process that focuses on the stages through which an individual passes when deciding to accept or reject the innovation.

ARPANET (Advanced Research Projects Agency Network) Developed by ARPA with support from the United States Department of Defense, this can be considered as the origin of all networks, including the Internet. Arpanet lines were considered superfast for their time, *56 kilobits per second.* ARPA and DARPA are used interchangeably, as the agency has used both names over the course of its existence.

Diffusion of an innovation A macro process concerned with the spread of an innovation from its source to the public.

Interface Message Processors (IMPs) The packet switches developed by the Defense Advance Research Project Agency (DARPA) in 1968.

Information and communications technologies (ICTs) Technologies that facilitate the capture, processing, storage, transfer, and presentation of information.

Internet host A computer system connected to the Internet—either a single terminal directly connected or a computer system that allows multiple users to access network services through it.

Network control protocol (NCP) The initial ARPANET host-to-host protocol developed by the Network Working Group (NWG) in 1970.

NSFNET (National Science Foundation Network) The first backbone for the U.S. portion of the Internet. It was originally conceived as a way for researchers to submit jobs to supercomputers located at various universities around the U.S.

Transmission control protocol/Internet protocol (TCP/IP) A protocol designed to meet the needs of an open-architecture network environment. TCP verifies the correct delivery of data from client to server. TCP adds support to detect errors or lost data and to trigger retransmission until the data is correctly and completely received. IP is responsible for moving packets of data from node to node. IP forwards each packet based on a four-octet destination address known as the IP number. IP operates on gateway machines that move data from department to organization to region and then around the world. In the future, IP is projected to move to six-octet addressing.

Global Issues

Babita Gupta, *California State University, Monterey Bay*

INTRODUCTION TO GLOBAL ELECTRONIC COMMERCE

Globalization as a term evokes strong emotions—either as an inevitable force that will transform lives of people worldwide for the better or as a force that will increase existing inequities and dilute local cultures. Globalization refers to the process of diffusion of people and their knowledge across nations, cultures, and economies. From an economic viewpoint, globalization is the process of many distinct national economies integrating into one global economy through free trade and free capital mobility, but also by easy or uncontrolled migration (Daly, 1998).

Global trade has existed for hundreds, perhaps thousands, of years as a result of breakthroughs in navigation technologies that allowed people to travel to distant lands and open new markets in exotic goods. In the more recent past, innovations in transportation and communication have allowed global business to expand dramatically at decreasing marginal costs. The Internet has emerged as another enabling technology in the process of globalization and global business expansion, facilitated by collaborations between public and private enterprises across borders to expand and develop new know-how (Iammarino & Mitchie, 1998). However, much of what is usually referred to as "globalization" is more accurately the process of "internationalization," in which a company expands its domestic base globally utilizing technological capabilities such as the Internet and international collaborations strategies such as mergers and acquisitions (Howells & Mitchie, 1998). From organizational perspective, firms that pursue a transnational strategy by locating their organizational activity in a region or country where they can efficiently utilize local assets and are likely to be more globally competitive (Boudreau, Loch, Robey, & Straud, 1998).

Global Electronic Commerce Growth

In the early 1990s, many analysts predicted that the Internet would transform the global economy by making possible a single world economy with insignificant national boundaries (de la Torre & Moxon, 2001). These predictions, however, proved to be unrealistic, as the Internet, like any other technology, operates within the context of the cultural, political, and economic impulses of the people of any country and needs to be considered in a broader context than just the organizational context.

According to one estimate (Forrester Projects $6.8 Trillion for 2004, 2002), by 2004, the United States alone would account for more than 47% of worldwide electronic commerce sales. Despite high variance in electronic commerce volume figures among various sources, worldwide expenditures distribution in the business-to-consumer (B-to-C) and business-to-business (B-to-B) markets among world regions show a clear domination of North American markets (Iyer, Gupta, & Taube, 2002b). Table 1 summarizes the growth of global electronic commerce as reported by various sources. It suggests that the gap between North America and other world regions is smaller for B-to-B than B-to-C electronic commerce (Kshetri & Dholakia, 2002).

The Internet Diffusion

Research suggests that the per capita income or economy of a nation is not the only explanation for the uneven growth of electronic commerce. Diffusion of new technologies such as the Internet differs among countries and is a function of a country's unique cultural,

Table 1 B-to-C and B-to-B Electronic Commerce Revenue Estimates Across World Regions

World Regions	B-to-C E-commerce Revenue Estimates	B-to-B E-commerce Revenue Estimates
North America (5.6% of world population)	*Y2000:* $38 billion 47.5 billion* *Y2004 Projections:* $184 billion, 197.9 billion* *Y2006 Projections:* $211 billion**	*Y2000:* $1.2 trillion(59% of global revenues) $159 billion* *Y2004 Projections:* $4.8 trillion $1.6 trillion* *Y2006 Projections:* $7.13 trillion**
Europe (13.5% of world population)	*Y1999:* $3.5 billion *Y2000:* $8.1 billion* *Y2004 Projections:* $182.5 billion* *Y2006 Projections:* $144 billion**	*Y1998:* $3.75 billion *Y2000:* $26.2 billion* *Y2002 Projections:* $174 billions $132.7 billion* *Y2004 Projections:* $797.3 billion* *Y2006 Projections:* $2.4 trillion**
Asia-Pacific Rim (60.2% of world population)	*Y1999:* $2.8 billion *Y2000:* $3.2 billion* *Y2004 Projections:* $38 billion* *Y2006 Projections:* $185 billion**	*Y1999:* $9.2 billion (excluding Japan) *Y2000:* $36.2 billion* *Y2003 Projections:* $430 billion $199.3 billion* *Y2004 Projections:* $1 trillion $300 billion* *Y2006 Projections:* $2.46 trillion**
Latin America (8.3% of world population)	*Y1999:* $77 million *Y2000:* $70 million* *Y2003 Projections:* $3.8 billion $5.5 billion* *Y2006 Projections:* $16 billion**	*Y2000:* $2.9 billion* *Y2004 Projections:* $76 billion $58.4 billion* *Y2006 Projections:* $216 billion**
Africa/Middle East* (12.4% of world population)	*Y2000:* $20 million* *Y2004 Projections:* $1.6 billion* *Y2006 Projections:* $5 billion**	*Y2000:* $1.7 billion* *Y2004 Projections:* $17.7 billion* *Y2006 Projections:* $69 billion**

economic, legal, religious, and political forces. The role of governments in providing incentives for IT innovation and diffusion in the form of regulatory and policy frameworks is well documented (King et al., 1994). Wolcott, Press, McHenry, Goodman, and Foster (2001) developed a framework using six dimensions to describe Internet diffusion across nations. *Connectivity infrastructure* describes underlying telecommunication networks necessary for the presence of the Internet; *pervasiveness* refers to the number of Internet users in a country; *sectoral* *absorption* is a measure of Internet use in organizations within a country; *organizational infrastructure* refers to the number and capabilities of organizations that can provide Internet services to users; *geographic dispersion* refers to the extent of geographic distribution of such organization throughout the nation; and *sophistication of use* refers to both how many people use the Internet and how they use it.

Research studies of the role of institutional influences in technology innovation (King et al., 1994; Montealegre, 1999), growth factors in B-to-B electronic commerce (Kshetri & Dholakia, 2002), and global electronic commerce (Farhoomand, Tuunainen, & Yee, 2000; Kshetri, 2001) indicate that adoption and diffusion of electronic commerce within a country and between countries is facilitated (or hindered) by the following:

Geopolitical issues such as effective partnership between government and private sectors, attitudes toward foreign investments, investments in infrastructure, subsidies, taxation, and other regulatory policies.

Cultural and social factors that determine how individuals in a country feel toward technological change and their level of trust in financial and business institutions.

Technology issues such as telecommunication infrastructure, adoption of uniform technical standards, and availability of a skills base to adopt and use new technologies.

Financial and economic issues such as viability of financial institutions, currency exchanges, payment options, availability of skilled human capital, distribution infrastructure, and effective trading policies.

This chapter discusses these issues in the globalization context of the Internet and electronic commerce and the resulting global digital divide. Its sections are organized as follows: a discussion of global electronic commerce and its advantages and disadvantages; role of governments in enacting regulations and laws to address cross-border issues arising due to the Internet; privacy and security issues that impact the growth of electronic commerce as a result of the lack of consensus among sovereign entities; the state of telecommunication and physical infrastructure, which are still nonexistent in many parts of the world; the state of financial services; and the cultural issues that impact the adoption and growth of Internet technologies and electronic commerce. We conclude with strategies that may be useful in spurring the growth of Internet technologies worldwide and some directions for future research.

GLOBAL ELECTRONIC COMMERCE

The modern economy is largely based on the production and distribution of products and services according to well-established economic laws in quantifiable measures such as gross national product and per capita income. These economic concepts determine the relative economic status of nations. As the information technology is transforming the "industrial" economy (i.e., economic growth through maximizing output) to the "informational" economy (i.e., economic growth through efficiencies in information processing and the creation and accumulation of knowledge), it is leading to the emergence of informational capitalism, where companies employ information technologies for profitability and nations are motivated to facilitate infrastructure for creating an information economy and thus to be competitive in the global economy (Venkatesh, 1999).

Current Models for Measuring Global Electronic Commerce Readiness

Before we can begin to comprehend the reasons for the uneven growth of electronic commerce worldwide, it is important to understand the models used to compare electronic commerce growth across countries.

The e-business country opportunity index, one such framework developed by the Gartner Group, is based on the Internet penetration ratio (the percentage of a country's population with access to Internet) against e-commerce transaction values per person achieved by that country (Iyer, Taube, & Raquet, 2002a). Figure 1 includes the United States and some European countries and shows that the United States has a substantial lead over other countries benchmarked in the index (Iyer et al., 2002a).

The gross domestic product (GDP)/Internet penetration matrix, another matrix developed by the Gartner Group, maps total Internet usage in percentage of population against GDP per capita and includes several non-European countries as well (see Table 2, which uses this index to group countries into four basic clusters).

In the past few years, a number of assessment tools using different frameworks have been developed to measure the readiness of a community, country, or region to benefit from information technology and electronic commerce. Although there are a number of such tools and they differ widely, most can be categorized as either *e-economy* or *e-society* assessment tools. E-economy assessment tools look at the ability of information and communications technologies (ICTs) to impact the economy, whereas e-society assessment tools look at the potential impact of

Table 2 GDP per Capita/Internet Penetration Ratio for Selected Countries

	High Internet Penetration	Low Internet Penetration
High GDP	U.S., Sweden, Canada, Australia	France, Japan, Germany
Low GDP	S. Korea, Singapore, Netherlands, UK	Brazil, China, Spain

Source: Iyer, Taube, & Raquet (2002a).

ICTs on the wider society (Comparison of E-Readiness Assessment Models, 2001).

Use of ICTs can contribute significantly to the growth of the global Internet by reducing transaction costs (through declining marginal costs) by facilitating transparency in the market processes that offer greater efficiencies. These lead to lowered costs of goods to consumers. Also, higher use of ICTs has a positive correlation with employment growth (Campbell, 2001). A country's population's access to the Internet and participation in its electronic commerce activities reflects its access to telephone networks, computer access, and available educational opportunities and its economic means.

The e-commerce readiness assessment tool created by the Asian Pacific Economic Cooperation (APEC) Electronic Commerce Steering Group in 2000 is geared "to help governments develop their own focussed policies, adapted to their specific environment, for the healthy development of e-commerce" (Comparison of E-Readiness Assessment Models, 2001, APEC's E-Commerce Readiness Assessment). This tool has six categories to measure readiness for e-commerce:

- Basic infrastructure and technology (speed, pricing, access, market competition, industry standards, foreign investment),
- Access to network services (bandwidth, industry diversity, export controls, credit card regulation),
- Use of the Internet (use in business, government, homes),
- Promotion and facilitation (industry led standards),
- Skills and human resources (ICT education, workforce), and
- Positioning for the digital economy (taxes and tariffs, industry self-regulation, government regulations, consumer trust) (Comparison of E-Readiness Assessment Models, 2001).

Based on the result of answers to questions based on these categories, each country is assigned an e-readiness level, which indicates that country's level of free trade, industry self-regulation, ease of exports, and compliance with international standards and trade agreements. A country with higher level of e-readiness exhibits fewer barriers to electronic commerce growth.

Each of these models provides a measure against a specific goal, and as such, would be useful only if used within the right context and with the recognition of its limitations. So far, there is no one tool that combines different frameworks of existing tools into one comprehensive tool to measure various aspects of e-readiness of a region.

Advantages of Global Electronic Commerce

Governments have traditionally encouraged globalization as it provides a means to expand markets, engage in knowledge and cultural exchange, and of course, generate higher revenues in the form of higher sales, profits, and/or taxes from increased trade. With worldwide electronic commerce revenues expected to reach $6.8 trillion by 2004 (Forrester Projects $6.8 Trillion for 2004, 2002), the Internet can provide the means for long-term sustainable competitive advantage. National and multinational companies are looking for ways to claim a share of this growing market. As world economies move toward an information economy from the traditional production-based economy, the Internet influences macroeconomic and microeconomic developments positively (Iyer et al., 2002a).

One enabling factor is the ability of the Internet to boost innovation by accelerating diffusion of ideas, information, and knowledge worldwide. At the macroeconomic level, as the size of potential markets increases with globalization of electronic commerce, entrepreneurs are willing to take more risks to reap rewards for uncovering lucrative new ideas, and thus to boost innovation additionally (Iyer et al., 2002a). At the microeconomic level, this has led to innovations in one-to-one marketing utilizing the immense number of data collected over Internet transactions and using that information to customize products or services to individual customers. For example, companies such as amazon provide dynamically customized views of products (and services) to customers based on those customers' previous online surfing and purchase patterns.

A second factor is the ability of the Internet to increase market efficiency. By increasing the real-time availability of information and the ability to match vast numbers of potential buyers with sellers that best meet their needs at increasingly low marginal costs, the Internet brings in new efficiencies that can be leveraged by a company to scale up at lower costs (Iyer et al., 2002a). Global intra-e-business with well-implemented intranets can allow a company to perform its internal functions and manage its resources with greater efficiency and foster cost-efficient collaborations. Global business-to-business electronic commerce provides another opportunity to leverage the Internet to automate relationships with customers, suppliers, and partners and improve supply-chain and electronic data interchange (EDI) transaction efficiencies.

The third factor is that the Internet has facilitated greater distribution of information and services, thus making services such as education, consulting, banking, and gambling globally accessible (Iyer et al., 2002a). The

Internet has opened up a new low-marginal-cost distribution channel that is shaping supply-chain operations, especially in the business-to-business sector.

Disadvantages/Challenges of Global Electronic Commerce

Although the Internet offers unprecedented opportunities in the global markets, formulating strategies to take advantage of these opportunities is not trivial, either at the organizational or at the policy-making institutional level. Companies are often facing competitive pressures to invest in electronic commerce. In order to determine the appropriate electronic commerce strategy, a company needs to understand how it is positioned compared to its competitors. In addition to complex technology issues, it has to decide which country to invest in and consider the high costs when developing a realistic strategy. There are various direct and indirect costs of expanding business via the Internet including the cost of realigning business processes, both external and internal, training employees and partners, and managing a global workforce. There is still a notion of the Internet as a free channel of distribution and, therefore, a tendency to underestimate the associated costs and overestimate the market size forecasts and ensuing profits. This is compounded by the fact that the models to assess Internet costs and benefits are still evolving.

Electronic commerce globalization also presents unique management challenges. These range from dealing with global customers with widely varying structural, cultural, and behavioral demographics to managing geographically dispersed global employees and global teams and managing compensation issues equitably in workforces spanning national boundaries. Some management issues may also arise due to the reluctance of a team to relinquish local autonomy and share information about markets and customers with other teams on a global scale. Devising policies that find a balance between information sharing across a company to stay competitive in global market space and allowing decision-making ability at local levels is a key issue. The added challenge is the regulatory complexities involved in any international trade. In fact, this has given rise to several companies that provide access to comprehensive databases of import and export regulations of countries and offer consulting in global trade management.

The other challenges are in understanding and managing the structural conditions such as physical, social, and economic arrangements necessary for e-commerce adoption by individuals and organizations (Markus & Soh, 2002). These conditions vary widely among countries and even within countries. For example, for a business-to-consumer site in Asia, a company could encounter issues such as high variance in urban-to-rural population ratio in Asian countries, difficulties in access to the potential market due to poor transportation, and lack of other electronic commerce infrastructure. Also, due to high population densities in urban areas, most businesses usually deliver everything people need or desire to their homes and offices in a convenient and cost-effective manner. This obviates the need for online shopping from the point of view of convenience for a large part of this market. In addition, many in Asia have never used credit cards or done catalog shopping and, therefore, are not drawn to online shopping readily (Markus & Soh, 2002).

Table 3 Internet Usage Across the World

World Region	Internet Usage Ratio
Africa	0.50%
South Asia	0.40%
Arab States	0.60%
East Asia	2.33%
Latin America/Caribbean	3.33%
North America/Europe	50.00%
Global Average	6.67%

Source: Jensen (2002).

At the institutional level, government entities have to balance the policies that push for Internet diffusion for economic development with the loss of governmental controls. Another issue in electronic commerce globalization is the dilemma faced by developing and underdeveloped nations on what priority should be placed on reallocating scarce resources to create the telecommunication infrastructure necessary for electronic commerce growth. These reallocations take resources away from much more profound needs of their citizens, such as education, food, clean water, shelter, and health care.

Global Digital Divide

The term *digital divide* has come into widespread use after appearing in the 1995 U.S. Department of Commerce report *Falling Through the Net: A Survey of 'Have Nots' in Rural and Urban America* (Lu, 2001). The digital divide refers to "great disparities in opportunity to access the Internet and the information and educational/business opportunities tied to this access" (Lu, 2001, p. 1). The digital divide can be measured by inequity in access to the use of information and communication technologies such as number of telephone lines, Internet hosts, or mobile phones per inhabitant. Various aspects such as literacy rate, education facilities, geographic area, income, and other demographic factors affect the degree of digital divide. Studies show that although the digital divide exists even within wealthier nations, the gap between the information-rich and -poor within their societies has been closing rapidly for the past few years. However, the same is not true of developing or underdeveloped nations, where disparities in access to basic telecommunication infrastructures are even greater (see Table 3).

ROLE OF GOVERNMENTS IN GLOBAL ELECTRONIC COMMERCE

The political climate in a country has a direct correlation with the willingness of foreign companies to consider expanding their electronic commerce operations in that country. Companies are understandably reluctant to invest in countries prone to frequent coups and wars, or those that have widespread corruption, internal law and order problems, or fiscal unpredictability. Another factor that influences this decision is the level of government controls and regulations that a business has to deal with for its operations.

The extent of Internet diffusion in a country is a function of the political ideology and will that shape its information technology (IT) policies and the legislative and regulative policy environment, and therefore, the growth of the Internet in that country. It is heavily influenced by what opportunities and threats this diffusion poses for the sociopolitical climate of that country. For example, in China, the spread of electronic commerce presents a dilemma for the Chinese regime, as on one hand it presents huge economic opportunities, whereas on the other hand it presents the threat of knowledge diffusion that is outside of governmental control and may result in diminution of the power of the state. Thus, government policies and decisions can act as a stimulant or as an inhibitor for the growth of electronic commerce. This certainly creates a predicament for firms that acquiesce in such policies. For example, Yahoo!, which has Internet operations in China, recently came under fire from human-rights groups for complying with the Chinese laws and thus filtering out content that was deemed pernicious information jeopardizing state security and stability.

Global Internet Regulations

Global electronic commerce raises unprecedented issues in the areas of jurisprudence, applicable law (any rule of law that could be applied by any national or arbitral tribunal in the event of a dispute arising between a business and a consumer who interact online), consumer protection, and taxation of electronic commerce transactions. Although business-to-business global electronic commerce presents fewer problems with its already existing mature contractual practices among various parties, this is less so with transnational business-to-consumer electronic commerce. Various international organizations are currently engaged in dialog to come up with policy directives to deal with these concerns and achieve a consensus among participating nations. There are inherent problems with drafting regulations that would apply to all participating nations. For example, the protocol on the Cybercrime Convention on Hate Speech drafted by the Council of Europe was not signed by United States, as the First Amendment under the U.S. constitution protected some acts criminalized under the protocol.

Similar concerns exist in other areas involving electronic commerce transactions entered into by non-European Union (non-EU) firms and EU consumers. According to a letter by the U.S. Council for International Business to the European Commission (USCIB Letter, 2002), there are a number of concerns on the proposed imposition of value-added tax (VAT) on non-EU firms engaging in electronic commerce with EU consumers, as it unduly burdens these firms.

As a consequence of these uncertainties, many companies prefer not to incur expenses related to compliance with a myriad of rules, instead limiting themselves to conducting business with partners and consumers of countries that have well-established policies on such matters. This of course inhibits the growth of global electronic commerce, as a large number of consumers worldwide are denied access to online marketplaces.

Web site content regulations and strict governmental controls over Web content also have an adverse effect on electronic commerce. Countries that have seen the most growth are adopting the model of Internet service provider (ISP) self-regulation combined with user-empowering technologies such as Web filtering and monitoring software to provide a balanced and flexible solution to content control.

Consumer trust is an important ingredient for the adoption and success of electronic commerce practices and is influenced by tangible factors such as privacy and security of networks and encryption policies, as well as intangible factors such as branding, consumer empowerment, industry accreditation systems and regulations, industry self-regulation, and consumer protection laws.

Taxation codes in each country, and tax treaties among nations to deal with globalization, had originally been formulated when even the notion of a digital economy with its borderless attributes was not around. Taxation systems in response to electronic commerce are just beginning to evolve. With increasing globalization, there is a critical need for adoption of a worldwide tax base for corporations with operations under different local tax laws to avoid double taxation, and to provide incentives to attract foreign direct investment. An additional issue is the non-taxation of online transactions (which reduces the tax revenues for tax administrators), but the physical delivery of the goods across national or state borders may still have substantial tariffs and import/export restrictions attached to it. Monitoring taxation for online transactions would require sufficient infrastructure on the part of the tax governing bodies, which may not be feasible for most developing countries for some time. The Organization for Economic Co-operation and Development (OECD) has published various reports that highlight challenges posed by global growth of the Internet in issues related to regulating cross-border financial services and taxes.

Legal Issues in Global Electronic Commerce

For global electronic commerce growth, laws are necessary to protect the individual's and company's right to conduct electronic commerce safely and securely. There are specific legal issues regarding the protection of intellectual property and rights to privacy and security.

Intellectual property is defined by the World Intellectual Property Organization (WIPO) as creations of the mind: inventions, literary and artistic works, and symbols, names, images, and designs used in commerce. Intellectual property is divided into two categories: industrial property, which includes inventions (patents), trademarks, and industrial designs; and copyright, which includes literary and artistic works such as novels, poems and plays, films, musical works, artistic works such as drawings, paintings, photographs, and sculptures, and architectural designs (About Intellectual Property, 2002).

Intellectual property laws that pertain to copyrights, patents, and trademarks give companies exclusive rights that can provide competitive advantages. Before the advent of the Internet, intellectual law had sovereign boundaries. However, in the digital world, such territorial boundaries disappear, raising questions regarding jurisdiction on these issues. The Internet, by the very nature of its technology, makes a "temporary" copy every time material is accessed, which stand in direct violation of copyright laws. Governments are beginning to address this issue. The 1996 Trade Related Aspects of Intellectual Property (TRIPS) agreement defines standards of intellectual property rights and enforcement mechanisms for individual countries to follow and incorporates these into the existing dispute settlement mechanism of the World Trade Organization (WTO) (TRIPS, 2002).

To implement TRIPS, the United Stated passed the Digital Millennium Copyright Act (DMCA) in 1998, which also addresses several other areas such as the circumvention of copyright protection systems, fair use in a digital environment, and Internet service provider liability (including details on safe harbors, damages, and "notice and takedown" practices). In Europe, the United Kingdom has passed three laws, the Data Protection Act 1998 (DPA), the Electronic Communications Act 2000 (ECA), and the Regulation of Investigatory Powers Act 2000 (RIPA). These address several issues including legality of digital signatures, rights of enforcement agencies to read encrypted data, and regulations regarding the use of personal data. One of the problems in electronic commerce transactions has been the potential security breach due to authentication problems (i.e., ensuring that the sender of an electronic message is correctly identified and validated). Digital signatures, digital encryption codes attached to transmitted messages that can authenticate the senders, are emerging as a solution to confirm that a digital signature will satisfy the requirements for a signature. The EU adopted a Directive on Electronic Signatures in 1999 and the United Nations Commission on International Trade Law (UNCITRAL) adopted the Uniform Rules on Electronic Signatures in the summer of 2001. Other parts of the world have been slow to adopt such legislation but are beginning to address intellectual property issues.

Trademark rights are another potentially thorny issue, as conflicts may arise when the same or similar trademark may be owned by companies in different countries or different standards that may exist in different countries to determine trademark infringements. Domain names, the Web addresses used to uniquely identify electronic commerce sites, are an example of trademarks that may give rise to potential problems in different countries. Domain name disputes are subject to the Uniform Domain Name Dispute Resolution Policy (UDRP), which was adopted by the Internet Corporation for Assigned Names and Numbers (ICANN) and is administered by the WIPO.

PRIVACY AND SECURITY ISSUES IN GLOBAL ELECTRONIC COMMERCE

As companies rely on global networks to do business, privacy and security of information becomes a critical issue, for consumers as well as companies. It is estimated that half of all small and medium-sized businesses will fall victim to Internet attacks by 2003 (McCusker, 2001). Companies from other countries may comply with their country's laws, but those laws may not conform to a standard that will adequately protect security of information. Countries eager to realize the promises of global electronic commerce are now formulating laws for Internet-security-related crimes. The treaty signed by 30 countries at Budapest in November 2001, the Convention of Cybercrime, is aimed at addressing the lack of common standards. "The treaty has a threefold aim: to lay down common definitions of certain criminal offences relating to the use of the new technologies, to define methods for criminal investigations and prosecution, and to define methods for international communication. The criminal offences concerned are as follows:

Those committed against the confidentiality, integrity and availability of computer data or systems (such as the spreading of viruses);

Computer-related offences (such as virtual fraud and forgery);

Content-related offences (such as the possession and intentional distribution of child pornography);

Offences related to infringements of intellectual property and related rights" (The Convention on Cybercrime, 2002).

The growth of global electronic commerce is also impeded by the lack of global patent and copyright protection and the lack of an international body to enforce the rights of companies without infringing on the freedom of governments to pursue their own goals.

Privacy Issues

Privacy refers to the right of a person to control his or her own personal information (Head & Yuan, 2001). In the United States, widespread industry resistance to government regulation has persuaded the Federal Trade Commission (FTC) to adopt a passive approach to enacting laws to ensure privacy, instead relying on industry to regulate itself around five basic principles of notice, choice, access, security, and redress. One of the most popular self-regulatory mechanisms is TRUSTe, a nonprofit initiative whose main purpose is to ensure that sites are adhering to the privacy notices posted by using random member site checks for compliance with privacy policies. The privacy laws in the 15 member states of the EU are markedly different. Instead of being self-regulated, European privacy laws are government regulated through the Data Protection Directive adopted in 1998. European rules forbid the transfer of personal data to a country that does not provide a level of protection similar to its own.

These opposing schools of thought on privacy threaten to hamper the ability of U.S. companies to engage in e-commerce with the EU countries without the risk of the U.S. businesses incurring penalties (McKenna, 2001). Therefore, the U.S. companies could be denied access to information from their own European subsidiaries or other companies located in Europe. On a global scale, personal data on millions of individuals could be sent through the Internet to companies worldwide where privacy laws may vary from stringent to ambiguous to nonexistent. The current state of these laws raises the specter of serious setbacks to companies located in non-stringent-privacy-law countries trying to engage in electronic commerce activities in countries with rigorous privacy laws.

In July 2000, the EU and the United States compromised on the Safe Harbor Agreement as a way to bridge the policy gap in which U.S. companies can avoid sanctions if they develop a self-regulatory privacy program adhering to the Safe Harbor's requirements. The seven primary principles of the Safe Harbor Agreement are notice, choice, onward transfer, security, data integrity, access, and enforcement (Shimanek, 2001). Recently the Federal Trade Commission (FTC) investigated Microsoft as part of the FTC's enforcement of the Safe Harbor Act. Microsoft came under scrutiny for not taking adequate steps to protect the privacy of Microsoft Passport Service's U.S. customers. In the settlement reached in August 2002, Microsoft consumer privacy laws would be under governmental oversight for the next 20 years. This is signaling a shift in the accommodation of international companies in adhering to the laws of each nation in the direction of global information privacy law standards to be consistent with privacy laws of the EU (Rudraswamy & Vance, 2001). A recent example of a bill under consideration by the California legislature (as of August 2002) to limit the use of a customer's personal data by financial companies may raise the bar for other states within the United States.

Transborder data flows or TDBFs are the exchange of personal and intracorporate data across national boundaries that include operational data, personnel data, electronic transfer of money, and technical and scientific data (Chen, Tu, & Lin, 2002; Rudraswamy & Vance, 2001). Because TDBFs involve personal data, due to the differences among countries in the level of protection accorded to the privacy of individuals and legal entities, TDBFs laws vary across national boundaries, posing serious challenges to formulation of global data standards to ensure global data sharing. Many countries have stringent TDBFs laws prohibiting personnel data transfer, raising difficulties in global human resource management for multinational corporations wishing to expand into new markets (Chen et al., 2002).

Security of Information Issues

Security of information refers to the ability of the *owner* of information to control that information (Head & Yuan, 2001). Some examples of security violations are access control problems, where an unauthorized party gains access to sensitive information (e.g., payroll records); integrity problems, where the contents of a message between two parties are altered without their knowledge; authentication problems, where it is not possible to ascertain a sender's identity; nonrepudiation problems, where the sender or receiver of a message can deny transmittal or receipt; and availability problems, where unauthorized parties can make use of system assets. Lack of security has major repercussions for a company; it may lose the trust of its customers, affecting its brand, lose revenues, and incur costs arising out of security breaches, thus losing strategic advantage.

Worldwide, companies use various security models to keep their systems and Internet transactions secure. These include the use of public key encryption, IP security, Web security based on SSL/SET (Server Sockets Layer/Secure Electronic Transactions), and firewalls.

Encryption/decryption policies are another leading issue in the facilitation of electronic commerce. Secure online transactions are an imperative to ensure authenticity and integrity of information exchange among parties. Whereas businesses want to use encryption that cannot be decrypted by any unauthorized entity, governments worry that their inability to intercept and decipher such messages would result in more malicious activities and threats to national security. This is one of the reasons that governments are reluctant to share these technologies and have specific policies in place to prevent this. In the United States, the Department of Justice controls the export review process and the National Security Agency (NSA) remains the final arbiter of whether to grant encryption products export licenses. Some countries have not formulated any encryption import/export policies, whereas others such as Singapore have stringent controls in place, including controls on domestic use of cryptography.

INFRASTRUCTURE ISSUES IN GLOBAL ELECTRONIC COMMERCE

Global electronic activities such as EDI (electronic data interchange) have existed for over 25 years. However, the supporting technological infrastructure was expensive and therefore usually only affordable by larger corporations. The Internet revolution allowed the emergence and growth of inexpensive and flexible infrastructure that has allowed smaller companies and individual entrepreneurs to enter into this market space and thus accelerate the growth of global electronic commerce.

When the technical infrastructure needs of a country to foster electronic commerce growth are considered, regional policies, political stability, cultural uniqueness, economic viability, and its neighbors and major trading partners all play an important role. This also raises some pertinent questions such as whether, for a developing country, it is truly worth investing in electronic commerce infrastructure at the expense of other, more basic infrastructure needs.

Telecommunication Infrastructure

Telecommunication hardware and software are necessary precursors to any electronic commerce activity and are usually representative of a country's technical competency. The specifics of various communities, regions, cultural beliefs, market practices, or income levels in a nation may affect the level of that nation's telecommunication infrastructure. Local topology plays a major role in determining whether or not laying down the infrastructure is feasible or how evenly the infrastructure is spread out spatially. Weather and climate anomalies affect the successful stringing of telephone wires or laying down of underground fiber optic networks. As telecommunication companies are increasing the available options in Internet services, this is driving down the costs, further spurring local demands for Internet access.

Cost of local calls can sometimes be a prohibitive factor in Internet usage. For example, whereas in the United States, calls to local Internet service providers (ISPs) are free, this is not the case in most other countries. Several countries such as Argentina, Chile, Belize, Colombia, Barbados, and Uruguay have come up with innovative solutions such as public Internet terminals and cybercafés to solve the problems of high costs of owning necessary hardware and software for high-speed Internet access for low-income citizens and those in remote areas. The lack of uniform worldwide technical standards and electronic transmission standards is a key challenge for companies aspiring to engage in global electronic commerce. Overly rigid and bureaucratic regulations can stifle the growth of telecommunication infrastructure and limit the speed of technology diffusion and market expansion. Liberalization leads to increased access and affordability of services, which accrues wider societal benefits.

Uniform technical standards are necessary to ensure interconnectivity and interoperability of information technology systems between countries engaging on electronic commerce. The Global Information Infrastructure Commission (GIIC) has determined that inadequate standards and the lack of interoperability and interconnection will delay the development of the GII and electronic commerce. Several organizations such as the International Telecommunication Union (ITU), the International Standards Organization (ISO), and the European Telecommunications Standardization Institute (ETSI) are cooperating to study this issue from a global perspective and develop technical standards through cooperation.

International domain names are called country-code top level domains (ccTLD Resource Materials, 2002) and they are allocated to each sovereign nation or territory of a nation based on a unique two-character code through the Internet Corporation for Assigned Names and Numbers (ICANN). Although this body has successfully implemented a standardized process for assigning domain names, there is still the problem of the disproportionate numbers of domain names being in English and the limited interoperability between translations of these domain names into the target languages of the countries.

Fulfillment Infrastructure

The development of order fulfillment infrastructure in the cycle of an online transaction is another necessary step to allow delivery of physical goods ordered online. The real-time nature of electronic commerce has raised consumer expectations regarding online purchasing behavior (Ahuja, Gupta, & Raman, forthcoming). An important objective of a successful global electronic commerce business is to deliver products and services across borders as quickly and dependably as possible. Thus rapid customs clearance is critical in the electronic commerce value chain, and the absence of a preclearance system is going to result in the loss of electronic commerce efficiencies. The lack of reliable transportation systems to ensure speedy and safe deliveries is a major reason for slower electronic commerce growth in regions outside of North America and Europe. Growth in other regions is only possible if business and customer clearance services are adequate and if the physical distribution system is reliable, fast, and affordable.

FINANCIAL ISSUES IN GLOBAL ELECTRONIC COMMERCE

Robust financial institutions, particularly the stability of the banking sector, are a prerequisite for the functioning of the modern world economy, which is also increasingly interdependent. Some of the issues that affect the growth of global electronic commerce are the state of online financial institutions and services, policies relating to these financial institutions, and the availability of financial capital funding for global e-commerce. E-commerce requires specialized support in financial services and an advance payment system.

Currency Issues

An online transaction is not complete until the business receives the payments in the correct currency. Given the different currencies that are used throughout the world, companies will need e-banking services that can operate in such an environment. In addition, exchange rate fluctuations affect a corporation's overall financial performance. Banking services that can facilitate these kinds of financial services are attractive to companies, as these can boost their financial performance by diluting currency exchange and funds transfer risks. Some companies such as WorldPay, Inc., provide solutions that can enable a company to conduct online transactions in 130 currencies.

Online Payment Systems

Commercial activity, especially between a business and an individual, is still largely on a cash basis in a large part of the world. Transactions on a credit basis (e.g., using credit cards or checks) may only be available in a few large metropolitan cities. In these countries, people routinely carry huge amounts of cash in their wallets, as that is the only mode of payment for buying a cup of tea or truckloads of material for building a house. Against such a background, it requires a tremendous change in financial processes as well as behavioral patterns to enact successful electronic commerce activity. Given that even in countries where credit transactions have been the norm for decades, consumers are still reluctant to pay online to unseen merchants for a variety of reasons, the problem is exacerbated in countries where the use of credit is still a nascent practice. Another issue in some countries is that consumers are used to paying upon delivery of goods/services and, therefore, online transactions requiring upfront payment for later delivery raise trust issues and have still to gain widespread acceptance.

The three key drivers of online payment system success are merchant acceptance, authentication, and security. In the United States, the recent enactment of the Electronic Signatures in Global and National Commerce Act (E-SIGN) provides an increased impetus for the growth of domestic electronic commerce, as well as incentives for other countries to follow suit. The E-SIGN Act provides the same certainties for conducting online business as exist for doing offline.

CULTURAL ISSUES IN GLOBAL ELECTRONIC COMMERCE

The Internet has offered unparalleled global exposure to companies through Web sites, intranets, and extranets. This exposure, although affording new opportunities and global distribution capabilities, also raises issues of how to cater to local markets by taking into account local cultures, languages, and behavior.

Localization

Localization refers to the unique set of requirements within each country, and sometimes within regions in a country, that combine jurisdictional requirements with local consumer needs, social and cultural patterns, behavior, beliefs, and language(s). This also raises the stakes in Web site design issues on ensuring international and local usability. Cultural issues affect a country's new technology adoption patterns (Palvia, Palvia, & Whitworth, 2002; Straub, Loch, & Hill, 2001). The nature of social networks affects the perception of change that any new technology brings in its wake. For example, is the prevailing culture resistant to new technologies because of perceptions of associated job loss, changes in social dynamics, or loss of a way of life? Localization matters for innovation, and a global company must develop localization strategies to take advantage of the local strengths, including local experts, and to proactively enhance the environment for innovation and commercialization in locations where it operates (Farhoomand et al., 2000; Porter, 2001).

Language, Geography, and Religion

For a company targeting a country for its products and services, language is one of the most obvious concerns. Every year, the number of non-English-speaking Internet users is increasing; in the year 2000, they outnumbered English speaking Internet users for the first time. Until quite recently, one problem with displaying letters and characters of a language had to do with the lack of a standard encoding mechanism in computer systems. Characters other than standard ASCII displayed on Web pages were traditionally encoded in HTML through the use of character entity references, so that an umlauted lower case a (ä), for example, was encoded as &auml or its numerical equivalent (&#228;). Although this system worked for major Western European languages, it did not for non-roman-alphabet-based languages such as Chinese, Cyrillic, and Japanese. With the emergence of the Unicode Standard and the availability of tools supporting it, this is likely to lead to more Web sites being able to render characters in a particular language's character set. Another level of language concern is the display of Web site content in users' native language in a way that takes into account its cultural context and incorporates its nuances. This is much harder to address without significant spending of resources to get it right and avoid linguistic faux pas. The multiplicity of languages in Asia–Pacific Rim and European countries has been a major obstacle to achieving business-to-business operation economies of scale (Kshetri & Dholakia, 2002).

In designing a Web site for the users of a country, another thing to keep in mind is the time zones used there. Different countries write dates differently; for example, 5/10/02 mean completely different things in the United States and in India. Different countries have different religions, and that in turn provides a distinct flavor to the yearly calendar in use there. The use of colors in a Web site is an integral part of Web site design. It is also open to cultural interpretation, as color symbolisms vary across cultures, and therefore requires understanding of the cultural context in which a site is going to be viewed.

Culture

Differences in cultural beliefs of a society are well known to influence the way people react to the use of technology and information system adoption, development, and implementation (Hofstede, 1997; Kaarst-Brown & Evaristo, 2001; Palvia, Palvia, & Whitworth, 2002; Straub et al., 2001). For example, despite technical and regulatory infrastructure in place, and high use of the Internet for communication purposes, Europe is far behind the United States in the use of Internet for electronic commerce. The reluctance of Europeans to shop online and engage in electronic commerce could be of cultural origin. Cultural differences among nations also are related to the degree of privacy sensitivity and privacy concerns for data protection of their citizens or corporations and are known to strongly correlate to with the regulatory approach of a nation (Rudraswamy & Vance, 2001). Also, global companies need to recognize that local cultures and beliefs influence organizational effectiveness and, therefore, need to adopt appropriate leadership styles and organizational structure suitable for each culture (Okunoye & Karsten, 2002).

There is, however, a need to be cautious in regard to the understanding of what constitutes a "national culture" (Myers & Tan, 2002; Straub, Loch, Evaristo, Karahanna, & Srite, 2002). Emerging research in this area suggests "that IS researchers interested in conducting research on culture and globalization should adopt a more dynamic view of culture—one that sees culture as contested, temporal and emergent" (Myers & Tan, 2002, p. 24).

STRATEGIES FOR THE GROWTH OF GLOBAL ELECTRONIC COMMERCE

A commitment to entry into the information economy guided by policies that emphasize both market forces and government structures is likely to prove to be a better strategy than relying on just one or the other alone. ICTs are enablers of globalization, boosting the movement of tangible and intangible assets over connected networks across national boundaries. Poor telecommunication infrastructure in a country may result in that country lagging behind even further in the emerging global digital economy, widening the digital divide. Countries that have restructured state services to provide better access to ICTs for their citizens and have formulated government programs to develop necessary skills through increase in education levels, job training, adult education, and in particular, programs that invest in achieving higher level skills in science and technology for long-term advantages have been able to achieve higher Internet growth rates and growth in related markets (Campbell, 2001). The growth of research and development and entrepreneurial activities is tied into the availability of high-level skills. Therefore, investment in higher education is an integral part of policies; for example, the growth of the ICT industry in Bangalore in India, Xian in China, and Silicon Valley in the United States is tied to their close proximity to well-known universities (Campbell, 2001).

In just the past decade, many countries have adopted strategies that seek to facilitate market access through privatization of the telecommunication industry, the extent of which varies among the many world regions. Privatization drives down prices, making telecommunication infrastructure more affordable, more accessible, and of improved quality. Governments are also providing tax incentive subsidies to attract foreign direct investments and to procure capital to compensate for lack of venture capital within the country. Similar strategies being adopted worldwide by various governments consist of providing tax incentives for companies to invest in research and development initiatives and continuing education in information-technology-related areas, providing tax subsidies for software and hardware development and for sharing scant telecommunication resources to optimize their collective usage, building a local pool of knowledge workers to spur local entrepreneurial activities and facilitating access to local and international financial capital and markets to build domestic and international demand. Another way for governments to spur corporate investment in Internet technologies is to adopt these technologies for governmental business, and thus provide a model of effectiveness of these technologies as well as providing accessibility and transparency.

Implementing some of these strategies has helped several developing countries to become increasingly integrated into the global economy through growth in the export of software and skill-intensive software services, such as call-centers. India is one such example. According to the case study in the final report of the Digital Opportunity Initiative produced in July 2001, the Indian software industry has grown at a staggering annual rate of over 50%, from a mere $150 million in 1991–1992 to $5.7 billion in 1999–2000 (Appendix 3 National ICT Approaches, 2002).

CONCLUSIONS AND FUTURE DIRECTIONS

Global electronic commerce, with its promise of globalization on an unprecedented scale, raises some pertinent issues about the equitable distribution of its benefits among developed and developing nations and closing the digital divide among them. Strategies formulated within the context of a holistic understanding of the specific environment within a country will be the key to the overall success of Internet diffusion there. Strategies that provide for integration and cooperation between the public and the private sectors are essential for the successful transfer of knowledge and technological infrastructure needed for e-commerce growth. Global e-commerce can only become a reality if the underlying technology is diffused throughout a society. Countries that have been most successful in harnessing the Internet have done this as a result of the combined efforts of government and the private sector through high investments in higher education and human capital, building infrastructures through deregulation, and providing a climate that promote fair competition and economic freedom. Governments that have yet to formulate national policies with clear and stable frameworks to reduce complexities and costs of participating in the global digital economy may be placing limitations on the growth of entrepreneurial ventures in the digital marketplace and denying their citizens access to the benefits of the Internet. Given the imperative need to combat the digital divide, various international coalitions such as Asia–Pacific Economic Cooperation (APEC) have formed to combat it and to improve the quality of life for disadvantaged people by 2010.

Longitudinal studies on the impact of the Internet and electronic commerce on the economic development at a societal and individual level are needed. This research can help developing countries formulate and adopt policies and strategies that can help narrow the digital divide and focus on providing basic and higher education, producing local and relevant content, and effectively using technology throughout society to provide opportunities to realize the benefits of electronic commerce for their citizens.

ACKNOWLEDGMENT

The author would like to thank the anonymous referees for their helpful suggestions and comments to improve this paper.

GLOSSARY

Authentication The process of ensuring the identity of another entity on the Internet.

Business-to-business (B-to-B) A term that describes transactions among businesses.

Business-to-consumer (B-to-C) A term that describes transactions between an individual buyer and a business.

Digital certificates Software provided by a trusted third-party certification authority to authenticate the holder of a public encryption key.

Domain name system (DNS) Maps Internet addresses. An Internet host needs a domain name that has an associated Internet protocol (IP) address record. The DNS is a database system that looks up host IP addresses based upon domain names.

E-readiness Refers to a country's ability to take advantage of the Internet as an engine of economic growth and human development by utilizing its telecommunication infrastructure, human resources, financial resources, and legal and regulatory policies.

Electronic data interchange (EDI) A format for exchanging business data (e.g., purchase orders) among organizations developed by the Data Interchange Standards Association to facilitate commerce.

Encryption A technology using complex mathematical algorithms to encode and decode information for security purposes during transmission. Only those who have an authorized decryption key can decipher an encrypted message.

Firewall Hardware and software systems that isolate a private network from the public network by providing a location for monitoring security-related events and allowing only authorized traffic to pass.

Globalization Refers to the process of diffusion of people and their knowledge across nations, cultures, and economies.

Global digital divide Refers to asymmetry or inequity in the distribution, access, and use of information and communication technologies among world regions.

Global electronic commerce The buying and selling of business services over telecommunication networks where the two parties involved in this exchange are in different countries.

Information and communication technologies (ICTs) Refer to numbers of devices such as telephone lines, Internet hosts, or mobile phones per inhabitant that provide a measure of Internet diffusion in a country.

IP security An IP level security protocol that secures all TCP/IP traffic between two networks by encrypting each IP packet that leaves the system and authenticating packets that enter.

One-to-one marketing A form of marketing where a firm can customize its products and services to fit each customer's unique needs and characteristics.

Public key encryption Asymmetrical key encryption that uses a pair of public and private keys to ensure security and authenticity of a transmitted message online. A message is first encrypted by the sender using his or her private key and then using the widely available public key of the message recipient. This encrypted message can then be decrypted only by the recipient using a LIFO order of decryption—first using his or her private key, and then decrypting using the sender's widely available public key.

Secure electronic transmission (SET) A security protocol embedded in a users' Web browser and in Web servers to encrypt all online communications. It is designed to be transparent to the end user.

Secure socket layer (SSL) A security protocol initiated by Visa, MasterCard, Microsoft, Netscape, and others and designed to protect credit card transactions on the Internet. SSL allows client/server applications to communicate using encryption, where servers are always authenticated and clients are optionally authenticated. It sets up a secure end-to-end link over which http or any other application protocols can operate.

Supply chain Refers to a set of activities related to ordering, manufacturing, fulfillment, and payment flow that involve an organization, its suppliers, contract manufacturers, and distributors, and the end customers.

United Nations Commission on International Trade Law (UNCITRAL) Established by the United Nations General Assembly in 1966 to reduce or remove obstacles to international trade created by disparities in national laws. Its mandate is to work toward a progressive harmonization and unification of the law of international trade.

INTRODUCTION

Groupware refers to computer- and networked-based technologies that help people accomplish a group's objective. Some forms provide greater support for real-time collaboration than others (such as electronic meeting support systems, chat rooms, shared whiteboards, and real-time videoconferencing), some can support the individual's work, as well as work that can only be accomplished collaboratively (e.g., collective writing). Helping people who are in the same place at the same time (e.g., meetings) is the forte of some types of groupware, and other forms excel at connecting group members who might be continents and time zones apart (such as e-mail and shared database access). Some are geared to support specific group subtasks (e.g., shared calendaring and scheduling, e-mail), whereas others are designed for a wider array of integrated support functions (such as dispersed project management). To make this more complicated, the Internet has driven both the amazing popularity and adoption of these tools, but it has also driven the creation of new classes of tools that are proving important (e.g., shared databases). In this chapter, we first remark on the for purpose of groupware and then present some defining concepts and classifications for these myriad tools. We then explore some generic and common functionalities of groupware tools and turn to detailed descriptions of some popular modern examples and show how they map to our classifying scheme. We then adopt a management perspective and present a theory-based framework for mapping these functionalities to the varying circumstances of individual and group work. The final part of the chapter addresses issues of human productivity and groupware as well as issues surrounding the changes in organizational and human processes that often accompany the proliferation of groupware-supported work.

WHY GROUPWARE?

There has been more than five centuries of research devoted to group and team processes in an effort to understand why the desired synergy of group work is often elusive and why instead group work is often difficult and inefficient. Figure 1 lists the most common positive and negative influences on collaborative work.

Many things can go wrong with group work. Participants may fail to understand their goals, lack focus, or have hidden agendas. Some people may be afraid to speak up, and others may dominate the discussion. Misunderstandings occur through different interpretations of language, gesture, or expression. Besides being difficult, teamwork is expensive. A meeting of several managers or executives may cost several thousands of dollars per hour in salary costs alone. In Fortune 500 companies, there are more than 12 million formal meetings per day in the United States—more than 3 billion meetings per year. American managers typically spend about 20% of their time in formal meetings and up to 85% of their time communicating. For all its difficulties, group work is still essential. People must collaborate to solve tough problems. As business becomes more global in scope and computers become more ubiquitous in the workplace, the need for collaboration—and the means to achieve it—has surely continued to increase. Enter groupware, with functionalities that—when appropriately selected, applied, and managed—can bring users tremendous support for their group's tasks (Collaborative Strategies, 2002).

DEFINING AND CLASSIFYING GROUPWARE IN THE INTERNET AGE

Groupware is technology—typically software and networks—designed to support people working in groups. Under this broad definition, any technology that is used to communicate, cooperate, coordinate, solve problems, compete, or negotiate is classified as groupware. This definition can apply to some of the newest forms, such as informational Web pages and multiuser database applications, as well as to more established and familiar forms such as e-mail, newsgroups, videophones, or chat. The simplicity and breadth of this definition is intentional because definitions of groupware tend to evolve as rapidly as the technologies themselves, often becoming

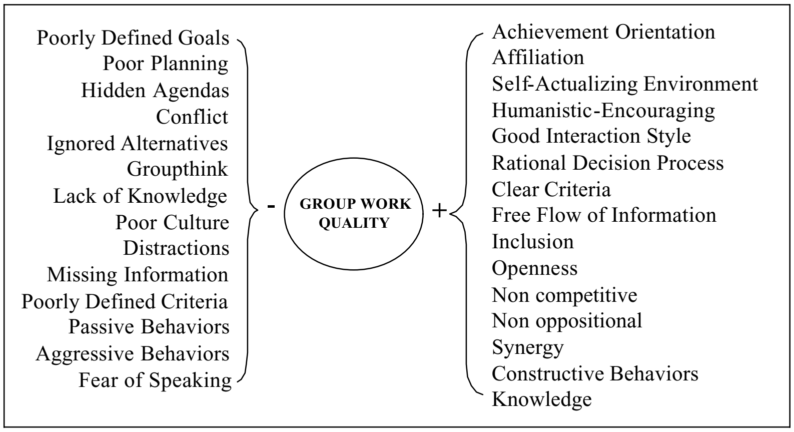

Figure 1: Influences on the quality of group work.

outdated because new technologies support group work in ways that were not represented. For example, an early definition for groupware was intentional group processes plus software to support them. At the time, this definition placed more emphasis on the activities of the group and much less on the technologies, which were limited. As we describe, although much of that early definition is valid, the reality that it does not address is that much group work contains a great deal of individual work. Many modern forms of groupware support not only the actual group work, but also much of the individual group members' work that may precede, be contemporaneous with, or follow that actual interactive group processes.

A later definition of groupware by Johansen (1988) is "specialized computer aids that are designed for the use of collaborative work groups." Again, this definition rightly focused on the actual group collaborative processes but does not mirror the current reality of how the tools extend to support the individual work processes that underpin group work. A major contribution by Johansen and others, however, was to provide a categorization scheme for groupware technologies that is still valuable today. As shown in Table 1, groupware technologies can largely be categorized along two primary dimensions:

- whether users of the groupware are working together at the same time ("real-time" or "synchronous" groupware) or different times ("asynchronous" groupware) and
- whether users are working together in the same place ("colocated" or "face-to-face") or in different places ("distributed" or "dispersed").

Another way to understand groupware is by the generic group processes that it supports: *communication* (pushing or pulling information), *collaboration* (shared information and building shared understanding), and *coordination* (delegation of task, group technique, sequential sign-offs, etc.). Some definitions of groupware call erroneously for the added dimension of a common goal. Although all systems require some agreement among participants (at minimum that they should agree to participate in the process), groupware can readily support negotiation-type interactions. Management of conflict is often a crucial feature of a groupware system (a voting tool is a good example of this incorporated in groupware designed to support meetings). This classification scheme also does not pay much attention to individual work processes that can be supported by groupware and are a component of group work, however, and it does not emphasize geographic location or temporality.

To build on these earlier perspectives and integrate them with the realities of individual work processes, as well as to reflect the ubiquity of access afforded by the Internet (and commonly, proprietary organizational networks and intranets), we offer a new model of groupware. Table 2 illustrates an emerging model for groupware as

Table 1 Traditional Dimensions of Groupware

	SAME TIME "SYNCHRONOUS"	DIFFERENT TIME "ASYNCHRONOUS"
Same Place: "Colocated"	Group support system Group decision support systems Presentation support	Shared work spaces
Different Place: "Dispersed"	Videophones Whiteboards Chat Virtual rooms	E-mail Threaded discussion Workflow

Table 2 A Categorization of Groupware Systems by Time and Targeted User Audience

	ASYNCHRONOUS GROUPWARE	ANYTIME/ANYPLACE GROUPWARE	SYNCHRONOUS GROUPWARE
Large	Database-oriented portals Collaborative portals E-community Newsgroup/usenet list Servers	E-learning/virtual classrooms	Web real-time communication Audio/video conferencing
Limited	Telework virtual workplaces Workflow systems Personal portals Group calendars	Distributed project management Collaborative writing Threaded discussion	Group decision support systems Meeting support Chat Shared whiteboard
Individual/Dyad	E-mail	Mobile/wireless messaging	Collaborative customer relationship management

represented by a 3 by 3 matrix of the nine discrete yet interrelated software groups. From a user's perspective, the horizontal axis represents a spectrum between synchronous and asynchronous functionality (in typical usage) but now includes "anytime/anyplace" to connote accessibility to information or functionality that the tool can provide. As we will see later, many modern forms of groupware, though primarily synchronous or asynchronous, have features that are accessible anytime and anyplace if one has an Internet or Intranet connection and a browser (Coleman, 1997). The vertical axis represents the group size targeted by the technology. In this representation, the "place" dimension of Table 1 above has disappeared—networks have so increased in speed and computers have become so ubiquitous and powerful, that geographical dispersion has lost its categorization power. For instance, any computer-supported meeting can be attended in face-to-face mode or by cyberspace connection.

GROUPWARE FUNCTIONALITIES IN THE INTERNET AGE

Common Groupware Functionalities

Although stand-alone groupware components such as e-mail can still be purchased separately, many modern products offer a number of common functionalities (e.g., e-mail) integrated into one suite. These common functionalities (or characteristics) might include the following.

Graphical User Interfaces

Most groupware programs today can take advantage of the color graphics and sound capabilities of multimedia computers. They are often made available via the Internet as either a client and server application or an application that uses a common browser interface.

WYSIWIS

This stands for What You See Is What I See. It is analogous to two people each at their own home watching the same television show at the same time. Computer technology extends this concept in groupware products and allows users to interact and communicate in a WYSIWIS environment.

Integration

Most groupware products integrate components of different applications into a standard interface so the product feels like a multifaceted tool.

Online Communication

Discussions can be held in real time, with active interaction between participants. Several products allow for textual and video exchanges in real time.

Replication and Synchronization

Replication is the process of duplicating and updating data in multiple computers on a network, some of which are permanently connected to the networks. Others, such as laptops, may only be connected at intermittent times. Synchronization is the goal of having all computers in a distributed network providing the same information at the same time. The replication and synchronization concept has two components: (a) everyone should have access to the same information in the database and be able to replicate the data locally and (b) several users can make changes to the same document, and somehow the system synchronizes all those changes into one master copy of the database. If the replication manager has multiple update requests to the same record, it sends out messages asking for clarification as to what the correct entry should be. An example of this function is the use of a shared database of product inventory by a distributed sales force. When each person sells some units, the database would update itself so that there is an accurate count of inventory available to all users.

Remote Access

Using database replication and synchronization, remote users can access and update information held in a groupware database (see example in previous section).

Workflow

Workflow is a typical groupware subsystem that manages a task through the steps required for its completion. It results in the automation of standard procedures (such as records management in personnel operations) by imposing a set of agreed on business rules on the procedure. Each task (or set of tasks), when finished, automatically initiates the next step in the process, until the entire procedure is completed. Although some users implement self-contained workflow systems, the technology often appears in more recent groupware and image management systems. Lotus Notes for Domino, for example, provides workflow applications that can be customized to an organization's particular needs.

Time Management

These groupware products offer group calendar diaries and group project schedules to help managers as well as subordinates better coordinate their time. Microsoft's Outlook, among other products, offers these and related functionalities.

Secretarial Functions

These are background processes that perform "clean up" or "overhead" services for users. For example, the secretary would manage the real-time messaging system to manage the receipt of messages by accepting high-priority interactions but blocking unnecessary interruptions and redirecting (and prioritizing) those less important messages to the users' electronic mail platform. These filtering functions are common in many email groupware products.

Project Management

Groupware's increasing adoption is due to its ability to support project management endeavors easily. As personal computers and networks have become more powerful, they have provided the necessary performance for today's groupware, imaging, and document management applications. These technologies, originally distinct, have become more integrated into many organizations with the aim of supporting project management. This type of system improves distributed project management through controlled management of documents, schedules, and personnel; allowing project personnel to be dispersed geographically without regard to location or time; providing communication among project personnel through a variety of means, including e-mail and discussion forums; and, because project personnel and project information are linked, project information remains current and accessible. The right information gets to the right people at the right time.

Cutting-Edge Groupware Functionalities

As we noted earlier, it is still useful to categorize groupware tools on the basis of whether they support synchronous or asynchronous work, although some modern groupware tools support processes that do not fit neatly into these two categories. For simplicity sake, we divide our discussion of modern Internet-age groupware into these two categories and comment on how the technologies fit into this classification scheme (see Table 2).

Asynchronous Groupware

Asynchronous groupware can take a variety of forms from the early and simple (but useful and enduring) such as e-mail to the most modern and complex such as Lotus Notes for Domino, described in the following paragraph. Although some forms such as e-mail were often freestanding organizational communication support systems, run on a firm's local area network, all of the forms we describe can and typically do run on the Internet (as well as on private portions of the Internet such as corporate intranets and extranets). Functional descriptions of some of these systems follow.

System profile: Lotus Notes for Domino—a database-oriented portal. Notes is a sophisticated asynchronous groupware system from the Lotus Corporation (http://www.lotus.com), a subsidiary of IBM. Notes provides a traditional group support functions that are tightly integrated to provide a virtual "workspace," library, and secretary for its users. Group members are able to communicate via e-mail, store all digitized information related to a project in a dedicated and secure database, and obtain scheduling and calendaring support aid in project management. These functions allow an organization's workers to interact so that users at different geographic locations can share information with each other, exchange comment publicly or privately, and keep track of project schedules, guidelines and procedures, plans, white papers, and so on. Notes keeps track of changes and makes updates to replications of all databases in use at any site.

Notes runs on a special server called the Lotus Domino Server. The servers and workstations use a client and server processing model, and replicated databases are updated using special programs called remote procedure call requests. Notes can be coordinated with Web servers and applications on a company's intranets.

In addition, Notes has strong workflow structuring capabilities and provides the basis for a document management system, well integrated with its database functions. Although it ships with these and a number of other customizable application "shells," Notes also provides simple facilities so that custom end-user applications can be developed. Given the product's inherent complexity, new users, as well as application developers, will face a steep learning curve.

Some aspects of Notes (e.g., the database functions) can be used by individuals as well as small and large groups. The database, for example, also would fit into our "anytime–anyplace" dimension by virtue of its Internet or intranet accessability. Other aspects such as e-mail fit more neatly into our "asynchronous" and our individual and dyad dimensions, although the latter could extend to large groups when used to support list serve functions.

Collaborative portals. Found on the Internet or intranets, collaborative portals (e.g., Blackboard 5, described in the next paragraph) are a single point of useful, comprehensive, ubiquitous, and integrated access. There are corporate, community (e-community), and personal portals that cater to specific communities of interest by providing tailored content. Groupware has recently been developed to automate the technical aspects of deploying a Web-browser-based portal such that end users are freed from the rigid limitations of traditional portal technology (Web page development) and enables them to conduct business by the terms of their own communities, interests, tasks, and job responsibilities. Portals increasingly are becoming collaborative tools: They can manage personal data, create spontaneous collaborative work spaces, allow real-time chat capabilities, and increase communication effectiveness by keeping track of who is online within the community (with pertinent information about them such as topics of interest and job function). These tools are also “anytime–anyplace” and can support small groups. They may be asynchronous, serving more as passive postings of information, or when enabled with the appropriate technology, support near-synchronous interaction (e.g., a chat room).

System profile: Blackboard 5. This community portal system features a highly customizable community portal environment that unifies academics, commerce, communities, and administrative services online through one integrated interface. This advanced functionality is backed by a sophisticated product architecture that runs on relational databases and can be scaled to support tens of thousands of users through a multiserver configuration.

Newsgroups/Usenet. Usenet is a collection of user-submitted notes or messages on various subjects that are posted to servers on a worldwide network. Each subject collection of posted notes is known as a newsgroup. There are thousands of newsgroups, and it is possible for a user to form a new one. Newsgroups are similar to e-mail systems in spirit but are intended for messages among large groups of people instead of one-on-one communication. In practice, the main difference between newsgroups and mailing lists is that newsgroups only show messages to a user when explicitly requested, whereas mailing lists deliver messages as they become available. Most browsers, such as those from Netscape and Microsoft, provide Usenet support and access to any newsgroups that users select. On the Web, Google and other sites provide a subject-oriented directory as well as a search approach to newsgroups and helps users register to participate in them. In addition, there are other newsgroup readers that run as separate programs. This technology is typically asynchronous with anytime–anyplace access via the network and supports large and small groups.

Listserv. A listserv is a small program that automatically redistributes e-mail to names on a mailing list. Users can subscribe to a mailing list by sending an e-mail note to a mailing list they learn about; listserv will automatically add the name and distribute future e-mail postings to every subscriber. (Requests to subscribe and unsubscribe are sent to a special address “the list servers” so that all subscribers do not see these requests.) This technology is typically asynchronous with anytime-anyplace access via the network and supports large and small groups.

Workflow systems. These systems allow digital versions of documents to be routed through organizations through a relatively fixed process. A simple example of a workflow application is an expense report in an organization: An employee enters an expense report and submits it; a copy is archived and then routed to the employee’s manager for approval. The manager receives the document, electronically approves it, and sends it on. The expense is registered to the group’s account and forwarded to the accounting department for payment. Workflow systems may provide features such as routing, development of forms, and support for differing roles and privileges.

Workflow systems can be described according to the type of process they are designed to deal with, and there are essentially three types of workflow systems:

1. **Image-based workflow systems** are designed to automate the flow of paper through an organization by transferring the paper to digital “images.” These were the first workflow systems that gained wide acceptance. These systems are closely associated with “imaging” technology and emphasize the routing and processing of digitized images. Lotus Notes, for example, supports both document management (via scanning or “imaging”) and workflow by directing the digitized material via user-defined routes.
2. **Form-based workflow systems** are designed to route forms intelligently throughout an organization. These forms, unlike images, are text-based and consist of editable fields. Forms are automatically routed according to the information entered on the form. In addition, these form-based systems can notify or remind people when action is due, providing a higher level of capability than image-based workflow systems. Notes can also provide customizable forms (e.g., invoices).
3. **Coordination-based workflow systems** are designed to facilitate the completion of work by providing a framework for coordination of action. The framework is aimed to address the domain of human concerns (business processes), rather than the optimization of information or material processes. Such systems have the potential to improve organizational productivity by addressing the issues necessary for customer satisfaction, rather than automating procedures that are not closely related to customer satisfaction. Customer relationship management systems, for example, can be set up to route customer problems to specialists.

Workflow systems can support individual and dyadic functions but are typically used to support larger groups. They are typically asynchronous and may permit anytime–anyplace access.

Group calendars. These systems allow scheduling, project management, and coordination among many people and may provide support for scheduling equipment as well. Typical features detect when schedules conflict or find meeting times that will work for everyone. Group calendars also help to locate people. Typical concerns are privacy (users may feel that certain activities are not public matters), completeness (users may neglect to enter their schedules into the system), and accuracy (users may feel that the time it takes to enter schedule information is not justified by the benefits of the calendar). Calendars are also typically asynchronous with anytime–anyplace access.

E-mail. By far the most common groupware application, basic e-mail technology is designed to pass simple messages between two people. Today, however, even relatively basic e-mail systems typically include interesting features for forwarding messages, filing messages, creating mailing groups, and attaching files with a message. Other features that have been explored include automatic sorting and processing of messages, automatic routing, and structured communication (messages requiring certain information). E-mail, although typically asynchronous, can appear to become "near synchronous" with a fast enough network.

Synchronous Groupware

Synchronous groupware systems (e.g., GroupSystems, described in the following paragraph) are interactive computer-based environments (physical and virtual) that support individuals (collocated or dispersed) working together at the same time. This emerging generation of groupware is also incorporating new technologies, such as Internet telephony, videoconferencing, speech recognition, and simplified yet secure connections with corporate databases. However, the key point of collaborative software remains connecting the "islands of knowledge" represented by each employee for the organization's greater good.

System profile: GroupSystems—a meeting support system. GroupSystems (http://www.groupsystems.com) offers a comprehensive suite of that can shorten the cycle time for business processes such as strategic planning, product development, and decision making. Three features that apply to all tools in the GroupSystems suite:

1. Simultaneous contribution, in which everyone is "speaking" at once, saving time and increasing productivity.
2. Anonymity, in which the identity of each contributor is unknown so participants tend to feel freer to express their opinions, and ideas are evaluated more objectively.
3. Complete records, in which, at the end of a meeting, users can easily produce a complete and accurate report of all ideas, comments, and vote results, in Word or rich text format (.rtf).

There are seven tools in the GroupSystems suite. Each focuses on a specific aspect of a group effort, including idea generation, evaluation, organization, and exploration. For example, the electronic brainstorming module, a tool that supports simultaneous and anonymous idea sharing, is commonly used for team building, broad or focused brainstorming, and visioning or strategic planning sessions. The group voting module supports eight voting methods, including a customizable point scale, and makes the decision process efficient, flexible, and powerful. Organizations use the voting module to evaluate, make decisions, and build consensus.

Early forms of the GroupSystems tool set were designed to run on local area networks, often in dedicated meeting rooms with networked personal computers, electronic whiteboards, and audiovisual support. More recent forms are now Web-enabled and provide similar functionality to distributed meetings. In addition, these systems are among the oldest and best researched types of groupware (e.g., Nunamaker, Briggs, Mittleman, Vogel, & Balthazard, 1997).

Typical synchronous groupware include the following.

Chat systems. These permit many people to write messages in real time in a public space. As each person submits a message, it appears at the bottom of a scrolling screen. Chat groups are usually formed by listing in a directory chat rooms by name, location, number of people, topic of discussion, and so on. Chat systems, like e-mail, may be accessed anytime–anyplace when hosted on an Internet server or may be available only at certain times or through certain connections if run on a proprietary intranet.

Shared whiteboards. An electronic whiteboard is one of several writeable presentation display systems that can be used in a classroom or videoconference. These generally fall into one of three categories: stand-alone copy boards, which allow users to scan and print out the content of the whiteboard; peripheral boards, which transfer information in the form of digital files to an attached computer; and interactive boards, which are like large touch-screen monitors that can be synchronized to an attached computer, allowing users to interact with the display, visit Web sites, and access databases directly from the board. Some peripheral boards can accommodate a projector that can be calibrated to the display, making them interactive. There are a number of add-on whiteboard digitizer products available that can also be used to make traditional dry-erase whiteboards interactive.

In cyberspace, a whiteboard is a space on the display screen in which one or more participants write or draw, using a mouse, keyboard, or other input device. It allows users to view and draw on a shared drawing surface even from different locations. This can be used, for instance, during a phone call, allowing each person to jot down notes (e.g., a name, phone number, or map) or to work collaboratively on a visual problem. Most shared whiteboards are designed for informal conversation, but they may also serve structured communications or more sophisticated drawing tasks, such as collaborative graphic design, publishing, or engineering applications. Microsoft's NetMeeting allows collaborative real-time use of its PowerPoint application via the Web. Users can pass control of the cursor to each other while sharing a single view of a common screen, thus collaborating on the development of a slide or graphic. Although whiteboards might be real physical devices or virtual representations, the information they capture can be accessed anytime–anyplace when they are connected to a network.

Collaborative customer relationship management (CRM). Collaborative CRM systems support the communication and coordination across the customer life cycle between channels and customer touch points. They are aimed at providing an enhanced understanding and management of the customer relationship—increasing knowledge of customer behavior, building switching costs, and increasing customer satisfaction and retention, especially relationship-centric, process-centric, and productivity-centric collaboration and a more mature collaborative CRM market. Collaborative CRM addresses the problems of traditional CRM solutions that are inwardly focused on an enterprise, not on the customer. By understanding the heterogeneous environment of most enterprise application portfolios, collaborative CRM provides a framework that sales, service, marketing, and product development organizations can work together but still maintain their unique way of doing business. Some CRM functions are similar to workflow and are asynchronous, but others support the synchronous interaction that organizational teams use to provide customer support.

Videoconference. A videoconference is a live connection between people in separate locations for the purpose of communication, usually involving audio and often text as well as video. At its simplest, videoconferencing provides transmission of static images and text between two locations. At its most sophisticated, it provides transmission of full-motion video images and high-quality audio between multiple locations.

Videoconferencing software is quickly becoming standard computer equipment. For example, Microsoft's NetMeeting is included in Windows 2000 and is also available for free download from the NetMeeting homepage. For personal use, free or inexpensive videoconference software and a digital camera afford the user easy and inexpensive live connections to distant friends and family. Although the audio and video quality of such a minimal setup is not high, the combined benefits of a video link and long-distance savings may be persuasive.

The tangible benefits for businesses using videoconferencing include lower travel costs and profits gained from offering videoconferencing as an aspect of customer service. The intangible benefits include the facilitation of group work among geographically distant teammates and a stronger sense of community among business contacts, both within and between companies. In terms of group work, users can chat, transfer files, share programs, send and receive graphic data, and operate computers from remote locations. On a more personal level, the face-to-face connection adds nonverbal communication to the exchange and allows participants to develop a stronger sense of familiarity with individuals they may never actually meet in person.

A videoconference can be thought of as a phone call with pictures—Microsoft refers to this aspect of its NetMeeting package as a "Web phone"—and indications suggest that videoconferencing will some day become the primary mode of distance communication. Web-enabled, videoconferencing is accessible anytime–anyplace, although bandwidth considerations can limit the quality of transmission and reception.

Audio–video communications. Real-time communication (RTC) systems allow two-way or multiway calling with live video—essentially a telephone system with an additional visual component. Cost and compatibility issues limited early use of video systems to scheduled videoconference meeting rooms. Video is advantageous when visual information is discussed but may not provide a substantial benefit in most cases in which conventional audio telephones are adequate. In addition to supporting conversations, video may also be used in less direct collaborative situations, such as by providing a view of activities at a remote location.

Many RTC systems allow for rooms with controlled access or with moderators to lead the discussions, but most of the topics of interest to researchers involve issues related to unmoderated RTC including anonymity, following the stream of conversation, scalability with number of users, and abusive users. Although chatlike systems are possible using nontext media, the text version of chat has the rather interesting aspect of having a direct transcript of the conversation, which not only has long-term value but also allows for backward reference during conversation making it easier for people to drop into a conversation midway through it and still pick up on the ongoing discussion.

Threaded-discussion systems. Threaded-discussions systems are a place where messages can be posted for public display. The groupware tool allows participants to communicate with each other asynchronously. Communication takes place by having participants create a continuous chain of posted messages on a single topic. This chain is known as a "thread" or a "threaded discussion." Several parallel threads can make up a full conversation. The threads can then be used to build a hierarchy with the content. In some instances, a threaded discussion may also be called a bulletin board or a forum. A discussion can be used as a place where participants can discuss general issues, discuss the specifics of an issue, or organize related content. With a threaded-discussion tool, users can read posted messages, compose new messages, attach documents to posted messages, search and compile posted messages. Like e-mail and its variants, these systems are anytime–anyplace accessible with the right connection and hardware.

Decision support systems. These systems are designed to facilitate groups in decision-making situations. They provide tools for brainstorming, critiquing ideas, putting weights and probabilities on events and alternatives, and voting. Such systems enable presumably more rational and even-handed decisions. Primarily designed to facilitate meetings, they encourage equal participation by, for instance, providing anonymity or enforcing process structure (like a nominal group technique or a Delphi technique). Although in the past some forms were primarily designed for same-place–same-time interaction, many individual tools can be installed on a network for anytime–anyplace access. Some integrated suites such as GroupSystems (profiled earlier) are now available in Web-enabled formats.

Virtual workplace. The virtual workplace concept seeks to create an electronic facsimile of an office workplace in which coworkers meet and work. This is typically

Table 3 The Groupware Grid

	COMMUNICATIONS SUPPORT	DELIBERATION SUPPORT	INFORMATION ACCESS SUPPORT
Concerted Work Level			
Coordinated Work Level	░	░	░
Individual Work Level	▓	▓	▓

manifested as a Web site that has pictures of team members, links to instant messaging, a link to asynchronous discussion boards, as well as access to all the documents and database links needed. The goal is to enhance also the sense of being on a team by giving dispersed team members a "place" to go, where they can all "meet" (i.e., communicate textually and possibly telephonically or visually in real time). Lotus Notes for Domino features a number of functionalities that support this goal.

Collaborative writing systems. These system may provide both real-time and offline support. Word processors may provide asynchronous support by showing authorship and by allowing users to track changes and make annotations to documents. Authors collaborating on a document may also be given tools to help plan and coordinate the authoring process, such as methods for locking parts of the document or linking separately authored documents. Synchronous support allows authors to see each other's changes as they make them and usually needs to provide an additional communication channel to the authors as they work (via videophones or chat). Microsoft's NetMeeting provides this synchronous functionality with its Word application and similar functionality with its spreadsheet (Excel), database (Access), and graphics programs (PowerPoint).

Mobile and wireless messaging. Messaging is the ability to see whether a chosen friend or coworker is connected to a network and, if they are, to exchange relatively short messages with them. Messaging differs from e-mail in the immediacy of the message exchange and also makes a continued exchange simpler than sending e-mail back and forth. Most exchanges are text only, although some services now allow voice and attachments.

For messaging to work, the sender and receiver must both subscribe to a network service and be online at the same time, and the intended recipient must be willing to accept instant messages. Under most conditions, messaging is truly "instant." Even during peak Internet usage periods, the delay is rarely more than a second or two. It is possible for two people to have a real-time online "conversation" by messaging each other back and forth.

Mapping Groupware Functionality to Work Processes

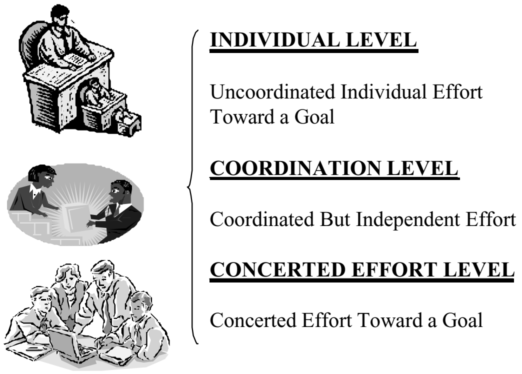
The broad (and expanding) range of modern groupware functionality means that those who adopt the technology would benefit from some guidance. To this end, the Groupware Grid (Table 3) can serve as a theory-based heuristic model for mapping the functionalities of groupware technology to organizational work. The Groupware Grid is useful for managers to understand how to understand the dimensions of individual and group work that can be supported by the different general functionalities. It is consistent with our technology-oriented classification scheme presented earlier in the chapter but places its emphasis on the type of work that would be supported.

Team Theory and the Groupware Grid

The horizontal axis of the Groupware Grid derives from the team theory of group productivity (adapted from Briggs, 1994). *Webster's Dictionary* defines a team as a collection of people working together for some specific purpose. Team theory is a causal model for the productivity of a team. It asserts that team members divide their limited attention resources among three cognitive processes: communication, deliberation, and information access. Team theory posits that these processes interfere with one another, limiting group productivity.

Team theory's communication construct posits that people devote attention to choosing words, behaviors, images, and artifacts, and presenting them through a medium to other team members. Team theory's deliberation construct asserts that people devote cognitive effort to forming intentions toward accomplishing the goal-solving activities: make sense of the problem, develop and evaluate alternatives, select and plan a course of action, monitor results, and so on. The information-access construct addresses the attention demands of finding, storing, processing, and retrieving the information the group members need to support their deliberation. Team theory posits that a key function of information is to increase the likelihood that the outcome one expects will be obtained by choosing one course of action over another. Information has value to the extent that it is available when a choice must be made, to the extent that it is accurate and complete. The value of information is offset by the cost of acquiring, storing, processing, and retrieving it, however.

Team theory also posits that the cognitive effort required for communication, deliberation, and information access is motivated by goal congruence—the degree to which the vested interests of individual team members are compatible with the group goal. Team members whose interests are aligned with those of the group will exert more effort to achieve the goal than those whose interests are not served by the group goal. The Groupware Grid does not address goal congruence because goal



INDIVIDUAL LEVEL
Uncoordinated Individual Effort Toward a Goal
COORDINATION LEVEL
Coordinated But Independent Effort
CONCERTED EFFORT LEVEL
Concerted Effort Toward a Goal

Figure 2: Three levels of group work.

congruence may have more to do with the way a team wields the technology than with the technology's inherent nature. Therefore, the horizontal axis of the grid addresses the potential for technology to reduce the cognitive costs of joint effort. Groups may become less productive if the attention demands for communication, deliberation, or information access become too high. Groupware may improve productivity to the degree that it reduces the attention costs of these three processes.

Three Levels of Group Work and the Groupware Grid

The vertical axis of the Groupware Grid consists of three levels of group effort (Figure 2). Sometimes a team may operate at the individual work level, with members making individual efforts that require no coordination. Other times team members may interact at the coordinated work level. At this level, as with a technical sales team, the work requires careful coordination between otherwise independent individual efforts. Sometimes a team may operate at the concerted work level, that is, several parts of an organization must support the sales team to ensure future results. Teams working at this level must make a continuous concerted effort beyond short-lived coordination. For example, the sales department of an industrial manufacturer must routinely interact with its engineering department to help determine customer specifications on a new product. Today, there are even interorganizational cross-functional teams that provide concerted efforts to support increasingly complex value chains for products and services.

The demands placed on the team vary depending on the level of work in which they are engaged. There is groupware technology to support teams working at all three levels. The Groupware Grid can thus be used to map the contributions of a single groupware tool or an entire groupware environment (see Table 4). A given technology will probably provide support in more than one cell. The potential for productivity of different environments can be compared by examining their respective grids. For example, the shared database aspect of a product such as Lotus Notes is often used asynchronously and offers little support at the concerted work level but offers strong support for communication and information access at the coordination level. Furthermore, a team database offers only indirect support for deliberations at the coordination level, but a project management and workflow automation system offers strong support for deliberations at that level.

Synchronous groupware that supports meetings, for instance, offers a great deal of support for communication, deliberation, and information access at the concerted work level. For example, the parallel input and anonymous interventions can improve communication during a concerted effort. Other groupware tools affect deliberation in different ways. For instance, a brainstorming tool prevents a group from thinking deeply while encouraging them to diverge from familiar thinking patterns. An idea organizer, on the other hand, encourages a divergent group to focus quickly on a narrow set of key issues. With ubiquitous access to the Internet and client and server access to corporate databases, emerging synchronous groupware tools can support information access at the concerted work level by providing rapid access to the information in the minds of teammates by providing permanent transcripts of past electronic interactions, or by providing an information search engine.

Table 4 Potential Contributions of Groupware to Support Productivity Processes, as Viewed in the Groupware Grid

	COMMUNICATIONS SUPPORT	DELIBERATION SUPPORT	INFORMATION ACCESS SUPPORT
Concerted Work Level	Anonymity Parallel contributions Virtual presence Synchronous communication	Structured processes Distributed participation Alternative analysis Process focus	Database access Online search engines Organizational memory Concept classification
Coordinated Work Level	Asynchronous communication Sequential contributions	Distributed project management Scheduling Automated workflow	Shared data Coordinated filtering
Individual Work Level	Message preparation Communication structure	Modeling support Simulation support Hypothesis testing Logic analysis	Individual data Filtering Categorizing

GROUPWARE MANAGEMENT ISSUES: PRODUCTIVITY AND ORGANIZATIONAL IMPACT

Perhaps the most important management issues surrounding Web-based collaboration tools are how to use them to enhance productivity and how to manage their organizational impacts. Not all organizations that adopt groupware reap the potential benefits, and this is often due to the same factors that can plague the adoption of any information technology. Companies may try to implement a product that is not designed for its intended use, they may not think through exactly what benefits they wish to accrue from the technology, they may not invest sufficient efforts in training and support, and they may not understand that some of processes are amenable to team and group work (technologically supported or not) but others are not. Adoption of Web-based collaboration support systems is often tantamount to a large and often ill-defined management initiative such as total quality management (TQM) or business process reengineering—that is, success or failure of the adoption is often difficult to measure, benefits will emerge at different and often unpredictable rates, and human issues such as culture, politics, power, incentive and personality either facilitate success or bring the project to its knees. We cannot pursue systems planning and development here but instead devote some discussion first to groupware issues that derive from individual users and their interaction with groupware-supported team members and second to issues that derive from an organization's larger culture.

Groupware and Productivity

Organizations may not realize that some group or team members may not have the personality, motivation, or teamwork and communication skills to be effective in their roles. These issues are now beginning to receive attention from researchers examining the performance of groupware-supported workers and teams (e.g., Potter & Balthazard, 2002). Findings suggest that first, people collaborating via groupware do not leave their personalities at the virtual door simply because their new communication mode is textual and possibly asynchronous (e.g., Hiltz & Turoff, 1993). People's personalities drive how they interact with one another in both the face-to-face world and the virtual world; in both modes, people are similarly affected by each other's individual style of interacting. These effects can determine whether a group enjoys enhanced or diminished information sharing, enhanced, or diminished task performance (e.g., decision making) and positive or negative sentiments such as buy-in to the team's solution or product, satisfaction with the team's processes, and the team's cohesion. The important implication is that groupware means group work, and not all people are equally skilled in group communication and work processes or otherwise predisposed to work best in a team situation. Interventions such as training are needed to help some groupware-supported people adopt more appropriate interaction skills before they tackle a task. Alternatively, future groupware could incorporate interfaces, communication aids, protocols, and intelligent agents designed to promote, for example, participation, constructive interaction, and team building.

Organizational Impacts of Groupware

For several years, researchers have compiled evidence that information technology such as groupware or other forms of computer-mediated communication can alter a number of relationships and processes in the workplace (e.g., DeSanctis & Fulk, 2002). An organizational hierarchy that has traditionally exhibited mostly top-down dispersion of information may find that the communication support capacities of a collaborative information system create new lateral and bottom-up flows of information. In more radical manifestations, command-and-control structures in the organization can be circumvented as employees reinvent information-intensive processes based on expertise, interest, and resources, rather than restrictive operating procedures, protocols, or customs. Some researchers suggest that, once in place, collaborative systems become the vehicle for organizational redesign, and as such their more profound effects are largely emergent. In many cases, not all purposes or uses of the systems can be identified beforehand. Therefore, their management should reflect more of a "wait and see" attitude and an acceptance of the fact that they may give rise to a number of unanticipated benefits (e.g., Orlikowski, 1992).

Another common finding is the spontaneous creation of online communities of interest or professional practice. These can be the gateways into larger organizational strategic concerns such as knowledge management. Effectively managed collaborative technologies can and often do provide the venue for knowledge sharing—an important input into the knowledge management process, particularly when derived from communities of professional practice or interest (Constant, Sproull, & Kiesler, 1999; Pickering & King, 1999).

The national cultures of groupware users can also become a management issue for transnational organizations. Different traditions, social mores, and internal and national political realities can drive preferences for certain technologies and interaction modes (i.e., text, video, threaded discussion, e-mail; Potter & Balthazard, 1999). In addition, preference of various groupware technologies can also differ by gender (Potter, Balthazard, & Elder, 2000).

This more expansive "sociological" view of the management of these systems is informed by knowing the politics and culture of the organization on one level and the personalities of system users on another level. These—as much as the technology's functionality—ultimately will drive the use and potential benefits of the system. As noted earlier, some suspension of "standard operating procedure" or organizational status quo is a common result of these systems, and leaders often have to deal with relatively rapid changes in how things are done and, perhaps more important, how procedures and technologies are perceived in their organization. Many aspects of an organization's culture are "genies in a bottle" that are released when a new communication and collaboration system allows transcendence of predetermined, traditional communication paths. The good news is that installing the collaborative communication technology found in many groupware products into healthy organizations will likely spur new organizational knowledge, improved practices, and synergistic relationships to emerge.

CONCLUSION

Modern Internet-based groupware offers a plethora of useful functionality that is driving sizeable gains in organizational productivity by streamlining collaborative work that was traditionally encumbered by distance and time. It is also driving the reinvention of business processes, spontaneously altering the nature and connection of communication-driven relationships and enabling an unprecedented growth in organizational and professional knowledge. At the same time, such impact can represent important management challenges that need to receive increased attention from managers and researchers alike as the proliferation of Internet-based groupware continues. Thoughtful assessment of groupware functionalities matched with a true understanding of the human side as well as the work process side of the organizational context will ensure the creative and effective adoption of these revolutionary technologies in the foreseeable future.

GLOSSARY

Anytime–anywhere Groupware components and resources such as databases and threaded discussions that can be accessed via the Internet from any location at any time.

Asynchronous groupware Groupware that does not allow users to interact in real time.

Groupware Technology-typically software and networks—designed to support people working in groups.

Groupware grid A theory-based heuristic model for mapping the functionalities of groupware technology to organizational work.

Organizational impact Effects on work processes, social and authority hierarchies, and communication pathways and processes that can occur with groupware adoption.

Synchronous groupware Groupware designed to allow two or more users to interact in real time.

Team theory A causal model for the productivity of a team developed by Briggs (1994), asserting that team members divide their limited attention resources among three cognitive processes: communication, deliberation, and information access.

Guidelines for a Comprehensive Security System

Margarita Maria Lenk, *Colorado State University*

INTRODUCTION

Security for Internet-related distributed networks is not a product, service, or status produced or purchased at one point in time, nor is it a one-time decision that can be expected to be valid over a period of time. Modern distributed networks are continuously changing. Each day there are new technologies, new risks, and new threats that challenge the status quo and must be considered. Security, therefore, is a complex continuous process that actively involves stakeholders and participants who have differing priorities for and valuations of the assets involved. A careful, systematic approach to the task of network security can provide the reliable assurance over time needed by organizations who utilize the Internet. This chapter models such a process for an organization's security team to utilize in designing, implementing, and maintaining comprehensive Internet-related system security. A review of the assets involved, their risk sources and probable effects, and a spectrum of prescriptive measures is provided. The inherent bias in this model, supported by many real-world security successes and failures, is the belief that a lack of management support and involvement in a systematic approach toward comprehensive security has been associated with many Internet-related network security problems. Many of the primary causes of security failures (e.g., lack of enough qualified IT staff, insufficient/ineffective funding for IT needs, communication barriers between the IT staff and top management) may have been mitigated or eliminated with active top management support and involvement (Stein, 1999; SANS, 2002; Allen, 2001).

A perfect comprehensive security system would protect all assets from all possible damaging events, whether intentional or not in nature. However, restricted resources, technological realities and advances, and human characteristics more often result in less-than-perfect comprehensive security systems. For-profit, nonprofit, and government agencies all operate with a limit on the utilization of capital for electronic security. Also, top management's attitude toward funding security can be less than enthusiastic for a variety of reasons, which are discussed in this chapter. The discovery and application of new technologies or new uses of existing technologies also change security risk sources and assessments. Finally, any system that involves human beings is subject to possibilities of unintentional errors due to fatigue, illness, lack of training and supervision, and malicious actions due to attention, resentment, revenge, and control needs (Garfinkel & Stafford, 2001; IOMA, 2000).

Even when powerfully effective individual and joint security elements are present in a network, the entire network security will only be as strong as its weakest link. In other words, it is the unlocked door that invites entry. A burglar is at best only momentarily delayed if he first finds a locked door with state-of-the art security before finding the unlocked door. Furthermore, Internet-connected networks and their environments are continuously changing and security teams need to continuously screen for new assets, new risks, and new solutions. The task for security teams, then, involves not only designing an efficient and effective security system, but also continually assessing and testing the system in efforts to find and correct its weakest links. This chapter will provide a structured process for this seemingly formidable task. Anderson (2001) states that "building systems in the face of malice is one of the most important, interesting, and difficult tasks facing engineers in the twenty-first century."

BUILDING YOUR SECURITY TEAM

Comprehensive security system management involves the creation and delegation of authority to a knowledgeable, trusted security team. The membership of that team should depend upon the size of the organization, the dependence of the organization and its business partners on their Internet-related networks for critical business processes (suppliers, customers, creditors, banks, etc.), and the level of risks associated with the organization's industry and practices (regulatory agencies, legal liabilities, etc.). All policies and resolutions emerging from this team should be formalized in writing, signed by each of the team members, and be guidance for each of the systems' administrators for implementation and maintenance purposes.

Suggested membership for the comprehensive security team would include top management, a finance officer, an internal audit officer, system administrators, major user group representatives, and major business partner representatives. Business partners may be suppliers, contract laborers, outsourced process providers, bankers, creditors, and customers. While many organizations prevent outsourced "employees" from becoming too familiar with their systems (e.g., need-to-know controls), new types of business affiliations and Web services are creating fuzzier lines between the organization and its environment. The different stakeholders, whether in the organization or in the nexus of surrounding business partners, have varying priorities for and valuations of the assets involved in the distributed network systems. Their needs and viewpoints need to be included, either as members of the security team or accessible by the security team, for the security system to be effective.

The inclusion of top management representatives and a top financial officer on these security teams is important for several reasons. First, top management's attention typically first goes to issues of market, customer, and product or service quality and fulfillment. The provision of Internet-related network security does not directly bring in any new markets, new customers, or more revenue from existing customers. However, just as security failures can cause business failures or significant negative impacts on corporate image, the indirect effects of effective visible security measures and the perceptions of trust therefrom can have a sizable positive effect on customers' choices.

Another reason for top management representation on the comprehensive security team is due to the importance of the influence of top management's participation on the culture, formal and informal, of the organization. Management variables related to security risk for an organization include the philosophies, operating styles, integrity, and competences of top management, the delegation of authorities and responsibilities in the organization (the structure), the quality of the board of director's audit committee, and the policies and procedures for human resources (Greenstein and Vasarhelyi, 2002).

The inclusion of a top finance officer in the security committee membership is important for two primary reasons. First, the cash outflows required for security are oftentimes poorly estimated or understood in timing, justification, and/or amount by nonfinance business people. Cash outflows related to system security goals are not clearly matched to correlated or resulting cash inflows. Second, "benchmark" comparisons to competitor's security-related cash outflows or security incidents may not performed, and without an IT security-knowledgeable finance officer, finance committees often reach to the IT budget to cut overhead costs. Involvement of a top finance officer can assist in the sustained success of investment in corporate security in all of these situations. The inclusion of an internal auditor on the security committee is primarily for the consideration of making sure that all security measures taken can be verified as to their effectiveness in some manner (otherwise, it may be impossible to deduct the benefit of the investment), as well as enabling the auditor to know the level of internal control inherent to the electronic processes performed on the network. Collaborations with the internal auditors in this regard can result in cost efficiencies in the internal auditing department, as well as providing documentation that may result in cost efficiencies for the external independent audit process.

Finally, for comprehensive security policies, procedures, tools, and equipment to be taken seriously by the rest of the employees and other stakeholders, the support and involvement of top management is essential. Participation in the security team is an efficient communication that management is willing to "walk the talk" of the importance of security for the organization.

THE ASSET-SECURITY CONTINUUM

A centuries-old personal reflection model from India presents a continuum model that relates a person's beliefs system to their destiny. The continuum illustrates the relationships between beliefs and thoughts, thoughts and choice of actions, actions and habits, and habits and ultimate destiny, or end state. The "lesson" within this saying is not about trying to understand how your beliefs are related to your destiny, but rather comes from the research and reflection performed at any one or more of the individual dyads within the continuum: beliefs-to-thoughts, thought-to-actions, actions-to-habits, and habits-to-destiny. The greater the correlation built into these dyads, the greater the probability that you will reach your desired destiny. This methodology of breaking down a large task into smaller localized tasks is similar to the milestone execution focus in project management and system development guidelines, an approach also recommended here in this chapter for the development and maintenance of a comprehensive security system.

This continuum conceptualization can be applied to comprehensive security systems. As can be seen in Figure 1, the asset-security continuum contains the individual elements of a business' assets, risks, threats, controls, and security goals. This continuum begins with the identification and prioritization of the business assets, whether tangible or intangible, physical or logical. Then the abstract risks that can cause loss, costs, or damage to an organization's assets are considered. Next, the specific threats, or causes of those risks, are identified. This is followed by the consideration of general and specific controls that may reduce or eliminate those threats. Finally, the specific effectiveness, efficiency, or trust-creating security goals of the organization are presented. Comprehensive security is maximized when careful research and reflection occurs for each of the dyads in the asset-security continuum. The power of this model lies in the correlation within the individual linkages rather than in the endpoints.

Assets are tangible, digital, and intangible aspects of a business which provide future value. Assets can be servers, payroll systems, customer lists, or even the knowledge of the database administrator. Assets need to be identified and then dynamically categorized in terms of their priority with respect to the corporate mission and strategies. The prioritization of assets becomes complicated when the timing of the risks and threats are taken

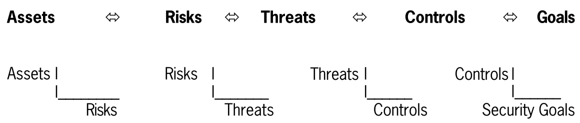

Figure 1: The asset-security continuum.

into consideration. For example, if the payroll application were to crash immediately after the electronic fund transfer instructions were sent to the bank, the corporation would have the time until the next pay-day to recover the payroll application. However, if the payroll application were to crash one hour before the normal fund transfer to employee accounts, the payroll system would have a much higher priority for the security system.

Risks are defined as events that cause an organization to lose value. Risks can create a very wide range of negative effects, including business interruption, legal or regulatory sanctions, excessive costs, lack of independence, losing revenues, losing customer loyalty, and losing intellectual property. Risks can be the reduced capacity to produce new intellectual property or reduced operating flexibility in the future.

Threats are the specific causes of risk. Threats can emerge from external or internal sources. Examples of threats from the external environment include a lack of or new regulatory or legal standards, new competitors, malicious or curious hackers, new technologies, misuse or abuse of your data by application service providers, earthquakes, floods, or war-related attacks. Examples of threats from the internal environment include malicious employees, software or hardware failures, unintentional human error, lack of buy-in toward the importance of security-related team-work, outdated systems, undocumented systems, and even unaudited systems.

Controls are policies, procedures, techniques, tools, habits, and leadership structures and attitudes designed to reduce threats to an organization. Alternatively, controls are designed to maximize the probabilities regarding the achievement of organizational goals and responsibilities of security, the efficiency and effectiveness of operations, and legal and regulatory compliance. Controls can be as pervasive as top management's attitude or style and the standard hiring practices utilized by an organization, or as specific as a reasonableness check on one field of transactions from one day in a database for a specific application. Controls can be classified as preventative if they restrict the event from occurring, detective if they sound an alarm when the event is discovered, and corrective if they help restore the situation to prior to the security-reducing event. Passwords are preventative controls because they are designed to keep unauthorized access from occurring. Logouts are detective controls that shut down log-in opportunities when a specific number of failed log-in attempts occur. Backups are corrective controls that restore the system to the state at the last time that the backups were made. Controls can be required or discretionary, depending upon the specifics of the situation or the judgment of the individual. Controls can be evaluated for effectiveness, which regards how the control helps to increase the probability that a particular security goal is achieved. Also controls can be categorized for efficiency, in terms of the number of threats mitigated by a particular control. Conversely, control redundancy (more than one control for a particular asset, process, or store) may be desired for highly vulnerable or valuable items for a business.

Security goals are the specific statements made by an organization to explain and communicate their security-related objectives. For example, organizations dependent upon their Web commerce may want their Web servers functional 24 hours per day, 7 days per week. Companies with proprietary Web services may want to keep their code or methods confidential. Companies negotiating online with their suppliers or their customers may want to keep the negotiations secret so that none of the other competitors learn of their decisions. The security objectives should be stated in a manner that encourages assessment with specific confidence intervals and system reliability goals clearly articulated.

Two examples of the utilization of the asset-security continuum are provided to illustrate its usefulness for comprehensive security teams. Consider purchasing negotiations with a primary supplier as the asset. Risks related to this asset include rising costs, for example, due to damages to the relationship with this supplier. Threats that increase this risk include errors in the online purchasing system, such as duplicate, erroneous, or nonauthorized orders. Control procedures designed to mitigate these threats include automated field verification procedures, encryption and digital signatures for all electronic communications with this supplier in order to achieve a security goal confidence that all communications have been confidential and authenticated. A second example involves a business's customer database as the asset. A risk to this asset includes reduced customer service. While there are several threats that could cause this risk, one of which could be a lack of integrity in the data regarding the customers (which could be due to hackers modifying the database, careless employees inputting errors, ineffective database design that does not allow important queries to be performed, etc.). Control plans that reduce these threats range from access controls (e.g., passwords and/or encryption) to application design and modification procedures and controls. The security goal for this example could be to have real-time accurate information on all customers. The next sections of this chapter review each of the individual components of the asset-security continuum: assets, risks, threats, controls, and security goals.

DYAD TABLES

One of the more powerful ways to utilize the asset-security continuum is to break down the whole model into four two-element dyads: assets-to-risks, risks-to-threats, threats-to-controls, and controls-to-security goals. Figure 1 illustrates these dyads below each of the linkages in the model. For example, the left-most dyad plots the organization's priority assets as the rows of the table and the abstract risks to the organization as the columns. The cells of the table can be discussed by the security team, and then filled if a particular risk column affects the asset listed in that row. Similarly, the next dyad plots the abstract risks with the specific threats, or causes of loss for the organization. In this dyad table, a particular risk may be caused by a number of threats; likewise, a particular threat may eventuate a business risk. Just as in the centuries-old Indian saying where the belief system assists the ultimate destiny through the personal work done on each of the individual dyads, the correlation between the assets and the comprehensive security system is maximized when the comprehensive security team studies each of the four dyads within the asset-security continuum.

IDENTIFYING AND CLASSIFYING YOUR ASSETS

Organizations derive their current and future value from their assets. Their assets may be physical or digital, such as property, equipment, data or software, or intangible such as intellectual capital or having a reputation of providing the best service. Organizational security teams must devise a system to first identify all value-providing assets of an organization and second, prioritize, or place a relative value, on each asset. This is not an easy task due to the different stakeholders present or represented on the team. Each party typically has a unique set of asset priorities that must be somehow reconciled into a comprehensive security system. Moreover, security teams must consider the dynamic nature of most environments and organizations; assets change for a variety of reasons (e.g., business restructurings, new technologies, new partnerships). Finally, the priorities of different assets are sometimes a function of the timing of the threat. For example, consider a two-week payroll application as the asset, and its inability to function as the risk. Threats related to this risk include hardware and software failure, malicious human actions, and even power outages. The priority of the payroll application asset will be much higher if the threat occurs immediately before direct deposits of employees' paychecks than if the threat occurs immediately after the employees get paid (which would provide you with two weeks in which to correct the problem).

Comprehensive security systems must therefore know an organization's assets to know how much to spend protecting which assets. Most organizations have current or near-current lists of the physical assets related to the distributed network: servers; motherboards; CPUs; memory modules; network interface, video, serial, and printer port cards; printers; scanners; multimedia devices; screens; power supplies; hard, floppy, and tape drives; CD ROM readers; modems; and network cables, hubs, switches, bridges, and routers. Proper documentation of the original copies of current software, service packs, and operating systems is recommended. Database administrators typically have lists and libraries containing descriptions of their system components.

Oftentimes many organizations do not have lists of their logical or intangible assets. Several alternative methods can help the security team get started. First, the team can begin by reviewing the organizational mission, strategies, and tactics. For each goal articulated in these items, the team can determine the assets required to make the desired outcomes occur. Alternatively, a framework provided by Lynn (2001) provides guidance by organizing security assets as related to communication, staff responsibilities, supplier issues, data and property protection, and operations.

Microsoft (2003) recommends organizing assets by asset type as the best practice. A multiattribute classification scheme for the organization's physical assets involves the following categories: asset type (e.g., hardware, software, library references, communication equipment or channel wiring, wireless and portable tools); scope of asset utilization (general or specific application); organizational owner of the asset; physical or logical residence for the asset (with the physical asset identification number if relevant); relevant contract ancillaries (service level, warranties, updates, key contacts, etc.); sensitivity of data (e.g., personnel files, customer information); backups; and whether audit records are kept. Nonphysical assets must also be categorized and evaluated, even though they may be more difficult to articulate and value. Nonphysical assets that create value for the organization include branding; public image; customer service and product quality reputation; information processing availability, confidentiality and integrity; and distributed network configurations.

Once identified, the assets need to be prioritized in terms of their relative importance for security-related investments. These priorities can differ between stakeholders (e.g., a salesperson may value a customer database more highly than a purchasing agent). Most security system methodologies utilize a four- to six-level method for priorities, with a wide range of labels for each level. For example, the highest level of asset may be termed "strategic" if impairment to the asset even for a small amount of time could cause serious interruption for the business. An example of a critical asset for an online bookstore would be its online shopping cart technology. The second highest level of priority could be labeled "tactical" meaning that while the company could probably continue to function for the short run in an impaired state, the company would suffer significant losses in the long run without these assets. The next level of priority may be termed "noncritical," indicating that the organization could function for a longer period without the asset; however, there may be cost or service effects on the long run that warrant consideration. The lowest level of asset priority could be labeled "insensitive," which means that if the asset is lost, the organization would easily find another way to create the value that the insensitive asset provided before the threat was realized.

Microsoft (2003) suggests that the best practices for data classifications are those that indicate the level of criticality or sensitivity toward loss or disclosure to unauthorized audiences. Sensitive data has a higher than average need for assurance of accuracy and completeness (e.g., financial data). Confidential data have a higher than average need for confidentiality (e.g., customer lists and ordering history). Private data are items that could lead to legal consequences for the organization if accessed inappropriately (e.g., personnel health information). Public data are data that will not create a loss of value for the organization if it were to be inadvertently accessed, even if there is a policy to keep that information proprietary. Note that these dimensions are not a continuum, and any one asset may register on more than one dimension.

IDENTIFYING RISKS, THREATS, AND PROBABLE LOSSES

There are many risks to our Internet-related wired and wireless networked environments. Exponential growth in the number of Internet transmissions is evidence that

Table 1 Sample Sources of Threats to Comprehensive Security

Advanced intrusion scanning techniques
Airwave jamming techniques
Burglary
Concurrency errors
Cross-site scripting
Digital payment alterations/fraud
Disabled automated audit functions
Distributed attack tools (that do not work)
Distributed denial of service attacks
Electronic and wave emissions
Encryption key mismanagement
External events
Fault tolerance errors or omissions
Filtering technologies bugs
Geographic separations from solutions
Hijacking sessions
Holes in operating system access controls
Human error
Identity theft
Intellectual property theft
Lack of employee training/supervision
Malicious human behavior
Misconfiguration of e-mail protocols
Naming convention errors
Out-of-date hardware protection systems
Out-of-date intrusion detection systems
Password mismanagement
Phone phreaking
Physical environment issues
Privacy violations
Race conditions (multistage attacks)
Remote access violations
Server and e-mail system bugs
Slack security culture
Sniffing
Spoofing
Stack overflow attacks
Stack smashing (memory overwrites)
Staged attacks
SYN flooding
Third-party services
Turnover in IT administration
Viruses, worms, and Trojan horses
Vulnerable CGI programs
Weak SNMP protocol
Web bugs (attached to HTML)

more and more organizations are utilizing the Internet for internal and external processes. This increased dependence upon the open Internet environment heightens the importance of being aware and prepared for the increased risks to security.

Table 1 provides a comprehensive list of the sources of threats to an organization's distributed network security. Threats can emerge from inside the organization as a result of leadership, technologies, humans, or physical environment problems. Threats can also result from external sources, either malicious independent parties, past or present business partners, or environmental changes (Rubin, 2001).

Significant risks can be caused by any of the stakeholders, employees, or unrelated hackers through viruses, manipulations of or errors/failures in software, hardware, telecommunications, or just plain old human error. Moreover, a comprehensive security team must discuss the importance of market or individual stakeholder perceptions of Internet-related risks, which tend to be higher than the actual risk of doing business online. These perceptions are fueled by the real fact that while a physical burglar can only enter one house at a time, a virtual burglar can enter many doors at one time, and it may be difficult to tell which doors have been opened.

Cisco (2001) identifies the primary perpetrators who reduce organizational security as unrelated hackers or snoops and unaware or disgruntled staff, either current or past employees. These perpetrators are interested in accessing, altering, damaging, copying, and stealing assets, whether digital or physical. Many times their most common vehicles include password guessing; introducing viruses, worms, and Trojan horses; reconnaissance attacks such as social engineering (whose purpose is information gathering); and the use of sniffers and scanners. Their primary targets are system access points; modification of authentication services and FTP functionality; interception of data; denial of service; and manipulation of e-mail accounts, databases, and confidential information. Other common threats include packet replaying, packet modification, and IP spoofing.

Microsoft (2003) recommends that the security team identify all of the possible threats that can access, alter, damage, destroy, or steal each asset. The threat assessment can be performed one asset at a time, each one considered independently or within groups of similar assets. For example, the asset of stored economic transaction information can face intentional and unintentional threats such as hardware or software errors; malicious codes such as viruses, Trojan horses, or worms; modifications made by authorized or unauthorized access, human error, negligence, or ignorance; changes in regulations or laws; natural disasters such as fires; or damage due to power surges, excess water or dust, or vandalism.

MAXIMUM COST OF CONTROLS

Once the assets have been identified and prioritized, the risks related to each of those assets articulated, and the threats that cause each of those risks researched and expressed, then the next step is to calculate the maximum cost of controls. The maximum cost calculation is an expected value algorithm founded on a simple economic principle that the security for an asset should never be more than the value of the asset, or the value of the loss an organization would experience should the asset become compromised.

The first step is to calculate the probability that the threats for each risk will affect the identified asset. This involves judgment, experience, and expertise. Microsoft

Table 2 Types of Comprehensive Security Controls

Ad blockers
Audit trails, logs, and alarms
Backups
Board of directors audit committee
Client-side digital certificates
Cluster server technologies
Code signing methods
Configuration structures and policies
Cookie crushers and other privacy protections
Cryptography
Digital identity certifications and authentications and public key infrastructures
Disaster recovery planning
DNS protection
Evidential issues
Firewalls and other filtering devices
Intrusion detection and response
Logging mechanisms
Mobile code and agents
Mobile code controls
Overall commitment to security through enforced policies
Overall management style and support
Password and other access technologies: user authorizations
Protection from threats such as viruses
Quality service providers
RAID techniques (disk mirroring)
Redundant capacity
Securing sessions: SSL and other options
SSL server certificates
Web application controls
Web page content access control

(2003) recommends that the best practices prepare the data for this decision either by external experts hired for this task or by employees working with the asset as the process increases security awareness and ownership. Likelihood of threat occurrence estimates can be developed from prior event records, past experiences, or published reports, or purchased from insurance or utility companies.

The second step is to calculate the conditional probability that a loss will occur given that the threat has occurred. This is a conditional probability and is based on the assumption that some of the time, the threats occur without causing loss to the organization. Examples of this are sniffing that occurs on insensitive data, or many types of human errors in daily activities.

The third step is to calculate the loss to the organization by estimating the loss in monetary terms. This estimate should include the replacement costs of the damaged assets but also the hours of time spent internally on the situation (time that could have been spent on productive tasks), as well as the intangible effects on relationships (e.g., the loss of trust, or timeliness and/or accuracy of customer orders). Again, past experience, current partners, and loss experts can assist with this estimation.

The fourth step is to calculate the expected value of the loss conditional on the threat occurring. This is the product of the monetary value estimate of the loss and the conditional probability that a loss will occur given that the threat has occurred. This multiplication product is the maximum cost that an organization should invest in security solutions for that asset for that threat/set of threats.

TYPES OF CONTROLS

Security controls, also called security tools, include an extensive choice of administrative structures and a variety of technologies ranging from antivirus software to audit-tracking solutions to dedicated hardware such as firewalls and intrusion detection systems. Table 2 lists many of the most common types of comprehensive security system controls.

Many security teams struggle to put some sort of organization on the pool of security controls. Some security teams organize the controls by type of asset, some by type of risk, and some by type of threat. Some teams categorize the control options into categories derived from the nature of how they work, as preventative, detective, or corrective of security violations. A similar classification scheme organizes controls as preventative, inspection, detection of internal failure, and correction of external failure. Other classification schemes separate the manual controls from the automated or computerized controls, or by whether the exercise of the control is mandatory or discretionary. Others organize controls with respect to where they apply to the distributed network asset components: hardware, software, mobile units, data, telecommunication channels, third-party issues, management, auditors, and employees. Yet others classify the controls according to their pervasiveness or specificity. Finally, many organizations classify their controls by the nature of the control (e.g., cryptography, firewall, intrusion detection system).

If the security team utilized databases to save their asset-security continuum information, they can write and retrieve efficient queries on assets, risks, threats, controls, or security goals (with either relational or indexed hierarchical databases). Regardless of how an organization organizes their information regarding security controls, security team members must (1) define the cost and purpose (expected benefit) of each control, (2) distribute knowledge and responsibility for the control, and (3) regularly audit the efficiency and effectiveness of each control.

Most comprehensive security teams write general organizational security policies that explain the culture toward security, top management's support for security, and top management's attitude toward intentional violations of security policy. These general policies typically discuss general e-mail, Internet access, password, remote access, and the security policies for communication of suspected violations and adverse events. Employees should be able to clearly understand the expectations for security-related behaviors, performance, and accountability. The two most common problems regarding general security policies are that (1) the policy is written in a manner that does not communicate clearly to the employees, and (2) the policy is not read or utilized by any employees. Oftentimes the general security policies are written to be in compliance with the recommendations of the corporate attorney or the independent auditor. Management may utilize a variety of tools, such as security newsletters, lobby videos, and guest speakers on security issues followed by question-and-answer periods, to increase the visibility of and commitment to general security policies.

The security controls that involve human interaction must be analyzed closely for effectiveness and hidden costs. First, there needs to be a balance between the benefit of the control procedure and the effect on the individual performing the procedure. Many times, too many controls on a task will make the task inefficient and the employee may skip the controls that slow down his or her performance. If controls are too loose, on the other hand, then there may be security threats due to lack of control. Examples of frustrating control plans and the human responses they elicit include too-long passwords that become post-its on monitors, too restrictive account lockouts that may result in denial of service, and too many door keypads that may motivate someone to prop the door open.

Cisco (2001) offers several "top" security controls to keep in mind as part of a comprehensive network security solution. The use of nonobvious passwords that are changed every three months, education of employees and business partners regarding the risks associated with e-mail attachments, and the use of the same current antivirus software throughout the organization are recommended. Immediate removal of network access when employees are terminated, the use of centrally administrated servers for all remote access traffic, and the removal of all nonutilized network services are also highlighted as important Internet-related controls for distributed networks. Cisco also recommends maintaining current versions of Web server software and the continual review of the organizations' assets and risks to determine the continued effectiveness of the comprehensive security solution.

Network configuration choices dramatically affect the security issues within the network. Network services should only involve the minimum necessary functionality, network administrator "back-doors" should all be closed off, and network policies and procedures should be clearly stated, kept current, and periodically audited. Networks are in a state of continuous change, with new topographies, resources, and users. Network-level controls include integrity-checking utilities and documentation of registry changes, system development and maintenance records, and network-testing results. Network scanning software is a preventative control that can be utilized to locate security weaknesses before there is an adverse security incident. Cisco (2001) recommends that organizations hire professionals with expertise for periodic security assessments on distributed networks.

Internet protocols (IP) determine the security rules with regards to Web servers and clients (browsers). Threats can attack Web servers directly or indirectly use the Web server to attack internal systems. Particularly vulnerable are Web servers' operating systems and Web server software. IP-based networks were originally engineered to be open systems, and efforts at maintaining openness while improving security can be inefficient. Even with sound security procedures, networks utilizing the IP protocols are still open to threats such as sniffing, man-in-the-middle attacks, and spoofing.

The most common forms of security control for Web servers are firewalls and intrusion detection systems, both of which filter users and packets coming in or going out to the Internet. These controls can be hardware, software, or hybrid solutions. Firewalls, for example, can stop unauthorized traffic both incoming and outgoing, can direct allowed incoming traffic, can protect network resources by hiding data and even internal systems from inquiring entry requests, and can have audit functionalities to log requests and traffic. Types of firewalls include packet filtering gateways, application gateways, and hybrid systems. Intrusion detection systems can work at the network, host, or application levels. Both firewalls and intrusion detection systems work to restrict access to authorized users and authorized types of packets coming in to or going out from internal authorized sources or users. The functionality is similar to the use of physical locks and peep-holes on doors: only those either recognized or with the appropriate key are allowed to enter.

Passwords are the most common access restriction control. Password policies should be developed by the network administrators and should clearly explain the responsibilities of the users for how and when their passwords are created, stored, utilized, changed, and deleted. Passwords need to be periodically modified by the users, and changes audited by the system administrators. Access management is simplified when user groups are established, with policies written specifically for each user group. Employees should be trained to delete all stored items, especially passwords, after a session on a computer at cyber cafes and airport lounges. Individuals should be allowed to try to log in with a password a few times before account lockout policies are activated. After lockout begins, the user must contact a system administrator for access.

Another essential control for networked environments is antivirus software. This software detects viruses entering or on a system, identifies the particular virus, and then removes the virus either before, during, or after it executes. Antivirus software utilizes three types of detection tools. Static detection is the strongest tool of the three, detecting the virus before execution. Further downstream is detection by interception, where the software catches a virus's attempts to infect either boot sectors, applications, or data files. Third is the method of detection by modification audits, which search for unexpected modification of executables. This control is the furthest downstream of the three methods, only detecting the virus well after it has been infecting the system. In this case, the antivirus software must systematically search through the system to remove all possible instances of the virus.

Controls related to validity and verification of identity involve authentication of the sender or receiver of transmitted messages. Controls related to authentication include digital certificates or public key certificates from certificate authorities, biometric devices, smart cards with private keys, and passwords. These authentication controls are recommended even in the situations where encrypted "tunnels" of secure traffic have been created on the Internet as virtual private networks. Other access measures include dual- and triple-item tests, challenge-response systems, and call-back procedures for remote access attempts.

Encryption tools can scramble characters within messages and/or messages within Web sessions (e.g., SSL) to make it more difficult for unauthorized access. Encryption can be utilized to ensure data integrity through the use of digital signatures, which are message digests encrypted with the sender's private key, to be decrypted usually by the receiver with the sender's public key. Public trust is encouraged because the sender first registers with a Certificate Authority who provides the sender with a private key for the encryption. The sender digests the message and then encrypts the message and its digest with the private, or secret, key. If the recipient of the message is doubtful about the sender, he/she can check with the Certificate Authority for validation of the identity of the sender.

Public-key, private-key dual encryption pairs are utilized to provide sender and receiver authentication and confidentiality. Pretty good privacy (PGP) and S/MIME (secure/multipurpose Internet mail extensions) are two methods that can authenticate the originator and provide message confidentiality. S/MIME digitally signs and encrypts each e-mail message: sender authentication (validating the origin), message integrity (detecting whether any changes have been made to the contents), message confidentiality (no unauthorized recipients), and nonrepudiation (validating origin, receipt, timing, and contents). After transmission, files stored on a network server may also need to be secured. Microsoft's encrypting files systems (EFS) is a Microsoft NT example of a symmetric key encryption for stored files.

Network auditing tools assist administrators to monitor activity in order to detect rather than prevent any problems. For example, audit logs contain records of logins, file accesses, password changes, and logoffs. Most audit software has extensive log files and audit trails that are useful to research the source of a bug or a break-in, and to determine the amount and scope of the damage. Audit logs are also useful documentation for legal testimony and for claims toward insurance recoveries. Risks associated with auditing include unauthorized modification to the audit log tables and system performance degradation.

Recovery controls include the creation of backups, and redundant processing capacity in the case of contingency or disaster recovery planning. Comprehensive security teams need to create backup policies, decide which files are backed up (e.g., databases, mail servers, user files, registries), how often they will be created, on which media, on which type of backup device (e.g., CD writers, tape drives, network shares), and when the backups will be periodically tested. Storage of backups can be onsite in a fireproof safe, or offsite, either in a hot site, cold site, or safety deposit box.

Disaster recovery plans typically identify an incident response team that is trained to know how to respond to an emergency. The location of reboot disks, the original software installation disks and license agreements, the names and addresses of vendor contacts, records of disk partition descriptions, and hardware configurations are all important to provide to the incident response team members.

Fault tolerance, disk mirroring, disk duplexing, and desk striping with parity are different types of redundant array of inline disks (RAID) techniques, which are methods of backing up distributed network servers. Each method has its benefits and drawbacks. For example, disk mirroring backs up more of what is on the original disk than some of the other methods, but it is the least efficient in terms of disk storage utilization. Desk striping with parity separates data and parity information so that if there is a disaster, the information can be rebuilt with greater probability. This control works best when large database read operations are performed more often than write operations, and is weak when high-speed data retrieval is needed, or when many write operations are required.

Cluster server technologies are groups of servers that have been programmed to act as a single, large unit. Resources and responsibilities are distributed between the servers within the cluster. One of the main advantages is the resulting low probability of down time because if one server fails, the other servers continue to function. The more servers and backup systems that are added to the cluster, the lower the risk of system failure and the greater the likelihood of system availability. Another benefit of cluster server technologies is load balancing, which maximizes performance of the network by improving the throughput, a primary goal of Web, e-commerce, and FTP application servers (Cisco, 2001).

Additional topics oftentimes included in comprehensive security controls and procedures involve event handling, software patches, operating system weaknesses, architectural segregation of internal/external zones when using firewalls, and application development policies related to secure access. The best practices for each of these topics depend on the platform and software involved. However, the creation, analysis, and maintenance of documentation regarding corporate error level philosophy, the number and type of errors, and clearly articulated committee responsibility are important across all of these topics.

Once the comprehensive security set of controls has been identified, prioritized, and organized, the security team must decide the specifics of the policies, methodologies, and technologies that will be utilized. Then the security team must decide how to communicate the new or existing policies, changes, and security alerts to all of the stakeholders utilizing the Internet-related distributed network. Third, the security team must design an implementation plan, execute the plan, and periodically audit and assess the continual effectiveness of the comprehensive security system.

SECURITY GOALS

The effectiveness of a comprehensive security system can only be measured against stated, measurable comprehensive security goals. Therefore, it is the responsibility of the security team to evaluate the mission and strategies of the organization along with the prioritized assets in order to develop a set of explicit security goals. These goals may be stated in terms of the organization's mission and strategies, the functions of the prioritized assets, or the most devastating threats that will be avoided or reduced by the security system.

Lynn (2001) suggests security goals to be organized in terms of corporate communications (involving employees, insurance companies, suppliers, customers, regulatory agencies, technical support services, etc.), staff responsibilities (in terms of the chain of command, individual responsibilities, and checks for task coverage), supplier issues (how long would it take to get you up and running?), data protection (system performance, system of backups, and schedule of testing), property protection (equipment, furnishings, library, supplies, etc.), and operations (software, operating systems, emergency lighting, sprinklers, smoke detectors, extinguishers, utility shutoffs, backup generators, evacuation procedures, exit routes).

CONCLUSION

The purpose of this chapter was to provide a state-of-the-art overview of the primary components, issues, and solutions for businesses interested in comprehensive Internet-related network security. This chapter, therefore, presents a comprehensive security strategy organizations can utilize to plan, analyze, implement, and maintain their Internet-related security systems. The first step creates a cross-functional security team with top management membership. The second step identifies both the priority assets (including property, data, and people) and risks affecting those assets. The third step evaluates the specific threats that create the risks, and calculates the maximum cost of controls. The fourth step researches and plans appropriate controls for the priority assets and risks. The nature of these controls ranges from general to specific controls, preventative to corrective, and manual versus computerized. Finally, the correlation between the chosen controls and the overall security goals for the organization is assessed.

This structure of the continuum emphasizes the important interrelationships between the elements of the asset-security model. The process of working through the dyads within the model will develop a deeper understanding of the security relationships. The importance of top management "buy-in" is emphasized, for validity, economic, and other methods of support to be taken seriously.

GLOSSARY

Access control A set of mechanisms and policies that restrict use of various computer resources.

Account lockout A security feature that closes log-in access to a user account if a number of failed logon attempts occur within a specified duration of time. Lockout is based on security policy lockout settings.

Antivirus software Used to prevent viruses from damaging a computer or to remove viruses from the computer.

Application gateway An application program that runs on a firewall system on a proxy-server between two networks to keep the computers behind the firewall protected. Two connections, one between the client and the proxy-server and the other between the proxy-server and the destination, are required. When all communication is conducted through the proxy-server, the computers behind the firewall are protected.

Audit-tracking solution An automated solution for activities like coordination, assignment, evaluation, and response development for internal and external audit findings and recommendations, which would otherwise be time consuming and prone to delays. A Web-based solution may make access to the audit information easy, secure, and very cost effective.

Audit trail A record that shows who has accessed a computer system, and where and what operations were performed during a given period of time. Audit trails are used for system reliability, accuracy, security, and recovery purposes.

Authentication A process of identifying an individual utilizing a computer resource, usually based on a username and password.

Authorization A process of giving access to a system based on the identity of the user.

Boot sector The first sector on every floppy and hard disk, containing an executable program that is executed every time a PC is switched on or booted.

Biometric devices Devices that use biometric techniques to identify and authenticate individuals or users. Biometrics are the authentication techniques that rely on measurable physical characteristics that can be automatically checked, including computer analysis of fingerprints, speech, and facial characteristics.

Callback procedure A procedure executed from a remote log-in attempt. Basically the network server or main computer sends a signal to the authorized computer node, which can be received only if the log-in attempt is being made at that authorized computer.

Certificate authority A trusted third-party organization or company that issues digital certificates that are used to create digital signatures and public–private key pairs. They are a critical component in data security and e-commerce because they guarantee the two parties exchanging information are really who they claim to be.

Cluster A collection of systems connected to share devices, whereupon all systems can read or write to all of the devices. The individual computers in a cluster are referred to as nodes.

Cluster server technologies Usually of two types—shared-disk and shared-nothing. The former implementation allows all cluster participants (nodes) to own and access cluster disk resources. In the latter, several nodes in the cluster may have access to a device or resource, but the resource is owned and managed by only one system at a time. Each node has its own memory, system disk, operating system, and subset of the cluster's resources.

Cold site A disaster recovery service that allows a business to continue computer and network operations even in the face of computer or equipment failure, by providing office space, but the customer provides and installs all the equipment needed to continue operations. It is less expensive, but takes longer to get an enterprise in full operation after the disaster.

Cross-site scripting (also called XSS) Occurs when a Web application gets malicious data from a user, usually in the form of a hyperlink. The request looks less suspicious to the user when clicked on, but may lead to threats like account hijacking, changing of user settings, cookie theft/poisoning, or false advertising.

Cryptography The art of protecting information by transforming it (by encrypting it) into an unreadable format, called cipher text. Only those who possess a secret key should be able to decipher (or decrypt) the message into plain text.

Cyber café A public or private location where one can connect via a computer to the Internet, typically for a flat fee plus a time-for-services fee.

Database A software application designed to help users organize information, so that a computer program can quickly find and select desired information. Databases can be thought of as an electronic filing system.

Digital certificate An attachment to an electronic message to verify that a user sending a message is who he or she claims to be, and to provide the receiver with the means to encode a reply. It is issued by a certification authority (CA), containing your name, a serial number, expiration dates, and a copy of the certificate holder's public key.

Digital signature Acts as the functional equivalent of a paper signature. A digital signature uniquely identifies a sender and can make a document binding. It can also be used to ensure that the original content of the message or document that has been conveyed is unchanged. They are becoming increasingly important in e-commerce as a component of authentication schemes.

Disk duplexing or mirroring A technique in which data are written to two duplicate disks simultaneously. If one of the disk drives fails, the system can instantly switch to the other disk without any loss of data or service. It is commonly used in online database systems where it is critical that the data be accessible at all times. In other words, it makes for reliable data redundancy.

Disk striping A technique for spreading data over multiple disk drives. The computer system breaks a body of data into units and spreads these units across available disks. Disk striping can speed up operations that retrieve data from disk storage.

Distributed network A network where the resources are divided up and shared among many computers to reduce the burden on any one system. A distributed network is the main characteristic of the Internet.

Encryption The translation or coding of data into a secret code for data security. Encrypted data is called "cipher text" while unencrypted data is called "plain text."

Fault tolerance The ability of a system to respond gracefully to an unexpected hardware or software failure. There are many levels of fault tolerance, from the ability to continue operation in the event of a power failure to performing every operation on two or more duplicate systems, so if one fails, the other can take over.

Firewall A system designed to prevent unauthorized access to or from a private network. Firewalls can be implemented in either hardware and/or software. All messages entering or leaving a network pass through the firewall, which examines each message and blocks those that do not meet specified security criteria.

FTP (file transfer protocol) Used on the Internet for sending or transferring files from one location to another.

Host A computer server in a network that runs applications used by or from other computers (e.g., Web servers, file servers, and application servers).

Hot site A commercial disaster recovery service that allows a business to continue computer and network operations even in the face of a failure. The affected enterprise can move all data processing operations to a hot site that has all the equipment needed for the enterprise to continue operation, including office space and furniture, telephone jacks, and computer equipment.

Integrity A measure to protect data or resources from unauthorized modification to ensure information security. Data whose integrity cannot be ascertained are said to be corrupted.

Integrity checking utilities Programs used for executing file system integrity checks on remote hosts from a server and sending reports via e-mail.

Internet The world-wide collection of interconnected networks and computers using and sharing information based on set rules defined by protocols like the TCP/IP.

Intrusion detection system An inspection system that checks all inbound and outbound network activities and identifies suspicious patterns that may indicate a network or system attack or break-in.

IP spoofing A technique to gain unauthorized access to computers. Here an intruder sends a message to a computer with an IP address indicating that the message is coming from a trusted host, thereby beguiling the user.

IP-based network A network running on the Internet protocol. Each computer on the Internet (known as a host) has at least one IP address that uniquely identifies it from all other computers.

Key A string of bits used in cryptography that allows people to encrypt and decrypt data. The key determines the mapping of the plaintext to the ciphertext.

Load balancing Distributing processing and communication activities evenly across a computer network so that no single device is overwhelmed. Busy Web sites typically employ two or more Web servers in a load balancing scheme. If one server starts to get overloaded, requests are forwarded to another server that has more capacity.

Log-in The opening procedure used to connect to a computer system by using credentials like "username" and "password." Also, the act of typing in your username and password.

Log-out The closing procedure used to disconnect from a computer system or formally end a session with the system. Once you log out, you must log back in to regain access.

Network Formed when any two or more computers are connected together to share resources. Networks are established to enable the sharing of information, files, and applications between users via multiple systems.

Network administrator "back-door" A hidden "entrance" for an administrator to access a network.

Online shopping cart A piece of software that acts as a catalog for an online store and also performs the ordering process. A shopping cart is an interface between a company's Web site and its infrastructure that allows consumers to select merchandise, review what they have selected, make necessary modifications or additions, and eventually, purchase the items in the cart.

Operating system A software that serves as an interface between the system hardware and the users. The operating system is the most important program on a computer. Operating systems perform basic tasks, like recognizing input from the keyboard, sending output to the display screen, keeping track of files and directories on the hard drive, and controlling peripheral devices such as disk drives and printers.

Packet A piece or block of message/information/data transmitted over a network (packet-switching network) that contains the destination address labeled to the data. In IP networks, packets are often called datagrams.

Packet filtering A method of controlling access to a network by analyzing incoming and outgoing packets and letting them pass or stopping them based on the IP addresses of the source and destination, thereby serving as one of the many techniques used for implementing security firewalls.

Packet filtering gateway A packet filter that analyzes each IP packet at the network layer and determines whether to pass or block it based on a set of rules. If it allows communication between two specific addresses, packets are allowed to travel through the firewall to the specified address. If no rule is available for a given address, the packet is rejected and not allowed to pass through the firewall.

Packet modification Modifying a packet that leads to sending incorrect or corrupted information across the network.

Packet replaying Replaying a packet to find out what was previously sent.

Password A code used to log in or gain access to a locked or secure system.

PGP (pretty good privacy) A message encryption technique based on the public-key method, which uses two keys—one public key that you share with anyone from whom you want to receive a message, the other a private key that you use to decrypt messages that you receive. PGP is one of the most common ways to protect messages on the Internet because it is effective, easy to use, and free.

Phone phreaking The act of cracking the phone network or entering it in an unauthorized manner to use it, for example, to make "free" phone calls.

Private key The undisclosed key in a matched key pair (that is, the private key and the public key) that each party must safeguard for public key cryptography. The private key is known only by the recipient of the message while the public key is known to everyone.

Proxy server An Internet server that controls the access of the client computers to the Internet. It can stop clients from accessing undesirable Web addresses, improve performance by storing Web pages locally, and hide the internal network's identity, so that it is difficult for external users to monitor.

Public key certificate A digitally signed document that serves to validate the sender's authorization and name. The document consists of a specially formatted block of data that contains the name of the certificate holder, the holder's public key, and the digital signature of a certification authority for authentication.

Public key encryption A cryptographic system using two keys—a public key known to everyone and a private or secret key known only to the recipient of the message. For instance, when John wants to send a secure message to Jane, he uses Jane's public key to encrypt the message. Jane then uses her private key to decrypt it so that she can make any sense out of it.

Public key A value provided by some designated authority as a key which, when combined with a private key, can be used to effectively encrypt and decrypt messages and digital signatures.

Query A request for information to a database.

RAID [redundant array of independent (or inexpensive) disks] A combination of two or more drives (frequently on servers) used together for better fault tolerance and increased performance.

Reboot Restarting a computer.

Reboot disks Disks used to reboot a system.

Remote access The ability to log on to a network from a different, distant, or remote location.

Service pack An update to a version of software that fixes an existing problem, such as a bug, or provides enhancements to the product. These enhancements and fixes will appear in the next version of the product.

S/MIME Multipurpose Internet mail extension (MIME) is originally a standard for defining the types of files attached to standard Internet mail messages. It is used in situations where one computer program needs to communicate with another program about what kind of file is being sent. Secure multipurpose internet mail extension (S/MIME) describes how encryption information and a digital certificate can be included as part of the message body.

Smart card A small electronic device about the size of a credit card that contains electronic memory, and possibly an embedded integrated circuit (IC).

Sniffer A program or device that monitors the flow of data in a network. Can be used for both legitimate network management functions and stealing information off a network. Sniffers are very dangerous because they are virtually impossible to detect and can be inserted almost anywhere.

SSL (secure sockets layer) A program layer that manages the security of message transmission in a network.

Software Computer instructions or data that are stored electronically. In contrast, storage devices and display devices that show or operate the instructions or data are hardware.

SYN flooding Bombarding a system with dozens of false connection requests a minute that leads to degradation of the system's ability to give service to legitimate connection requests. This attack is also called the denial-of-service attack.

System access point A hardware or software that acts as a communication hub for users of a wireless device to connect to a wired LAN. They are important for providing heightened wireless security.

System administrator The individual responsible for maintaining a multiuser computer system. Small organizations may have only one system administrator, while large organizations and enterprises may have a team of system administrators.

Trojan horses Impostor files that claim to be something desirable but, in fact, are malicious. Unlike viruses, Trojan horse programs do not replicate themselves. Trojans contain malicious code that when triggered cause loss, or even theft, of data.

Virtual burglar A type of hacker that steals information on the Web.

Virus A program or piece of code that is loaded onto your computer without your knowledge and runs against your wishes. Viruses can also replicate themselves. A simple virus can make a copy of itself over and over again and is very dangerous because it will quickly use all available memory and bring the system to a halt. An even more dangerous type of virus is capable of transmitting itself across networks and bypassing security systems.

Web commerce (e-commerce or electronic commerce) Business over the Internet, specifically, the electronic transfer of value across the Internet in exchange for the delivery of a service or product.

Web server A computer that stores and delivers Web pages to other computers.

Web server software The software designed to be used on a Web server, for accepting, managing, and responding to Internet requests for sessions.

Web server's operating system The operating system that controls the functionality of a Web server.

Wired network A network wired together through cables or physical connections as compared to a wireless network where radio frequencies are generally used to make connections.

Wireless network A network interconnected with radio waves or other signals instead of through a cabling or physical connection.

Worm A program or algorithm that replicates itself over a computer network, usually performing malicious actions, such as shutting the system down or using up the computer's resources. Worms replicate themselves from system to system without the use of a host file as opposed to viruses, which require the spreading of an infected host file.

H

Health Insurance and Managed Care

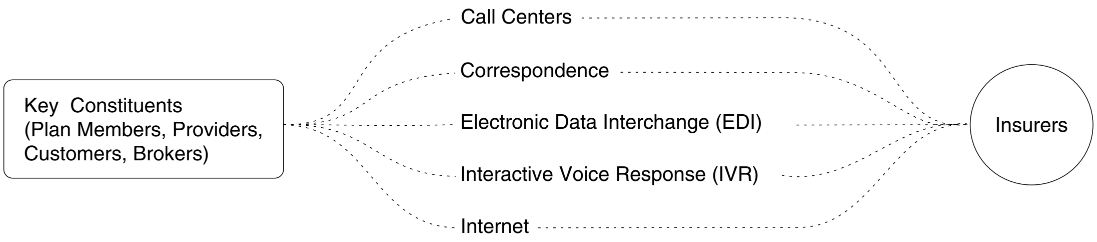
Etienne E. Pracht, *University of South Florida*

INTRODUCTION

Health insurance in the United States traces its origins to 1847 when coverage became available against rail and steamboat accidents. The next major development occurred almost 100 years later during World War II, when restrictions on wage increases impelled employers to offer fringe benefits such as health insurance as a means to attract additional laborers. Since then, the industry has grown increasingly sophisticated and, in the absence of national health insurance coverage, is now controlled largely by the private sector. The number of direct health and medical insurance carriers grew from 47 to 3,238 during the 20th century (Raffel & Barsukiewicz, 2002; U.S. Census Bureau, 2000). In 2001, 70.9% of the population purchased insurance coverage from private firms, primarily through their place of employment. Government health plans, primarily Medicare and Medicaid, covered almost 24.7% of the population, and a fraction of the population received health insurance coverage from a combination of private health plans, Medicare, and Medicaid. (The insurance status figures contain some duplication. According to the U.S. Census Bureau, *Current Population Survey,* 1.99% of the population received coverage from Medicaid and private insurance, 7.61% received coverage from Medicare and private insurance, and 1.89% received coverage from Medicare and Medicaid. The privately insured population obtains coverage primarily through employment [64% of the total population].) In that same year, 14.6% of the population did not have any health insurance coverage (U.S. Census Bureau, 2002).

Total U.S. national health care expenditures in 2000 were $1.3 trillion, accounting for more than 13% of the gross domestic product. According to projections from the U.S. Centers for Medicare & Medicaid Services, health care expenditures will grow to $2.8 trillion by the year 2011 (Centers for Medicare & Medicaid Services, 2001). Health insurance coverage, the fee for service structure in particular, along with advances in medical technology, has been identified as a major contributor to the enormous growth in U.S. health care expenditures (Dorenfest, 2000; Fuchs, 1996; Weisbrod, 1991). Understandably, emphasis has shifted to cost containment, and through pressure from employers and the government, insurers are increasingly forced to compete on the basis of cost. Competition among insurers has traditionally focused on reducing premiums by manipulating deductibles and copayments and avoiding high-risk individuals. More recently, managed care has introduced provider incentives to reduce utilization while promoting outcomes-based strategies to implement most effective courses of treatment or "best practices." The Internet revolution has created the potential for cost reductions through improved productivity in the administration of health insurance and, more broadly, the health care industry.

This paper discusses the application of the Internet and e-commerce technologies in the health insurance industry. Current examples augment an industry system-wide perspective for the discussion. The structure of the industry, and in particular the lack of standardization, is highlighted as one of the defining parameters that determine the implementation and effective use of information technologies. The next section discusses the relationships between existing technologies and the various stakeholders of the industry. The section Technical and Practical Applications examines the technical and practical considerations of implementing information technologies. The section E-application analyzes five categories of applications of the Internet and e-commerce in the health insurance industry. The final section presents a summary and conclusions.



Key Constituents
(Plan Members, Providers,
Customers, Brokers)
Call Centers
Correspondence
Electronic Data Interchange (EDI)
Interactive Voice Response (IVR)
Internet
Insurers

Figure 1: Methods of interaction between insurers and their key constituents.

HEALTH INSURANCE, THE INTERNET, AND E-COMMERCE

Interactions between insurers, as third-party payers, and their main constituents, enrollees, employers, and providers, take place to process basic insurance functions. Internet applications concerning these functions are discussed in more detail under E-application. Enrollees and employers may contact insurers to purchase, verify, change, or drop coverage. Providers may contact (or be contacted by) third-party payers regarding patient eligibility confirmation, claims submission, or patient referral information. Insurers, in turn, may use this medium to facilitate some functions relating to contractual agreements with providers such as certification or recertification. The Internet, as noted below, is a viable alternative tool to interaction between third-party payers and their key constituents (Figure 1).

Internet functions as both a replacement and complement to existing information technology (IT). For example, in 1999, PreferredOne, a health benefits management company serving the upper Midwest, reported that a clinic reduced its telephone calls by more than 50% after implementing an online system for claim status inquiries, eligibility verification, and payer's contact information (Hofflander, 1999). The advantages are obvious: online services per contact episode are substantially less costly compared to telephone calls and, once implemented, require minimal labor resources, yielding additional savings. According to a California PPO the cost of a typical call to their center was approximately $7, compared to $0.20 for an online system (Runy, 2000). At the same time, enrollee services may be greatly improved.

In addition to speed, the Internet offers a quantum leap forward in functionality, touting a new level of sophistication in information display using a graphical user interface, interactive capability, and vastly improved organization of complex information. It represents a platform for tremendous enhancement and integration of functions. Voice, video, and data traffic can all be combined under one platform to increase efficiency. Electronic data interchange (EDI) and interactive voice response (IVR) functions will likely be handled increasingly by Internet-based applications. Certainly, Web-based applications can make use of readily available e-mail technology to replace traditional postal service correspondence. The Internet also offers a greater potential for networking and connecting geographically dispersed organizations. An excellent example of this is the Colorado-Fayette Medical Center, which is spread over seven campuses in three towns and two counties, consisting of a 38-bed hospital, two rural health clinics, a nursing home, an assisted-living facility, an outpatient center, and a unit for Alzheimer's patient (Bacus & Zunke, 2001). A new wide area network with Internet access enabled the organization to "improve its Web presence, allow radiologic image viewing at all sites, negotiate more favorable prices from vendors, implement electronic communication for staff members, and take advantage of on-line education opportunities" (Bacus & Zunke, 2001).

In the case of EDI, the Internet also acts as an alternative platform for electronic transactions (Figure 2). Smaller provider groups that previously used paper forms because they found the resource requirements of more traditional EDI systems prohibitively expensive may find that the Internet offers a cost-effective method for implementing the approach (see National Research Council, 2000, p. 90, for a specific example). In this regard, the Internet is predicted to have a prominent role as the Health Insurance Portability and Accountability Act (HIPAA) is implemented. HIPAA regulations and practical and technical considerations pertaining to the use of the Internet for EDI are discussed in more detail under Technical and Practical Considerations.

Stakeholders

Groups affected by applications of the Internet and e-commerce technologies in health insurance and managed care are enrollees, employers, providers, brokers or intermediaries, the government, Internet applications

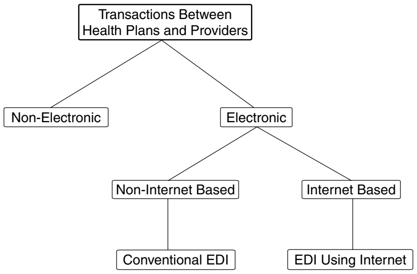


Figure 2: Electronic transactions between health plans and providers.

providers, and, of course, the insurers themselves. The information distributed or made available to the respective stakeholders must be properly structured and dedicated to specific needs. Enrollees require information concerning their coverage, personal health, and care. They may be interested in tracking administrative matters as well, involving claims, copayment schedules, and scheduling of secondary visits. Employers are primarily interested in cost and quality aspects, billing, and other administrative functions pertaining to the structure of insurance plans and employee utilization of health resources. Providers may be interested in the more technical aspects of medicine and efficient communication with various insurers. Finally, insurers are interested in remaining competitive, reducing the cost of care without compromising quality, and meeting state regulations. For these purposes, streamlining administrative procedures is crucial, a process in which the Internet can play an important role. Concerning patient care, efficient delivery involves not only tremendous amounts of information in real time, but also the cultivation of stable, consistent, factual, and good relationships between the various stakeholders, particularly providers and plan members. The behavioral relationship between plan members and providers has been identified as an important component in the delivery of efficient and cost-effective care. While further discussion of this topic is beyond the scope of this chapter, it has been widely discussed in the literature, for example, in the context of Medicaid managed care. For more in-depth discussions of this and related issues, see, for example, Hurley, Freund, and Paul (1993); Luft (1978); Manning, Leibowitz, Goldberg, Rogers, and Newhouse (1984); Newhouse, Schwartz, Williams, and Witsberger (1985); and Pauly, Hillman, and Kerstein (1990).

The IT and labor resource demands of a system which satisfies these needs can be challenging. Insurers have two advantages and incentives over other private sector stakeholders for transforming the e-health marketplace from one dominated by independent, noninteractive, general information Web sites to one coordinated, engaging, and personalized. First, they have the strongest fiscal incentives, since successful implementation of a streamlined and effective e-health mechanism would be extremely helpful concerning their primary goal of containing costs and maximizing profit. Second, insurers already possess the required administrative and financial resources and the information required, most of which is already in electronic format (Korpman, 2001).

The Internet and Intermediaries

A profound impact of the Internet is the transparency of information. The ease of online comparisons of products, based on defining characteristics such as price and quality, has made sellers susceptible to greater competition and given consumers enhanced decision-making power. In addition to simplifying information and reducing the cost of price and quality comparisons, the Internet acts as an effective tool for coordinating activities traditionally involved with selecting and purchasing goods and services. While consumers as a group are unlikely to make purchasing decisions (e.g., health insurance plan selection, copayment levels, and deductibles) based solely on Internet searches, insurers will be forced to modify traditional marketing practices more and more as the population becomes increasingly savvy about the Web.

Cost reductions generated by the Internet through advances in operational efficiency are likely to be transferred to customers due to increased price transparency. (While the focus here is on cost, it should be noted that enhanced transparency might result in increased competition based on other aspects instead, for example quality, while holding the price constant. In any case, the consumer should benefit from the change.) As the segment of the population that embraces the Internet grows, competition will increase, further narrowing operating margins. Consequently, increasing pressure on insurers to reduce costs will force them to market directly to consumers and decrease reliance on brokers or intermediaries, reducing or eliminating commissions, which can reach as high as 30% of administrative expenses of managed care plans (Goldsmith, 2000). This process is known as disintermediation. Present examples include investment firms eliminating stockbrokers by offering services online and large automotive corporations placing their parts specifications online to solicit competitive bids from manufacturers. Amazon.com, Priceline.com, and Monster.com (which have taken on the status of household names) all act to eliminate or replace the traditional middleman. The e-health marketplace is already utilizing this direct marketing function of the Internet (see E-application) on a limited scale.

TECHNICAL AND PRACTICAL CONSIDERATIONS

Considerations pertaining to the implementation of Internet, or electronic information technology, may be grossly classified as nontechnical and technical. Nontechnical considerations range from general ignorance and reluctance to important logistical and managerial challenges involved with adoption of new or standardized electronic information technologies, whether they are Internet-based or otherwise. The magnitude of these challenges and, perhaps more importantly, the associated operational risks will vary according to factors such as the scale of the proposed change, the organization's size, current information technology, and management structure. The fragmentation of existing systems concerning types of applications, platforms, operating systems, and network protocols (see discussion below) is only one in a series of obstacles the industry faces. Transforming an existing system, whether it is paper-based, consists of a single self-contained computer system, or is comprised of disparate systems, may be costly and time-consuming as one moves through the stages of implementation, including installing, testing, training, and maintaining. Prior to implementation, additional resources may be required to gather the information necessary to make sensible decisions involving the new system. In large organizations, particularly those that are geographically dispersed and maintain separate management structures, reaching an agreement over, for example, the software vendor, the type of system, and the functionality of that system may be difficult. This may be an especially sensitive concern if one considers long-term maintenance contracts that may accompany new systems. Individual providers may be particularly reluctant to enter such agreements.

The National Research Council (2000) identifies and discusses the relative importance of five technical considerations:

Bandwidth—The rate, measured in bits per second, at which information is transmitted through a network.

Latency—The time required to transmit data across the network. Real-time applications, for example, require low latency, while other applications, e.g., e-mail, are less demanding in this regard.

Ubiquity—The relative accessibility of a network. This function depends on such factors as geographic dispersion and regulations regarding participation.

Availability—The continuous accessibility of the network, the applications of which it is composed, and the services it offers.

Security—Availability, confidentiality, and integrity of information.

With regard to bandwidth and latency, advances in technology, coupled with the relatively modest requirements of administrative and customer service tasks, make these technological concerns largely nonissues. The significance of ubiquity, or relative accessibility of a network, requirements is contingent on the scale and frequency of use and the dispersion of users. The Internet is expected to play an important role in reducing the degree of ubiquity required by providing low-cost access to providers and administrators of geographically dispersed organizations (National Research Council, 2000). The importance of availability depends largely on the urgency of the transaction being executed. For example, referral certification and prior authorization requests concerning an enrollee's immediate care needs require relatively high availability. Other, less formidable and sometimes trivial, obstacles include lack of processing capacity, poor quality of applications, and inadequate understanding of the Internet and its potential benefits (Schaich, 1998).

Security was identified as the most important technical consideration in the adoption of Web-based and other e-commerce applications by the health insurance industry (National Research Council, 2000). The discussion here presents only an outline of the security issues. A more in-depth analysis is beyond the scope of this chapter. Interested readers may refer to Department of Health and Human Services (2000) and National Research Council (2000). Current information may be found at http://www.hhs.gov/ocr/hipaa/finalreg.html (accessed October 9, 2002).

The most sensitive aspect of security in electronic commerce concerns privacy, or, in other words, the confidentiality and authorized use of patient data. Many administrative transactions, for example medical claims, include highly sensitive and personal information pertaining to patients' health status, ailments, diagnoses, and treatments. Potential misuses of individual health information include unfavorable insurance decisions, employment decisions, and other adverse social outcomes (Lumpkin, 2000).

In addition to the technical aspects, privacy of personal health data involves important political and ethical considerations. Indeed, patient privacy has been debated in Congress since HIPAA was enacted in 1996. In 1998, Donna E. Shalala, the Secretary of the U.S. Department of Health and Human Services (HHS), submitted recommendations to Congress concerning security requirements for patient records. The recommendations called for specific legislation to protect patient privacy or individually identifiable health information. In the absence of such legislation, a 1996 HIPAA mandate stipulated that HHS would impose its own privacy, confidentiality, and security regulations. The final regulations resulting from the HIPAA mandate apply to insurers, health care clearinghouses, and certain health care providers. The objective of the resulting rules is to give consumers increased control over health information. Essentially, providers and insurers are required to seek consent from patients before information can be shared for treatment, payment, and other health care operations. The regulations also specify disclosure requirements, appropriate uses of related information, and available recourse if privacy protections are violated.

The second, far less politically charged, aspect of security relates to the process of maintaining and transmitting information. Protection of information is of vital importance both when it exists at rest (e.g., in a physician's office) or in transit (on paper or electronically) during transmission. Protection of printed information involves measures such as controlling and monitoring access and implementing organizational procedures that focus on the security of health information. Protecting electronic information, particularly during transmission, involves a different set of challenges. It is noteworthy that these security concerns are gradually diminishing with advances in encryption, authentication, and certification technologies (Department of Health and Human Services, 2000; Gerberick, Huber, & Rudloff, 1999).

Secure access to information, both in reality and as perceived by health plan constituents, is required if the Internet is to be used successfully in managing basic health insurance functions. The rapid growth in the number of health-specific Internet users and Web sites indicates that consumers as a group have reached a reasonably high comfort level with this technology. According to recent surveys (Fox & Raine, 2000; Taylor, 1999) 60 to 70 million U.S. residents went online in search of health information at the turn of the millennium, and 17,000 specialized Web sites had been created in response to this demand (Taylor, 1999).

The legislation is not without its critics. The health insurance industry argued that it is already held to rigorous security standards and that implementation of the proposed rules would impose substantial new costs, which would, at least in part, offset the benefits of standardization. Critics also point out that the 1996 HIPAA legislation was formulated in a pre-Internet environment, and therefore was ignorant of important new entities such as Internet and application service providers (Cunningham, 2000). Nonetheless, the use of security and privacy standards, both in the public and private sectors, is expected to boost adoption of electronic communications and improve the efficiency and effectiveness of the health insurance industry.

Lack of Standardization

Although most information demanded by interested parties is already flowing through EDI systems in electronic formats, the health insurance industry (and, indeed, the health industry as a whole) has been relatively slow to adopt Web-based applications on a larger scale. It should be noted that, while a large proportion of demanded information is already in electronic format, many systems housing the data are not interoperable with the Internet. Numerous obstacles, including the nontechnical and five technical considerations discussed above, have been cited for this apparent lag. However, the most serious impediment to the proliferation of Web-based applications is the extreme lack of standardization that characterizes the industry. In addition to the more obvious source of variation across organizations, resulting from the adoption of different applications, mergers and acquisition also attributed to considerable variation within institutions.

Problems associated with a lack of standardization are heightened in large integrated delivery systems (IDS) where communication between member organizations is a key factor in performance. A large IDS may be composed of a number of geographically dispersed member organizations, perhaps acting as independent decision-making units, with a wide array of applications running on different platforms. These may, in turn, be controlled by different operating systems and network protocols. The magnitude of the problem and the potential benefits from a seamless information-sharing arrangement are positively correlated. The industry has recognized this fact and many organizations have accepted the Internet as the most promising platform for achieving the vital objective of seamless integration of diverse information sources.

The lack of standardization in health information systems (e.g., transfer protocols, information content, and response protocols) affects the willingness of individual providers to adopt new platforms for managing administrative tasks. The provider's benefit of a new interface depends on the percentage of her business that will be affected. The larger the number of insurers a given provider has relationships with, the smaller will be the share of total business associated with any individual plan, and, therefore, the smaller the benefits (and therefore the incentive) of adopting a new e-health system sponsored by a given health plan. Standardization of processes into a single interface, allowing providers to communicate with insurers in a consistent manner, will significantly reduce their reluctance to undergo what may constitute a major overhaul of their current operations. In part, legislation specified in the HIPAA in 1996 was aimed at resolving these problems.

HIPAA Administrative Simplification Legislation

The HIPAA was passed by Congress in 1996 to stabilize health coverage for individuals during disruptive events such as changing or losing jobs, pregnancy, moving, or divorce. A less noted provision of HIPAA, but of profound importance within the context of health insurance and e-commerce, is administrative simplification. This provision stipulates the establishment of standards for health information and measures relating to the security, confidentiality, and privacy of that information. Information-sensitive activities that will be affected are health claims processing, enrollment and disenrollment of members, eligibility verification, referral certification and authorization, health plan premium payments, health claims status confirmation, health care payment and remittance advice, and coordination of benefits (Department of Health and Human Services, 2000). Furthermore, HIPAA will, subsequently, require standardization of injury reports and claims attachments. The standards will apply to all private sector and government health plans, health care clearinghouses, and health care providers that elect to make use of affected electronic transactions.

According to the Centers for Medicare and Medicaid Services (CMS), approximately 400 different formats are currently in use for health care claims. The deadline for compliance with the standardization of administrative transactions is currently set for October 2003 (http://www.wedi.org), three years after they were adopted (Department of Health and Human Services, 2000). Standardization of electronic claims and other transactions will allow providers to use the same format for submitting forms to any of the insurers with whom they are affiliated. Providers will also receive electronic transactions, for example referral authorizations, in standardized formats from insurers. As a consequence, providers should find electronic data interchange to be a relatively attractive alternative to paper claims. Transactions conducted over the Internet must also conform to the standards in the area of data content. Some flexibility is allowed to ensure compatibility with online transmission modes.

Primarily insurers, insurance companies, and other payers who will be required to adapt or replace their current systems will feel the initial impact of the HIPAA standardization rules. Much of the administrative simplification provision is aimed at increasing the use of EDI, whether it is Internet based or otherwise. Providers are affected only to the extent that they submit claims electronically. Considering the substantial benefits and financial incentives, the majority of providers are expected to join the effort. For providers who previously were required to maintain multiple formats for doing business with different plans, standardization will make it easier to conduct or adopt EDI. Savings are expected from several sources: reduced labor requirements for managing multiple formats; reduced need for software development and maintenance required to handle multiple formats; elimination or minimization of costly errors resulting from needless duplication and manual data entry; and reduced

[a] Discounted using a 7% rate.

reliance on time-consuming, relatively costly, and uncertain postal services.

The Department of Health and Human Services (2000) estimated the growth in EDI use for physicians, hospitals, and other providers. EDI use by physicians before HIPAA is relatively low compared to the remaining provider groups, implying that the largest gains are expected to be realized in that segment of the industry. The percent growth of EDI use among physicians is assumed to average 22% two years after implementation of the standards. The growth in EDI use by hospitals and nonphysician providers is estimated to average 6 to 7% between 2004 and 2011. The growth in EDI use of this group during the two years immediately following the deadline for compliance is estimated to be between 3 and 6%.

Table 1 shows the Department of Health and Human Services' estimates of cost savings resulting from HIPAA legislation for the next decade. The cost estimates are based on the size and complexity of existing systems, the ability to implement using existing low-cost translator software, and reliance on health care clearinghouses to create standard transactions (Department of Health and Human Services, 2000). Total discounted net savings resulting from the HIPAA-legislated standardization is projected to be $19.7 billion between 2002 and 2011.

The effect of the administrative simplification provision is not limited to the mere implementation of EDI by insurers and providers. Standards for financial and administrative transactions are expected to have a profound impact on health care practice and delivery. A key element of the evidence-based approach to medical practice is effective information management and retrieval, which relies heavily on consistency and uniformity of identifiers, values, and formats of units of data which compose a patient record. HIPAA represents an important step in this direction by establishing uniform rules for the identification and content of more than 400 data fields commonly used in administrative transactions. System-wide standardization initiated by this legislation has the potential to promote more effective medical management by enabling transparency of "best practices" both within and across health care organizations. It is noteworthy that significant practical considerations, particularly those involving patient privacy and confidentiality (see discussion above concerning practical and technical considerations), must be resolved before these benefits can be realized.

Internet Communications Security and HCFA Privacy Act-Protected Information

The potential role of the Internet concerning EDI cannot be ignored. However, the advantages of the Internet are associated with a substantially increased risk to the confidentiality and integrity of information. Recognizing that its design makes it difficult, if not impossible, to eliminate security risks HCFA temporarily prohibited the use of the Internet for the transmission of "HCFA Privacy Act-protected and other sensitive HCFA information by its components and Medicare/Medicaid partners, as well as other entities authorized to use this data." (*WEDI/AFEHCT Internet Security Interoperability Pilot Certification Authority Task Group,* 1999; Workgroup for Electronic Data Interchange [WEDI] and the Association for Electronic Health Care Transactions [AFEHCT]. The HCFA Privacy Act is directly linked to the Privacy Act of 1974. According to Section 5 U.S.C. 552a (e) (10) of that Act, federal systems must "establish appropriate administrative, technical, and physical safeguards to insure the security and confidentiality of records and to protect against any anticipated threats or hazards to their security or integrity which could result in substantial harm, embarrassment, inconvenience, or unfairness to any individual on whom information is maintained.") The WEDI/AFEHCT was charged in 1998 with examining the privacy concerns underlying the Internet and transmission of HCFA Privacy Act-protected information. The resulting policy specifies acceptable methods of encryption to secure confidentiality and integrity of the data and the use of authentication or identification procedures that assure that both the sender and recipient are known to each other and are authorized to receive and decrypt the information. The policy also specifies that organizations that wish to use the Internet to transmit HCFA Privacy Act-protected data have a security plan and comply with HCFA audits designed to verify that all requirements are satisfied.

Non-Internet data transmissions, including local data-at-rest or local host or network systems, are not affected by these additional security requirements. Although organizations are expected to act responsibly with data-at-rest or information stored on local site networks, the extra security requirements associated with transmissions over the Internet are likely to make the latter a relatively less attractive alternative. Indeed, estimates of Internet use involving sensitive information, for example submission of insurance claims, are low (National Research Council, 2000). Large-scale adoption of the Internet for transmission of sensitive information by HCFA and Medicare and Medicaid may act as a signal to private sector entities that the technology is safe and trustworthy. Until then, the private sector may be expected to take a "wait and observe" approach.

E-APPLICATION

The Internet, and, more broadly, information technologies, can influence the health insurance industry in two ways. First, traditional health insurance administrative and customer service tasks are highly adaptable to the Internet. These functions include network development and management, enrollment and eligibility verification, and claims submission and payment. The benefits of a Web-based health benefits management system include reductions in transactions costs, increased velocity of transactions, and increased transparency of the customer service process. The potential for cost reductions from a streamlined Web-based operations process is substantial. According to one estimate, successful implementation of such a system could reduce traditional health insurance-related administrative functions by as much as 70 to 90% (Goldsmith, 2000). The distribution, consulting, and administrative expense of health benefits were estimated at $18 billion annually, with sales and marketing, benefits consultants, and health plan overhead claiming, respectively, $5 billion, $3 billion, and $10 billion (cited in Goldsmith, 2000, from J. P. Lathrop, G. Ahlquist, & D. Knott [2000, Second Quarter], Healthcare's new electronic marketplace, *Strategy+Business, 36*). Net savings from the adoption of e-commerce solutions could be at least $3.6 billion according to a study by Ernst and Young (also cited in Goldsmith, 2000, from P. Kongstvedt [2000, February], 1999 *Managed care benchmarking study,* Washington: Ernst and Young).

A second area where electronic information technologies may play an important role relates to the area of medical management. The contribution of information technologies in this area is difficult to measure, but is, nonetheless, of tremendous interest, particularly to the managed care segment of the industry. Minimization of medical uncertainty and the pursuit of best practices remains an important goal of managed care. Information technology can help realize this goal by enhancing consistency and comprehensiveness of patient records and streamlining the coordination of care.

This section discusses application of the Internet and e-commerce technologies concerning plan selection, benefits management, self-funded insurance, network development, and claims management. Next, it examines the use of the Internet as a tool to educate and guide enrollees. This is followed by a discussion of the role of information technology in medical management.

Plan Selection, Benefits Management, and Self-Funded Insurance

To the extent that choice of health insurance plans is possible, the Internet can act as a powerful tool to facilitate selection. In addition to premium rates, plan selection depends on a variety of quality measurements such as customer service ratings, access to specialists, and the degree of emphasis on preventive care. Employers' interest in these quality measures is clear considering the substantial opportunity costs associated with employee sick days.

Quality information regarding health insurance plans on the Internet ranges from advertising on corporate Web sites to online report cards issued by independent proprietary or not-for-profit organizations (Bates & Gawande, 2000). For example, the National Committee for Quality Assurance (NCQA) offers free online health plan report cards "based on an evaluation of clinical quality, member satisfaction and a comprehensive assessment of key systems and processes" (http://www.ncqa.org). An interactive Web site allows users to compare health insurance plans based on type and location. Another independent organization, HealthScope, created by a coalition of large employers, the Pacific Business Group on Health (PBGH), which used its leverage to require health plans to publish certain quality measurement data, provides customized comparisons for California health insurance plans (Bates & Gawande, 2000). HealthScope provides online comparisons based on health insurance plans' care for staying healthy, care for getting better, care for living with illness, doctor communication and services, and plan service. Plans are given a score in each area, categorizing them as poor, fair, good, or excellent. Each of the five quality measure is derived from a questionnaire. For example, a health plan's score in "care for staying healthy" depends on its activity concerning immunizations, screening for certain types of cancers, prenatal care, and screening for sexually transmitted diseases (for more detail, visit http://www.healthScope.org).

Traditionally, once a corporation selects a group plan, little, if any, potential exists for customization based on personal needs of individuals. The Internet provides an easy and effective method for allowing employees to personalize their health insurance coverage from a large menu of options. Employers' role as the financiers of health insurance coverage, perhaps in the form of a lump sum payment per employee, remains largely unchanged. Whether employers or employees bear the eventual financial burden of health insurance coverage is debatable (Pauly, 1997). For the purposes of this chapter, we focus on the organization that sponsors the health insurance policy. A move away from "one size fits all" to personalized, but financially viable, health insurance plans has important implications for efficiency and cost-effective delivery of medical care by helping patients effectively manage their own health.

Direct competition by insurers for corporate business is another way in which the Internet is influencing the industry. In 1999, Hewitt Associates piloted a program termed a Health Maintenance Organization (HMO) Internet Auction in which more than 50 insurers competed for the business of three large employers (IBM, Morgan Stanley, and Ikonwidth) on a secure Web site. In a series of iterations, plans were allowed to make and modify bids. With the help of unique identifiers, insurers, along with participating employers, were able to view a comparative listing of their bids alongside other measures such as a quality ranking and the level and proposed change of their rates from the previous year.

Hewitt Associates reports that the transparency of the bidding process produced the expected results (Beauregard, 2000). To the satisfaction of the participating employers, the average rate of increase was 2% lower compared to the experience of similar employers in comparable markets. However, two concerns were raised by this pilot test. First, despite security measures, insurers were concerned about placing proprietary data, such as premiums, on the Internet. Second, insurers were worried that employers would make selections based solely on price while ignoring quality and consumer satisfaction.

A potential manifestation of the increased transparency made possible by the Internet is a growth in self-funded health insurance. Many employers, usually those representing large and stable risk groups, take over the risk-bearing function of insurance, and the role of traditional health insurance firms is reduced to providing administrative and consulting support. Four administrative areas in which the Internet can promote this strategy and make a substantial impact are human resource management, medical claims management, medical management, and network development (Goldsmith, 2000). Human resource management functions are often labor intensive and are particularly adaptable to the Internet. Benefits arise from the large potential for cost savings through reductions in labor resources and the possible customization of health insurance plans based on individual needs. Once a plan has been selected, directly by an individual or indirectly through an employer, the Internet can serve as a navigational or educational tool to help members better understand their coverage and assume a more active role in managing their health (see the section below on Navigations and Education).

Network Development

A recent use of the Internet is customization of health coverage for individuals. Internet startups such as Definitely Health (http://www.healthcare.com) and Vivius (http://www.vivius.com) offer individuals a way to tailor a health network to their own unique needs. Participants select a primary care physician, a team of specialists, and a hospital that forms their own personal health network. Among other things, customers are promised greater control over their out-of-pocket costs, employers are promised greater predictability over health care benefits expenditures, and providers are promised control over their own pre-paid fee levels. Vivius advertises elimination of medical claims and referral forms and competitive bidding as a way to contain costs while allowing customers the freedom to choose their own providers. At the same time, providers gain more control over the prices they charge.

This model may serve the self-employed and those who do not have the option of less expensive group coverage. There are sizable obstacles that will have to be overcome before employers and employees will abandon more traditional health insurance models. A move to a do-it-yourself network may imply losing the benefits from large group coverage and special taxation arrangements associated with traditional employment-based health insurance coverage. In addition to employees and the labor unions that represent them, there are several other interest groups that can be expected to oppose a large scale move to the new system, for example, providers who would face capitated risks (Goldsmith, 2000).

Claims Management

Management of insurance claims-related functions is one of the most important administrative tasks performed by the typical provider. Claims management tasks include filing, verification of insurance coverage, determination of co-payment levels, getting approval for referral to a specialist, checking on the status of previously submitted claims, adjudication in case of disputes, and payment of claims. Provider organizations generally submit claims to multiple payers, each using different formats. Substantial labor resources may be required to handle these complicated transactions. Similarly, insurers employ large staffs in call centers to process calls from physicians' offices, plan members, and employers. For example, Regional Physicians Group of Columbus, GA employs more than 20 full-time staff devoted to insurance transactions. By moving to a Web-based system, the group expects to save approximately $0.5 million annually in personnel costs.

Compared to the other claims management functions, submitting is perhaps most amenable to an electronic medium, Internet-based or otherwise. According to estimates from the Department of Health and Human Services (see Table 1), at least 53% of physicians claims will be filed electronically in 2002. In 1999, 64.5% of claims processed by private and public health insurance plans were transmitted electronically (Faulkner & Gray, 2000). Faulkner and Gray (2000) also report that 84% of hospital claims and 89% of pharmacy claims were transmitted electronically in 1999. Hospitals and nonphysician providers have embraced electronic claims filing at a higher rate, reaching, respectively, estimated minimum use rates of 87 and 83%. Medicare and Medicaid, the two largest government-sponsored health plans, and Blue Cross/Blue Shield organizations have been much more supportive of this technology than HMOs and other commercial insurers. In 1999, HMOs and commercial insurers received, respectively, 18 and 45% of their claims electronically, compared to a nation wide total of 64.5% (National Research Council, 2000).

The percentage of electronically filed claims processed through the Internet is not clear. According to an assessment of the National Research Council (2000), relatively few provider organizations and third-party payers have the ability to transmit or receive claims through the Internet. Furthermore, even if this ability is present, security considerations (see Technical and Practical Considerations) make this medium a relatively less attractive alternative. However, a number of developments have taken place, suggesting a dramatically increased use of Web-based applications. In the public sector, Centers for Medicare and Medicaid Services has implemented the Internet-accessible Medicare Data Communications Network (National Research Council, 2000). In the private sector, Internet upstarts and insurers have also started using, or are planning to use, Web-based applications for managing claims-related functions. In an effort to increase its physician subscriber base and shift provider—payer transactions to the Internet, Healtheon/WebMD acquired Envoy Corporation, Medical Manager Corporation, and CareInsite (Danzon & Furukawa, 2001). Envoy Corporation was an electronic health transaction firm that processed approximately one billion claims annually. To challenge these Internet service providers and avoid having to use intermediaries, health insurance companies are actively developing and implementing Web-based applications. The most significant of such challenges is a system called MedUnite, a Web-based transaction system connecting health care providers and insurers (Baldwin, 2002; Danzon & Furukawa, 2001). Seven major insurance companies formed MedUnite, Inc.,: Aetna, Anthem, Cigna, Health Net, Oxford, PacifiCare, and WellPoint Health Networks.

Submitting claims through the Internet is only the tip of the iceberg. The same applications that allow providers to submit claims through the Internet could open the door to the wide variety of related functions, subsequently ballooning its potential to promote efficiency. Verifying a patient's eligibility, in particular, can be integrated. Reduced administrative expense constitutes the most obvious benefit of Internet-based patient eligibility verification to insurers and providers. The accuracy of information retrieved from an Internet-based real-time eligibility verification system can minimize, or even eliminate, delays in payments or denials of claims.

The financial and time burden on providers from eligibility verification using traditional EDI and telephone systems can be imposing. EDI clearinghouse fees range from $0.40 to $0.60 per inquiry. When labor costs are included, telephone eligibility verification for payers ranges from $2.00 to $4.00, while providers face a cost between $10 and $20 per transaction (Bingham, 2001). The cost of reprocessing claims, which were rejected due to ineligibility, is even higher at an estimated $20 to $40 (Bingham, 2001). The potential benefits of accurate real-time eligibility verification are demonstrated in the outpatient sector. In 1997, the Health Care Financing Administration estimated that a staggering 129 million claims are rejected annually as a result of ineligibility (Bingham, 2001). Bingham also provides a detailed analysis of inpatient and outpatient eligibility verification costs per encounter using EDI and telephone systems for managed care plans, indemnity insurers, and providers, and estimates a benefits-to-cost ratio of 6.41 for payers from implementing an Internet-based eligibility verification application. (The author uses an estimate of $0.10 per member per month cost to a software vendor and assumes an insurer covering 195,000 lives, a 40% eligibility verification rate, and estimated hardware and installation costs of $130,000 to derive a total estimated cost of $364,000. The cost savings from eliminating the need for EDI or telephone eligibility verification for 78,000 claims (40% of 195,000) are estimated at $2,331,927. The ratio of these estimated benefits and costs is 6.406.) This ratio does not include secondary benefits, which would accrue to providers, such as time saved, the ability to identify and take care of copayment arrangements at the point of contact, and elimination of bad debt.

In addition to allowing providers to submit claims and determine a patient's eligibility, Web-based real-time communications can significantly expedite referral authorizations. In most cases referral authorizations could be obtained while the patient is still present. In the remaining cases, the request may be transmitted electronically to a medical director for review who then returns it to the requesting office by the same means. In either case, a Web-based system represents a fast improvement over conventional methods, which generally involve lengthy and time-consuming paper forms. This type of real-time and two-way communication between physicians and payers constitutes one of the most important benefits of an Internet-based system. It is noteworthy that many managed care organizations are now reducing or eliminating their prior and referral authorization requirements, therefore, greatly diminishing the value of this function of the Internet.

There are three categories of online communications approaches between payers and physicians (Figure 3). The first consists of separate and independent communication between a physician's office and a single payer. The second approach involves an "electronic intermediary" (e.g., Healtheon/WebMD), which allows physicians to communicate with multiple plans using a standardized format. The third method is similar to the second, but replaces the independent "electronic intermediary" with a "payer portal" (e.g., MedUnite) administered directly by multiple collaborating insurers (Baldwin, 2002; Danzon & Furukawa, 2001). From the physicians' point of view, the latter two methods may be more attractive since they eliminate the need for managing multiple formats and protocols dictated by different plans. Whether a single approach will end up dominating the marketplace is not certain. First, the HIPAA administrative simplification provision was designed specifically to eliminate the difficulties and inefficiencies of managing multiple formats and protocols, thereby lessening some of the distinctions between the approaches. Furthermore, in a competitive marketplace where insurers and intermediaries alike must cater

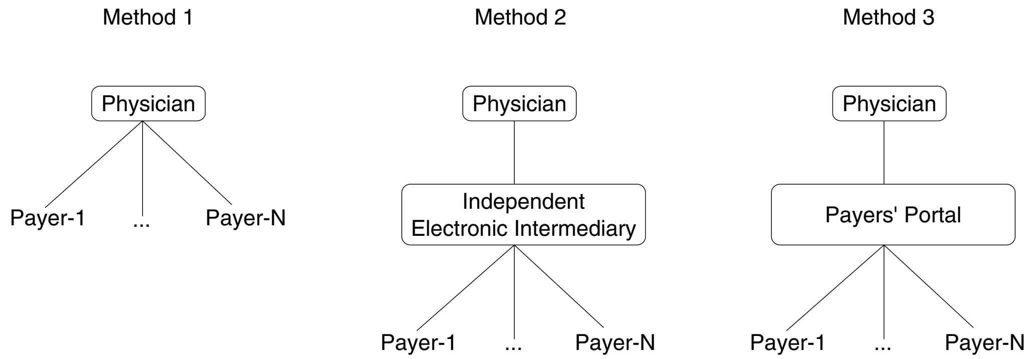

Figure 3: Online communications approaches between physicians and payers.

to a heterogeneous population of health care providers, employees, and employers, a variety of products is likely.

Navigation and Education

A logical start for insurer Web sites was to provide general information without any personal or confidential references. Accordingly, the first wave of third-party payer Web sites featured electronic brochures with general descriptions of the institutions, their products and services, news releases, employment ads, generic health and wellness information, and links to other health information sources. As consumers increasingly turned to the Internet for health information to better manage their own health, payer Web sites became gradually more sophisticated, with some organizations, for example UnitedHealthCare, a business segment of UnitedHealth Group, providing customized pages for members' personal interests. Other customized information found online includes utilization and financial reports, handbooks, directories, and guidelines to customer groups and providers. More interactive features include provider directories based on user-specified parameters such as location, specialty, and language.

Because of large information gaps between patients and providers, concerning appropriateness of diagnoses, treatments, and medical specialties, patients have traditionally assumed a passive role in their own care. (Asymmetries in information are identified as a principal reason for market failure in the health care industry. For an excellent analysis of this topic, see Arrow, 1963.) The complexities of medical care, combined with the laws that govern the delivery of that care, mean that patients will continue to rely on the expertise of professionals to a large extent. However, the Internet has opened the door to a tremendous amount of free information, both general and specific. Information on the Internet is not limited to treatment options, diseases, and diagnoses, but includes provider evaluations or report cards, and information about alternative medicine. By researching their medical conditions before contacting the health care system, consumers are playing an increasingly active role in decisions relevant to their care instead of passively relying on physicians, nurses, and other health care professionals.

Educational Web sites, containing both condition-specific and general educational material, are plentiful (see discussion of secure access under Technical and Practical Considerations). Unfortunately, much of this plentitude can be attributed to a lack of information quality control on the Internet (Winker et al., 2000). To combat medical misinformation on the Internet, the Health on the Net Foundation (HON) was founded in 1995. Although not widely utilized, HON offers their endorsement to those Web sites complying with the HON code of ethics, which emphasizes complementarity, confidentiality, attribution, justifiability, transparency of authorship, transparency of sponsorship, and honesty in advertising and editorial policy (see http://www.hon.ch). A survey of Web sites of 11 top HMOs revealed that none contained the HONCode icon to identify their subscription to the organization (Witherspoon, 2001). Despite the efforts of HON and similar organizations, "caveat emptor" is the recommended approach to information obtained from the Internet.

Web communication may be one-way or interactive. One-way communication serves primarily as a means to disseminate information. For example, this type of communication may be used to dispatch routine reminders for checkups and immunizations, information concerning specific illnesses and diagnoses, or educational information aimed at disease prevention. The Internet distinguishes itself from older technologies because of its ability to serve as a platform for efficient and effective interactive communication. Routine administrative functions, such as tracking medical claims, verification of enrollment, and analysis of benefits coverage, are greatly enhanced by the Internet's capabilities and are becoming increasingly available to plan members. Some insurers have begun using the Internet as a tool to assess members' needs, desires, and inquiries, or as a platform to facilitate dialog between patients and their physicians.

In the survey of 11 top-ranked HMOs mentioned above, Witherspoon (2001) assessed the extent to which these organizations make use of interactive technology on their

Web sites. The HMOs were selected based on their relative standings in rankings by *U.S. News & World Report* and *Newsweek*. Witherspoon rated interactivity of Web sites based on the availability and accessibility of nine functions. The functions include e-mail access to specific physicians or other providers, consumer feedback mechanisms, invitations to subscribe for newsletters and a listserv, ability to register for chat groups moderated by a physician or registered nurse, availability of a provider search engine, and the ability to register for classes via online technology. The following is a summary of some of the author's findings. Of the 11 sites examined, none offered e-mail links to specific health care providers, 6 included a consumer or visitor feedback mechanism, none provided a chat group of any kind, 2 offered subscription to an online newsletter, 5 provided an online provider search mechanism, and 2 allowed members to register online for health classes.

Following Witherspoon (2001), we conducted our own survey to determine how HMO Web sites have developed during the past year. Unfortunately, the sample of organizations could not be duplicated. Two organizations in the original sample either discontinued operating a particular plan or merged with another: the Kaiser Foundation, which ceased its operations in the Northeast, and the Matthew Thorton Health Plan in New Hampshire, which does not operate its own Web site but is incorporated into the regional Blue Cross/Blue Shield. The remaining sample was augmented using the top 40 of the 1999 *U.S. News & World Report* ranking of HMOs and point of service organizations. Of these organizations, several, for example Cigna and the Blue Cross/Blue Shield organizations, used the same Web site. After eliminating duplicates and Web sites that were offline, the sample contained 24 HMOs (see the Appendix). Unlike Witherspoon (2001) we do not rate a Web site's interactivity, but only assess the availability of specific functions. Our analysis suffers from the same shortcoming as the Witherspoon study. Although the sample size is substantially larger, it is, nonetheless, small from a statistical point of view, and only representative of the top HMOs. Furthermore, many of the Web sites analyzed included a section accessible only for members, requiring a log-in password. Some functions we searched for may have been available only through this section.

All 24 sites analyzed for this study, compared to fewer than 50% in the Witherspoon survey, offered a provider search engine. With a single exception, the provider search procedure was interactive, allowing users to specify such parameters as location, specialty, language, and gender of the provider. In addition to a provider search engine, 8 sites (33%) allowed members to change or select a primary care physician. Seven sites (29%) also provided brief physician profiles, offering members information on board certification status, hospital affiliation, medical school, and place of residency. However, none included e-mail links to specific providers. Eighteen of the sites (75%) included a newsletter or other plan-specific publication, and 9 (37.5%) allowed members to register for health classes online. Fourteen sites (58%) allowed members to submit feedback to the health plan through either e-mail or a special form available for download or printing. Similar to the Witherspoon survey, none of the sites invited members to register for a listserv or any kind of chat group.

Three sites (12.5%) offered, or will offer, members the ability to personalize their site experience. Personal Web pages, accessed through the organizations site, may include customized lists of health programs, lists of physicians and other providers, and financial information. Finally, 23 sites (96%) provided links to information supporting healthy lifestyles and preventive care.

Medical Management

The presence of health insurance tends to make consumers insensitive to the cost of medical care, leading to overuse of resources, or the use of unnecessary care with only minor or no added benefits. This phenomenon is sometimes referred to as moral hazard (Arrow, 1963; Pauly, 1968). Partly in response to this, the promotion of efficient delivery of health care remains a cornerstone of managed care. Efficiency suggests the elimination of inappropriate approaches to health care and the determination of the optimal quantity of care without compromising the quality of services provided to patients. Information plays a critical role in this regard. During their training and practice, physicians develop different beliefs concerning the safety and efficacy of treatments and the probability of specific diseases. The resulting variations in practice styles, both spatially and contemporaneously, are well documented in the literature (Wennberg, 1987; Wennberg et al., 1987). To the extent that these differences exist due to physicians' uncertainty and ignorance over best medical practices, the role of information is obvious. The more accurately the most appropriate therapeutic strategy can be defined, the better patients and physicians will be equipped to select an optimal treatment plan. The welfare gains from pursuing evidence-based "best" practices can be substantial (Phelps, 1992, 1995; Phelps & Parente, 1990).

In this regard, the importance of information, seamlessly integrated from all sources, cannot be overstated. Theoretically, information is a key ingredient of efficiency. Most importantly, information promotes efficient choices based on the value and marginal cost of the product. The outcomes-driven approach is still in its infancy and is stifled, at least in part, by the information challenge. The Internet, in its capacity to synthesize and present large amounts of information, is perfectly suited to promote this strategy. Web-based physician-oriented portals are a low-cost method for providing physicians with access to state-of-the-art decision support systems, targeted medical information, and continuing education (Danzon & Furukawa, 2001; Goldsmith, 2000). The tools used to promote outcomes-driven care include utilization review mechanisms. Utilization review can be after the fact, or retrospective, in advance, or prospective, or at the time of treatment, or concurrent. An example that highlights the advantages of the Internet over conventional methods, such as phone calls or mailings, is concurrent utilization review where expediency and immediacy of information are much more important than prospective or retrospective review. Approximately 83% of preferred provider organizations require concurrent utilization review for hospital stays.

Linking evidence-based health outcomes research with the Internet can reduce the fragmentation and lack of communication among caregivers, which is widely cited as a significant source of inefficiency and medical errors in the U.S. health care system. The Internet makes it possible to give all relevant providers, ranging from primary care physicians to specialists and inpatient departments, real-time shared access to patient-specific guidelines and records, in a fast and efficient manner. In the long run, the Internet can promote interaction between providers, actively involving them in patients' care from start to finish. Large integrated delivery systems, in particular, would benefit from such an approach, whether the information integration is accomplished through the Internet or some other platform, such as a private network. Internet technologies represent a cost-effective and logical option to achieve a high level of information integration in a relatively short period of time.

On the demand side of care, consumers are assuming an increasingly active role in the determination and delivery of their care (see the section Navigation and Education). In addition to disseminating information on diseases, diagnoses, treatments, and medical management criteria, insurers are involving members in the process of promoting cost-effective care with incentives, such as cost-sharing arrangements to avoid high-cost or high-risk providers (Goldsmith, 2000). This two-tiered system is used by preferred provider organizations and point of service organizations primarily as an incentive to encourage members to seek care from providers within the network. The Internet, in its capacity to guide consumers through the health care process, provides an excellent medium for insurers to publish their internal data on practice variations to help subscribers identify best practices.

CONCLUSION

Health insurance plays a central role in the health care industry. The health care revolution and the rapid increase in the number of lives covered by insurance created a tremendous demand for increased efficiency. Efforts of the health insurance industry to increase efficiency have focused on basic administrative functions, particularly those involving transactions between insurers and their constituents. The transition from paper-based transactions to electronic transfers was an important step forward, but did not reach stakeholders on a system-wide scale. The subsequent revolution of the Internet introduced exciting new possibilities but was, until recently, largely ignored by the industry. Fortunately, awareness of Internet technology is growing rapidly and will, undoubtedly, play an important and lasting role in achieving long sought after efficiencies. Concerning information technology, health insurance organizations have substantial advantages and incentives compared to other stakeholders, and are therefore expected to play a prominent role in its advancement in the industry.

A key characteristic of the Internet is its ability to generate efficiencies affecting directly, not only the largest stakeholders of the industry, but also individual health plan members and providers. However, there are significant obstacles the health insurance industry must cope with before it can explore the full potential of the Internet. Applications of e-commerce and Internet technologies in the health insurance industry concern communications between insurers, plan enrollees, and providers. The obstacles associated with implementation of these applications depend in large part on the type of information transferred between interested parties. Communication between insurers and plan members primarily concerns general and relatively less sensitive information. Therefore, implementation and proliferation of relevant Internet applications faced few obstacles. In contrast, information transfers between insurers and providers (insurer to provider, provider to insurer, insurer to insurer, and provider to provider) often involve sensitive, or HCFA Privacy Act-protected information, creating a special set of challenges particularly for Internet-based applications. Consequently, the industry has been relatively slow in adopting the Internet as a platform for these types of applications. Although advances in encryption, authentication, and certification make us more comfortable, security and confidentiality transcend technology, and will remain important considerations. Indeed, despite the HIPAA administrative simplification provision, privacy considerations will likely continue to suppress better information integration and standardization, particularly where it concerns the sharing of clinical information among providers and insurers.

In addition, important nontechnical obstacles to more widespread implementation of e-commerce and Internet technologies exist. At the institutional level, the operational risk involved with transforming information exchange technologies is identified as a major obstacle. Furthermore, while Internet use has increased dramatically across the population, substantial demographic inconsistencies remain (U.S. Department of Commerce, 2002), particularly based on age and income status. Apathy toward, and ignorance of, new technologies, both by providers and patients will continue to stifle more widespread adoption of such technologies. It will, therefore, be several years before the Internet's influence on the industry reaches its potential.

On the other hand, the Internet has demonstrated its staying power and its growth is certain. Web-based applications are becoming increasingly interactive, integrating information from a growing number of sources. This will eventually include medical records, making them accessible to providers across the spectrum of health care. What will be the impact on efficiency when all stakeholders are able to communicate effectively?

APPENDIX

[a] See Table A-2 for an explanation of the Web site function. A value of "1" indicates that the function was present on the Web site. A value of "0" implies that the function could not be located on the Web site. A period means that the availability of the option was unclear or links were indicated on the main Web site but could not be accessed at the time of the survey.

Table A-2 Web Site Functions Examined in Survey.

Column	Description of function
A	Asearch engine for providers
B	E-mail links to specific physicians
C	An option for selecting or changing a primary care provider
D	Physician profile
E	E-mail links to nonphysician providers
F	Ability to create and maintain a personalized Web page
G	Option to register for classes via the Internet
H	An online newsletter or other plan-specific publications
I	Option to register for an online listserv
J	Option to register for an online chat group moderated by a physician or registered nurse
K	Links to information supporting a healthy lifestyle and preventative care
L	A mechanism, other than a postal address, for consumer feedback. This includes either an e-mail address or an online form.

ACKNOWLEDGMENTS

The author thanks Jodi B. Pracht for research support and valuable comments that were instrumental in shaping this paper.

GLOSSARY

Availability The continuous accessibility of a network, the applications of which it is composed, and the services it offers.

Bandwidth The rate, measured in bits per second, at which information is transmitted through a network.

EDI Electronic data interchange.

CMS Centers for Medicare and Medicaid Services (formerly, the Health Care Financing Administration).

HCFA Health Care Financing Administration (see CMS).

HHS U.S. Department of Health and Human Services.

HMO Health Maintenance Organization.

HIPAA Health Insurance Portability and Accountability Act.

HON Health on the Net Foundation.

IDS Integrated delivery system.

POS Point of service.

IVR Interactive voice response.

IT Information technology.

Latency The time required for transmitting data across a network.

NCQA National Committee for Quality Assurance

PPO Preferred Provider Organization

Security The availability, confidentiality, and integrity of information.

Ubiquity The relative accessibility of a network.

WEDI/AFEHCT Workgroup for Electronic Data Interchange/Association for Electronic Health Care Transactions.

INTRODUCTION

An oft-repeated phrase from the best-selling *Being Digital* (Negroponte, 1995) is that computing "is not about computers any more. It is about living" (p. 6). This claim captures the pervasiveness with which our lives have become intertwined with computer-mediated communication. The question of the Internet's positive and negative effects has increasingly become a focus of public discussion. Media scholars point out that such concerns have a long history, however. The earliest forms of mediated communication (meaning non–face-to-face) date from prehistoric human art and symbols. Plato wanted to ban written poetry because he feared it might corrupt even the best individuals. Pythagoras forbid reading in his school out of fear that reliance on written communication would diminish mental capacities. When the telephone and television were introduced, there were also fears of loss of privacy and the homogenization of culture as well as concerns regarding indecent communication.

Yet mediated communication has not only prevailed, each new form has been adopted more rapidly and pervasively. The amazing growth of the Internet has far exceeded all other mass communication media and has implications for health and for the work of health professionals.

PSYCHOLOGICAL HEALTH ISSUES

Definitions of Self

In *Life on the Screen: Identity in the Age of the Internet,* Turkle (1995) discusses how online experiences can dramatically help or hinder the self through experimentation with multiple identities: "The Internet has become a significant social laboratory for experimenting with the constructions and reconstructions of self that characterize postmodern life" (p. 180). By interacting anonymously online, some people have found unparalleled opportunities to explore self, obtaining experiences difficult to find in real life—from pretending to be a member of the opposite sex to slaying a dragon. The Internet offers a rich place to act out or work through psychological issues. When used by someone who has a fragmented self in face-to-face reality, however, this can lead to problems, such as college students who spend many hours playing online games, leading to academic failure and even psychotic episodes. (Such dysfunctions are discussed further in the section on Internet addiction).

People whose lives might be changed the most by the Internet are those who have some antisocial aspect to their identity, such as extreme views or practices considered deviant by others in their social network. Those who initially communicate a taboo identity are subsequently more likely to both incorporate that identity into their sense of self and to disclose it to face-to-face friends. Thus, as often claimed, the Internet can be a kind of "social laboratory" in which people test their identities on strangers before embracing them and sharing them with friends and family (Tyler, 2002). Yet in some contexts, Internet use promotes behavior that is more normative and socially influenced. Social influence, rather than being filtered out, can be even stronger in computer-mediated communication compared to face-to-face (Spears, Postmes, Lea, & Wolbert, 2002).

Humanistic psychologists have warned that as humans become more dependent on technology and inhabit an increasingly technological world, "we too are subtly made-over and reinvented by the very technological world we invent" (Dodson, 2002, p. 17). As people try out multiple new identities online and experiment with virtual reality simulations of reality, the self becomes more mutable and fragmentary than it has ever been in human history. "To value machines and virtual reality over our humanity is a choice that will clash head-on with 500,000 years of biological wisdom. . . . The question now is: how are the relationships we are forming with computers changing what it means to be human?" (Heckler, 2001, p. 278).

One example of this impact is how readily the computer metaphor for the brain has been adopted both in the health professions and in popular culture. The choice of linguistic metaphor has profound implications for how that phenomenon is viewed and interacted with (Lakoff & Johnson, 1983). In the case of health issues,

> Instead of confronting how we are creating and reacting to the stresses that cause human conflict and sickness, we look only to how we can maintain and repair the computer-brain. This translates into servicing the "human machine" with drugs; drugs for sleeping, drugs for waking up, drugs for shifting moods, drugs for recreation, for upset stomachs, for having sex . . . and so on. As if taking ourselves in for a lube job and oil change will fix the problem. Our acquiescence to technology has lowered us to its level, rather than pulling it up to our level. (Heckler, 2001)

Even technology's critics are also searching for ways that it can lead to enhanced connections with others and a deeper sense of self, however.

Consciousness

The Internet is potentially a vehicle for expanding consciousness as it expands human contact with "altered realities." The sharing and communication capacities of the Internet are creating what has been termed an *electronic neurosphere,* a global mind that will change health care, theology, and the way we think about ourselves. The interface of human brains and computers will extend both human and machine intelligence and lead to changes in consciousness. With increased practice in absorption (deep experiential immersion characteristic of online communication) in altered constructed realities online, humans average experience of "altered reality" will expand (Gackenbach, 1998).

Social Interactions

An early and well-publicized study of the psychological effects of the Internet reported that heavy Internet use was associated with lower social involvement, less family communication, and depressed mood (Kraut et al., 1998). A 3-year follow-up by the same researchers, however, found the subjects no longer showed these effects (Kraut et al., 2002). As users became more experienced with the Internet and their competence improves, they become more skilled at getting social support from others online. Internet use leads to positive personal and social effects such as an increase in communication, social involvement, and psychological well-being, factors associated with improved—not reduced—mental health.

Research into computer use by the elderly also reveals its positive social potential. A study of a computer instructional program on the quality of life of senior citizens found that at first participants showed reluctance but then enthusiasm about using the computer as they progressed in functional skills. Eventually, participants showed improvements in level of independence, more interest in other activities, a shift in mood toward a more positive temperament, and transfer of physical skills to other areas (Groves & Slack, 1994).

CHESS is an online computer-based patient support system that targeted elderly women with breast cancer. In a study by Gustafson et al. (2001), at 2-month follow-up, the CHESS group was significantly more competent at seeking information, more comfortable participating in care, and had greater confidence in doctor(s). At 5-month follow-up, the CHESS group had significantly better social support and also greater information competence. Obtaining social support for health challenges is one of the major and oldest uses of the Internet. Newsgroups, which are online asynchronous threaded discussions, predate the World Wide Web by more than 20 years, and even though Web-based support groups have made it even easier to communicate online, newsgroups are still actively used to obtain social support.

As people become more mobile, the Internet also becomes more important to maintain contact with family and friends. Internet usage by people who have relocated jobs has been found to ease their adjustment and also provide a means for enhancing business and personal relationships (Haupt, 1998). In general, the Internet has had positive social consequences in people's everyday lives because it increases the frequency and quality of interpersonal communications. Early fears that Internet use would be associated with social isolation and dependence seem unsupported by more recent findings.

Internet Relationships

Disinhibition refers to a lack of interpersonal feedback characteristic of face-to-face communication. This can lead to enhanced self-disclosure and also personal attacks as many people feel freer to express themselves during online communication. Three potential causes of disinhibited behavior online are as follows:

1. **Deindividuation—**reduction in accountability cues that leads to decreased self-regulation
2. **Reduced Social Cues—**the limited nonverbal cues to communicate meaning
3. **Social Presence—**a lowered sense of being there and accountable for one's actions

Online relationships, contrary to early beliefs, can become close, meaningful, and lasting (McKenna, Green, & Gleason, 2002). People often bring relationships formed on the Internet into the real world. Studies show that female Internet users had more online contact than their male counterparts, with more contacts for romantic relationships than for friendships. Further studies found that relationships formed initially online were as stable after 2 years as those formed face-to-face. It appears that many of the concerns expressed about the quality of Internet interactions are unfounded.

Family Life

The Internet can contribute to dysfunction when family life is disrupted by technologically captured moments, such as always-on instant messaging, telemarketing phone calls during dinner, and unattended television and radio creating background noise. Dysfunctional use of the Internet by children as well as adults can result in diminished participation in the family with members becoming isolated, each person wrapped in his or her own "techno-cocoon."

At the end of the day, Mom is preparing dinner while checking the answer machine, head glued to the portable phone while she returns calls. One child is playing games on the computer in his bedroom, another is talking on her own phone, and the youngest is playing Nintendo. Dad comes home later from work and goes immediately to the computer (Weil & Rosen, n.d.).

When the children become the family computer and Internet expert, parents, although proud, may also be disconcerted by the shift in authority in the family structure (Kiesler, Bozena, Lundmark, & Kraut, 2000).

Childhood and Adolescence

The gaming industry that began with video games and now includes online gaming grosses more per year than the movie industry. It is a force that all parents and health workers need to contend with in their interactions with children. Emes (1997), in a review of the research on the effects of video games on children's well-being, concluded as follows:

> Results show that playing video games is associated with a variety of physical effects including increased metabolic and heart rate, seizures, and tendonitis. Aggressive behavior may result from playing video games, especially among younger children. There is no direct relationship between psychopathology or academic performance and playing video games. Overall findings indicate that although video games have some adverse effects, they are also valuable learning tools. (p. 409)

Game playing improves dynamic spatial ability, which is linked to measures of reaction time and speed of mental processing, which in turn are thought to be linked with general measures of intellectual ability (Jackson, Vernon, & Jackson, 1993). Video game play increases choice reaction time, spatial skills, scientific problem solving skills, and intelligence. Interactive media use also increases parallel processing abilities or multitasking (Greenfield, Brannon, & Lohr, 1996). Furthermore, there is no research data supporting the popular notion of loss of attention span associated with video game and Internet activities. Multitasking may have the negative consequence of losing depth of information processing while gaining breadth (Greenfield, 2000).

Despite these positive effects, exposing infants and young children to video games and the Internet often does not engage their major learning style, which is through their sensorimotor system, and thus may have negative effects on their cognitive development.

Access to pornography by minors is a major concern. Adult-oriented sites make up approximately 2% of all content on the World Wide Web. Although sexually explicit material comprises only a small fraction of online content, that fraction is highly visible and accounts for a significant amount of Web traffic. Although such material exists in magazines, television, movies, and billboards, pornography on the Web is much more accessible to children. Graphic images can find their way onto a child's computer screen without being actively sought. In addition, the anonymity of the Internet makes it easier for strangers to interact with children. Exposure to sexually violent material has been found to be related to attitudinal changes, with both men and women more likely to display callous attitudes toward female victims, such as stating that a rape was the fault of the victim or that she brought it on herself. Exposure to nonviolent sexual material increased the acceptability of premarital sex for teenagers compared with teenagers who were not similarly exposed (Huston, Wartella, & Donnerstein, 1998; Lawrence & Giles, 1999).

Most of the concern has focused on the adult online entertainment industry, which generates about $1 billion a year. According to the Nielsen/Net Ratings, nearly 16% of visitors to adult-oriented sites in February 2002 were under the age of 18. No studies have been able to tease apart the effects of Internet versus television versus print media exposure to sexually explicit material; however, the concern remains that the Internet provides increased access to such material, even when it is not being sought, such as when searches return sites with pornographic content unrelated or peripherally related to the search terms (e.g., fairies, cartoons). Some schools and libraries use filtering software to exclude such sites, and home computer versions of filtering software are also available (Thornburgh & Lin, 2002).

Socialization Effects

The influence of exposure to violence in games has been an area of concern. Most teenagers own their own video or computer games and spend 5 to 13 hours a week playing them. Additionally, nearly half of eighth and ninth graders report that they want more violence in their games. At-risk boys spend more time playing games than their peers, and they play more violent games. Youth who report an increased appetite for violence in video games are more likely to have gotten into physical fights in the previous year. Thus, there is reason to be concerned about exposure to violence in online games.

Most games have no female roles, and the ones that do typically involve damsels in distress. Because of the social element of Internet communications (e.g., instant messaging and chat), girls are quickly catching up with boys in their computer skills. Most adolescents use the Internet like a telephone rather than as an opportunity to try different personalities and identities. Girls are heavier users of chat rooms, whereas boys are heavier users of online games, but for both instant messaging was the most used element of online activities. Thus, Internet use is similar to traditional means of youth social interaction (Gross, Juvonen, & Gable, 2002).

Internet Addiction

Dysfunctional Internet use patterns are often referred to as Internet addiction, although there is no psychiatric diagnosis called Internet addiction listed in the *Diagnostic and Statistical Manual of Mental Disorders* (DSM; American Psychiatric Association, 1994). To become an official diagnosis, research must show that Internet addiction disorder can be reliably diagnosed and that the diagnosis correlates with outcome, treatment results, histories, and prognosis.

Although some argue that the Internet is merely a communications medium and cannot be compared with addictive stimuli such as drugs and alcohol, others point to the growing number of cases related to overuse of the Internet seen in clinics and private practices. It seems closer to pathological gambling, an impulse disorder in the 4th edition of the *DSM* rather than a type of substance-related disorder. Studies are in fact establishing a connection between problematic Internet use and impulse disorder. For example, a study of 20 people with problematic Internet use found that all of them met diagnostic criteria for an impulse control disorder (Shapira, Goldsmith, Keck, Khosla, & McElroy, 2000).

Dysfunctional Internet usage occurs when people spend too much time online to the detriment of their social and financial well-being. Several types of problematic online behaviors have been documented, such as online gambling, online shopping, day trading, cybersex affairs, online gaming, violent computer games played by children, and participation in chat rooms. One study found that 6% of the 17,251 persons surveyed met criteria for compulsive Internet use (Greenfield, 1999). One of the earliest articles illustrating dysfunctional use of the Internet was the case study of a 43-year-old woman whose preoccupation with chat rooms eventually destroyed her 17-year marriage (Young, 1996).

Problems can also originate in the workplace. People whose jobs require extensive computer use tend to have pervasive and characteristic cognitive styles characterized by "multitasking" with high-speed processing. They can develop problems including loss of mid- and long-term goal directedness, diminished length of attention span, disrupted patterns of living (e.g., sleeping, eating), and detached or disturbed social relationships, often using the computer as the focal point for all contact with the world. (Fenichel, n.d.).

Assessment of Internet Addiction

Psychologist Kimberly S. Young (1998) conducted a 3-year study of Internet addiction that led her to propose a definition that involves having experienced four or more of the following symptoms during the past year:

1. Do you feel preoccupied with the Internet or online services and think about it while offline?
2. Do you feel a need to spend more and more time on line to achieve satisfaction?
3. Are you unable to control your online use?
4. Do you feel restless or irritable when attempting to cut down or stop your online use?
5. Do you go online to escape problems or relieve feelings such as helplessness, guilt, anxiety, or depression?
6. Do you lie to family members or friends to conceal how often and how long you stay online?
7. Do you risk the loss of a significant relationship, job, or educational or career opportunity?
8. Do you keep returning even after spending too much money on online fees?
9. Do you go through withdrawal when offline, such as increased depression, moodiness, or irritability?
10. Do you stay online longer than you originally intended?

Dr. Young (n.d.) has created interactive online tests for Internet addiction based on these criteria, although reliability and validity data are not reported. Dr. Young has created tests for specific Internet-related problems, including Cybersexual Addiction, Obsessive Online Traders, Compulsive Online Gambling, Online Auction Addiction, and A Parent's Assessment of Child's Internet Addiction.

No accepted guidelines for distinguishing "normal" enthusiasm from "pathological" preoccupation with the Internet exist as of yet. (Why aren't people who spend a lot of time reading called "book addicts" instead of being affectionately called "bookworms"?) It is clear, however, that people have lost their jobs, flunked out of school, and been divorced because Internet use consumed all their time. Such extreme cases demonstrate the need to pay attention to Internet use patterns. More research is needed in the area of Internet addiction to determine reliable and valid criteria.

Treatment

Suler (1999) proposed a treatment approach based on the observation that people become "addicted" to the Internet when they have disconnected from their face-to-face life. Their online activity becomes a world unto itself, which they don't talk about with the people in their face-to-face life. It can then become a walled-off substitute or escape from their life.

Because Internet addiction, as with all others types of addiction, entails isolation from others and prioritizing of the compulsive activity over all other aspects of life, Suler proposes that treatment be targeted to integrate online and offline worlds by

- Telling online companions about one's offline life,
- Telling offline companions about one's online life,
- Meeting online companions in person,
- Meeting offline companions online,
- Bringing online behavior offline, and
- Bringing offline behavior online.

Young, who founded the Center for Online Addiction, leads an online self-help group for Internet addictions. Although some would compare this to holding an Alcoholics Anonymous meeting in a bar, she has been able to engage people in reevaluating and altering their patterns of Internet usage using this approach. She believes that, as with other addictions, it is first necessary for the person to break through denial. She reports that Internet addiction does not require abstinence for a healthy and life-enhancing recovery. Her treatment approach focuses on finding a balance between Internet use and other life activities. The treatment model is similar for eating disorders or controlled drinking programs. The focus is to identify the triggers of binge behavior and relearn how to use the behavior in moderation (Young, n.d.).

Technostress

Technostress refers to any negative impact on attitudes, thoughts, behaviors, or body physiology that is caused either directly or indirectly by technology. One well-documented form of technostress is the escalating problem of information overload. Just as fat has replaced starvation as this nation's number one dietary concern, information overload has replaced information scarcity as an important new emotional, social, and political problem. Until recently, the production, distribution, and processing of information remained evenly balanced. People could receive and think about information at roughly the same pace it was generated. Since the mid-20th century, computers, television, satellites, and the Internet have created a condition of hyper-production and hyper-distribution that has surpassed human processing abilities (Shenk, 1998).

The impact of information overload is particularly apparent in the workplace as more and more people spend their time at work sorting through e-mail, voice messages, and Web pages while their day is interrupted by ringing phones, dinging e-mails, and squealing fax machines. A study of employees at Fortune 1000 companies found that they averaged 178 messages a day and three interruptions an hour (Rosen & Weil, 1997). A typical day can look like this:

> You walk in the door at 8:02 a.m. to be greeted by your secretary. She hands you a stack of 18 "While You Were Out" slips that she has transcribed from your voicemail. With your overstuffed briefcase in one hand, your laptop in the other, and the stack of folders under your arm. You consider trying to squeeze the messages between two available fingers. "Oh, wait," she says, and points to three Federal Express packages. No way to carry it all now, so you head off to unload the work you brought back from home.
>
> Your desk looks like a war zone—and your side lost. A quick glance at your computer reminds you to check your e-mail. What? 26 messages! How can that be? You checked it before you went to bed last night and spent 45 minutes answering all the messages. As you read your e-mail, you flip through yesterday's mail. The phone rings, and you half-listen to one of your employees as you scroll through your e-mail to decide what to answer now and what can wait until later.
>
> Your day has just begun and already you are exhausted. You feel like an octopus, with your arms and brain moving in multiple directions at the same time. By the time you have finished your work day—technically eight hours later (ha!)—you will have started and stopped dozens of tasks. The phone, the fax, the beep of an incoming e-mail all wrench your mind from what you are doing and thinking. When you finally return to your work, often you have lost your train of thought. (Rosen & Weil, 1998)

Symptoms of Technostress

Technostress can affect memory, leading people to lose track of what they wanted to do or say. Getting a peaceful night's sleep becomes difficult when overstimulated minds buzz and chatter, and enjoying laid back recreational activities is disrupted by preoccupation with to-do lists, calls, errands, memos, and more. Headaches, irritability, gastrointestinal discomfort, heart problems, and hypertension can also be related to technostress. In addition, information technologies allow people to work 5 p.m. to 9 a.m. as well as normal daytime hours from 8 to 5. Rosen, who has conducted research on human–computer interaction in the workplace, maintains, "Our brains aren't wired to 'multitask' the way our computers are. We're testing the limits of our human abilities" (Rosen & Weil, 2000).

The scientific understanding of the body's response to this assault on the mind is still in its infancy, but it draws on Selye's (1978) classic work on stress. Technostressed individuals not only live on the edge of constant crisis, some seem to prefer life that way. It has been hypothesized that they are addicted to their own adrenaline.

Coping With Technostress

People need to learn new ways to cope with the constant demand to learn new skills, meet speedier turnaround times, and be accessible 24 hours a day. The pace of technological innovation and intrusion into lives is unprecedented and requires a radical rethinking of how people relate to technology. Yet managed appropriately, technology can enhance both the quality and efficiency of everyday life.

Weil and Rosen (1997) offer some tips to help people manage the information flow:

Sift and Trash. Try to focus on the information you really need instead of news blips that distract. Think critically and separate the gems from the dross.

Set Limits. Ration the time you spend watching television, listening to the radio, and cruising the Internet. Designate the best times for people to call or fax you.

Respond on Your Own Time. Disable the e-mail ding and turn off the ringer on the fax machine. You can respond after you've finished other tasks.

Relax When Technology Makes You Wait. Instead of getting irritated while your e-mail boots or a company's telephone system puts you on hold, use that time to rest or tend to small tasks.

Use the Technologies That Work for You. You don't have to acquire every new technology. If beepers and cell phones cause you stress, stick with voicemail.

Schedule Time Away From Information. Set aside slots for exercise, sports, dinner with friends, and family vacations.

Technophobia

Surveys show that 85% of the U.S. population feels uncomfortable with technology. Only about 10–15% of the industrialized population are "eager adopters." Hesitant "prove its" make up about 50–60% of the population, and resisters 30% or so (Ellen, Beardon, & Sharma, 1991). A survey by Dell Computer identified 55% of Americans as technophobic (Dell Computer Corporation, 1993). The percentage of the population who are becoming hesitant and resistant is increasing. Over a 3-year period, clerical workers became more hesitant and resistant toward technology while managers and executives became more resistant (Rosen & Weil, 2000).

Technophobia can have detrimental effects on careers because workers who use computers on their jobs earn 10–15% more than those who do not even after holding education, income, occupation, and other characteristics constant. Thus, avoiding computers can be costly. People who don't feel comfortable with technology often feel inferior and intimidated, as though their boundaries are being invaded. Studies have shown that the key psychological factor determining resistance to technological change is the person's perceived ability to use a product successfully (which can be improved with training).

PHYSICAL HEALTH ISSUES

Repetitive Strain Injuries

Repetitive strain injuries (RSIs) are a response to excessive and repetitive demands placed on the body. RSIs all have a similar cause: excessive wear and tear on the soft tissues of the body (tendons, nerves, circulatory system, etc.) related to performing the same task over and over again, from clicking a mouse to straining to see the computer monitor. Disorders related to work that requires repetitive motion are increasing. They account for nearly half of all reported work-related illness, and carpal tunnel syndrome is estimated to account for more than 41% of these repetitive motion disorders. Researchers have defined six key risk factors in the workplace for the development of these disorders, including carpal tunnel syndrome (CTS): repetition, high force, awkward joint posture, direct pressure, vibration, and prolonged constrained posture. Experts estimate that between 7% and 16% of the population experience CTS. The incidence appears to be increasing. How much is directly related to computer use has not been established, but typing is considered a major source of RSIs (Szabo, 1998).

Other Health Problems

Computer vision syndrome is defined by the American Optometric Association the "complex of eye and vision problems related to near work, which are experienced during or related to computer use including eyestrain, blurred vision, dry and irritated eyes, slow refocusing, sensitivity to light, double vision, and color distortion.

Prevention

Experts in the field believe that a sound ergonomics program can resolve the majority of health issues associated with computer use. Linden (1995), a specialist in body and movement awareness education, advises, "The first and most basic element of computer safety is body awareness. We must be able to feel and understand the functioning of each body component, from our legs to our eyes, so we can detect strain and nip it in the bud" (p. 3).

Second, Linden prescribes proper movement breaks. Bodies are designed for movement, not for static work. Computer users should take a brief, 5-second movement break at the keyboard every 10 minutes. The third element is to choose equipment and workstation setup to ensure comfortable ergonomic use. The Centers for Disease Control (n.d.) publishes ergonomic guidelines for computer use covering work area, desk/workstation, chair, monitor, keyboard, mouse, lighting, work habits, laptop computer.

IMPACT ON THE HEALTH PROFESSIONS

Health Information

Consumers

More than 60% of Internet users sought health information in the past 6 months (Ferguson, 2002). The Internet is a revolutionary information technology that rivals speech, writing, and books in its potential to transform the exchange of human knowledge. The Internet already contains vast archives of scientific and health literature that is accessed not only by health professionals but also by consumers. A new area has developed called consumer health informatics that deals with this recent ability of consumers to access the entire body of published health care and scientific literature online, in abstract form via PsycINFO, MEDLINE, and other important searchable bibliographic databases. More than 30,000 Web sites offer medical information (Ferguson, 2002).

For consumers, information gathered online can have both helpful and potentially harmful impact. Certainly it can help by providing useful information regarding conditions, symptoms, or drugs, but this information can also contribute to risks such as the following:

1. Propagating inaccurate science and fraudulent cures;
2. Wasting time or money;
3. Instilling unnecessary guilt, fear, anger;
4. Making prognoses worse by delaying treatment; and
5. Leading to alienation or withdrawal from health care.

To some extent, these risks are part of all forms of information seeking. They essentially address a larger issue of how people react to and manage the vast amount of information available today, which can create anxiety and information overload.

Professionals

In addition to the vast amount of medical information now posted on the Internet, peer-reviewed research evidence that was once available only to clinicians is now accessible to everyone. The National Institutes of Health and CenterWatch maintain public online listings of investigative clinical trails and newly Food and Drug

Administration–approved therapies. Medical references such as the Merck Manual are accessible online. Patients now come to appointments armed with research evidence and knowledge about the latest treatment options, information that had previously been available only to health care professionals. This is changing some of the ways that health professionals interact with their patients because patients often are more involved in negotiating their treatments.

For health professionals, the Internet provides access to research on clinical interventions and online seminars for exchanging professional knowledge, news, and meeting announcements. In addition, the Internet contains numerous pamphlets, brochures, and other self-help resources that can be given to clients. Health professionals use e-mail to conduct research, write articles, and disseminate professional news and events.

Health professionals must be constantly engaged in learning activities. The Internet is fast becoming the prevailing infotechnology for learning, especially activities involving information retrieval, processing, creation, and communication. Its usefulness in training skills such as direct care in nursing and psychotherapy is still limited, but the Internet is a powerful infotechnology tool for staying current with research findings, learning about developments in the health field, and engaging in peer collaboration and supervision. This shift in educational principles and practices related to networked digital technologies will affect the whole clinical educational enterprise. As one example, the venerable clinical training institutions of ground rounds is now being placed online—at the University of California at Los Angeles (UCLA), Stanford, and University of Chicago.

Since Hippocrates, health professionals have held interdisciplinary case seminars to disseminate the latest understandings in their fields. The Internet allows health professionals to participate in online case seminars that expand their personal knowledge base and refine their professional skills. Like a case seminar, the Internet is inherently cross-disciplinary. During a search, resources on health are found from the perspectives of all health care disciplines (e.g., medicine, psychology, nursing, social work, etc.). The information exchange and communication capacities of the Internet create a global virtual case seminar which provides access to cross-disciplinary resources and colleagues.

Telehealth and Psychological Services

Telehealth is generally used as an umbrella term to describe all the possible variations of healthcare services using telecommunications, such as health assessment, diagnosis, intervention, consultation, supervision, education, and information across distance. Telehealth includes the delivery of health services via the Internet but also includes telephone, television, video, and fax. There is a convergence of functions and hardware in the telecommunications field. Videoconferencing, for example, can be conducted over the Internet using cameras connected to computers, or the data can be sent over telephone lines, or over a closed proprietary Intranet. Telehealth is likely to become a significant part of the future of health care. The U.S. government already heavily invests in telehealth—more than $20 billion in 2000 (mostly in the military). Congress specifically included funding for $200 million per year for telemedicine reimbursement in Medicare. Telehealth has already become a major part of certain specialties.

In medicine, several specialties have already developed approaches that make use of the Internet. Teleradiology, the sending of X rays, computed tomographic scans, or magnetic resonance images (store-and-forward images) is the most common application of telehealth in use today. There are hundreds of medical centers, clinics, and individual physicians who use some form of teleradiology. In telepathology, images of pathology slides are sent from one location to another for diagnostic consultation. Dermatology also makes use of interactive technology for exams. Digital images may be taken of skin conditions, and sent to a dermatologist for diagnosis.

Two-way interactive television (IATV) is used particularly in rural and wilderness health care when a "face-to-face" consultation is necessary. It is usually between the patient and his or her provider in one location and a specialist in another location. Videoconferencing equipment at both locations allow a "real-time" consultation to take place. It can make specialty care more accessible to underserved populations. Video consultations from a rural clinic to a specialist can alleviate prohibitive travel and associated costs for patients. Videoconferencing also opens up new possibilities for continuing education or training for isolated or rural health practitioners, who may not be able to leave a rural practice to take part in professional meetings or educational opportunities.

The military and some university research centers are involved in developing robotics equipment for telesurgery applications. A surgeon in one location can remotely control a robotics arm for surgery in another location. The military has developed this technology particularly for battlefield use, and some U.S. academic medical centers and research organizations are also testing and using the technology.

The first use of telecommunications in mental health projects date back to 1959, when the University of Nebraska School of Medicine began experimenting with a closed-circuit television link to provide psychiatric and other health services between the Nebraska Psychiatric Institute and Norfolk State Hospital. Telehealth is just taking off as a means of delivering professional service. Although barriers and challenges to the adoption of telehealth have been discussed since its inception, only in the last few years has a solid consensus emerged as to what those barriers are and just how they should be addressed. That consensus, coupled with consumer and commercial demand for affordable telecommunications technology, has spurred health care communications and other manufacturers to develop affordable, user-friendly systems. Finally, legislators, seeing affordable technological options, hearing consensus around both barriers and solutions, and receiving requests from undeserved constituents that the government help implement such solutions, have begun to act to ensure that telehealth technology becomes a significant part of the continuing evolution of health care (Kirby, Hardesty, & Nickelson, 1998).

Online Therapy

The first attempt to use computers for delivery of therapy dates back to a 1972 demonstration of a psychotherapy session between computers at Stanford and UCLA. The earliest known organized service to provide mental health advice online is Ask Uncle Ezra, a free service offered to students of Cornell University in Ithaca, New York (named for Ezra Cornell, the University's founder), which has been in continuous operation since September 1986. Fee-based mental health services offered to the public began to appear on the Internet in mid-1995. Most were of the "mental health advice" type, offering to answer one question for a small fee. Ainsworth (2002) maintains a Web site database that describes what services online therapists offer, ranging from e-mailed answers to questions to two-way video, and she also runs credentials checks to make sure they have the licenses and degrees they claim. She reports that in the fall of 1995, when she first did a search, she found 12 e-therapists practicing on the Internet. By 2002, her database had grown to include more than 300 private-practice Web sites on which e-therapists offer services, and the new e-clinic represent collectively nearly 700 more e-therapists.

Despite the increasing numbers, use of the Internet to provide psychotherapy is controversial. Even most therapists who deliver services via the Internet do not claim that what they are doing is psychotherapy. Most clearly state that the exchanges are educational rather than therapeutic in nature. Traditional psychotherapy does not seem to be part of the online offer of mental health services. Yet there is little doubt that many people have been helped, some profoundly, by interacting with mental health professionals over the Internet. Ainsworth (2002) describes her personal e-mail-based online therapy, which lasted 2 years without ever seeing or talking to her therapist.

> I would compare it to keeping a journal in that every day when I wrote him an e-mail I explored my thoughts and feelings in great depth. But usually when you keep a journal it doesn't talk back to you. He challenged me. The fact that we communicated by e-mail, I think, made me feel like he was inside my head and present in my life.

The International Society for Mental Health Online (http://ISMHO.org) was formed in 1997 to promote the understanding, use, and development of online communication, information and technology for the international mental health community. After considerable discussion and debate, they published "Suggested Principles for the Online Provision of Mental Health Services." Their guidelines address many issues that apply to all forms of therapy but have a unique application to online modes of delivery, such as the following:

- Ensuring competence in online delivery of therapy,
- Conformity with state online practice guidelines,
- Structure of the online services,
- Turnaround time, and
- Privacy of the counselor (the therapist's right not to have e-mail or other communications disseminated).

A promising area in online delivery of health services is virtual reality exposure therapy, which involves exposing the patient to a virtual environment containing the feared stimulus in place of taking the patient into a real environment or having the patient imagine the stimulus. A team of therapists and computer scientists developed a treatment for fear of heights (acrophobia) that was shown to be effective in reducing acrophobic subjects' anxiety and avoidance of heights and in improving attitudes toward heights. The developers note that this virtual reality approach is particularly amenable to telehealth:

> Virtual reality exposure therapy is appropriate for networked delivery of clinical psychology and psychiatry services to remote locations. Since the patient is receiving therapy within a virtual environment, the clinician conducting the therapy session could be present physically or participate via computer networks from a remote location. (Kooper, n.d.)

State regulations vary from state to state, however, and by virtue of state-based licensing system for health professionals, guidelines developed in one state would only apply to therapists licensed in that state. The patchwork of licensing regulations has functioned as an impediment to dissemination of telehealth initiatives. For example, in California, the Telemedicine Act of 1996, while mandating some forms of payment for telemedicine, does restrict the provision of mental health services to patients within the state boundary. Yet few doubt that telehealth will play an increasing role in health delivery, as the Internet expands it influence on a wider and wider range of human behavior and experience.

CONCLUSION

The Internet offers both consumers and professionals new opportunities to expand their knowledge base and to obtain support for their health problems and work. Yet, as with other technologies, there are costs to the fabric of the psyche and society that require adjustments in how people relate to the medium and each other. Despite its recent development, the rate of adoption of online communication is unparalleled in human history. It will be many more years before the full implications of the Internet for health and well-being are understood and addressed. Meanwhile, the Internet will expand in its usefulness and create new problems for society to address.

GLOSSARY

Disinhibition A lack of interpersonal feedback characteristic of face-to-face communication that can lead to enhanced self-disclosure as well as personal attacks.

Internet addiction Dysfunctional Internet use patterns.

Mediated communication Non–face-to-face interactions conducted with a communication medium.

Neurosphere A "global mind" created by the information sharing and communication capacities of the Internet.

History of the Internet

John Sherry, *Purdue University*
Colleen Brown, *Purdue University*

INTRODUCTION

In his prophetic and now famous 1945 *Atlantic Monthly* article, Vannevar Bush noted that inefficiencies in the exchange of new theory and discovery slowed scientific progress. He envisioned a system for rapid dissemination and organization of scientific information, instantly available to all who seek it, which he named the "memex." The memex was to be a "transparent platen" on which books, pictures, periodicals, newspapers, longhand notes, photographs, and other information would be provided to anyone who had access to the machine and knowledge of its indexing system. He foresaw scientists accessing information from around the world at unprecedented rates based on the same associational principles by which the human mind operates. Further, he saw scientists and professional data miners recording their journey through the data such that anyone who was interested could follow. A half century after the article appeared, his vision was realized in the form of the World Wide Web and related Internet technologies. This is the story of the inventors, ideas, and innovations that made Bush's vision a reality.

The Internet was created by a collection of visionaries and executed by hundreds of individuals whose contributions helped develop the technology (for a time line, see Figure 1). The result is the technological and intellectual infrastructure of the Information Age, supporting the majority of the emerging economy for the 21st century. How did this marvel come to be? This chapter tells the story of the creation of the Internet and the World Wide Web. Guided by a unique vision of computer communication in a world of calculating machines and driven by the desire to solve a series of complex engineering problems, the Internet emerged as an open-architecture marvel of scientific and engineering cooperation. The principles that guided the creation of the Internet typify the finest realization of American cooperative scientific ideals. The Internet as we know it is the result of dedication to a set of core principles: that this communication system be the result of cooperation among interested parties, be open to new ideas, and be scalable. The vision was realized in a series of fits and starts, problems and solutions, ideas and the implementation of those ideas by engineers pushing the boundaries of current technology. It is the result of intellectual and political argumentation and compromise, funded by the military–industrial complex, but realized in the world of the academic. This chapter can hardly be called a history, though, because the open architecture of the Internet encourages further experimentation. Instead, this chapter can best be called a beginning.

A UNIQUE VISION

The Industrial Revolution of the 19th century brought about the development of technologies that allowed people, ideas, and products to travel across long distances in a short amount of time, facilitating exploration of scientific and technological frontiers (Moschovitis, Poole, Schuyler, & Senft, 1999). Nineteenth-century scientific exploration laid the groundwork for the technological antecedents of modern computing and networking that came into popular use in the first half of the 20th century, from the telephone to such early colossal computers as ENIAC. These early 20th-century technologies were similarly dedicated to two goals: the desire to increase the ease of communication across distance and the desire to provide resources that assist humans in the efficient processing of information. However, it was the charged atmosphere surrounding the Cold War that provided the initial momentum to bring these two goals together as a matter of national defense and pride.

The Marriage of Science and National Defense

By the late 1940s, the Soviet Union had long-range bombers and atomic capabilities. The Department of Defense, under President Harry Truman, enlisted the help of researchers at RAND and the Massachusetts Institute of Technology (MIT) Lincoln Laboratory to develop the

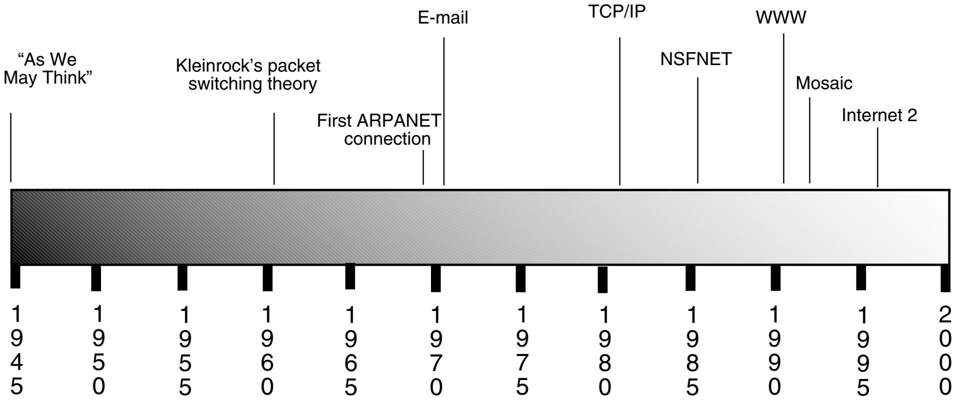

Figure 1: Timeline of major Internet events.

Semi-Automated Ground Environment (SAGE) to detect and counteract Soviet airborne attacks (Segaller, 1998). It was at this time, the 1940s and early 1950s, that many of the graduate students and scientists at MIT and Lincoln gained the preliminary experience necessary to create networked computers, including connecting computers to phone lines, using computers to handle real-time data coming from antennas and submarines, digitizing communications, and developing and refining faster, more reliable computers (Segaller, 1998).

On October 4, 1957, the Soviets launched Sputnik, the first human-made Earth satellite. The Eisenhower administration's fears of technological weakness were ignited; the Soviet Union was leading the United States in space technology. Science and technology were instantly wed to national defense and the relationship was thrust into the social and political limelight as President Eisenhower, a strident supporter of science prior to Sputnik, ensured the panicked public that he was committed to providing massive support for defense research. Eisenhower immediately convened a meeting of his Presidential Science Advisory Committee, and in November 1957, he appointed MIT president James Killian as the official presidential scientific advisor (Hafner & Lyon, 1996).

ARPA Is Created

Working closely with President Eisenhower and the Secretary of Defense, Neil McElroy, Killian recommended that Congress create the Advanced Research Projects Agency (ARPA) within the Department of Defense (Zakon, 2002). Congress quickly approved start-up funds of $520 million and an annual budget of $2 billion. In early 1958, ARPA was officially established as the U.S. government's sole research agency dedicated to the development of space-related military technology. The vigorous national commitment to beating the Soviets in defense and space technology had officially begun for the government and the American public. Although much of the computer-related funding at this time came from the Department of Defense, many of the scientists involved with ARPA used the surge in governmental support as an opportunity to realize their academic pursuits (Abbate, 1999). The intersection of military, governmental, academic, and public goals remains an integral part of the creation and maintenance of the modern Internet.

In 1958, the National Aeronautics and Space Administration (NASA) was split from the computer research section at ARPA in order to oversee all space exploration and missile research and to assure that this technology was developed in the civilian sector. ARPA was left with the relatively meager budget of about $150 million. However, the removal of space and missile research from ARPA's agenda allowed researchers to focus greater effort on the emerging fields of computer science and information processing. At this point, ARPA directly funded most of the top computer science researchers in the United States and at least partially funded projects at most of the research centers and universities engaged in high-tech endeavors (Hafner & Lyon, 1996).

Networking Visions Emerge

In 1962, the first director of ARPA, Jack Ruina, hired mathematician, behavioral psychologist, and burgeoning computer science connoisseur Joseph C. R. "Lick" Licklider to head ARPA's command and control division. In his groundbreaking essay "Man-Computer Symbiosis," Licklider (1960) proposed the idea of interactive computing, an idea taken for granted by every personal computer user today. Inspired by the visionary works by Bush (1945) and Alan Turing (1950) on the use of computers to augment human intelligence, Licklider also prophesized that computers would become more than mere calculating tools. He envisioned that the relationship between humans and computers would evolve and result in cooperative decision making and problem solving in real time, that is, without the long delays that characterized computing in the 1950s (Licklider, 1960).

In addition to envisioning the eventual state of interaction between human and computer, Licklider was the first to envision the linking of many computers at locations distant from each other. Nine years before it became a reality, he wrote:

> It seems reasonable to envision . . . a "thinking center" that will incorporate the functions of present-day libraries together with anticipated

> advances in information storage and retrieval... The picture readily enlarges itself into a network of such centers, connected to one another by wide-band communication lines and to individual users by leased-wire services. In such a system, the speed of the computers would be balanced, and the cost of the gigantic memories and the sophisticated programs would be divided by the number of users. (Licklider, 1960, p. 15)

Licklider expanded on the idea of a system of linked computers in a series of historically important memorandums written with Wesley Clark, entitled "On-Line Man Computer Communications" (Licklider & Clark, 1962). They wrote of a "galactic network" where computers and information would be linked and accessible to everyone. Larry Roberts, a successor of Licklider's at MIT, commented that, "[t]he vision [of linking many computers together] was really Lick's originally. Lick saw this vision in the early sixties. He didn't have a clue how to build it. But he knew it was important" (Segaller, 1998, p. 40).

Licklider's outline of an interactive network linking people and resources together was also seen as a possible solution to a practical problem surrounding computing in the early 1960s: stretched resources. In the 1950s and 1960s, ARPA had commissioned laboratories around the country to carry out a variety of projects in science and technology, providing each with large, expensive mainframe computers manufactured by different companies. Individual laboratories altered their computers, adding different applications, packages, and hardware, and each subsequent laboratory wanted the latest computing capabilities available. The enormous costs of building separate units for each project began to snowball.

In early 1966, Robert Taylor, director of the Information Processing Techniques Office (IPTO, the computing division of ARPA), proposed a remedy to the scarce resource problem that incorporated the latest research and developments: Build a system of electronic connections between research computers at different geographical locations across the country to allow convenient, quick, and inexpensive sharing of resources between many scientists (Hafner & Lyon, 1996). The idea of networking was already being implemented on a smaller scale, for example linking two computers together (Marill & Roberts, 1966), but nothing that approached the scale or complexity of Taylor's proposition had been attempted so far. The technology of the time did support such a notion. In 1958, communications engineers at Bell Laboratories had built the modulator–demodulator, or simply "modem" (Anderberg, 2002). The modem made it possible to convert data from the digital computer format into the analog telephone line format, send it over existing phone lines, and translate it back to digital computer format. By using the long-distance infrastructure already in place, the task of linking many computers for the purpose of sharing resources was indeed an attractive and financially sound proposal. In 1966, Taylor pitched the idea to his boss, ARPA Director Charlie Hertzfeld, and received approval and financial support to build the experimental network. In 1967, Taylor enticed Larry Roberts to leave Lincoln Lab and join him at ARPA to begin planning the proposed computer network, which would soon become known as the ARPANET (Segaller, 1998).

Networking: From Theory to Practice

Although Licklider imagined what a distributed, interactive computer network could accomplish and Taylor imagined what problems it could solve, Leonard Kleinrock had theorized in 1961 the new communication technology that could make such a network possible (Hafner & Lyon, 1996). Two major obstacles to creating a long-distance computer network were (a) being able to receive and process data over existing phone lines fast enough to allow efficient, real-time processing, and (b) creating a network that could support the unique needs involved in the exchange of computer-generated data. While an MIT graduate student in 1961, Kleinrock proposed what would later be called "packet-switching" technology, the most efficient way to send data over a network (Kleinrock, 1961, 1964). Two other researchers, Bob Davies at the British National Physical Laboratory (NPL) and Paul Baran at the RAND Corporation, were also investigating the idea of packet switching in unrelated research projects in the early 1960s (Baran, 1964; Davis, Bartlett, Cantlebury, & Wilkinson, 1967). Ultimately, Davies and his group of researchers at NPL would be the first to test a packet-switching network within a building, in Middlesex, England, in 1967 (Zakon, 2002).

Packets, Queuing, Demand Access—The Theory of Networking

Packet switching involved chopping messages into packets, assigning each packet a number, sending the packets of data independently through the network, and reassembling the packets at the other end in the proper order in readable form (Hafner & Lyon, 1996). The packets could queue up at nodes in the network until they were requested (demand access). In this fashion, network resources could be used as needed and not tied up with open circuits. Researchers hypothesized that packet switching would be a dramatic improvement over circuit-switched telephone networking because it avoided the inefficiency of a continuously open connection. In order to put packet-switching data transfer theory into action, however, ARPANET researchers had to address several key obstacles.

ARPANET planners were well aware that the computers that would be connected to the network were incompatible. Each ARPA-funded site had purchased different mainframe computers from different companies, using different operating systems and different languages (Segaller, 1998). Moreover, each site research team was only familiar with the operation of the computer in their respective laboratory. How could these mainframe computers be connected, share data, and communicate with one another with a minimum of errors? Taylor called a meeting of ARPA-funded researchers at the University of Michigan in early 1967 to discuss this and other unresolved network design issues (Anderberg, 2002).

Building on an idea proposed by Wesley Clark, a computer scientist at Washington University in St. Louis, the ARPA researchers envisioned a system of smaller,

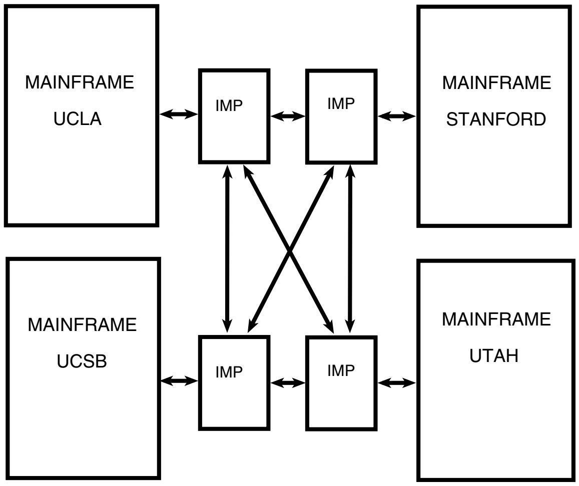

Figure 2: The interface message processing design.

intermediate computers called Interface Message Processors (IMPs) to solve the mainframe-to-mainframe incompatibility problem (Abbate, 1999). Each IMP would act as an interface between the network and its mainframe computer (see Figure 2). Every mainframe had to send the same format packets to the IMPS and there was a standard interface all mainframes had to implement. NCP dealt with incompatibilities on an end-to-end basis. Each site's mainframe would communicate with its own IMP, and all IMPs would be designed to communicate with one another using the same operating system and speaking the same language. Roberts distributed a Request for Quotation (RFQ) to design and build the IMPs in July 1968 and received more than 100 proposals. He awarded the contract to Frank Heart and his team of computer scientists at Bolt, Benerak, & Newman (BBN) in Cambridge, Massachusetts, in December 1968 (Anderberg, 2002). The final step was deciding which sites would initially be connected to the network. Four sites, each with its own particular research specialties, were chosen: UCLA; the University of California, Santa Barbara (UCSB); Stanford Research Institute; and the University of Utah. The deadline for establishing the network at UCLA was set, somewhat arbitrarily according to Heart, for September 1, 1969, only nine months after the initial proposal was presented. Heart and his group would have $1 million and less than a year to turn theory into a working system (Hafner & Lyon, 1996).

In the summer of 1968, IPTO organized a meeting for graduate students from the universities that would be the first sites connected to the network to discuss the technological aspects of the proposed network. The meeting gave rise to the Network Working Group (NWG), which solidified the collaborative nature of the ARPANET project (Abbate, 1999). Rather than one single scientist taking charge of the direction of the group, the attendees recorded their thoughts and deliberations in a set of notes that Steve Crocker soon named Request for Comment (RFC). Crocker published the first RFC in April 1969, detailing the interface between the hosts and IMPs and asking for input on problems (Crocker, 1969). The RFC became firmly established as a means of communicating information and seeking feedback about networking issues, and it was supported by all levels of researchers. This open manner of sharing ideas in the realm of scientific discovery remains in place to this day and, by many accounts, influenced the eventual spirit of community associated with the modern-day Internet (Internet Society, 1999). The entire series of RFCs have been collected and catalogued by Jon Postel, the RFC editor for more than 30 years, and are available for viewing (RFC Editor Homepage, n.d.).

It is important to note that at this point, the number of researchers working on the development of ARPANET was relatively small. In fact, as news of the proposed network spread to scientific circles across the country, the idea was met with little enthusiasm. To the many ARPA-funded research teams, the idea of sharing resources across a network meant that "outsiders" would be meddling in their private computing centers and that their hard-earned computing equipment and power would be depleted. To researchers who still hoped that ARPA would fund their projects, the idea of a network meant that ARPA might not purchase new mainframes for them. Roberts, Taylor, and Licklider tried to win the support of the largely uninterested and skeptical ARPA-funded researchers, eventually resorting to subtle "blackmail" (Segaller, 1998), reminding each site that as they were being supported by ARPA to the tune of hundreds of thousands, if not millions, of dollars a year, they should be just as enthusiastic about the project as the project managers were. Needless to say, ARPA-funded researchers started to outwardly come around, though inwardly most doubted the venture would work (Moschovitis, Poole, Schuyler, & Senft, 1999).

ARPANET Comes Alive

By early 1969, the researchers at BBN were working around the clock to develop the IMPs by the deadline, while the research teams at each university were busy developing the custom software and hardware that would allow communication between their mainframe and the IMP. Significant challenges arose every day, all of which had to be resolved under the pressure of the looming deadline. To everyone's amazement, the UCLA IMP was delivered in time for the September 1 deadline and the IMP-mainframe connection was ready to go a few days later (Zakon, 1993). The first test of the packet-switching technology, between the UCLA IMP and its mainframe, was a success. On September 2, 1969, the two machines began talking to each other. The second IMP arrived, at Stanford Research Institute, on schedule one month later and their first official test occurred on October 1, 1969 (Hafner & Lyon, 1996).

The plan was to log-on from the UCLA host to the Stanford host by typing "LOG IN." An L was typed at UCLA and Stanford received an L. An O was typed at UCLA and Stanford received an O. A G was attempted and the system crashed. A couple of hours later, however, the system was up and running again, and the researchers successfully logged onto the network, performed some minimal operations, and logged off. The connection between UCLA and Stanford was a success, and the remaining two nodes, one at UCSB, and one at the University of Utah, were working by the end of the year (Zakon, 1993). The technology of ARPANET proved that a long-distance packet-switching computer network was possible. Eventually, the ARPANET helped ARPA cut its computer budget by 30% and impressed the skeptics by providing them with more computing power and allowing researchers at different institutes to exchange papers, data, ideas, and software programs and upgrades.

GROWING THE NETWORK

The fifth ARPANET node was installed at BBN in March 1970, and over the next few years, Vint Cerf and Steve Crocker, under Kleinrock at UCLA, and Frank Heart and Bob Kahn, then at BBN, all worked to push the network to the limit, intentionally breaking the network in order to discover weaknesses in the design. They also formed the International Network Working Group in 1972 to coordinate standards. As the number of sites connected to the network steadily grew, moving from the West Coast to the East Coast, new technological innovations kept emerging, some expected and some surprising.

Electronic Mail: The "Killer" Application

In 1971, Ray Tomlinson, a computer engineer at BBN, devised an experimental program, called CPYNET, for sending files between computers. Tomlinson added an additional program to CPYNET for sending and receiving messages, called SNDMSG and READMAIL (Hafner & Lyon, 1996). Within a few months, Tomlinson's application was being used to send messages over the network to machines in different geographical locations. Tomlinson paired each user's name with the user's host machine identification using the symbol "@" (meaning "at"), not knowing he was coining the universal symbol of the soon-to-be wired world (Hafner & Lyon, 1996). The resulting application, "e-mail" for short, was the first killer application for the emerging network. The network e-mail capability spread rapidly, quickly becoming the most widespread use for the network in the early years. Kleinrock noted that "[a]s soon as e-mail came on, it took over the network. We said, 'Wow, that's interesting'. We should have noticed there was something going on here. There was a social phenomenon happening" (Segaller, 1998, p. 105). The original purpose of the network, to share computing resources across distant geographical locations, was surpassed by its use as a communications tool. The instant popularity of e-mail among the scientists came as quite a surprise because the rationale for building the network was to share access to computers, not access to people (Abbate, 1999). Other applications were soon developed that facilitated the creation of "virtual" work groups and news groups, firmly establishing the network as a "virtual community" (Moschovitis, et al., 1999).

ARPANET Makes Its Public Debut

At this point, the use of ARPANET was almost exclusively confined to the networking branch of the computer science community, and the general public was unaware of the existence of it. Roberts knew that if the network was ever going to be widely adopted, it was time for a demonstration. Kahn and a small group of principle investigators were asked to devise a showcase of network capabilities. In 1972, ARPANET debuted to the public at the International Conference on Computer Communications (ICCC) in Washington, D.C. (Moschovitis, et al., 1999). By that time, ARPANET had expanded to 15 nodes with 23 sites.

ARPANET's debut to computer vendors, university representatives, government officials, scientists from a variety of disciplines, and the press at ICCC was a success. The system crashed only once over the weekend conference, and oddly enough, this gave Kahn and his colleagues the opportunity to show that problems were fixable (Hafner & Lyon, 1996). The conference attendees were astonished, curious, and anxious to become a part of the network; the buzz had officially begun. Although access to ARPANET was still under the tight control of ARPA and the U.S. Department of Defense, the demonstration at ICCC ignited curiosity and confidence in other networking projects. The early 1970s proved to be an intense period of network experimentation. Within 3 years of the first ARPANET transmission over telephone lines, different types of networks using packet-switching technology emerged. ARPANET remained under the control of the Department of Defense; thus, rather than expand the existing ARPANET, new networks were created. Networks that linked computers through radio connections, such as the ALOHAnet at the University of Hawaii, and ones that used satellites to link computers, such as SATnet, were popping up all over the world (Segaller, 1998).

A NETWORK OF NETWORKS

The success at the ICCC conference swelled the ranks of computer scientists who were interested in packet-switching networks. But the 1972 conference revealed that there remained a significant obstacle to realizing Licklider's ultimate vision of "... a 'thinking center' that will incorporate the functions of present-day libraries together with anticipated advances in information storage and retrieval and the symbiotic functions." Although computers within a network could be used for time-sharing electronic communication and the sharing of files, these same options were not possible between networks. That is, a computer scientist working at the University of Utah (ARPANET) could not exchange files with a colleague at the University of Michigan (MERIT). In order for the existing computer networks to become connected, there needed to be a new protocol so that computers on different networks could communicate with each other.

Robert Kahn began researching the internetworking problem at ARPA in 1973 (Kahn, 1994). In many ways, the problem of inter-networking was similar to the earlier problem of making dissimilar computers communicate that had been solved by using the IMPs. That is, each network used a different language to control the packet switching, preventing computers on different networks from being able to communicate with each other.

Kahn decided that the network of networks needed an open architecture that would allow for innovation within networks, without requiring existing networks to abandon their software. The problem of connecting networks was solved similarly to the earlier problem of connecting computers in a network. Kahn's main collaborator, Vinton Cerf, proposed the idea of "gateways" between the networks that would employ a common language or protocol. These gateways would allow networks to interconnect in much the same way that the IMPs originally allowed computers to interconnect. Thus, Kahn and his team specified a set of four requirements for the inter-network:

> Each distinct network would have to stand on its own and no internal changes could be required to any such network to connect it to the Internet. Communications would be on a best effort basis. If a packet didn't make it to the final destination, it would shortly be retransmitted from the source. Black boxes would be used to connect the networks; these would later be called gateways and routers. There would be no information retained by the gateways about the individual flows of packets passing through them, thereby keeping them simple and avoiding complicated adaptation and recovery from various failure modes. There would be no global control at the operations level. (Leiner, et al., 1994)

A common language was needed to allow computers from different networks to communicate with one another. Network control protocol (NCP), the software used to oversee packet switching on the ARPANET, lacked end-to-end host error control because packets never traveled outside the ARPANET. Cerf and Kahn wrote the transmission control protocol/Internet protocol suite (TCP/IP) to implement the packet-switching process at gateways (Cerf & Kahn, 1974). It took four incarnations before the final TCP/IP software was considered ready for deployment. TCP would be responsible for service features involved in the packet-switching process, including flow control and lost packet recovery, whereas the IP was used for the addressing and forwarding of individual packets. Standardized 32-bit IP addresses were assigned to each computer on the Internet; the first 8 bits signified the network and the other 24 bits designated the host on that network. Initially, TCP/IP protocol was used to connect the ARPANET (50 kbps) land lines, the Packet Radio Net (PRNET at 400/100 kbps), and the Packet Satellite Net (SATNET at 64 kbps; Kahn, 1994). On January 1, 1983, the ARPANET made the transition from NCP to TCP/IP as the standard protocol for networking on ARPANET. Now, it was possible to interconnect networks and the *Internet* was born.

Standardization of the TCP/IP software led to the development of commercially available gateways and routers for industry workstations, minicomputers, and mainframes. As the number of local area networks (LANs) increased, so did potential engineering incompatibility problems. The Internet Activities Board (IAB) was founded in 1983 to oversee standardization of networks. For example, the IAB designated three network types based on the expansion of network interconnectivity: class A, which were large-scale national networks; class B regional networks; and class C local area networks. With increasing interconnection came difficulty in locating information on the Internet. IP addresses of all host computers were found in a distributed file called HOSTS.TXT. Eventually, the updating of this file became a bottleneck, so Paul Mockapetris of USC/ISI invented the domain name system (DNS) to alleviate this problem (1983a, 1983b). DNS assigns and tracks easy-to-remember names to IP addresses across the Internet (e.g., purdue.edu).

The ARPANET/MILNET Split

By 1984, the computer architecture for the Internet was in place, and a number of computer networks, both governmental and commercial, had emerged. Within a few years, there were a number of networks linking geographically proximate universities. Among these networks were the following.

ARPANET (1969)—UCLA, Stanford University, UCBS, University of Utah, BBN, MIT, RAND Corporation, SDC, Harvard University, MIT's Lincoln Laboratory, University of Illinois—Urbana/Champaign, Case Western Reserve University, Carnegie Mellon University, NASA/Ames.

MERIT (1969)—University of Michigan, Michigan State University, Wayne State University.

THEORYNET (1977)—University of Wisconsin.

USENET (1979)—Duke University and University of North Carolina.

CSNET (1981)—University of Delaware, Purdue University, University of Wisconsin, RAND Corporation, and BBN.

BITNET (1981)—City University of New York and Yale University.

The expansion of the Internet to broader academic and commercial interests raised concerns about the security of Department of Defense information on the Internet. For that reason, the military component of the Internet was separated from the Internet, resulting in two networks: ARPANET and MILNET (the new military portion of the Internet). Computers on the MILNET would still be able to communicate with computers on the ARPANET, but the architecture was designed such that MILNET could be quickly disconnected from ARPANET in case of a threat of a security breach.

The NSFNet

Perceiving the advantage of the Internet for scientific research, the National Science Foundation (NSF) decided to expand use of the Internet beyond the limited number of computer scientists and defense contractors and make it available to all disciplines for research and education. Dennis Jennings was responsible for the initial decision to use TCP/IP to build a network linking the NSF-sponsored super computer sites. In 1986, the NSF brought in Steven Wolff to oversee construction of a new research network (Leiner, et al., 1994). Wolff was charged with developing a computer network that would facilitate cooperative research and that would eventually outgrow its need for NSF funding. In order to do this, Wolff created policy designed to encourage broad-based use of the Internet while encouraging the creation of separate, commercial, long-haul networks. The NSF required universities seeking funding for an Internet connection to make connections available to all qualified users on campus. Further, they encouraged growth of regional networks by urging regional networks to seek commercial, nonacademic customers in order to expand use of the networks, take advantage of increased economies of scale, and ultimately lower subscription costs. They also wrote the Acceptable Use Policy, which restricted use of the national NSF network to academic and research work (National Science Foundation, 1986). It was believed that denying commercial users access to the national network would encourage creation of nationwide commercial networks. This strategy paid off when commercial Internet long-haul carriers UUNET and PSI opened.

In 1986, the NSF launched the NSFNET backbone, a high-speed (56 kbs) network connection between six supercomputer centers running across the United States. It was built by MCI, IBM, and MERIT (the University of Michigan). The supercomputer centers were at Princeton, Cornell, Carnegie-Melon, the University of Illinois, the University of Colorado, and the University of California, San Diego. In under nine years, the NSFNET backbone grew from 6 nodes at 56 kbs to 21 nodes at 45 mbs, connecting 50,000 networks on all seven continents and in space.

FINDING OURSELVES IN VIRTUAL SPACE

A network with the breadth and reach of the Internet quickly surpassed users' ability to keep track of the location of information. With 50,000 networks, keeping track of files and IP addresses quickly became impossible. Soon computer scientists began writing software to help users find and transfer files. One of the most popular was Gopher, released in 1991 by Paul Lindner and Mark P. McCahill from the University of Minnesota. Gopher, and its descendents, allowed users to search through "Gopher space" for files to transfer via file transfer protocol (FTP). Gopher was an Internet protocol that provided menu-driven file-and-data retrieval from remote computer servers (Anklesaria, et al., 1993). Gopher sites organized files for retrieval and were set up to be searched by users. Although they were text based, these early versions of internet searching software greatly simplified the problem of finding files on the Internet.

All this was soon to change. Desktop computers were becoming easier to use because of graphical user interfaces, developed at the Xerox Palo Alto Research Center (PARC), and the commercially distributed Apple Macintosh operating system, in 1984. One year after the introduction of the Macintosh operating system, Microsoft released the Windows 1.0 operating system in an attempt to replace MS-DOS text commands with an intuitive point-and-click graphical user interface similar to the Macintosh operating system, although the Windows operating system would not become commercially popular until the introduction of version 3.0 in 1990 (Microsoft, 2002). Computing power that the early Internet pioneers could only dream of had found its way to business desktops, elementary school classrooms, and home recreation rooms. Access to the Internet was increasingly supplied to the general public through commercial gateways and public access points, such as Michigan's MERIT network and Cleveland's Freenet. The number of hosts on the Internet had grown exponentially through the 80s (see Figure 3). But the biggest change in the Internet was still to arrive.

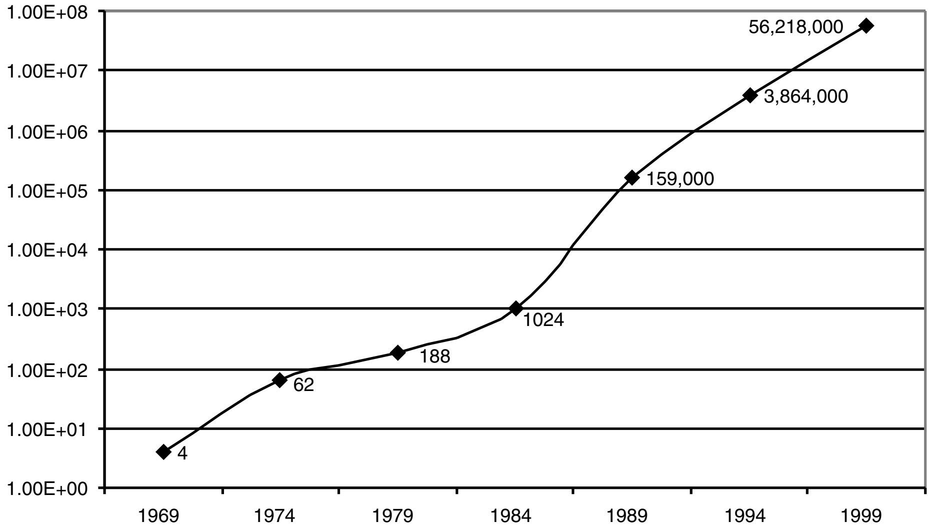

Figure 3: Exponential growth of Internet hosts.

The World Wide Web

In the late 1980s, Tim Berners-Lee was a research fellow at the European Laboratory for Particle Physics (CERN) in Switzerland. He had become intrigued with using computers to organize information via hyperlinked connections. As his ideas developed, his vision fixed on a scalable system for linking related documents via the Internet. It was important that such a system not use a central database to keep track of files, as updating the database would limit its speed and size to available resources (because of computer storage limits and the human resources needed for updating the database). Instead, Berners-Lee wanted all system users to be able to both find and contribute information. Administrators at CERN had a difficult time understanding what use they could make of Berners-Lee's invention and would not provide financial support for him to pursue the idea. Nonetheless, he persevered and finally received financial support in the form of a new NeXT computer.

Steve Jobs was forced out of Apple in 1985 and started up NeXT computers. Jobs felt his computers were the "next" great advance after the Macintosh for desktop computers. Berners-Lee found that much of what he needed to create his World Wide Web (WWW) hyperlinking software was available on his NeXT computer. He developed an early prototype WWW browser to make the CERN phone directory available online. From this modest success, he continued to promote the use of the WWW both inside and outside of CERN. He traveled to the United States to display the WWW at a conference of hypertext developers, posted information about the WWW on Internet user groups, and provided telnet access to the browser on a server at CERN so that people could try it out.

Berners-Lee's (1999) vision was that the WWW would maximize flexibility while accommodating standards that were already in play on the Internet. He wanted the WWW to be open to existing Internet protocols, so he designed it to read FTP, Gopher, network news (NNTP), wide area information server (WAIS), and other documents. This was accomplished, in part, by specifying the protocol at the beginning of the link address or uniform resource locator (URL). For example, links to FTP files began with "ftp://. . . " whereas links to Gopher sites began "gopher://. . . ." His own protocol for linking hypertext documents is the now familiar hypertext transfer protocol (HTTP). This software provided instructions on how to download and connect hypertext documents via the Internet. Finally, Berners-Lee standardized the language that Web page designers would use, called hypertext markup language (HTML).

The First Browsers and the Rise of Popular Internet

Despite the obvious advantages of the WWW, which we see in retrospect, few in the computing world were eager to adopt this new technology (Berners-Lee, 1999). Although Web browsers were developed for operating systems commonly used by computer programmers (e.g., UNIX), they were not available for the most commercially popular operating systems (PC, Mac), and Web editors were even more rare. Without a browser that was easy to install and without abundant content to discover, the Web was unlikely to take off. In 1993, Marc Andreessen and colleagues at the University of Illinois National Center for Supercomputing Applications (NCSA) released Mosaic, a web browser that was eventually available for UNIX, Macintosh, and PC. The immediate advantage of Mosaic was that it was graphical, user friendly, and easy to install. Mosaic caught on quickly, thanks in part to an aggressive public relations campaign by the University of Illinois. WWW use increased at a rate of over 340,000% in the first year. Soon new technologies proliferated on the WWW. By the end of 1995, real-time audio streaming was made available by RealAudio, RT-FM had begun netcasting from Las Vegas, the Arizona law firm Canter & Siegel introduced "spam" to the Internet by mass e-mailing of advertising for immigration services, banner ads were introduced, Sun Microsystems introduced JAVA, and virtual reality markup language (VRML) made its appearance on the Web.

In 1994, Mark Andreessen left the NCSA to form Netscape Communications with Jim Clark. Netscape soon produced its own version of the Mosaic browser, making it available for free to educational institutions and for a small fee to others wanting the use the WWW. Microsoft was slow to realize the potential of the WWW but aggressively joined the Web when Bill Gates decided to bundle a Web browser with the new release of Windows 95. Rather than write their own code, Microsoft bought the rights to a NCSA spin-off browser from a small company called Spyglass for $2 million (Berners-Lee, 1999). This marked the beginning of what became known as the "browser wars" between Netscape and Microsoft. Sensing competition in the market that they thought they controlled, Netscape urged the Justice Department to pursue antitrust action against Microsoft for bundling the browser with the most popular desktop operating system. Versions of this case, particularly in an antitrust suit brought by the U.S. Department of Justice, continue to be tied up in the courts (CNN, 2002).

In the years following 1995, the Internet, WWW, and related technologies became part of the public consciousness. Magazines, newspapers, and television programs increased coverage of this new technology. Debates erupted on Capitol Hill in Washington, D.C., about what content could be allowed on the Web. Maybe most important for the continued development and commercialization of the Internet, Congress passed the Telecommunication Act of 1996, opening up media and telecommunications companies to increased competition. People became troubled by such security issues as "hacks" and "viruses" even as they slowly began purchasing products from "e-tail" outlets, such as Amazon.com, and auctions sites, such as eBay.com.

CONCLUSION

The precursors of the Internet have outlived their usefulness. The ARPANET shut down in 1990 and the original NSFNET backbone followed in 1995. The NSF created the vBNS (very high performance backbone network service) through MCI in 1994 and it was used to link supercomputer centers sponsored by NSF. Nonetheless, there remains a place on the Internet restricted from trade and dedicated to researching and developing new communication technologies. Internet2 is a project of the University Consortium for Advanced Internet Development (UCAID) and it uses both the vBNS network and the Abilene Network from QWEST to achieve desired flexibility. Internet2, the very-high-speed backbone network, was created in 1996 and limited to research only. Internet2 continues to expand the horizons of new technologies, introducing richer communication experiences via three-dimensional immersive environments.

The Internet was born of the excitement of solving complex engineering problems in an open and collaborative manner. This led to an open-architecture design that has been flexible enough to support exponential growth in hosts and users as well as technological innovation in software. With a minimum of governance, the Internet has grown to be the information infrastructure for the 21st century, supporting exchange of audio and video files, animations such as Shockwave Flash, three-dimensional interfaces such as VRML, media wrappers such as QuickTime, chat rooms, and instant messaging. It is difficult to imagine where innovations on the Internet will take us, but it is clear we will never see the Internet in its final form. If future designers adhere to the simple rules of the Internet pioneers—an open architecture built through cooperation—we will likely never see the Internet stop evolving.

GLOSSARY

Advanced Research Projects Agency Network (ARPANET) Created by the U.S. Advanced Research Agency (ARPA) in 1969. ARPANET was a wide area network linking computers at various university research centers. ARPANET is considered the precursor to the modern-day Internet.

Analog Electronic transmissions that represent data by continuous signals of varying frequency (versus being sent as an "on or off" data transmission; see *Digital*).

Circuit switching A communication technology in which a dedicated path is established between the source and destination for the duration of the transmission. The telephone network is an example of a circuit-switching network.

Digital Electronic transmissions that represent data in various combinations or strings of 1's and 0's, with 1 representing "on," or "positive, and 0 representing "off," or "nonpositive."

Host A computer system containing data that is accessed by a user at a remote location.

Interface message processors (IMP) Smaller, intermediate computers connected to the mainframes involved in ARPANET. The IMPs were packet switches dedicated to the communications "subnet."

Internet A vast system of linked computer networks, international in scope, that facilitates data transfer and communication services, such as remote log-in, file transfer (FTP), electronic mail (e-mail), newsgroups, and the World Wide Web (www); always capitalized.

Intranet Internal network utilized within organizations allowing file sharing and collaboration. Intranets cannot (generally) be accessed from outside the organization.

IP address A numeric address that identifies host computers on the Internet.

Local area network (LAN) A network that connects computers in a relatively small geographical area (generally no more than 2 miles). LANs are used in offices, buildings, or a set of buildings.

Network A collection of two or more computers (and/or printers, routers, switches, or other devices) connected to one another allowing data to be shared and used over communication paths.

Network control protocol The host-to-host protocol of the ARPANET that operated above the layer of packet switching implemented in the IMPS. Once ARPANET transitioned from NCP to TCP/IP, it was possible to connect to other independent networks.

Node A connection point in a network, either for redistribution of data or as an end point for data transmissions.

Packet switching Method used to efficiently move data around on a network. Data is divided into smaller pieces called packets, assigned a number and destination, sent independently through the network, and reassembled at the other end.

Protocol Formal set of rules that govern how devices on a network exchange information; the "language" of a network.

Request for Comment (RFC) Document series used among researchers as the primary means of communicating ideas and information about the Internet.

Router The device that forwards packets between networks.

Transmission control protocol/Internet protocol (TCP/IP) The common language that allows existing networks to be connected, or "inter-networked." TCP implements flow control and recovery in packet switching, and IP is used for addressing and forwarding individual packets. TCP runs over IP and the two form part of a layered protocol stack.

Uniform resource locator (URL) A character string describing the location and access method of a resource on the Internet.

World Wide Web Invented in 1991 by Tim Berners-Lee, the World Wide Web is an application that facilitates exchange of hypertext documents via the internet. It uses a variety of protocols including HTTP, HTML, FTP, VRML, XML, and SSL.

HTML/XHTML (HyperText Markup Language/ Extensible HyperText Markup Language)

Mark Michael, *King's College*

INTRODUCTION

The World Wide Web Consortium's (W3C) claim that "HTML is the *lingua franca* for publishing hypertext on the World Wide Web" (W3C, 2003b) is no idle boast. In fact, by definition, the Web (a specific aspect of the Internet) did not exist until the introduction of the Internet's most famous duo: *HyperText Markup Language* (*HTML*) for structuring and formatting documents without the use of special characters and the *Hypertext Transfer Protocol* (*HTTP*) needed to transport HTML documents across the Internet.

HTML rapidly outgrew its original, limited purpose, viz., to display the text of Web pages and provide the ability for the viewer of one document to link to another. A great number of capabilities have been added to its repertoire. This growth was more chaotic than that for most languages. While Web development is not in quite the state of disarray that it once was, it still suffers from having to placate browsers with different methods of rendering HTML documents.

HTML has even outgrown the Web. It is also used as a format for e-mail messages and as a vehicle for displaying information about a computer's file directory. At the same time, the Web has outgrown HTML. New technologies have outstripped HTML's ability to adapt.

W3C is vigorously attempting an HTML renaissance. The reborn edition, the *Extensible HyperText Markup Language* (*XHTML*), is actually a family of languages and modules. Recommendations on these and supporting applications are coming out at such a fast clip that it is impossible to predict what the state of affairs will be by the time this is in print. What is clear is that HTML has reached the end of its usefulness as an all-purpose markup language for the Web, and the torch has been passed to XHTML.

Consequently, we will focus on XHTML. What we say about HTML is intended to provide a better understanding of XHTML as it stands at the moment this is written. Likewise, what is written here is merely a foundation for understanding XHTML in whatever incarnation it exists when this is read.

THE HISTORY OF HTML AND XHTML

To the extent that a sequence of distinct versions of a language can be considered a continuum, XHTML must clearly be seen as part of the continual evolution of HTML. W3C views XHTML as a family of document types; the HTML document types are in the extended family. W3C acknowledges this continuity by giving an overview of the entire HTML/XHTML lineage (except HTML 1.0) in a single Web page (W3C,2003b).

In recent years, the XHTML family tree—and the larger neighborhood—has begun to look more like a complex braiding of threads, with modularization coming between versions; extensions such as MathML preceding that; Document Object Model (DOM), Cascading Style Sheets (CSS), and Extensible Markup Language (XML) evolving in parallel; and alternative representations (XML Schemas) being thrown in as well.

The Genesis and Evolution of HTML

The inspiration for HTML can be found in the Standardized General Markup Language (SGML), which had been used for coding the structure of electronic documents since 1986. Tim Berners-Lee led work at the Conseil Européen pour la Recherche Nucléaire (CERN) in Switzerland to develop a simpler scheme—HTML—which also had the ability to include hyperlinks. The protocol—HTTP—needed to send HTML documents across the Internet was developed concurrently. CERN launched the markup language and the protocol in 1991, thus creating the World Wide Web.

HTML 1.0 was designed purely for rendering text-based documents in text-only browsers. Supported elements included: `title`, paragraph (`p`), headings (`h1` to `h6`), definition lists, unordered lists, and, most importantly anchor (`a`), for linking between documents. The characters `<`, `>`, and `&` were also part of the alphabet for the language.

The World Wide Web Consortium was formed in 1994 to provide guidance with regard to Web-related matters. Its early life saw its leadership role usurped by others, perhaps due to its initial slowness to act.

It was not until 1996 that W3C approved HTML 2.0, despite the fact that a successor to that version was proposed in 1993! It was only at this point that the `html`, `head`, `body`, `base`, `link`, `meta`, and `form` elements were officially added to the language. Ordered lists, inline elements (`b`, `cite`, `code`, `em`, `kbd`, `samp`, `strong`, `u`, and `var`), block elements (blockquote and pre), and breaks (`br` and `hr`) were also added. *Character entities* (e.g., `&copy;`) could now be used to render special characters (e.g., ©). Perhaps the biggest improvement was that graphic files could be rendered by browsers such as Mosaic and Cello thanks to the `img` element. This version possessed much of the functionality required of static Web pages.

The belated endorsement of HTML 2.0 was actually at the end of the fiercest period (1993–1996) of the "browser wars." The competition between newcomer Microsoft Internet Explorer and Netscape Navigator (later Communicator), which had replaced Mosaic as the dominant browser, created both chaos and a slew of innovations (some of which were eventually adopted by W3C) as each browser supported features not in the W3C recommendations. Despite the predicament this caused, Web developers nevertheless frequently chose to "optimize" their code for one or the other browser rather than code for the least common denominator. Thus, HTML documents contained elements, attributes, or values supported by only one browser, and "best viewed with" messages appeared at the bottom of many pages.

HTML 3.2, the next official W3C recommendation, came in January 1997. (HTML 3.0 was a proposal submitted to W3C but not endorsed.) This represented W3C's mostly successful attempt to regain control of the situation. Important new elements were `style`, `script`, and `div.` Inline elements added were `big`, `small`, `sub`, and `sup.` Other new elements (which are now on the way out) were `applet`, `center`, and `font`. *Image maps* were introduced to allow *hotspots* within images to act as hyperlinks. Another useful addition was the ability to specify colors in the `#RRGGBB` format, in which three pairs of hexadecimal digits represent the intensities (0–255, in decimal) of the red, green, and blue components of an additive color.

HTML 4: The Final Version

HTML 4.0 was released by W3C in December 1997. New elements were `object` (in place of Internet Explorer's `embed`), `abbr`, `acronym`, `colgroup`, `col`, `tbody`, `tfoot`, and `thead`. The `font` element was deprecated while support for style sheets was improved. The addition of the `<!DOCTYPE>` statement allowed specifying which Document Type Definition (DTD), i.e., version, of HTML 4 applied to the document. Documents could also be written in any language.

An important change was the introduction of event attributes, which could, for instance, invoke JavaScript code. These can be broken down into four categories:

1. window events (for `body` and `frameset` elements)—`onload` and `onunload`;
2. events only for `form` elements or their children—`onchange`, `onsubmit`, `onreset`, and `onselect`;
3. keyboard events (for `block` and `inline` elements)—`onkeydown`, `onkeypressed`, and `onkeyup`; and
4. mouse events (for `block` and `inline` elements)—`onclick`, `ondblclick`, `onmousedown`, `onmousemove`, `onmouseover`, `onmouseout`, and `onmouseup`.

The final W3C recommendation on HTML, HTML 4.01, was released on December 24, 1999. This was merely a clarification of some attributes and the removal of `mailto` (properly a protocol to be included in a URI) as a possible value of a `form` element's `action` attribute. ISO HTML, the International Organization for Standards/International Electrotechnical Commission's standardized subset of HTML 4.01, was released as ISO/IEC 15445:2000 in May 2000 (ISO/IEC, 2000). The first nail had already been hammered in HTML's coffin by January 2000, when W3C released its first proposed recommendation for XHTML.

In looking back at its meteoric career, we see that HTML was originally conceived to manage content. It evolved to manage presentation, but a better approach arose: Cascading Style Sheets (the subject of a separate chapter).

The lack of clear separation of content and presentation was accompanied by a lack of well-defined structure. These failings prevent applications from searching and referencing documents based on their semantics.

More important, HTML does not have the flexibility to accommodate future or even current technologies. On one hand, it does not allow high-powered platforms to realize their potential to render complex content. On the other hand, it is too bloated for platforms with limited (if any) screen space and modest computing power. Ultimately, it was the inability of HTML to further adapt that forced its dramatic metamorphosis.

XML: A New Direction

To understand XHTML, it is necessary to first take a step back.

In 1996, even while W3C was struggling to catch up with the browsers, it began a separate project: the *Extensible Markup Language,* the subject of a separate chapter. This was to be a markup language as powerful as but simpler than SGML.

XML is a *metalanguage* in that it provides a general structure for defining markup languages. In particular, XML defines what are elements and attributes, but leaves it to a user agent (a browser, e-mail program, etc.) to interpret what each element and attribute means.

Superficially, the syntax of XML resembles HTML in that there are tags (the identifiers for an element enclosed in angle brackets) and attributes, which are assigned values using an equal sign.

Structurally, XML, like a programming language, demands perfect grammar. Browsers had a long tradition of rendering imperfect HTML pages, often by correctly reading the mind of the page's author. This mind reading was inconsistent across browsers: one would render `&copy` as the copyright symbol despite the missing semicolon, but another would display the characters as text. Yet developers got away with a great deal of sloppiness. An XML-based user agent is expected to reject a malformed XML document rather than attempt to mind read.

The two versions of XHTML that have reached Recommendation status as this is written (1.0 and 1.1) are based on XML 1.0, which is defined in (W3C, 2000a). (Later, we will see this reflected in the first line of code in Table 1.)

The Advent of XHTML

XHTML has been variously described as

1. HTML + XML;
2. a merger, marriage, or hybrid of HTML and XML;
3. a step toward or transition to XML;
4. the next phase or generation of HTML.

Since XHTML "is both XML-conforming and, if some simple guidelines are followed, operates in HTML 4 conforming user agents" (W3C, 2002a), it is tempting to think of XHTML as a kind of intersection of HTML and XML.

However, XML does not directly provide a language specification for XHTML. Rather, XML is a general framework for defining an unlimited number of different languages, of which XHTML is just one. The most accurate statement is that made by W3C: "XHTML is a reformulation of HTML as an XML application" (W3C, 2002a). This does not mean that XHTML is software that uses XML (as a browser might). Rather, it is a set of tags (specified in a Document Type Definition or an XML Schema) that applies XML to a particular domain. Some domains might be highly specific, such as vector graphics or mathematical notation for SVG and MathML, respectively (discussed later). XHTML is a general-purpose markup language whose domain encompasses much of what needs to be done in Web pages.

Flexibility is the primary impetus for using XML as a foundation for specifying how Web content should be marked up. The Web needs to be able to adapt to ever-changing technology, which is developing greater capabilities while also branching off into more different platforms, which often have very restricted resources. Thus, the needed flexibility comes in two forms: (1) the ability to contract XHTML and (2) the ability to extend it by allowing its integration into other electronic documents or the inclusion of other XML applications in XHTML documents. The initial W3C recommendation, XHTML 1.0 (which, we will see, is actually three different recommendations), is just a first step toward modularizing the language specification so that parts can be subtracted from or added to the language to fit a particular platform. It is a bridge to the XHTML 1.1 recommendation, which incorporates modularization. We will concentrate on XHTML 1.0 and comment on the changes in XHTML 1.1.

A second motivation for moving to XHTML is to separate more sharply content from the presentation of that content. To that end, a number of features of HTML 4 have been deprecated. In some cases, an entire element has been eliminated; in other cases, an attribute of an element has been eliminated, with equally profound consequences.

A third goal of XHTML is to enforce the rules of well-formed code. Traditionally, browsers have simply ignored tags they did not recognize; no error messages would display. If a tag was malformed, e.g., `<html<`, the browser would attempt to render it as text (in whatever the current font, size, and color was). In the extreme case, an "HTML document" might contain no HTML code at all! The smallest Web page that can be displayed is a single ASCII character, which a well-meaning browser simply displays as text in a default font. Years of living in this somewhat lawless environment have encouraged poor habits, which must now be unlearned. An XHTML-conforming user agent must verify the well-formedness of a document.

XHTML 1.0 FUNDAMENTALS

Despite W3C's thoughtful work (already several years old), the message to migrate to XHTML has not been widely embraced. A vast amount of new HTML code is written or generated each day. Here we take the forward-looking approach: presenting the rules for writing valid XHTML code and dealing in a later section with updating HTML legacy code.

Syntax

Since XML is case-sensitive and XHTML is an XML application, all XHTML identifiers must appear in all lowercase letters. This is the opposite of the all-uppercase tradition in writing HTML code. HTML is actually case-insensitive, so that`<BR>`, `<Br>`, `<bR>`, and `<br>` should be interpreted equivalently; but only the last version is valid in XHTML.

Another implication is that the ampersand (`&`), left angle bracket (`<`), and right angle bracket (`>`) characters cannot be used as character data. When not intended as markup characters, they must be encoded as `&amp;`, `&lt;`, and `&gt;`, respectively. Likewise, the apostrophe/single quotation mark (`'`) and double quotation mark (`"`) should be encoded as `&#39;` (XML's `&apos;` is not supported by older browsers) and `&quot;`, respectively, within attribute values using the same delimiter. Furthermore, the form feed character (U#000C in Unicode, decimal code 12 in ASCII) is illegal.

A variety of special symbols can be displayed by means of mnemonic or numerical codes. One of the most useful is `&nbsp;` for a *nonbreaking space,* a blank space which will be rendered despite a browser's *normalization* of character data by ignoring excess whitespace; this is an essential tool for forcing an empty cell in a table to be outlined in the same way as a nonempty cell.

An HTML/XHTML *element* has an *opening tag*, which is the element's type enclosed in angle brackets (< >). Elements must be closed in the sense that an opening tag must be matched by a *closing tag*. The latter is signified by a forward slash followed by the element's type, as in

```
<p>The text of a paragraph.</p>
```

An exception is empty elements. Certain elements, such as `br` (a forced line break), would never contain any content. The opening and closing tags of such elements (`<br></br>`) can be combined into a single tag, which contains a forward slash after the element's identifier, as in `<br/>`. A blank space should be provided before the forward slash (`<br />`) so that older browsers will correctly recognize the element. (On the other hand, the intentional use of `<br/>` with no blank space is a kluge that can sometimes compensate for variations in how different browsers provide vertical spacing, for example, after tables.)

All elements may have certain *attributes*. Some elements have required attributes. Attributes reside in the opening tag, following the element's type and a blank space. Multiple attributes are separated by blanks. Unlike in HTML, attributes in XHTML must always be followed by an equals sign (=) and a value, which is enclosed in matching single or double quotation marks. Some attributes can take on an unlimited number of values, some can only take on a small number of specified values, and some are termed *Boolean* (an abuse of terminology). In HTML, an attribute of this last type would either be present or absent in the code; for example, a check box on a form is either `checked` or it is not. This was referred to as *attribute minimization*. It might seem logical for XHTML to demand a value of `"true"` be assigned to any Boolean attribute present. Instead, the required value is the very same reserved word as the attribute, but enclosed in quotation marks (e.g., `checked = "checked"`). Thus, a name may be both an attribute and a value.

In a few cases, the same identifier may represent an element in one context and an attribute in another. An example is `title`. As an element, it provides text that a browser may display in its title bar. As an attribute of a block or inline element, it can provide text that a newer browser may display in a transient balloon when the user's mouse cursor pauses over the element so attributed.

Comments in both HTML and XHTML are stored within a special kind of tag, as in

```
<!-- These comments will be ignored. -->
```

The enclosed text will not be processed by the user agent interpreting the document. The delimiters can enclose forced line breaks, so a single comment may encompass multiple lines. A comment should not, however, contain consecutive hyphens (`--`).

A traditional (optional) use of comments is to shield scripts from applications that do not handle them. An example of this format is

```
<script type="text/javascript">
<!--// start hiding script from JavaScript-
  challenged browsers
   // JavaScript code goes here
// end of hidden script -->
</script>
```

Applications that do interpret scripts will disregard the apparent cue (`<!--`) to ignore the code between the opening and closing script tags. JavaScript implements the end-of-line (`//`) form for comments, used also in C++. The final JavaScript comment hides from the JavaScript interpreter the closing of the XHTML comment. Note the recommended blank space before `-->`.

This technique is now discouraged for XHTML. Instead, scripts (including internal style sheets) should be contained in a CDATA (character data) section to indicate to the user agent that it should not be parsed as XHTML. A sample section is

```
<![CDATA[ character data here is not parsed
  as XML ]]>
```

But the delimiters of the character data section (`<![CDATA[ and ]]>`) should in turn be hidden as comments from the viewpoint of the application interpreting the character data; C-style comments (beginning with `/*` and ending with `*/`) will work with both JavaScript and CSS. The safest course of action is to use a `link` element to reference an external file that contains the script.

Document Type Definitions (DTDs) and XML Schemas

Any XML document conforms to the specifications within a *Document Type Definition* (*DTD*). This is a declaration, using an Extended Backus-Naur Form (EBNF) grammar, of the valid elements, the appropriate attributes for these elements, and the acceptable range of values for attributes.

Corresponding to the three HTML 4 DTDs are three XHTML DTDs with the same names: XHTML 1.0 Strict, XHTML 1.0 Transitional, and XHTML 1.0 Frameset. For simplicity, we will henceforth refer to these DTDs as *Strict, Transitional,* and *Frameset,* respectively. As the names suggest, the first of these is the most restrictive, the second is seen as temporary in nature, and the third supports frames (which, by implication, are not endorsed for the long term). We will restrict our attention almost entirely to Strict since it is the basis for the only (admittedly modularized) XHTML 1.1 DTD.

Unlike the situation with standards organizations, all publications of the W3C are technically considered to be recommendations. Important in the history of the Internet has been the disregard for these recommendations. In particular, competition between Microsoft Internet Explorer and Netscape Navigator saw each browser supporting extensions to the recommendations then in effect; some of those innovations died on the vine (such as Netscape's `layer` element) while others were eventually incorporated in future W3C recommendations.

An alternative to DTDs is XML Schemas. Unlike a DTD, an *XML Schema* is itself an XML document. Consequently,

Table 1 Sample Minimal XHTML Documents with No Content

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN"
  "http://www.w3.org/TR/xhtml1/DTD/xhtml-strict.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
  <head>
    <title></title>
  </head>
  <body>
  </body>
</html>
```

(a) for XHTML 1.0 Strict

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Frameset//EN"
  "http://www.w3.org/TR/xhtml1/DTD/xhtml-frameset.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
  <head>
    <title></title>
  </head>
  <frameset>
  </frameset>
</html>
```

(b) for XHTML 1.0 Frameset

it can be manipulated like any other XML document. Each approach requires validating parsers (so well-formedness will be enforced). XML Schemas have the advantage of being able to validate the contents of an element to verify that it consists of the expected type of data. On the other hand, an XML Schema cannot accommodate character entities. However, a Web page can make use of both a DTD and an XML Schema (see W3C, 2002b). Some expect XML Schemas to eventually supplant DTDs.

Document Structure and the Document Object Model (DOM)

Table 1 contrasts sample valid Strict and Frameset documents with no content.

In each case, the first line of code is an XML declaration indicating the XML version and the encoding used. The encoding is a particular mapping of characters in a natural language to a sequence of zeroes and ones. UTF-8, the default XML encoding, is highly recommended for the Internet since it enjoys the widest browser support. Using 1–4 bytes per character, it includes the standard set of 128 ASCII characters as well as Unicode (a registered trademark of the Unicode Consortium), which encodes the characters of most of the world's major languages.

Technically, an XML document does not require this XML declaration if encoding is UTF-8 or UTF-16. However, the inclusion of the XML declaration may cause problems for some browsers parsing a document as HTML; if this is expected to be a problem, the `<?xml>` tag should be omitted, and the character encoding should instead be indicated in a `meta` element (described later).

The second line of code is a `DOCTYPE` declaration that specifies the root element of the DTD (see later), information about the DTD and its owner (W3C), and finally the DTD's URI. See Sauers & Wyke (2001) for more details.

The third line of code is the opening tag for the HTML document. Its first attribute specifies an XML namespace by means of the URI of the particular file which defines the allowable element types and attribute names. In this case, the namespace applies to the entire document. Different portions of an XML document could have different namespaces, allowing the same name to have different meanings in each portion. In such cases, a namespace prefix can be used to allow unambiguous use of a name and its homonym from a different namespace. For details on XML namespaces and how they differ from conventional namespaces, see W3C (1999).

The second and third attributes in the opening HTML tag specify (in two different ways) a two-letter code for the natural language in use (e.g., `"en"` for English).

The *root element* of a well-formed XHTML document must be an `html` element. This must have two child elements. The first, a `head` element, will hold information about the document. The second part of the document will be one of two types. A typical document, one conforming to Strict or Transitional, will have a `body` element to hold all the content to be rendered. An occasional document will merely serve to set the stage for several documents to be rendered at once. It will have a `frameset` element and conform to Frameset. (As explained later, this element may have a grandchild `body` element and all that it could ordinarily contain.)

The indentation shown is not required, as both HTML and XHTML ignore excess whitespace, e.g., the second and subsequent blanks in a sequence of consecutive blanks. (However, nonessential whitespace within a tag may have unexpected consequences, such as preventing the pieces of a subdivided image from being reassembled snuggly in a table.) It is used here to indicate the structure of the document, that is, how elements are nested within one another. This time-honored tradition from programming was ignored by most Web authors, but is now making a comeback, perhaps encouraged by XHTML's demand for proper structure.

While well-formed HTML should also possess proper structure, XHTML has higher standards. For one, all elements must nest properly: if two elements overlap, one must be entirely contained within the other. Suppose one wanted to have a combination of italicized and boldfaced text of the form:

This is italicized ***and*** **boldfaced.**

It would be illegal in XHTML to script this with two inline elements as in

```
<i>This is italicized <b>and</i>
  boldfaced.</b>
```

Instead, one would need to use three inline elements, with one nested in another:

```
<i>This is italicized <b>and</b></i>
  <b>boldfaced.</b>
```

There are also strict limitations on which elements can nest in which. XML-based languages cannot specify in their DTDs exclusions of certain nestings. However, the following rules must be observed:

1. An a element cannot nest within another a element.
2. A pre element cannot contain any big, img, object, small, sub, or sup element.
3. A button element cannot contain any button, fieldset, form, iframe, input, isindex, label, select, or textarea element. (The iframe and isindex elements are not included in Strict in any case.)
4. A label element cannot nest within another label element.
5. A form element cannot nest within another form element.

Table 2, which recasts a table from Graham (2000) in a format that corresponds to how code would be written, contrasts the global structure of Strict and Frameset documents. Note that the latter type may have a body element as a great-grandchild element, but not as a child element of the root (html) element.

Table 2 also illustrates the nesting of block elements (discussed later) within the body element. It also shows the elements which can appear within the table, form, and list (dl, ol, ul) elements. Tables would seem to be self-explanatory, but their use and misuse are sufficiently important to merit a separate section later. Details about the form and list blocks' child and grandchild elements will not be included here. However, they are important blocks. Forms provide a way for users to interact with a Web page by submitting data. Lists may consist of unordered (bulleted) or ordered (numbered or lettered) items or may consist of terms and their definitions.

Note that there is a recursive aspect to these nestings. Explicit is that a frameset element may contain another frameset element (so that a screen can be subdivided *ad nauseum*). Most of the possible nestings are not illustrated. Notably, lists may contain other lists, though this is trickier than before; XHTML will demand that an inner list have a list *item* (li) as its direct parent. Likewise, a table may be the child of a *cell* (td) of an outer table. (As we shall see, nested tables have historically been very important for arranging content.)

All content that is to be rendered—text, images, and objects—must appear in the body element of a document. Most elements that appear within the body element can be classified as being either block elements or inline elements. Roughly speaking, *block elements* are larger sections, such as paragraphs (p). Following the analogy, an *inline element* would correspond to a portion of a paragraph. "Block" and "inline" are different levels in the structure of a document. In particular, no inline element may have a block element as a child, but every inline element must be embedded within a block element. A few elements (del, ins, script, and noscript) can be used at either level. As with paragraphs, block elements always begin on a new line and are often separated by vertical space. This is not the case with inline elements.

The div element has a unique role among block elements. Its opening and closing tags delimit a section of a document (without illegally crossing the boundaries of any other block element) so that it can be identified for formatting using CSS. An analogous inline element for delimiting a portion of a block element is span. These two elements are called *grouping elements*.

Associated with each element is the set of attributes it may (and, in some cases, must) have. Some attributes are unique to a particular element. Other, so-called generic attributes are shared by many elements. These are categorized as follows:

1. *Core attributes* (class, id, style, and title) identify an element.
2. *Internationalization (i18n) attributes* (dir, lang, and xml:lang) pertain to the natural language used in a document and the direction in which text is rendered.
3. *Event attributes* (onclick, ondblclick, onkeydown, onkeypress, onkeyup, onmousedown, onmousemove, onmouseout, onmouseover, and onmouseup) allow dynamic interaction by the user.
4. *Focus attributes* (accesskey, tabindex, onblur, and onfocus) apply to elements that could be the focus of the user's attention as indicated by the mouse or keyboard.

We make no attempt in the tables that follow to list event or focus attributes or any of the other attributes related to user interaction with an element, which involves Dynamic HTML, the subject of a separate chapter.

To better understand the hierarchical structure of a well-formed XHTML document, we illustrate a sample parse tree in Table 3.

Related to the issue of document structure is the *Document Object Model* (*DOM*) concept. This is a way of

Table 2 Sample Nestings of Block Elements in XHTML Documents

```

</html>
```

(b) Nesting in XHTML 1.0 Frameset

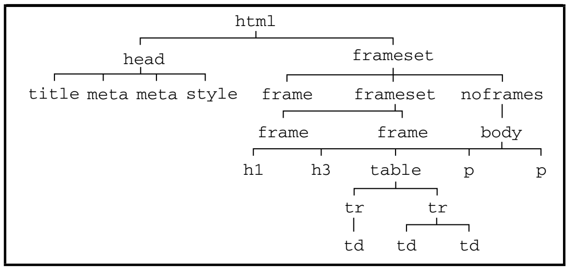
[a] Required element.

[b] Required child element if parent is present.

[c] Optional parent element.

[d] Same (grand)child elements as for `tbody`; cannot appear after or without a `tbody` sibling.

Table 3 Sample Structure of an XHTML 1.0 Frameset Document



referencing objects and subobjects related to a document. These could be elements, attributes of elements, or content within elements. An object might be information about a document (and not necessarily listed in the `head` element, as described next) or about the user agent (e.g., which version of which browser is being used). Having a way to reference items allows a client-side script to change those that are not read-only. For example, a script can be used to change simultaneously the URI of the documents loaded into two different frames.

As of this writing, W3C is finalizing DOM Level 3. The ultimate reality, however, is the DOM implemented by each individual browser. These have varied widely, even between versions of the "same" browser. (Netscape 4 and 6 offer a striking contrast.)

Obviously, having a well-defined, hierarchical structure within a document as demanded by XHTML can only aid any DOM in referencing objects. See the separate chapter on DHTML, where the DOM is of critical importance.

Document Information

The required `head` element of an XHTML document contains information about the document. The information is not rendered on the screen. However, the contents of the only required element within the document heading, the `title` element, will typically be displayed in a browser's title bar. The elements that can reside in the `head` are described and their attributes listed in Table 4.

The `base` element can be used to specify the URI on which all relative URIs within the document are based. A URI within a document can be stated either as a complete URI (starting with the protocol, e.g., `http`) or as a relative URI (with addresses being relative to the address of the current document, e.g.,`/images/shim.gif`). The use of `base` facilitates the moving of files to another server.

While a document can have at most one `title` or `base` element, it can have any number of the other types of elements listed in Table 4.

The `script` element allows one to provide code (perhaps in JavaScript) for a dynamic page, which reacts to the user's actions. A `noscript` element (within the `body` element) can hold alternative content for a browser that is unable or currently unwilling (according to its user's wishes) to execute scripts.

The `style` element can be used to include style information. This is becoming increasingly important as XHTML pushes us to better separate content and presentation.

Either script or style information can be included from an external file by means of a `link` element. This is the elegant way to use the same JavaScript code or CSS specifications in multiple documents, but it is now recommended practice even for use in a single document. See the separate chapters on DHTML and CSS.

Special mention should be made of `meta` elements because of the vast array of jobs they can perform. The `content` attribute is always required. Arguably the most useful attribute is `http-equiv`. A recommended usage is to specify for an HTML user agent the same character set as was specified for an XML user agent. (Or, in light of previous comments, the XML declaration might be omitted, and this would partially play its role.) A sample is

```
<meta http-equiv="Content-Type"
  content="text/html;
  charset=UTF-8" />
```

It is well known that `meta` elements are used by Web page authors to attract the attention of search engines. This is accomplished by code such as

Table 4 Document Information Elements for XHTML 1.0 Strict

Element	Description	Attribute(s)
`base`	Contains the document's base URL.	`href`
`link`	Specifies URI and type of an external script or style file.	`charset`, `class`, `dir`, `id`, `href`, `hreflang`, `lang`, `media`, `rel`, `rev`, `style`, `title`, `type`, `xml:lang`
`meta`	Contains information about content.	`content`[a], `dir`, `http-equiv`, `lang`, `name`, `scheme`, `xml:lang`
`script`	Contains code for dynamic content.	`charset`, `defer`, `src`, `type`[a], `xml:space`
`style`	Contains code to define formatting.	`dir`, `lang`, `media`, `title`, `type`[a], `xml:lang`, `xml:space`
`title`[b]	Contains text for browser title bar.	`dir`, `lang`, `xml:lang`

[a] Required attribute.
[b] Required child element within `head`.

Table 5 Nonempty Block Elements for XHTML 1.0 Strict

Element	Description	Attributes
address	Holds contact information for the document's author.	dir, id, class, lang, style,title, xml:lang
blockquote	Usually indents on left and right.	cite, dir, id, class, lang, style, title, xml:lang
div	Division: delimits content for specific formatting.	class, dir, id, lang, style, title, xml:lang
dl[b]	Holds a list of definitions.	class, dir, id, lang, style, title, xml:lang
form[b]	Form to be filled in.	accept, accept-charset, action[a], class, dir, enctype, id, lang, method, style, title, xml:lang
h1 to h6	Heading (largest to smallest): sets font-size.	class, dir, id, lang, style, title, xml:lang
ol[b]	Holds an ordered (numbered or lettered) list of items.	class, dir, id, lang, style, title, xml:lang
noscript	Contains alternative content when scripting is not supported.	class, dir, id, lang, style, title, xml:lang
p	Provides vertical whitespace around a paragraph.	class, dir, id, lang, style, title, xml:lang
pre	Text is "preformatted" (all whitespace preserved) and monospaced.	class, dir, id, lang, style, title, xml:lang, xml:space
table[b]	Arranges content in rows and columns.	border, cellpadding, cellspacing, class, dir, frame, id, lang, rules, style, summary, title, width, xml:lang
ul[b]	Holds an unordered (bulleted) list of items.	class, dir, id, lang, style, title, xml:lang

[a] Required attribute.
[b] Parent element (see Table 2 for possible child elements).

```
<meta name="keywords" content="cheap books"
  />
<meta name="description" content="Our
  discontinued items" />
```

The values of the `content` attribute have sometimes been used deceptively or unfairly. This has had legal consequences, such as successful lawsuits charging infringement on trademark rights.

There are also ways to attempt (!) the opposite—intentionally steer people away from a page. One way is to provide the *Platform for Internet Content Selection* (*PICS,* a W3C trademark) rating for a page; this system was originally designed as a filtering aid for parents and teachers, but is now in wider use (Boumphrey et al., 2000). Another technique is to give metainformation to indicate to *spiders* (a.k.a. *Web crawlers* or *bots*) that a page should not be indexed by a search engine and/or that links from that page are not to be followed for that purpose either.

A completely different use of a `meta` element is to control the loading of a page. An `"expires"` value for `http-equiv` can force a browser to load a new (rather than cached) copy of a page. A value of `"refresh"` causes a page to be reloaded after a specified time delay (10 s in the following example). Alternatively, the browser can be redirected to a different URI, perhaps to the new host server of the page. Often done primarily for visual impact, the splash page technique (illustrated here) was once popular.

```
<meta http-equiv="refresh" content="10;
  URL='page2.html'" />
```

Block Elements

Unlike in HTML, all content must reside within a block element. An easy mistake to make is to create vertical whitespace using `br` elements that are directly contained in the `body` element without being nested within a block element, such as the `p` element.

The allowable nonempty block elements are described and their attributes listed in Table 5.

Inline Elements

Inline elements fall into two categories based on the role they play.

Style elements or *physical style elements* exist solely to control the physical appearance, i.e., presentation of content; therefore, they are also referred to as *presentation elements*. (In the XHTML DTDs, they are called *font style elements*.) The elements in Table 6 are "reliable" in that they do what one would expect. Curiously, despite W3C's campaign to separate content and presentation, the only style elements eliminated from Strict are `s(=strike)` and `u`, which specified strikethrough and underlined text, respectively.

By contrast, most of the *descriptive elements* (called *phrase elements* in the XHTML DTDs) seem superfluous at first glance. As Table 7 illustrates, only `sub` and `sup`

Table 6 Inline Style (or Physical Style or Presentation) Elements for XHTML 1.0 Strict

Element	Description	Rendering
`b`	Boldfaced	**Boldfaced** text.
`big`	Bigger	Bigger relative to current font size.
`i`	Italicized	*Italicized* text.
`small`	Smaller	Smaller relative to current font size.
`tt`	Teletype	`Monospaced` text

do something that could not be accomplished by style elements. Some elements' contents are not even rendered with any distinctive visible characteristic. And the appearance of the content may vary from browser to browser. Yet these are precisely the elements good practice dictates that we use. The reason is that they convey the roles they play. They are sometimes called *logical* or *content-based elements* because they reveal the semantic structure of the document. An XML-aware application could search, reference, or modify a document based on the meaning associated with content that is wrapped in, for example, a `code` element.

Special Elements

Some of the most famous elements do not fit into any of our previous tables, as they play special roles. They are described and their attributes are listed in Table 8.

The anchor element (`a`) is the most important element of all, for without it we would have no hypertext! It may have content, which the viewer clicks on to link to another document or another location within the document. Often this content is text. The traditional, default rendering of such content in many browsers is blue, underlined text. If the contents of an anchor element is an `img` element (see later), the analogous default rendering adds a blue border to the image on which the user would click. Increasingly, CSS is being used to override these default renderings. If the anchor tag is empty and has a `name` attribute, it can be used as the destination of a link so the user can be brought to a specific location within a document. Clearly, such a tag would not need an `href` attribute, which specifies the URI of a destination.

Table 7 Descriptive (or Logical or Content-Based) Inline Elements for XHTML 1.0 Strict

Element	Description	Rendering
`abbr`	Abbreviation	No distinction in most browsers.
`acronym`	Acronym	No distinction in most browsers.
`cite`	Cited text	*Italicized* in most browsers.
`code`	Code	`Monospaced` in most browsers.
`dfn`	Definition	*Italicized* in most browsers.
`em`	Emphasis	*Italicized* in most browsers.
`kbd`	Keyboard	`Monospaced` text.
`q`	Quotation	No distinction in most browsers.
`samp`	Sample	`Monospaced` in most browsers.
`strong`	Strong	**Boldfaced** in most browsers.
`sub`	Subscript	$_{\text{Lowered}}$ relative to baseline.
`sup`	Superscript	$^{\text{Raised}}$ relative to baseline.
`var`	Variable	*Italicized* in most browsers.

The `img` element inserts a JPEG, GIF, or PNG image in a document. (The first two formats are well established and supported. The last format, introduced by W3C in 1996, is similar to GIF, but not reliant on a licensed compression algorithm.) There are two required attributes. The value of `src` is the URI of the image file. XHTML also enforces courtesy, i.e., specifying with the `alt` attribute what text should be displayed (or spoken by a voice synthesizer) if the image is not. It is always good practice to specify the `height` and `width` of an image, even if the intention is to load the image at its natural size. For if the browser knows the footprint in advance, it will not have to do more computations and rearrange content once the image is completely downloaded. The value of a `usemap` attribute can be used to point within the document to a `map` element whose child `area` elements specify hotspots within the image that can act as links; this situation is called a client-side image map. The `map` and `area` elements are not detailed here. See Boumphey et al. (2000) for more information on image maps.

Two special elements cause breaks in the presentation. The **`<br/>`** tag forces a line break, while the **`<hr/>`** tag creates a horizontal rule. These two elements differ greatly from the standpoint of XHTML, as `hr` is a block element, while `br` is an inline element.

The `object` element is an inline element that can be used to embed a wide variety of documents in an XHTML file. One such document is a Java Applet, which previously could be embedded using the now deprecated `applet` element. An `object` element's `param` child element (not listed in the tables) can be used to specify values for parameters used by the embedded document.

Two other elements, `ins` and `del`, are used to signify the insertion or deletion of content since a previous version of the document.

Finally, the highly specialized `bdo` element allows an advanced programmer to take control of character sequencing. The required `dir` attribute takes either `"ltr"` or `"rtl"` as a value to override the default (bidirectional) rendering algorithm.

STRATEGIES FOR WRITING XHTML CODE

Knowledge of the rules of a game does not automatically imply knowledge of how to play the game effectively. Likewise, knowledge of the syntax rules of a language does not imply understanding of how to communicate (write code) effectively. The issues that influence what constitutes good practice in writing XHTML code are often beyond the control of the programmer, for instance, the capabilities of a user's browser or the options the user has chosen for that browser's behavior.

Another issue, already discussed, has to do with Web authoring philosophy. From a superficial standpoint, inline style elements seem to be more manageable since

Table 8 Special Elements for XHTML 1.0 Strict

Element	Description	Attributes
a	Anchor: source of one link or destination of another link.	charset, class, classid, codetype, coords, dir, id, href, hreflang, lang, name, rel, rev, shape, title, type, xml:lang
bdo	Specifies left-to-right or right-to-left (rather than default, bi-directional) rendering.	dir[a], lang, xml:lang
br	Forces a line break.	class, id, style, title
del	Identifies content deleted since an earleir version	cite, class, datetime, dir, id, lang, style, title, xml:lang
hr	Horizontal rule.	class, dir, id, lang, name, style, title, xml:lang
img	JPEG, GIF, or PNG image.	alt[a], class, dir, id, ismap, height, lang, longdesc, name, src[a], title, usemap, width, xml:lang
ins	Identifies content inserted since an earleir version.	cite, class, datetime, dir, id, lang, style, title, xml:lang
object[b]	Specifies URI of external content file to be embedded.	archive, class, classid, codebase, codetype, data, declare, dir, id, height, lang, name, standby, style, title, type, usemap, width, xml:lang

[a] Required attribute.
[b] May have a param child element.

they deliver what they promise and have mnemonic names. In the long term, the document itself will be more manageable if the elements convey the role of the content. In other words, the descriptive elements in Table 7 are preferable to those in Table 6.

Frames

One of the most famous and controversial techniques in the development of Web pages is the use of *frames* to partition what superficially appears as one page into separate pages, which may or may not share some kind of linkage. In XHTML, this is accomplished in Frameset using the frameset element to replace the body element of a Strict or Transitional document. (Frameset is not simply a superset of Strict; the former does not support the body element's being a direct child of the html element, though it can be a great-grandchild element with a noframes parent element.)

If two frame elements are nested within the frameset element, the screen display will be subdivided into two independent areas, each displaying its own XHTML document. Whether the screen is divided horizontally or vertically depends on whether the frameset element has a rows or cols attribute. The value (actually a set of values) of that attribute determines how much of the screen is used by each frame. The screen can be subdivided in both directions at once or can be successively subdivided with nested frameset elements, though the disadvantages of screen fragmentation are obvious.

Thus to display frames, there is, in addition to the documents rendered within the individual frames, a controlling XHTML document that contains the frameset element that determines how the screen will be subdivided. Even though it may not provide any of the content rendered, it is the primary document in several senses. When a user requests a browser to display the source code being rendered, it is the sparse code for setting up the frames that will be displayed, unless the user somehow selects a particular frame (say, by clicking a mouse over it). The browser will display in its title bar the text specified in the title element within the frameset document; this is logical from the standpoint of the browser, which can only display one title.

Frames offer the opportunity for a combination of constancy and changeability. A classic application is to have a *navigation bar* on the left or top of the screen to maintain a set of links to other pages. It stays unchanged while the larger portion of the screen loads a new page. The code for the "navbar" will specify the initial URIs of the documents for both frames, but the current URIs will be determined (for at least one frame) by the viewer's interaction.

The original objection to frames was that not all browsers supported them. While fewer and fewer people with full-size screens are stuck using such browsers, many sites still provide alternative, nonframes versions of their pages. A rising issue is that of very small screens, say in hand-held devices. This will be dealt with in greater detail later, as we discuss the true potential of the XML approach to marking up hypertext.

For users wishing to cite Internet resources as formal references, perhaps in the bibliography of a report, frames present two problems. The title of the frameset document and therefore the title displayed does not change even when the page loaded into a frame does. The same is true of the address bar. Consequently, a naïve user who does not know how to "isolate" a frame to determine its precise source may provide a URI that is not specific enough to home in on the desired page; a reader of the inaccurate citation will have to navigate (and possibly search) further.

For users who want a hardcopy of a Web page, printing from a screen that actually displays two or more frames can be problematic.

Strict does not support frames. Even if one uses Frameset only for the controlling document and Strict for all documents loaded into individual frames (as some authors suggest), the purpose of frames has been defeated. This is because to load a document into a specific frame, the anchor (a) element commanding the load must specify the value of a target attribute; the value might be the value of a name/id attribute (id is preferred by XHTML, but name is needed for compatibility with older browsers) previously assigned to a frame, or it may be a relative value, such as "_top" (for the entire screen) or "_self" (for the frame making the call). But Strict does not support the target attribute! The alternative is to use JavaScript or server-side code to change the contents of a frame.

Clearly, W3C has put the handwriting on the wall for frames. The sole XHTML 1.1 DTD is based on Strict and, therefore, does not support frames.

Already, even among those sites using HTML rather than XHTML, the trend is to develop navigation schemes that superficially resemble frames-based pages, but actually use DHTML or server-side code to change the "main event" on a page while keeping the navigational area constant (or, better yet, modifying the navigational area slightly to indicate "where you are" or to expand or pop up submenus of links).

Tables

Another controversial component of Web pages is tables. Their purpose is to arrange content into rows and columns. Structurally, tr elements define rows, and they may have as children td (normal) and/or th (heading) cells. The latter have default formatting that usually entails boldfaced and horizontally centered text. A row may have rowspan and/or colspan attributes to merge cells into larger, rectangular cells. The formatting of entire columns can be controlled by means of col elements within a colgroup element (recall Table 2). The table element may have a caption element, and rows may be grouped within optional thead, tfoot, and/or tbody elements; if either or both thead and tfoot elements are used, they must precede a tbody element, although a tfoot element will be rendered below the tbody element.

By default, tables will display a "border," which actually includes vertical and horizontal walls around nonempty cells. If a consistent look is desired, an empty cell must be given some invisible content, such as a nonbreaking space (&nbsp;); an alternative, which is also used to ensure a minimum size for a cell, is an invisible GIF, in which every pixel is transparent.

The vast majority of tables in use in Web pages have a value of "0" for the border attribute. Thus, the viewer sees no walls between rows and columns. The page designer is using tables not to create visible boxes for content (the original intent), but to control the placement of content. This is a natural way to overcome browsers' reluctance to place items side by side. While browsers typically separate consecutive block elements with vertical whitespace, tables can be nested without extra space being created between a table and the walls of its parent td element. Web designers have reportedly nested tables as much as seven deep to obtain desired arrangements.

A sample application of tables is to slice an image into quadrants (for instance) and nest each in an anchor element in a td element. If the pieces fit together seamlessly, the user perceives one image as having four hotspots linking to different pages. This is an alternative to image maps.

One problem with tables is that browsers must compute how to fit things in a table, and this takes time—more time than if CSS had been used to position items. Perhaps a bigger problem is that each browser has its own algorithm for deciding *how* to fit content into cells. The way in which the total width of a table is distributed among columns can seem arbitrary and sometimes esthetically distressing. In reaction, Web designers have often "hardcoded" the width of tables and columns, which in turn has forced some viewers to scroll horizontally if the table does not fit their current window.

While the use of CSS is recommended over the use of tables for (transparently) arranging content, the fact remains that CSS support is irregular, especially among older browsers. The reality of the current browser climate pressures many developers to cling to tables.

Living without Deprecated Features of HTML

One of the significant deprecations in XHTML 1.0 is the center element. The simultaneous deprecation of the align attribute for most elements means that something as simple as placing a table in the middle of a page is now more complicated than it used to be. One solution is to use CSS. Another is to nest the target table within the sole cell of an outer table element with "100%" as the value of the width attribute. Since the td element still is allowed to have "center" as the value of the align attribute, the target table can be centered within the cell and, therefore, the page.

Another deprecated element is font, used to alter the size, font face, and/or font color of text contained in the element. The only substitute for this is to use CSS to define a style. The span or div element could be used to delimit the section of text to be altered. The latter element would be used to encompass one or more block elements, while the former would stay within a single block element. In either case, the element must have a class attribute whose value would be referenced by the style sheet. The situation is simpler if the target text is precisely the contents of an existing element, for then that element can carry the class attribute without need for a span or div element. "Inlining" the style with a style attribute for an element will not have the desired effect in Netscape 4 and may cause truly strange side effects. In any case, the style attribute of elements is removed from XHTML 1.1.

In a similar vein, Strict removes all formatting attributes of the hr element, forcing one to use CSS to exert even a modicum of control over the appearance of horizontal rules.

Conversion and Validation Tools

A number of tools exist for transforming legacy HTML code to XHTML. The most famous is Dave Raggett's HTML Tidy, originally hosted at W3C. The continued development of this application is now maintained by Source Forge (Source Forge, 2002). The platforms supported include many flavors of UNIX, Windows, and Mac

OS operating systems. Each version has a command-line interface. See St. Laurent & DeLong (2000) for a sample before-and-after look at Tidy's handiwork.

For the Windows platform, HTML Tidy can be augmented with a graphical user interface, Tidy UI, by Charles Reitzel (2003). Another option is to run HTML Tidy from within the much more comprehensive HTML-Kit (Chami.com, 2002), which also allows multiple files to be converted at once.

Despite the many options offered by these conversion tools, there is no way to automate the conversion process completely. Aside from the usual bugs, these programs have inherent limitations when it comes to imposing proper structure. An extreme example is when the HTML code is lacking a closing delimiter, such as a right angle bracket (>) or closing quotation mark. Even a less drastic flaw may cause a tool to issue a warning or error message, leaving the program's user to decide how to fix the problem by hand. There are times, however, when a tool does make a decision, and the result is inconsistent with the author's intentions or with a browser's rendering of the original HTML code. One situation would be incorrectly nested elements. Conversion tools must be viewed as potentially imperfect aides.

Whether authoring a page from scratch, converting legacy code, or generating code with an authoring system, purported XHTML code should be validated. The W3C MarkUp Validation Service (see W3C, 2002c) has recently been improved so that local files can be checked. When errors are found in a file, the source code can be listed with line numbers to quickly locate the problem. Predictably, however, a single error often results in multiple error messages. A parse tree can also be generated for a valid document. Furthermore, one can embed in a page a referrer "button" (actually `<p><a...><img.../></a></p>`) to allow a viewer to test the validity of the page's XHTML code.

The value of validating documents is in preparing for a future when (it is hoped) browsers no longer render a structurally defective document. A strictly conforming XHTML user agent must parse a document and check it for well-formedness (proper nesting of elements, etc.). Increasingly intelligent indexing and manipulation of Web resources (the "Semantic Web") will rely on the well-defined structure of documents. A validating user agent must additionally validate a document against its referenced DTD (to see that it is using only the allowed names, etc.). The specifics of user agent conformance can be found in section 3.2 of W3C (2002a).

Updating HTML-Generating Applications

As difficult as it may be to convert existing HTML code to XHTML code, there is a more vexing problem: converting the code that generates HTML. It could be PHP, Perl, ASP (Active Server Pages), or JSP (Java Server Pages) programs on a server constructing Web pages on the fly. Or it could be a Web authoring tool such as Microsoft FrontPage, Adobe GoLive, Macromedia Dreamweaver, Mozilla, or even a word processor. Or it could be JavaScript embedded in a page's code to dynamically create additional HTML code.

An excellent discussion of the issues involved in this aspect of the switchover to XHTML can be found in Chapter 11 of St. Laurent & DeLong (2000, p. 201), which claims that "the cleanup process is nearly as complicated as the work that was done on Y2K."

A glimpse of the difficulties can be seen by analyzing how developers have hand-coded HTML. Those behavior patterns translate into analogous authoring algorithms.

One flaw is to think of HTML tags as nonprinting characters in a word processor. An example is putting `<p>` tags at the end of lines as a kind of line break, rather than as an opening tag (which must later be matched by a closing tag). Another flaw is, thinking of `<li>` as a "bullet symbol" at the beginning of a list item, with no closing tag at the end of the item.

The importance of updating authoring tools and page generating code cannot be overstated. A substantial fraction of Web pages are not written "by hand," but are the product of Web authoring tools or are generated on demand, perhaps in response to a user's query.

Two XHTML authoring tools currently available are Macromedia's Dreamweaver MX and W3C's own Amaya, a combined browser and WYSIWYG editor (W3C, 2003c).

FUTURE DIRECTIONS

To date, many organizations have failed to see the need to convert old HTML code or even begin using XHTML code for new pages. They feel the move is not justified by the small return on investment they anticipate. In addition to updating commercial or in-house products for generating code, some companies face another problem. In environments where employees with minimal training have been contributing HTML code, those contributors must be retrained to meet the more demanding standards of XHTML.

Even while much of the Web development community drags its feet in coming into conformance with XHTML 1.0, W3C marches on. Just as some movie scripts are written with a sequel in mind, XHTML 1.0 was merely the beginning of a very deliberate trek toward XML. XHTML 1.1 represents another quantum leap in HTML/XHTML evolution. As of this writing, the Working Draft of the XHTML 2 specification breaks from tradition by foregoing backward compatibility (W3C, 2003a).

Extensions of XHTML

The potential for extensions of XHTML is unlimited. This is done with what W3C terms "modules." These are not technically part of XHTML, but additional XML applications with which XHTML can work. While the expectation is that new, specialized modules designed by individual vendors will proliferate, W3C began undertaking the development of its own modules even before XHTML was released. Two of these are the Mathematics Markup Language (MathML) and Scalable Vector Graphics (SVG), both W3C trademarks. These have been slow to gain acceptance, but some foresee SVG as becoming a serious open-source challenger to Macromedia's well-entrenched Flash.

The MathML module (W3C, 2001a), first released in 1997, provides a way of formatting mathematical expressions so that they will be rendered in the expected fashion. Elements, for example `mfrac` for fractions, specify the semantics of subobjects within an expression. Expressions can be dynamically manipulated by client-side or server-side script. Numerous applications—WebCT, to name just one—are MathML-aware. Yet support among browsers is not as simple or rosy a story as one might first believe. For example, in order for Internet Explorer 5.5+ to find where the MathPlayer plugin is installed locally, an `object` element must be added to the code (see Design Science, 2003). MathML content resides within this element:

```
<math xmlns="http://www.w3.org/1998/Math/
  MathML"> </math>
```

The SVG module carries even greater potential. Traditional graphical images for the Web have been in three formats: JPEG, GIF, and PNG. Each of these is a (compressed) bitmapped image, i.e., an array of pixels. Such images tend to be large and slow to download. Moreover, displaying an image at different sizes (to better accommodate a range of screen resolutions) results in either a blocky, "pixelated" appearance if an image is enlarged beyond its natural dimensions or a waste of time if an image is downloaded only to be displayed in shrunken form. Vector graphics encapsulate directions for how to draw an image. For images without photo-like detail, these directions result in smaller files and allow images to be drawn at any scale without loss of detail. Perhaps more important, an image can have parameters (colors, for instance) manipulated interactively. Obviously, the need for bitmapped images will remain.

For other extensions of XHTML, see the separate chapter on XML or Chapters 20-21 of Deitel et al. (2001).

Modularization and XHTML 1.1

The XHTML family began with XHTML 1.0 as a collection of DTDs. This was itself a transitional stage aimed at providing for (relatively) easy migration of legacy HTML code to well-formed XHTML code. The most important feature of the single XHTML 1.1 DTD is its XHTML modular framework. The purpose is to allow developers to use only the modules they need and to add suitable custom modules.

Starting with Strict, W3 made the following changes to derive XHTML 1.1:

1. All deprecated features were removed, not just those contained in Frameset and Transitional. The `name` attribute of the `a` and `map` elements, retained solely for compatibility with older browsers, was removed in favor of `id`. Similarly, the `lang` attribute was dropped for all elements in favor of `xml:lang`.
2. Ruby annotation was added. A *ruby* is a collection combining content and an annotation to be displayed above (and below, if there is a second annotation) the content, e.g., to provide the pronunciation of a foreign term. These are most often used with eastern Asian languages. For details on the use of ruby annotation, consult W3C (2001d).
3. The DTD was partitioned into modules as shown in Table 9.

Table 9 XHTML 1.1: Modularization

Module	Elements or Attributes
Structure	`body`, `head`, `html`, `title`
Text	`abbr`, `acronym`, `address`, `blockquote`, `br`, `cite`, `code`, `dfn`, `div`, `em`, `h`*n*(*n* = 1 to 6), `p`, `pre`, `kbd`, `q`, `samp`, `span`, `strong`, `var`
Hypertext	`a`
List	`dl`, `dt`, `dd`, `li`, `ol`, `ul`
Object	`object`, `param`
Presentation	`b`, `big`, `hr`, `i`, `small`, `sub`, `sup`, `tt`
Edit	`del`, `ins`
Bidirectional Text	`bdo`
Forms	`button`, `fieldset`, `form`, `input`, `label`, `legend`, `select`, `optgroup`, `option`, `textarea`
Table	`caption`, `col`, `colgroup`, `table`, `td`, `tfoot`, `th`, `thead`, `tr`
Image	`img`
Client-Side Image Map	`area`, `map`
Server-Side Image Map	attribute `ismap of img`
Intrinsic Events	event attributes
Metainformation	`meta`
Scripting	`noscript`, `script`
Stylesheet	`style` element[a]
Link	`link`
Base	`base`
Ruby Annotation	`ruby`, `rbc`, `rtc`, `rb`, `rt`, `rp`

[a] The `style` *attribute* is deprecated.

Note that the partitioning is not along the lines by which we categorized elements earlier. A module may contain both block and inline elements, for example.

The appropriate `DOCTYPE` declaration for an XHTML 1.1 document becomes

```
<!DOCTYPE html PUBLIC "//W3C//DTD XHTML
  1.1 //EN""http://www.w3.org/TR/xhtml11/
  DTD/xhtml11.dtd">
```

The opening `html` tag is the same as that for XHTML 1.0, except that the `lang` attribute is deleted. The default XML namespace remains the same.

XHTML Basic

The purpose of XHTML Basic is to provide a very small DTD for very small platforms, including mobile phones, PDAs (personal digital assistants), pagers, vending machines, set-top interfaces for televisions, digital book readers, smart watches, mobile game machines, and automobile navigation systems. However, it presents a minimal core which can provide bare-bones functionality on all platforms and which can be augmented by additional modules. The outline of XHTML Basic can be seen in Table 10.

XHTML Basic was released even before XHTML 1.1. It is based on an early version of the "Modularization of XHTML" recommendation, the latest version of which is W3C (2001b). W3C recommendations go through a progression of stages: Working Draft, Last Call Working Draft, Proposed Recommendation, Candidate Recommendation, and W3C Recommendation. Since the modules of XHTML Basic are based upon another, mature recommendation, W3C's HTML Working Group considers XHTML Basic to be stable as well (W3C, 2000b).

Comparing Table 10 with the earlier Table 9 shows which XHTML 1.1 modules are missing from the Basic DTD: Presentation, Edit, Bidirectional Text, Client-Side Image Map,Server-Side Image Map, Scripting, Stylesheet, and Ruby Annotation.

Table 10 XHTML Basic: The Least Common Denominator

Module	Elements
Structure[a]	`body`, `head`, `html`, `title`
Text[a]	`abbr`, `acronym`, `address`, `blockquote`, `br`, `cite`, `code`, `dfn`, `div`, `em`, `h`*n* (*n*=1 to 6), `kbd`, `p`, `pre`, `q`, `samp`, `span`, `strong`, `var`
Hypertext[a]	`a`
List[a]	`dl`, `dt`, `dd`, `li`, `ol`, `ul`
Object	`object`, `param`
Basic Forms[b]	`form`, `input`, `label`, `select`, `option`, `textarea`
Basic Tables[b]	`caption`, `table`, `td`, `th`, `tr`
Image	`img`
Metainformation	`meta`
Link	`link`
Base	`base`

[a] Required HXTML Host Language module.
[b] Abridged version of an XHTML 1.1 module.

In addition, the Forms and Tables modules have been trimmed considerably. An additional restriction is that tables cannot be nested. This common technique makes little sense in this context given the lack of screen space on the target platforms and the computational expense associated with rendering tables.

Particularly notable is the elimination of both the inline style elements and the `style` element. This means that formatting of displays is to be accomplished by using the `link` element to include an external style sheet. Such formatting is still possible, as the `span` and `div` elements for delimiting content and the `class` attribute are still supported.

Potentially even more significant is the lack of support for scripting, which is matched by the absence of event attributes. The intention is not to prohibit interactivity. Rather, events, e.g., an incoming phone call, are seen as being highly device-dependent. Consequently, platform-specific modules must be designed and implemented to achieve dynamic content.

CONCLUSION

HTML served the World Wide Web well during much of the Internet Age. In the previous millenium, it became forever frozen at Version 4.01.

The early history of HTML could be characterized by two words: recommendations ignored. Competition between two particular browsers, Microsoft Internet Explorer and Netscape Navigator/Communicator, produced extensions to W3C's recommendations, which influenced the expansion of the officially sanctioned HTML lexicon. At the same time, browsers chose not to support certain features contained in recommendations or supported them poorly or inconsistently. In some cases, the blame can be placed on vagueness in W3C's specifications. In extreme cases, browsers exhibited bizarre behavior which can only be described as major bugs.

Perhaps worst of all, browsers tolerated (and continue to tolerate) malformed HTML documents, encouraging the Web community to develop poor code-writing and code-generating habits. In particular, an HTML document is commonly viewed as text to be processed, not a tree to be parsed. Much existing code does not exhibit a well-defined structure that could be processed based on semantic content.

HTML itself is a hybrid product. In part, it manages content, in the spirit of SGML. But it has, over time, accrued formatting capabilities. This has contributed to the development of another bad habit: using HTML to manage the presentation. Admittedly, CSS arrived late on the scene, and browsers' irregular support for CSS has forced many developers to view HTML itself as a more reliable formatting tool.

HTML's fatal flaw, however, is its inability to adapt to future or, for that matter, present technology. On the one hand, it does not allow high-powered environments to realize their full potential to render complex or specialized content. On the other hand, it cannot accommodate the special requirements of small devices with limited (if any) screen space and modest computing power.

W3C's ultimate vision for the Web is to have a framework that can grow (possibly from a very tiny core) to fit the specific needs of any current or future platform. The basis for such a flexible tool is XML. XHTML, one particular XML application, is a transitional tool for ultimate conversion to XML; as such, it will likely persist for years.

The major contribution of XHTML 1.0 is the enforcement of structure: to be a valid XHTML (and, therefore, XML) document, it must be well-formed. Of the three DTDs or XML Schemas, Strict foreshadows the demise of frames—always controversial, once popular, but now fading in importance—and the further separation of content and presentation in XHTML 1.1.

XHTML 1.1's only DTD is fragmented into modules, the key to extensibility. Designed for a variety of small platforms, XHTML Basic prunes the modules in both number and (for two modules) size. Code from many special-purpose XML applications, such as MathML and SVG, can be incorporated in XHTML documents.

At each step in the evolution of HTML/XHTML, moving forward has entailed leaving some things behind. Controversy is sure to follow this continued evolution. So far, the conversion to XHTML (even on pages at W3C's Web site) has been slow. While this conversion does not have the urgency or criticality of Y2K—power plants will not turn into pumpkins when the clock strikes 12—failing to convert to XHTML translates into not realizing the full potential of the Internet.

GLOSSARY

Attribute Parameter associated with an *element;* located, along with its value, in the element's opening *tag*.

Block element *Element* that can contain data (text, images, etc.), *inline elements*, and/or other block elements; typically *rendered* with intervening whitespace (a line break and often vertical space) between it and neighboring block elements; "larger" than an inline element (as a paragraph is "larger" than a sentence).

Cascading Style Sheets (CSS) A method for formatting and/or positioning content within an *HTML* or *XHTML* document; a *W3C* trademark.

Deprecated Slated for deletion from future versions; not recommended for usage.

Document Object Model (DOM) A system for viewing the content of an *HTML* or *XHTML* document as being organized into objects, which can be programmatically accessed in an object-based fashion; a *W3C* trademark.

Document Type Definition (DTD) (for a family of documents) Document that specifies, using an Extended Backus-Naur Form grammar, the features of a valid document; for a particular version of *HTML* or *XHTML,* these features would include the valid element types, the names of attributes that can (or must) be associated with elements, and the suitable ranges of values that can be assigned to attributes.

Element The unit of structure in an *HTML* or *XHTML* document.

Extensible HyperText Markup Language (XHTML) A highly adaptable *markup* language to allow Web content to be *rendered* by a *user agent;* a *W3C* trademark.

Extensible Markup Language (XML) A general methodology for structuring data; defined (but not trademarked) by *W3C*.

Hyperlink or link Within a *hypertext* document, an *element* associated with a pointer to another (part of the) document; activating the element—typically by clicking on its *rendering* as a button, image, or highlighted text—takes the user to the new document (part); the most essential component of a hypertext document.

Hypertext Technique for interactively traversing an electronic document (or collection of documents) by following *hyperlinks* as an alternative to sequential traversal.

HyperText Markup Language (HTML) The original language for marking up content on the World Wide Web; invented by Tim Berners-Lee; further developed (upon the suggestions of many) and codified (but not trademarked) by *W3C*.

Hypertext Transfer Protocol (HTTP) A generic, stateless, object-oriented, application-level (level 7 in the ISO OSI model) protocol (typically associated with Port 80) that allows for negotiation of data representation; usable for a variety of tasks, e.g., distributed object-management systems, but most famous as the means of sending HTML code through the Internet.

Inline element *Element* that can contain only data (text, images, etc.) and other inline elements; "smaller" than a *block element* in the sense that it must be embedded within a block element; rendering generally does not automatically add whitespace as for block elements.

Markup language Language for defining the structure and formatting of a document by means of ordinary characters (rather than, for example, escape characters) within the document.

Metalanguage Language used to describe another language (for example, *XML* is the metalanguage for *XHTML*.)

Parse To analyze a document to determine its structure.

Render For a *user agent,* to present a document on a screen, printed page, etc.

Standardized General Markup Language (SGML) A *metalanguage* standardized by the International Standards Organization (ISO 8859); used to define the syntax of textual markup languages; the precursor of HTML.

Tag The opening or closing marker of an *element;* in *SGML*-derived languages, delimited by angle brackets (< >). (Empty elements are represented by a single tag.)

Universal Resource Identifier (URI) A string identifying a resource on the Web by means of a name or address. There are a multitude of URI addressing schemes (see http://www.w3.org/Addressing). Two particular subtypes of URI are

1. **Universal Resource Locator (URL)** The original term for resource addresses associated with common URI schemes such as http and ftp; no longer used in technical specifications, but still appears within values in `meta` *elements*.

2. **Universal Resource Name** (**URN**) A persistent name that identifies a resource regardless of the particular address to which the name currently resolves; address resolution requires an institutional commitment to persistence.

User agent Application, such as a Web browser or an e-mail program, that can *render* an *HTML* or *XML* document.

Valid (relative to a particular *DTD* or *XML Schema*) Conforming to the DTD or XML Schema—all *elements* and their *attributes* are declared in the DTD or XML Schema, each element has appropriate attributes (perhaps as required), and each attribute's value is in the appropriate range.

XML namespace (for a document or specified portion of a document) A (structured) collection of names that can be used as *element* types and *attribute* names, identified by the URI of the file defining the collection.

XML Schema An alternative to *DTD*s for specifying a language (module); written in *XML* syntax, so it can be manipulated like any other XML document.

Well-formed Having a well-defined structure—*elements* are correctly nested and contain any required child element/elements.

World Wide Web Consortium (**W3C**) An international organization that makes recommendations regarding Web-related technologies; a registered trademark. (Note: While one commonly sees "the W3C" in print, W3C itself generally does not apply the definite article to its abbreviation; compare this with the broadcasting corporations "ABC" and "the BBC.")

Human Factors and Ergonomics

Robert W. Proctor, *Purdue University*
Kim-Phuong L. Vu, *Purdue University*

INTRODUCTION

Human factors and ergonomics (HFE) is an interdisciplinary field devoted to designing and evaluating products and systems for effective and safe use by humans (Proctor & Van Zandt, 1994). The fundamental idea underlying HFE is that systems must be designed with the users in mind if the systems are to accomplish their goals effectively. Transactions initiated through the Internet typically involve extensive human interactions with the system because the purpose of the Internet is to convey information from user to user, business to business, and business to consumer. Because the focus of HFE is on human–machine interactions in general, with a specific emphasis on human–computer interactions, the field has much to offer to the design of user interfaces and applications for the Internet (Proctor et al., 2002).

HFE emerged from issues involving use of military systems in World War II (Green, Self, & Ellifritt, 1995). In subsequent decades, however, the field expanded into many areas, including computer and information systems. Traditionally, the main contributors to HFE have been industrial engineers and psychologists, but more recently, individuals with a range of backgrounds and interests from both academia and industry have become involved. Current technical groups for the Human Factors and Ergonomics Society include, for example, cognitive engineering and decision making, communication, computer systems, consumer products, Internet, performance and perception, system development, test and evaluation, and virtual environments (see http://www.hfes.org).

The concept of human–machine systems implies that all products and systems that involve humans can be divided into subsystems composed of the human aspects and the machine aspects. The focus is on designing interfaces that promote effective human–machine interaction and are consistent with the physical and mental capabilities of the human. HFE relies on basic research in psychology, biomechanics, physiology, and other areas for knowledge regarding the capabilities and limitations of humans (Proctor & Vu, 2003). Examples include the following: (a) central vision is specialized for perceiving detail and peripheral vision for detecting stimulus onsets and movement, (b) the capacity to attend to multiple stimuli is limited, (c) irrelevant features of stimulation often affect performance, (d) items in immediate memory are subject to rapid forgetting, (e) retrieval from long-term memory is dependent on the cues provided, and (f) human reasoning and decision making often rely on use of heuristics that simplify the task but may lead to errors.

The applied research that is at the heart of HFE has the goal of analyzing human performance in ecologically valid environments of the type in which people must operate on a daily basis. For the Internet, the environmental context of interest is the user interacting with Internet applications such as a Web browser or e-mail application. Principles, guidelines, and methods have been developed for assisting designers in designing for human use (Salvendy, 1997), and many techniques have been formulated for evaluating the usability of systems and products at all stages of the design process (Proctor et al., 2002). These principles and techniques are directly pertinent to designing for human interactions with the Internet.

HFE focuses on both physical and cognitive aspects of human use. Physical ergonomics is concerned with accommodating the physical properties of the human body in system design. Examples include design of chairs to be comfortable and support good work postures and design of control panels that allows the switches and controls to be reached and operated easily. Cognitive ergonomics is concerned with accommodating psychological properties of the human in system design, broadly defined to include everything from perception to execution of an action. Examples include use of color coding to distinguish alternative categories of events (e.g., traffic light) and design of decision support systems to aid human decision making.

HFE initially focused primarily on individual operators and users. Over the past decade, however, macroergonomics, which involves organizational and social factors, has received increasing research interest (Hendrick, 1997). Systems exist within an organizational context and often involve interactions among individuals within a group, and successful prediction of human performance requires consideration of these group factors. Among the macroergonomic topics of interest are team cognition and performance. Teams of people are involved in performance of many tasks. Examples include the flight crew of a commercial aircraft and the engineers of a company at different sites working together on a design project. The focus of concern in team cognition is how to enhance communication among team members to optimize performance of the team as a whole.

Human–computer interaction (HCI) has been a topic of burgeoning interest over the past 20 years (Jacko & Sears, 2003). During this period, several organizations devoted to HCI have been established (e.g., the Special Interest Group on Computer–Human Interaction (SIGCHI) of the Association for Computing Machinery; see http://www.acm.org/sigchi/), along with associated journals and conferences. For any task involving computer use, a range of physical and cognitive issues arise. One widely known physical injury associated with computer use is carpal tunnel syndrome. People who operate a keyboard for many hours on a daily basis are at risk for developing this syndrome, which involves neural damage in the area of the wrist. Many factors reduce the probability of developing carpal tunnel syndrome, including use of split, curved keyboards that allow the wrists to be kept straight rather than bent. An example of a cognitive consideration is the development of icons that convey specific actions of the interface to minimize memory demands of where specific commands are located in a menu. Icons can increase the speed in which functions are carried out, but if the icons are not recognizable, then more time is lost by wrong executions. Because of the rapid development of the Internet, an increasing portion of HCI research has been devoted specifically to issues of usability associated with the Internet (Nielsen, 2000).

HUMAN FACTORS AND ERGONOMICS IN DEVELOPMENT OF INTERNET INTERACTIONS

Initially, the Internet was used to enhance communication and transaction between businesses and organizations, and the population of users was restricted primarily to highly educated persons with some background in computers. In recent years, use of the Internet has expanded to the mass population, for which the user characteristics are highly varied. For the novice user, effective use of the World Wide Web can be a daunting challenge. Whereas designing for human use was important initially, it is essential now to allow easy access and use for the whole range of users.

Not only has the population of users expanded, but the variety of uses to which the Internet is put has increased substantially as well. Individuals can use the Internet to send and receive e-mail messages; to buy merchandise; to manage financial accounts; to download files, applications, and programs; to search for specific information or browse information relating to general topics; and so on. Each of these broad categories of activities comprises many specific tasks, which in turn comprise many subtasks. Given the enormous variety of user-initiated interactions with the Internet, it should be clear that a system designed without consideration of the user will not be successful. Evidence consistent with this view has been demonstrated repeatedly in the HCI literature (see, e.g., Najjar, 2001).

Considerable effort has been devoted to applying HFE to different aspects of Web design and evaluation (see Figure 1). Research has been conducted to identify problems associated with browser compatibility, Web site navigation, specific functions and features of a site, and search effectiveness. For example, studies have demonstrated that if a Web page takes a long time to download, users will become frustrated, have increased feelings of being lost, and judge the material to be less interesting and of lower quality than they would otherwise (e.g., Jacko, Sears, & Borella, 2000). To allow faster download times for Web pages, use of graphics and multimedia effects should be kept to minimum (Nielsen, 2000). Although efforts to improve usability with respect to the aforementioned features continue today, issues such as accessibility for different populations of users and promoting security for Web interactions have also become topics of concern. The increased emphasis on security and accessibility for all users is in part a consequence of the emergence of e-commerce in the global economy and use of the Web for educational purposes.

Because e-commerce yields large income for companies, Web sites that are not user-friendly and not perceived as secure will result in loss of income because users abandon the sites. It has been shown that increasing the usability of a Web site improves sales. IBM found a 400% increase in sales by improving the usability of their Web site (Tedeschi, 1999). A Web site that is user-compatible can also improve customers' satisfaction with the site, and Creative Good (2000) showed that by improving the users' experience, the number of customers and order size increases. When users go to a company's Web site in search of a specific product or category of products, they must be able to locate the product easily. Consequently, a major concern of most e-commerce sites is to develop or adopt a search engine that allows users to find their products easily. If the users cannot find what they are looking for, they cannot buy the item and will leave the site. Once the user is able to locate the product, the remaining interactions with the site also need to be user-friendly, or the user will not complete the checkout process and will abandon the items in the "shopping cart." Factors that influence a user's willingness to complete the checkout process include the length of the process, perceptions of security for credit card information, the ease with which information about shipping costs can be located, and privacy issues associated with registration (Najjar, 2001). Poor usability will reduce the number of consumers who purchase products from a business, as well as the likelihood of whether those consumers will return to the site for future purchases.

The Internet has also allowed exchange of data between researchers and collaboration among people at different locations in the world. For example, a researcher can e-mail a manuscript or post it to a Web page so that a colleague can access the file. When this capability first became available, the main benefit was to allow the individuals to exchange files. With such a procedure, however, it is difficult for the receiver to detect the changes made by the sender. Consequently, tools have been

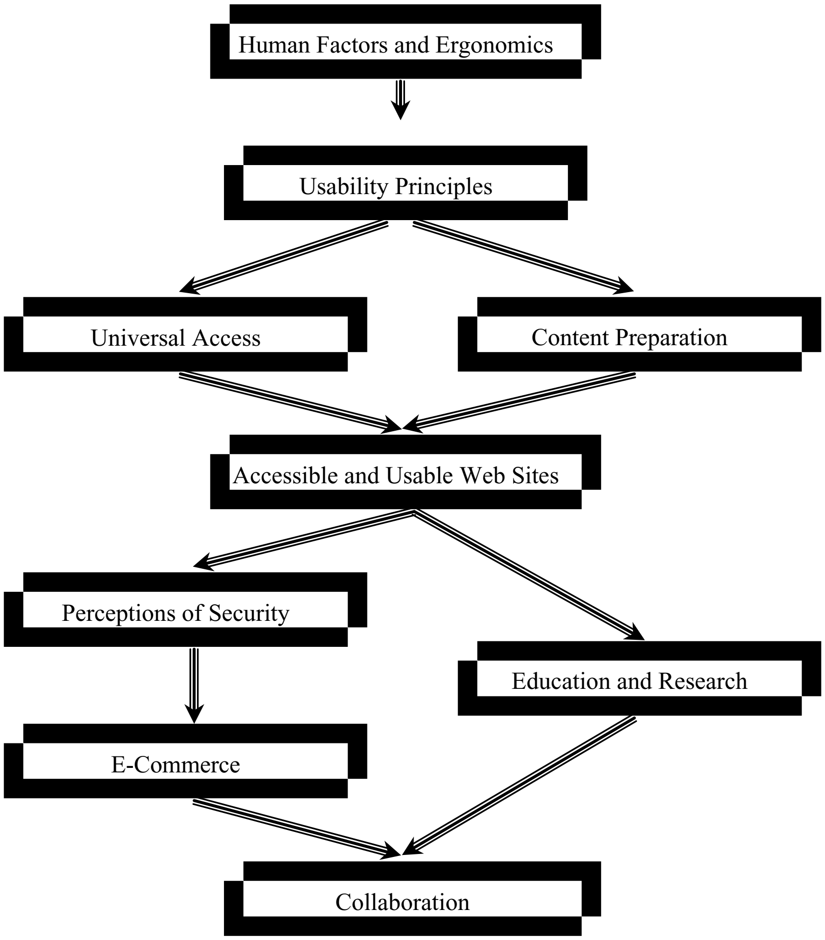

Figure 1: Illustration of how human factors and ergonomics is applied to different aspects of Web design and evaluation.

developed that enable the changes to be marked so that the receiver can locate them easily and either accept or reject them. How to facilitate collaboration on research and design projects is a topic of current interest in research on HCI (e.g., Neuwirth, Chandhok, Morris, Wenger, & Regli, 1998). For example, researchers are developing methods for automated assessment of team cognition using communication data. These methods allow online assessment of team cognition and can be used for designing and evaluating system interfaces and training programs (Kiekel, Cooke, Foltz, & Shope, 2001).

Web sites have also been developed for educational purposes that contain information relevant to material covered in a specific course as well as demonstrations of specific experiments or phenomena relevant to the subject matter (e.g., Birnbaum, 2000). These demonstrations have the potential of helping students understand the material better than traditional text coverage in textbooks, but not if the Web site and demonstrations are hard to use or the format difficult to understand. Sites intended to promote learning must be designed to match human information processing characteristics for them to be effective. For example, because reading from the computer screen is much slower than reading hard copies of the same material, text on the Web should be concise (Nielsen, 2000). The Internet has led to the possibility of better quality for distance education courses in that it can include real-time lectures and interactions between the instructor and the students. Also, the efficient transmission of documents reduces the time lag for students to receive feedback on assignments. Although the technology is available, if it is not usable by the targeted population, it cannot achieve the goals of promoting learning. Because the use and effectiveness of Web-based courses and materials is in its infancy, the continued application and incorporation of human factors principles and usability evaluations are needed to ensure its success in the future.

RETRIEVAL OF INFORMATION: IMPROVING WEB SEARCH

The Internet contains a vast amount of information that is growing and changing daily. Consequently, it is a challenge for users to locate the information they seek and that is most relevant to their concerns. Because of the vast information, a powerful search engine is essential. General and specific search engines for particular sites help users narrow down the information for which they are looking. If the search is successful, the user will find the desired information, but if it is not, the user must repeat the process until the information is found or he or she gives up. For an e-commerce site, with its own search engine, the number of searches in which users must engage before locating the targeted information affects the successfulness of the Web site. According to Nielsen, Snyder, Molich, and Farrell (2000), 33% of e-commerce users give up after three search queries. This statistic has important implications for business and stresses the importance of a good search engine for any large Web site.

Although search engines are important to the success of a Web site, current search engines are for the most part inadequate because they return too many irrelevant hits or provide search options that are difficult to use. Furthermore, search engines tend to be inconsistent with each other. For example, some search engines do not require the use of Boolean connectors such as "and," whereas others do. Furthermore, even if the same terms are entered into the search engines, different hits are often returned. The major problem leading to the poor design of search engines is that they were designed without incorporating knowledge regarding how users search for information (see, e.g., Proctor et al., 2002). Although some research has been devoted to understanding users' interactions with search engines, the results still do not provide an adequate description of what strategies users use to search for information and whether these strategies are specific to the task or generalizable to all Web searches.

Because humans' working memory and attentional capabilities are characterized by a limited capacity to process information, it is important for search engines to minimize the memory and attention loads. Tools should be provided to support users' decision making in high load situations. In addition to using the Web to search for specific information, it can be used to browse topics of general interest. Users approach their tasks with an analytic, goal-directed strategy when searching for specific information but with a more intuitive strategy when browsing. Chen, Wang, Proctor, and Salvendy (1997) found that the mean path length (the number of steps users take through continually using hyperlinks from a start URL) was twice as long for a nonspecific browsing task as for a specific search task. In other words, when browsing, users have a tendency to follow links from successive pages much more than they do when searching for specific information. Moreover, the specific browser functions that are used vary as a function of the type of task. The basic point is that Web sites and search engines need to be designed with both search and browsing in mind.

CONTENT PREPARATION FOR THE WEB

No matter how good a search engine for a particular Web site is, if the information contained in the site is poorly organized and displayed, users will not be able to locate and use the information. Thus, effective content design is required to promote successful interactions of the users with the Web site. Proctor et al. (2002) identified three areas of focus for content preparation in addition to search and retrieval of information: (a) knowledge elicitation, (b) structure and organization of information, and (c) presentation of information.

A Web site should convey information relevant to the user's task in a manner that is easy to understand. To determine what information needs to be conveyed, content designers must identify the information from the domain of interest that is needed to perform various tasks. Knowledge can be elicited from domain experts or from a group of potential users. Experts can specify what information should be conveyed, the way in which it should be structured, and the typical strategies used to retrieve the information. Users can also provide information regarding what information seems to be relevant to them and how this information should be presented. The difference between knowledge elicitation of experts and of potential users is that for the former the emphasis is placed on capturing what the expert knows, whereas for the latter, the emphasis is placed on understanding the knowledge that users bring for interacting with the system to predict their actions.

Because it is often difficult to identify which individuals will be able to provide the knowledge appropriate for different tasks, the process of knowledge elicitation is not simple. For example, the question arises of who the expert is. An expert in one area is not necessarily an expert in another, even if the two areas are related. Furthermore, different experts view issues from different points of view, making it difficult to generalize. Thus, it is best to include several experts in a domain and a range of users in the knowledge elicitation process.

Once information is elicited, it needs to be organized and structured in a manner to promote easy navigation through the structure and easy retrieval of information in the structure. Because each organization has different goals and characteristics that need to be reflected their Web site, the information that needs to be organized may differ in terms of the types of format and structure and need to be integrated into the Web site in a simple and intuitive manner. Users must be able to navigate through the Web site easily. To help communicate the site's structure to the users, the major sections and subsections of the site must be obviously displayed and navigation aides such as breadcrumbs and site maps should be made available (Najjar, 2001; Nielsen, 2000). Information also needs to be structured and organized in a manner that allows the site administrator to update the information easily. More important, the organization and structure of the information must satisfy the objectives and preferences of users or they will not use the site. As a result, the mode of behavior in which the user will be engaged should be determined to help organize the information in a manner that will be advantageous to the user. Although end users are typically not involved in the design of the information architecture of a Web site, their input in early design phases is crucial because the success of the site is often measured by the ability of the end users to interact with it to achieve the intended goals.

The last stage of content design involves presentation of information. The way in which the information is presented can affect the overall success of the Web site because even if the information can be elicited, organized, and retrieved, it needs to be presented in an effective and efficient manner to enhance usability. Preferences in the way that information should be presented differ across individuals. As a result, information can be presented in a way that is intuitive for some users but not others. For example, a Web designer may present information in a way that makes sense to him or her, but this presentation format may be difficult for most end users to understand, in turn making it difficult for them to interact with the site. To remedy this problem, user feedback from the targeted population can be obtained to improve the presentation format used in Web sites. There have been many demonstrations of the effectiveness of incorporating user input into the design of Web sites (see, e.g., Nielsen et al., 2000), but to date, most Web sites are designed without significant user input.

UNIVERSAL ACCESS

Because the Internet allows access of information from anywhere in the world and at any time, the issue of universal access has become a topic of concern (Stephanidis, 2001). Universal access is based on the idea that if Web sites were designed to comply with standard accessibility guidelines (e.g., the W3C-WAI guidelines produced by the World Wide Web Consortium), then the sites could be used by people with various characteristics. An important change in design conceptualization is that Web sites are no longer designed to be useable for the average user, but for all potential users. Thus, universal access requires a user-centered approach to Web design that would satisfy the broadest range of users.

Designing universally accessible Web sites would promote international and multidisciplinary exchange of information and help the expansion of e-commerce to the global market. One way to make Web sites accessible to an international audience is to translate them into different languages. Although this may seem like a trivial task because translation software is available, the translated information must be accurate and match the language structure of the population. It should not be raw translations that do not make much sense or require the user to engage in additional translations. More important, the way in which the information is conveyed when translated should match the mental models of the targeted population. For example, it has been shown that Chinese users prefer concrete knowledge representations, whereas American users prefer more abstract representations (Choong & Salvendy, 1999). Also, the symbology used in Web site should conform to the cultural norms of the population.

Another issue in promoting universal access is to make the Internet accessible to elderly and disabled users. The perceptual and cognitive capabilities of the various user groups must be taken into account. For example, because the ability to perceive detail decreases with age, larger font sizes should be available for elderly users. For users with disabilities, information presented in the Web site must be redundant across modalities (e.g., auditory and visual) so that the user is able to extract the information. Thus, there is a need to evaluate translated and modified versions of the Web site with respect to the users' preferences, abilities, and mental models.

One way to facilitate universal access is to have the interface adapt to the user. Adaptive user interfaces are those that automatically adapt to the behavior, needs, and requirements of users and to different contexts in which the interface is used. Because of the range of users, adaptive systems promote a good fit between the users and the Web interface. Weber and Stephanidis (2001) distinguish between two characteristics of adaptive systems: adaptability and adaptivity. Adaptability refers to the ability of a system to be preprogrammed to recognize known user characteristics. Adaptivity refers to the ability of a system to update its knowledge of the user while he or she interacts with the system and modify the system's behavior accordingly. Although adaptive systems can allow a larger range of users to access a site, adaptivity takes control away from users. If the level of adaptivity is more than what users are willing to tolerate, then they may stop using the site. The development of adaptive systems as means for establishing universal access is still in its initial stages. Thus, it is important that designers take human factors considerations into account when developing these systems to ensure successful interactions of the system with the human.

INFORMATION SECURITY

Because unauthorized users have potential access to any computer connected to the Internet, information security has come to be recognized as an increasingly important aspect of the Internet. Computer security breaches including theft of confidential corporate information, compromise of intellectual property, unauthorized modification of systems and data, and denial of service may occur if systems and the information stored in them are not kept secure. Most of the sophisticated methods that have been developed to provide increased computer security rely on individuals to implement and use them, but many of them were designed without the user in mind. Improper use by end users or system administrators often occurs because the procedures required of them are usually complicated and annoying. Furthermore, users may not be aware of the best methods for increasing security (e.g., how to generate passwords that are difficult to crack) or may just resist them. Consequently, the level of security that is actually provided is much less than the level that the methods could potentially provide. Not too surprisingly, then, the user is often considered to be the main limiting factor in security. Although systematic HFE evaluations to the area of information security are in their infancy, it is clear that that HFE has much to offer for improving the degree of security (Schultz, Proctor, Lien, & Salvendy, 2001).

A properly executed information security program requires appropriate program management and administration. Security administrators must (a) configure security methods appropriately, (b) monitor their status and detect intrusions, and (c) enable features and run add-on applications that increase the level of security. Methods of identification and authentication are concerned with determining who the user is and whether the user should be allowed access to information and systems. The most common method is that of entering a username and password. There are many issues regarding passwords, and they center around the fact that passwords impose a large memory load on the users. Passwords that are easy to remember are also easy to crack (Proctor, Lien, Vu, Schultz, & Salvendy, 2002). Alternatives to the username–password method of authentication include biometric measurements such as fingerprint recognition that are dependent on individual differences in some physical characteristic, and use of smart cards and token devices. All of these methods require additional steps for the user and create the potential for error and user resistance if usability is not considered.

Another concern of information security is ensuring data integrity, confidentiality, and availability. Corruption of stored information, release of information to unauthorized individuals, and lack of availability of information when it is needed can create legal and financial problems. For example, alteration of Web page content can lead to liabilities associated with unauthorized changes advertised prices, and other terms and conditions that can create public relations damage. The most common security method for guarding against unauthorized changes in data is to restrict access by setting permissions or access control lists. Yet the steps for setting permissions and access lists are usually long and complicated, making it difficult for users and administrators to follow them. Another method used to combat the data integrity problem involves computation and storage of cryptographic codes for all of the data on the server. Effective operation of this method requires numerous steps of user interaction, both in implementing programs that check data integrity and checking any output of these programs to determine whether unauthorized data changes have been made. Again, the complexity and workload imposed on the administrator must be kept within reasonable bounds for this method to be effective.

Remote intrusions and unauthorized accesses of databases likely will go unnoticed if there is not an intrusion detection program in place. Such a program can be based on system audit logging and intrusion detection systems, both of which pose high cognitive demands on system administrators. Regular inspection of system audit logs, which provide information about system usage characteristics, can lead system administrators to detect unauthorized usage patterns. The success of system audit logging for intrusion detection depends on the ability of administrators to recognize patterns that indicate intrusions. System logs usually are poorly formatted, displaying lines of monochrome text in uniform size and font, arranged in columns. With this format, it is difficult for system administrators to detect break-ins. It is important to display information in such a way as to make the patterns easier to detect, for example, by using perceptual cues to make critical information “pop out” and to train humans to recognize specific patterns “automatically.”

Information security is of particular concern to e-commerce and its numerous transactions (Garfinkel & Spafford, 1997). Corporations have invested billions of dollars toward providing secure transactions and fraud protection. The focus of providing a secure site for e-commerce is crucial for users to have confidence in purchasing the products offered by the site. Nonetheless, no matter how much security a system can provide, if a system is unusable and not perceived as being secure, users will choose alternative Web sites that are perceived as more usable and secure. In fact, as many as 20% of users reported that they discontinued an online purchase because they felt the site was not secure (Hill, 2001). It has been suggested that sites provide prominent links and symbols to promote information security and privacy (see, e.g., Najjar, 2001).

DETERMINING USER CHARACTERISTICS THROUGH TASK ANALYSIS, USER MODELING, AND USABILITY TESTING

The first step in designing, modifying, or improving a Web interface should be a task analysis to identify the activities that users must perform when interacting with the interface to achieve their tasks (Pearson & Weeks, 2001). The task analysis provides designers with the users’ background knowledge, expectancies, and actions while interacting with the system, allowing the designer to identify the weaknesses of the interface and insights on how to modify the interface to eliminate these weaknesses. A task analysis can begin with observation of users in the task environment to understand the setting in which they interact with the system. Afterward, information regarding specific tasks and activities can be obtained through an interview. The interview can consist of a series of questions and answers or inquiries that are answered while the user performs a specific task. Based on the observations and task descriptions, the evaluator can determine the knowledge needed, the procedures involved, and the users’ preferences for how to perform the task, as well as the assumptions and background knowledge that users bring to the task. Workflow charts can also be developed to capture the dynamic processes involved in performing a task. Information regarding difficulty in performing the task, design flaws, and aspects of the procedure that are not preferred by users can also be obtained.

A task analysis can be used for more formal user modeling to predict users’ performance in the specific context in which the task will be performed. User models can relate system features to users’ needs and be used to compare alternative designs. The most widely implemented user modeling technique in HCI is that of GOMS (goals, operators, methods, selection rules; Card, Moran, & Newell, 1983) analysis and its variants. Using this technique, the task is decomposed into goals and subgoals; the perceptual, cognitive, and motor operators used in performing the task; alternative methods for achieving the goals; and selection rules for determining which method to use. Estimates of the times for the cognitive operators are plugged in to the user models to generate predicted time to perform the tasks. GOMS analysis has been used successfully to predict the relative time required to use alternative interfaces (Pirolli, 1999).

Usability evaluations can improve a Web site by making the functions and goals of the Web site intuitive, effective, and consistent with users' preferences. Usability testing is the most well-known method used to evaluate the ease with which humans can interact with a system (Nielsen, 1997). Usability evaluations can be used to reveal much information about users interacting with the site such as features of the site that are not compatible with users' expectancy, the effectiveness of the site at facilitating users achieve their goals with ease, and changes to the site that would enhance its performance.

Usability testing is important when designing for the Internet because the sample of users is large, making it difficult for any site to maintain a "help desk" for questions. Furthermore, the number of similar and competing Web sites is numerous, making it easy for users to abandon one site if it is difficult to use in favor of a user-friendly site. Despite the benefits of incorporating usability evaluations in the design process, many sites are not including usability evaluations in their design process. There are many reasons usability evaluations are not incorporated throughout the design process, including, but not limited to (a) emphasis on conducting usability evaluations only in late design phases, when changes are difficult and expensive to make; (b) lack of support from management despite demonstrations of the effectiveness of usability evaluations; and (c) the use of guidelines as a substitute for usability testing.

There are many methods used for evaluating the usability of Web sites, which are briefly described next. Some methods are used in the initial stage of the design process, which allows the designer to gather information about the population that the Web site targets. Others methods involve usability experts systematically evaluating the individual Web pages and site to ensure that functions are consistent and follow basic standards and guidelines. Finally, some methods allow the designer to determine how users use and interact with the Web site either directly or indirectly.

Naturalistic and field observations allow designers to see how users interact with a Web site unobtrusively in a natural setting. For example, designers can observe users interacting with a particular Web site on a display computer. Contextual inquiries can be used to supplement observation data that helps the usability engineer understand the background of the user and how he or she will use the Web site. Focus groups usually consist of a group of users who are brought together to discuss different functions and features of a Web site. The group is usually moderated by a usability engineer leads the discussion. Focus groups can reveal information regarding what functions of the Web site are problematic or undesirable and allow brainstorming on how these problems can be remedied.

Questionnaires are often used to gather information about user preferences for the features and presentation of the Web site. With the use of e-mail and Web-based surveys, questionnaires allow quick gathering of preference data from a small or wide range of users. The response rate for questionnaires is typically low, however, and users may not always prefer the most optimal designs. User journals, logs, and diaries involve users writing down the specific activities in which they engage when interacting with the site. The users are asked not only to log their activities, but also to write down their thoughts regarding any interactions with the site. It is important to emphasize that the users be conscientiousness in keeping complete logs to ensure that the data are accurate and that the entries can be understood at a later date.

The usability specialist conducts heuristic analyses and walkthroughs to find problems with a Web site. For heuristic analysis, several usability evaluators interact and examine the interface of the Web site to rate the degree to which the site complies with established guidelines. The evaluators should work independently to increase the likelihood that most problematic aspects will be identified. Heuristic analyses are conducted in early design phases because they provide quick methods to find major usability problems. Whereas heuristic analyses are conducted from a usability specialist perspective, walkthroughs are conducted from user's point of view—that is, the usability specialist pretends to be the user interacting with the site with a set of scenarios. This cognitive walkthrough allows the engineer to note problems that prevent users from completing their tasks. With a pluralistic walkthrough, the usability specialist works with the user when he or she is interacting with the Web site. The users interact with the Web site as they would normally, and the usability specialist records any problems or issues with the product.

Usability lab testing is a technique for assessing the usability of a completed Web site or an incomplete version of a Web site. In a usability lab test, users are given a representative set of scenarios that they would typically perform with the Web site. The session is usually videotaped and mediated by a usability specialist. Performance measures include the time needed to complete a task, whether the user is able to complete the task, and the severity of errors. While the user is interacting with the interface, the user may be asked to think aloud or verbalize his or her thought processes, feelings, preferences, and problems experienced with the site or task. The user also answers questions relating to the usability of the Web site as a whole.

GENERAL GUIDELINES FOR INCORPORATING HUMAN FACTORS AND ERGONOMICS INTO THE DESIGN OF INTERNET SITES AND INTERNET-BASED APPLICATIONS

The material reviewed in this chapter suggests the following general guidelines for incorporating human factors and ergonomics into Web site design and evaluation:

- Determine the targeted population of users.
- Make the Web site compatible with user characteristics and preferences.
- Use established guidelines to aid in the design of Web interfaces.
- Incorporate usability evaluations throughout the design cycle.
- Present information in a concise and accurate manner.

- Structure and organize information in a way that enables easy navigation and access of information within the site.
- Design the site so that the information can be easily updated and maintained.
- Make search options available and ensure that the search features are efficient and effective.
- Ensure that the Web site or application is perceived as secure and that the information stored or transmitted is secure.
- Allow and promote universal access.

More detailed guidelines regarding specific aspects of usability issues and the Internet can be found in a variety of sources, which are cited in papers by Najjar (2001) and Proctor et al. (2002) and summarized in books such as that by Nielsen (2000). Some of the specific methods and guidelines are more effective for some purposes than for others. Thus, readers should make sure that the guidelines and methods they are consulting are appropriate for the intended purpose.

GLOSSARY

Cognitive ergonomics The area of ergonomics that focuses on consideration of psychological properties of users in system design.

Content preparation Preparing a Web site or application to be user-friendly, including determining the information to include, the way to structure this information, how to facilitate its retrieval, and how to present the information.

E-commerce Business transactions conducted via the Web, including business-to-business and business-to-consumer transactions.

Human factors and ergonomics An interdisciplinary field devoted to designing and evaluating products and systems for effective and safe use by humans.

Human–computer interaction An interdisciplinary field devoted to facilitating user interactions with computers.

Information security Methods for protecting information posted, stored, and transmitted electronically that are intended to ensure privacy, appropriate access to systems and information, and accuracy of information.

Macroergonomics The area of ergonomics that focuses on social and group interactions in the system context.

Physical ergonomics The area of ergonomics that focuses on consideration of physical and physiological properties of users in system design.

Task analysis An analysis of user tasks into goals, subgoals, strategies for achieving the goals, and processes involved in completing the task.

Universal access The availability of the Internet for use by anyone from anywhere at anytime and through any Web device.

Usability evaluations Methods that are intended to determine whether Web interfaces and other products are easy to use, easy to learn, and accepted by users.

Usability guidelines Guidelines established to promote usability and to standardize Web interfaces.

Web search A process by which users retrieve desired information from the Web.

INTRODUCTION

During the last decade the Internet has had a dramatic effect on our social and economic lives, changing the way we communicate, interact with others, and purchase products. It has also had a profound effect on the way we manage organizational processes including human resources (HR) management systems. For instance, results of recent surveys revealed that 70% of firms now use Internet-based employee self-service (ESS) systems to maintain employee records, 80% conduct online recruiting, and 40% use Web-based portals to communicate HR policies (Cedar, 2001; Towers Perrin, 2001). Although there are numerous reasons to use the Internet to facilitate HR processes, one of the primary reasons is that it helps organizations attract and retain employees, as well as improve employee productivity. Furthermore, researchers contend that the Internet helps organizations (a) streamline HR processes, (b) reduce cycle time, (c) facilitate organization communication, (d) increase employee access to information, and (e) improve the organization's overall ability to adapt to change (cf. Cardy & Miller, 2003; Gueutal, 2003; Stone, Stone-Romero, & Lukaszewski, 2003).

Although the Internet is thought to have a number of unique advantages, some researchers (Stone & Stone-Romero, 1998; Stone et al., 2003) have also argued that the Internet may pose potential threats to personal privacy. For example, the use of Web-based platforms may enable individuals and organizations to gain access to highly sensitive information about employees. In addition, the storage of personal information online may create permanent marks that may stigmatize individuals and preclude them from receiving valued, job-related outcomes (e.g., promotions, pay raises, training opportunities).

Despite the rise in the use of the Internet in the field of human resources management, few studies (Gueutal, 2003; Salas, Kosarzycki, Burke, Fiore, & Stone, 2002; Stone et al., 2003) have assessed the impact of the Internet on HR processes. Furthermore, little research (Eddy, Stone, & Stone-Romero, 1999; Lukaszewski & Stone, 2001; Stone & Stone-Romero, 1998) has directly examined the extent to which Web-based HR systems have the potential to violate employee privacy. Therefore, the primary purposes of this chapter are to (a) describe the role of the Internet in achieving HR system goals, (b) consider the impact of the Internet on the efficiency and effectiveness of HR systems, (c) identify the potential dysfunctional consequences of using the Internet in HR, with emphasis on employee privacy, and (d) offer guidance for future research and practice on the impact of the Internet on HR systems. As a result, in the sections that follow we consider the impact of the Internet on several specific HR processes, including recruitment, selection, performance appraisal, training, compensation and HR planning.

RECRUITMENT

Recruitment has been defined as the process of "searching for and obtaining potential job candidates in sufficient numbers and quality" to fulfill organizational goals (Dowling & Schuler, 1990, p. 47). As noted previously, the Internet is rapidly transforming the recruitment process in three key ways (a) facilitating the attraction of both internal and external job applicants, (b) providing a virtual realistic preview of organizations and jobs, and (c) evaluating the effectiveness of the recruitment process.

Attracting Job Applicants

Although traditional recruitment sources such as newspaper advertisements, private search firms, job fairs, and campus visits are still used to recruit job applicants, the Internet has changed the way in which many organizations announce job openings. For example, in 1997 approximately 58% of large firms posted job vacancies on the Internet; today almost 100% of firms announce job openings via their own Web sites or commercial sites (cf. Cedar, 2001; Gueutal, 2003).

The practice of using the Internet as a recruiting source, often called "e-cruiting," (Galanaki, 2002), started as a means of attracting individuals for technical positions by technology-driven firms such as Cisco Systems and Microsoft but has now expanded to include all types of job openings. Currently, the use of Internet recruitment strategies is thought to be beneficial to internal applicants, external applicants, and the organization as a whole. For example, external job candidates can easily search company Web sites for job openings and compare their knowledge, skill, and ability levels to job requirements. In addition, the use of the Internet can extend traditional searches worldwide, and potential job applicants can easily access job vacancy information anytime of the day or night. Furthermore, the shift to Web-based systems has resulted in a proliferation of national and international job data banks (e.g., Hotjobs.com) that enable applicants to compare and evaluate a wide array of positions (Higgs, Papper, & Carr, 2000). Moreover, some Internet recruiting software facilitates the electronic submission of resumes, bypassing the days or weeks associated with traditional resume handling.

Finally, firms can respond quickly to promising applicants to establish interviews. They can also use the Internet to notify applicants rapidly that their skill or education levels do not meet job requirements. Thus, the use of Internet recruiting may reduce the cycle time associated with traditional recruitment methods and streamline many of the labor-intensive administrative processes (e.g., reviewing resumes, sending follow-up letters to applicants) associated with recruiting. Given that applicants often judge organizations by the time lines and efficiency of administrative processes, a streamlined recruitment system may also have a positive influence on job applicants' image of the organization (Rynes, 1991).

Similarly, Internet recruiting and job posting may facilitate internal recruiting processes. Prior to the use of Internet recruiting, current employees may not have known about job openings within a firm either because they failed to inquire about openings or because that information was not easily accessible. With the advent of the Internet, however, firms are placing their vacancy notices on Web-based portals that may provide more timely job vacancy information to current employees and encourage them to apply for job openings. Given that internal applicants offer some advantages over external applicants, in terms of familiarity with the firm, prior training, and demonstrated job performance, organizations are likely to find that Internet recruiting provides a valuable source of unidentified, qualified internal job candidates. It may also allow organizations to use effectively the skills acquired by employees through training or educational programs (e.g., master of business administration or management of information systems degrees).

Interestingly, some Web-based systems used by large organizations (e.g., SAP, PeopleSoft) have the capacity to search employee records automatically to determine which employees are qualified for job openings. These same systems can then identify a match between employee knowledge, skill, and ability levels and job-based profiles. Finally, they are used to notify qualified applicants about internal job opportunities and inquire about their interest in the job vacancies. As a result, the use of Internet recruiting may increase job opportunities for current employees, enhance their satisfaction levels, and decrease turnover rates.

Furthermore, use of the Internet gives current employees the ability to take advantage of the rapidly growing ESS systems in which the Internet or firm Intranet are used to provide them with a wide array of HR information. For example, ESS systems allow employees to ensure that their records are updated to reflect current training and educational levels. Likewise, ESS systems provide current employees with the opportunity to review training requirements associated with jobs, which should help them plan their careers and enhance their promotion opportunities in organizations (cf. Gueutal, 2003).

Virtual Realistic Previews

As noted previously, another benefit of Internet recruiting is that it may allow organizations to provide a virtual realistic preview to job applicants. Realistic job previews (RJP) are typically used to ensure that the naive expectations of job candidates are brought more in line with organizational realities. Most research on RJPs has shown that their use increases employee satisfaction levels and reduces turnover rates (Rynes, 1991). Thus, organizations have long used organizational brochures or videotapes to provide applicants with a realistic preview of the job or organizational environment. The Internet can easily and inexpensively be used to provide job candidates with a "virtual" preview of a job or show them what it is like to work for the organization. For example, Ford Motor Company presents applicants with a series of typical situations they might encounter on the job to ensure that candidates know what to expect in the organization (Higgs et al., 2000). Such "high-tech–high-touch" approaches to RJPs should provide an important alternative to using brochures that are traditionally less flexible and often more expensive than online systems. In addition, virtual job previews may offer more detailed, current information than traditional brochures and allow candidates to personalize the recruitment process by indicating their preferences for working arrangements (e.g., telework, on-site training). Thus, the use of virtual job previews may help organizations improve the effectiveness of their overall recruitment and retention processes.

Evaluating Recruiting Effectiveness

In addition to helping organizations attract both internal and external candidates for job vacancies and providing virtual previews to job applicants, using the Internet can aid organizations in assessing the effectiveness of recruiting processes and strategies. For example, firms can monitor the Web-based portals of competitors to determine the types of hiring strategies being employed. Such tracking and monitoring capabilities provide insights that would have been difficult to secure in the past and may help organizations remain competitive in the labor market.

Similarly, organizations can use Internet tracking capabilities to build an internal database of candidates for future vacancies to reduce overall costs of future recruiting (Kavanagh, Gueutal, & Tannenbaum, 1990). In addition, these online systems can help HR managers evaluate the cost, timeliness, and effectiveness of the recruiting process. For example, the use of an Internet recruiting systems may provide HR managers or supervisors with reports that will enhance their ability to optimize recruitment strategies. Finally, the use of an Internet recruiting system can help control recruiting costs by improving the ratio of qualified candidates attracted to successful placements made. In summary, the Internet may improve the recruitment process for both job applicants and the organization by attracting a wider array of job applicants, improving the quality and amount of information available to applicants, increasing the speed and timeliness of the recruitment process, and enhancing the firm's ability to evaluate the recruitment process.

Caveats and Implications for Practitioners

Although we have noted a number of advantages of Internet recruiting, we urge HR professionals to understand the challenges that Internet recruiting may pose for organizations. For example, the use of Internet recruiting may result in a deluge of job applications, which can be extremely burdensome for HR departments to process manually. Furthermore, some ethnic minorities (e.g., Hispanic Americans, African Americans, Native Americans) and individuals from low socioeconomic environments may not have access to the Internet, resulting in a "digital divide." Therefore, the use of Internet recruiting may have a potential adverse impact on members of these groups. Thus, Stone et al. (2003) have argued that organizations may want to use Internet recruiting in conjunction with more traditional recruiting methods to ensure that all individuals have equal opportunities for employment with an organization.

In addition, not all Internet recruiting software offers the same capabilities. For example, those systems that will not accept online resumes directly but instead require applicants to "cut, paste, or rekey information" to forward their resumes may actually deter job candidates from applying for jobs. As a result, the degree to which their Web sites are not user-friendly can be a potential disadvantage for some organizations. Similarly, unless HR professionals require automatic search features on their software packages, an important source of internal job candidates may be lost. Likewise, the use of these same systems may serve as an obstacle to enhancing satisfaction and retention of valuable employees when organization policies are not aligned internally.

HR professionals must review policies to identify potential conflicts before introducing Internet recruiting techniques. For example, those organizations with policies that preclude disclosing salary ranges or use broadbanding salary ranges for multiple job levels may find that internal candidates applying for Internet-posted job vacancies are actually applying for jobs that would be a "down-grade." As a result, HR professionals should consider listing open job classification systems with clearly identified salary ranges to ensure that candidates are not discouraged or do not waste time applying for lower level jobs. In addition, managers who view subordinates as belonging solely to their department may perceive automatic vacancy matching as a "raid," threatening their operations. Thus, HR policies must be designed to emphasize cooperation among departments to ensure that all employees are recognized as valued assets to be developed through movement into jobs for which they are qualified.

SELECTION

The selection process has been the focus of considerable research aimed at helping organizations optimize the match between employee knowledge, skills and abilities, and job requirements (Guion, 1991). Thus, selection systems are often used to ensure that employees have the talents and skills needed to perform jobs, which should enhance the overall performance of the organization. Interestingly, Internet selection systems capabilities promise to improve the selection process in three ways: (a) by facilitating selection decisions and reducing biases in the selection process, (b) by reducing the time needed to fill job vacancies, and (c) by increasing the organization's ability to evaluate the validity of inferences made in the selection process.

Facilitating Selection Decisions

As noted previously, the use of the Internet or online systems may facilitate selection decision making in a number of ways. First, online systems may facilitate selection decisions through the use of sophisticated resume screening software. For example, upon receipt of an online resume, Web-based software can be used to scan the resume using key-word and other search techniques to determine if applicants meet basic skill and education requirements associated with job vacancies. When large numbers of applicants are involved, some firms also use interactive voice response technology (e.g., Wonderlic systems) to screen job applicants (Stone et al., 2003). Thus, the use of Internet-based selection systems may decrease the time it takes to fill job vacancies and improve the process of screening large numbers of resumes or job applications.

Second, although most selection systems have historically involved face-to-face interactions between job candidates and decision makers, the Internet has made it possible to gather a wide array of information about candidates in a rapid manner. For example, the Internet has made it easier to conduct background checks that identify criminal convictions or credit-related problems that may be important to success in many jobs (e.g., bank teller, police officer). Likewise it is now simple to verify degrees, licenses, and conduct reference checks that indicate prior employment dates, salary, job duties, and previous training. In addition, the same systems may also allow organizations to conduct online ability testing or conduct assessment centers that measure job applicant performance in a virtual work simulation or virtual team. Some organizations (e.g., Texas Instruments) also establish Web pages that allow job seekers to complete self-assessments to ensure that they are qualified for posted jobs (Higgs et al., 2000).

Furthermore, Ulrich (2001) argued that decision support systems (DSS) can be used to improve the selection process by providing interviewers with advanced information about job candidate strengths and weaknesses to help them structure interviews. Given this information, organizations can conduct initial screening interviews online, which saves interviewer time and recruiting costs. As noted previously, some organizations also use scoring keys to review resumes or application blanks for applicant qualifications. Thus, the use of Internet selection systems may allow organizations to improve the selection process by increasing the amount and timeliness of information available to decision makers.

Apart from decreasing the cycle time associated with the selection process and increasing the amount of information available to decision makers, another important benefit of using Internet selection is that the same systems may increase the quality of selection decisions by decreasing biases inherent in traditional face-to-face systems. As should be evident from our description of the resume screening process, Internet selection systems may be more likely to focus on applicants' knowledge, skills, and abilities rather than on factors unrelated to job performance (e.g., age, race, ethnicity, gender, or disability). Thus, the Internet may ensure that decision makers focus on objective information about applicants rather than information that may be potentially stigmatizing. As a result, the Internet can be a great equalizer and may decrease the biases inherent in face-to-face interactions via the interview or other selection systems. Consequently, the use of Internet selection systems may allow organizations to improve their selection decisions and enhance their overall performance (cf. Kiesler & Sproull, 1992; Spears, Postomes, Lea, & Wolbert, 2002).

Assessing the Validity of Selection Techniques

Selection processes must meet the highest possible standards to comply with legal, moral, and ethical hiring concerns. As a result, organizations may use the monitoring and tracking capabilities of Internet systems to ensure that tests (e.g., interviews, cognitive ability tests, work samples) are valid predictors of success on the job. Interestingly, although an automated screening system may save time and increase efficiency, some researchers have argued that organizations rarely ensure that the screening criteria are effective (Higgs et al., 2000). Thus, HR professionals should ensure that scoring keys are valid or correlated with job success before using them to screen large numbers of applicants.

Furthermore, the Internet may be used to assess the utility or cost-effectiveness of various selection techniques. For example, although assessment centers may be a valid means of selecting employees, their high cost may prohibit organizations from using them for all types of jobs. Use of the Internet to conduct virtual work samples may make such assessment centers more affordable, however, and increase the extent to which organizations use them to screen applicants. Moreover, ESS systems may also make it possible to extend the hiring process to its logical conclusion by assisting the new hire with his or her records and registration for company benefits or training. Ultimately, Internet tracking systems can be used to streamline and improve the effectiveness of the selection process (Gueutal, 2003).

Caveats and Implications for Practitioners

Although we have noted a number of benefits of Internet selection, HR professionals must be aware that applicants may react more negatively to online selection than to traditional selection systems because Internet selection depersonalizes the selection process. As a result, applicants may perceive that they cannot communicate all of their abilities (e.g., interpersonal or communication skills) via the Internet and may resent not being able to control the types of information disclosed in the hiring process. Some research by Martin and Nagao (cited in Higgs et al., 2000) supports this argument. Likewise, Spears et al. (2002) argued that Internet selection may be deindividuating because it does not provide a complete picture of the applicants' skills and abilities. As a result, decision makers may fill in gaps caused by missing or incomplete data and make negative inferences about job candidates' abilities to perform the job (Stone & Stone, 1987). Thus, applicants may be more likely to perceive that Internet selection systems are unfair, when compared with traditional selection systems. Furthermore, HR professionals may want to be aggressive in ensuring that Internet selection systems do not lead to applicant resentment which may preclude them from accepting jobs with the organization. Given that the Internet may not provide an accurate portrayal of an applicants' knowledge, skills, and abilities, we suggest that Internet systems be used in conjunction with more traditional procedures (e.g., situational interviews, work samples) to finalize applicant selections.

Likewise, HR professionals should be cautious when using the Internet to conduct ability testing or personality assessment. First, there is currently no way to guarantee that the applicant being considered is the one actually completing the test or inventory or that the applicant is completing the material without assistance from others. Thus, the integrity of ability test scores, personality inventories, and interview responses may be compromised when conducted via the Internet.

PERFORMANCE MANAGEMENT

Performance management is the umbrella term used to describe the HR function associated with "improving the performance of individuals, teams and the organization as a whole" (Cascio, 1998, p. 154). Performance management functions often include setting performance standards, appraising individual and team performance, giving feedback, and designing compensation and reward systems to motivate performance. The Internet contributes to performance management and performance appraisal in at least three ways: (a) by facilitating evaluation and monitoring of employee performance, (b) by assisting managers with administration and provision of feedback to employees, and (c) by assessing the effectiveness and accuracy of performance appraisals, including the identification of rating errors.

Evaluating Employee Performance and Providing Feedback

Internet systems may help managers monitor and appraise employee performance through the use of management self-service (MSS) systems, which track, analyze, and organize performance data about subordinates (Gueutal, 2003). These same systems may be beneficial because they provide managers with timely data about performance, including the consistency of performance over time, and may encourage managers to provide more frequent feedback to subordinates. Furthermore, the use of MSS systems may enable managers to compare performance across units, allowing them to evaluate more accurately the overall performance of their unit.

Internet performance appraisal systems may also facilitate the use of 360-degree performance feedback, which provides multisource information to individuals from supervisors, peers, customers, and subordinates. Although London and Smither (1995) note that 360-degree feedback has been used primarily for developmental purposes, Internet systems may ensure that feedback flows directly from internal and external customers to employees in a timely fashion. As a result, employees may be able to improve their performance and better meet the needs of their customers. Thus, Internet systems may help organizations reduce the cycle time associated with the performance evaluation process and enable managers to provide more direct and timely feedback to subordinates.

Evaluating the Effectiveness of Performance Appraisal

Apart from the impact on performance evaluation, Internet systems offer organizations the capability of tracking managers' ratings to identify rating errors (e.g., halo, central tendency, or leniency errors). Researchers have long argued that there are biases in the rating process that negatively affect the accuracy of performance ratings and negatively impact the extent to which employees accept feedback (Borman, White, Pulakos, & Oppler, 1991). Thus, the use of Internet systems designed to track and analyze patterns of ratings by individual managers may enable organizations to identify problems associated with ratings (e.g., friendship biases, central tendency, leniency errors) and help improve the accuracy and effectiveness of performance ratings. As a result, Internet and online systems may be used to evaluate the effectiveness of appraisals and provide heightened support for performance management and feedback systems in organizations.

Furthermore, these same online tracking capabilities may be used to design processes that monitor nonexempt employee tardiness, attendance, turnover, and disciplinary problems in organizations as part of a comprehensive performance management program. Ultimately, such attendance systems may also enable managers to improve forecasting of staffing needs and identify potential behavior problems early enough to allow preventive supervisory interventions.

Caveats and Implications for Practitioners

Although we have identified a number of unique advantages of Internet performance appraisal systems, HR professionals should recognize that Internet systems may also pose problems in organizations because such systems may depersonalize the rating process. First, the use of online performance appraisal systems may provide an incomplete picture of an employee's overall performance and neglect important factors such as good citizenship behaviors. Second, employees may react negatively to online performance evaluations because they create a greater psychological distance between raters and ratees, engendering less trust between supervisors and subordinates. For example, when performance is monitored and evaluated online, employees may perceive they have less control over the situation and become suspicious of supervisors' intentions. As a result, they may perceive that electronic monitoring is less fair than traditional appraisal systems and argue that such systems violate their individual rights. Consistent with this argument, research by Ambrose, Alder, and Noel (1998) suggests that individuals typically perceive that electronic performance monitoring is a violation of their rights unless there is justification for such systems and that justification is clearly conveyed to employees. Conversely, organizations that have geographically dispersed employees and teams may find that Internet-based systems aid the remote supervisor in staying abreast of activities and outcomes, thus positively facilitating effective performance management. Indeed, such Internet systems may be the best means of performance management for virtual organizations (Johnson & Isenhour, 2003).

In addition, HR professionals should ensure that use of Internet performance management systems do not inadvertently undermine commitment to legal and ethical organization goals. For example, use of these systems to monitor tardiness or actual hours of work on a daily basis for individuals classified as exempt under the Fair Labor Standards Act guidelines can result in forcing a change in classification from exempt to nonexempt solely because of that management practice. The consequence of this would be immediate company liability for 2 years of back pay for any overtime worked. Moreover, inappropriate use of monitoring tools could leave supervisors and the organization open to charges of invasion of privacy from customers and employees (Stone & Stone-Romero, 1998). Thoughtful consideration of how best to use online performance management, coupled with careful training of supervisors and periodic reviews by managers, can ensure that these systems fulfill their promise of focusing individuals and teams on goal achievement.

Finally, HR professionals need to prepare supervisors and managers adequately for the coproduction requirements associated with many managerial self-service systems (MSS) designed to help view subordinate performance records, access policies and procedures and complete performance appraisal. Although such systems provide a heretofore unimagined access to useful performance management tools, supervisors may be burdened with additional work previously performed by the HR department and perceive the system negatively. Thus, it is essential that managers be trained and become skilled in using the new MSS tools.

COMPENSATION AND BENEFITS

Compensation has been defined as all direct or indirect payments to individuals designed to induce them to join, remain, and contribute effectively to organization goals (March & Simon, 1958). It may include benefits such as health care, paid time off, education assistance, as well as salaries, wages, bonuses, or stock options (Gerhart & Milkovich, 1991). Managers are often concerned with developing compensation systems that simultaneously allow them to reduce labor costs while maintaining a competitive position in attracting and retaining desirable job candidates. Payroll and compensation support systems were among the first information systems developed and remain a crucial part of an organization's information systems today (Gueutal, 2003). Internet and online systems, however, can now provide additional value for managing compensation systems in three ways (a) by modeling the costs and benefits of various salary decisions, (b) by facilitating communication of compensation and benefits information to employees in a timely manner and (c) by giving employees the ability to enroll or change benefits through ESS.

Modeling Compensation Decisions

As noted previously, Internet systems are especially useful in designing compensation systems in organizations because such systems provide managers with the ability to model the costs and benefits of various compensation strategies, as well as evaluate various incentive systems. Furthermore, Internet systems may enable HR professionals and managers to gather salary and benefits data (compensation surveys) within and across industries and track trends in compensation systems (e.g., gainsharing, merit pay, skill-based pay) to remain competitive in the labor market. In addition, such systems can assist in tracking and analyzing the degree to which the compensation systems are effective in achieving organizational objectives, permitting modifications that improve the process on an ongoing basis.

Communicating Information to Employees

Historically, organizations have relied on employee handbooks and other printed materials to communicate compensation and benefit information to employees. Effective communication is essential because employees who fail to understand the rewards and benefits provided will not be motivated by the systems. The use of printed materials is often problematic, however, because the information is quickly outdated, requiring frequent updates each time benefits change. Such changes are not only expensive but often result in numerous inquiries from employees that are time-consuming and expensive to handle. In addition, employees do not always read the printed compensation materials, leaving them unaware of the compensation or benefits they receive in an organization. The use of Internet compensation systems and Web-based portals may greatly alleviate these problems and improve the extent to which employees receive timely communication about their compensation and benefits. Such communication is likely to enhance employee perceptions of the value of their benefits and provide a greater breadth of information through the use of such tools as FAQ (frequently asked questions) or online links to organization call centers. Furthermore, the ease with which Web sites can be updated makes the benefits communication process more flexible and may reduce overall organization costs. Although more than half of all organizations in North America use Web-based portals as a means of providing HR information, including benefits, to employees (Cedar, 2001), older technologies, such as interactive voice response and toll-free telephone systems, are still prevalent.

Use of Employee Self-Service Systems

One of the fastest growing trends in human resources management is the use of Web portals or ESS (Gueutal, 2003). The growing use of ESS systems parallels the rise in flexible (e.g., cafeteria) benefit plans aimed at meeting the needs of an increasingly diverse workforce. In particular, flexible benefit systems allow employees to choose among several benefit plans that may meet their individual needs. For example, a married employee may choose increased health care benefits, whereas a single employee may choose to allocate funds to supplemental retirement programs (e.g., 401K). The increased flexibility of cafeteria benefit plans has also increased their complexity, however, often including numerous providers and frequent changes in plan terms and conditions. The new Web-based ESS systems have enabled organizations to manage benefit systems more effectively. In particular, ESS capabilities permit employees to research and compare alternative benefit coverage, establish initial enrollment or change plans at a time or place convenient for them, with full round-the-clock access via the Internet. Access to other benefits, including 401K investment account information and retirement planning calculators, is frequently provided as well, including online links from the HR portal to remote service providers. In fact, such approaches to benefits management allow employees increased control over their benefits and may reduce the time it takes to make changes or update benefit plans. In general, increased Web-based system capabilities promise to expand the ways in which employees provide and receive information about all aspects of their work lives not just benefits (e.g., training, career planning and advancement opportunities).

Caveats and Implications for Practitioners

HR professionals have long used compensation systems as a means to motivate and retain employees. The use of Internet HR systems has the potential to shift much of the traditional HR compensation work to line managers. Explaining the advantages of moving this work and providing training to line managers will be essential in making such a transition. For example, one especially useful feature of Internet systems for the supervisor is the fully electronic processing of periodic salary increases or changes. The new systems will allow managers who are knowledgeable about a subordinate's performance to ensure that salary increases are equitable and consistent with organization policies. Likewise, Internet systems may be particularly useful for managers with subordinates in remote geographic locations or those who travel extensively and must perform their work via Internet links. Similarly, the move to global, geographically dispersed virtual organizations makes the communication of compensation practices and benefits particularly difficult. Offering ESS capabilities via the Internet can help bring such dispersed groups together, emphasizing the common link that all share with the organization.

TRAINING

Although the Internet has certainly influenced recruitment, selection, appraisal, and compensation processes, it may have had its most profound effect on the design and delivery of training in organizations. The primary reasons for this are that (a) organizations have transitioned from an industrial to a global, knowledge-based economy that relies heavily on the skills and abilities of employees and (b) training is a critical means of ensuring that employees have the skills needed to help organizations adapt to changes in the new environment (Salas & Cannon-Bowers, 2001). Furthermore, the rapid proliferation of technology has facilitated the provision of training via alternative electronic methods. Taken together, these trends have prompted organizations to place increased emphasis on enhancing employee knowledge, skills, and abilities and inspired them to use distance learning as a means of delivering training in a timely and cost-effective manner (PriceWaterhouseCoopers, 2002). Distance learning is often used as an umbrella term that includes e-learning (e.g., Web-based learning, virtual classrooms, computer-based learning, and digital collaboration) as well as delivery of training content via a variety of media (e.g., videotape, interactive television, Internet/intranet, CD-ROM, satellite broadcasts, etc.; Kosarzycki, Salas, DeRouin, & Fiore, 2003). Distance learning does not preclude the use of traditional classroom instruction, however, and frequently encompasses the integration of a variety of electronic media with face-to-face instruction.

As should be evident from these comments, the use of the Internet to facilitate distance learning is thought to have a number of benefits in organizations including (a) reduced training cycle times allowing the delivery of just-in-time and on-demand training, (b) increased flexibility allowing employees to learn at their own pace and control the sequence of instruction, (c) decreased training costs, and (f) improved online enrollment and tracking systems to facilitate training evaluation. These benefits, as well as specific issues associated with system capabilities and training content, are discussed in the following paragraphs.

Reduced Training Cycle Time

One of the potential advantages of using the Internet for distance learning is that the time needed to conduct training can be greatly reduced (Driscoll, 1999). For example, when a training need is identified, distance learning can be conducted immediately (e.g., just in time) in a consistent manner for employees throughout the world. As a result, the competency levels of all employees can be enhanced in a timely, efficient manner. Furthermore, distance learning may be especially useful when training is deconstructed into small content modules that can be administered over time, without loss of learning effectiveness. Small procedural changes requiring training, which may have been deferred because of the expense of modifying training materials and transporting employees to an off-site training center, can be administered more expeditiously via distance learning than traditional classroom methods (Peterson, Marostica, & Callahan, 1999). Moreover, desirable training capabilities, such as trainer–trainee or trainee–trainee interactions can also be facilitated via Internet e-mail or listserv systems. As a result, trainees may actually be able to communicate more frequently with trainers using distance learning than traditional training techniques.

Increased Training Flexibility

Another advantage of distance learning is that it may increase the flexibility of training delivery and allow for self-paced instruction (Driscoll, 1999). For example, the use of online enrollment and tracking systems allows employees to choose the timing and amount of training to be conducted at any point in time. Employees can complete all or any part of the training during a given session. Furthermore, employees may receive training via the Internet while traveling away from their primary work locations or elect to take the training in segments appropriate to their stage of development in a job. This unconstrained time-and-place approach to training may be particularly attractive for those employees who want to improve their skills but also need to balance work and family demands. Likewise, distance learning may enhance individual performance because employees are not absent from their jobs for long periods of time or can be trained during off-peak hours. Given that distance learning typically provides online skill assessment and feedback, employees may also be able to use such information to target or enhance their career opportunities (Anderson, 2002).

Decreased Training Costs

Another important benefit of distance learning is that it is thought to decrease the overall costs of training (Driscoll, 1999). For example, distance learning programs often result in economies of scale (e.g., standardized training programs) that are likely to reduce the overall expense of training in organizations. In addition, distance learning may also reduce travel costs, labor costs, and the cost of equipment or facilities (e.g., classroom space). Distance learning may also allow organizations to save on the costs of printing training materials and reduce costs by using the existing technical infrastructure (e.g., computers, networks) to facilitate training. As a result, Driscoll (1999) estimates that distance learning often results in an average cost savings of $1,500 per employee. In reported examples, Eli Lilly saved $800,000 in travel and salary costs, Hewlett-Packard saved $5.5 million, and Aetna saved $3 million, while training approximately 3,000 workers (Horton, 2000).

Evaluation of Training

A final benefit of using the Internet for distance learning is that such systems can facilitate the evaluation of training. Although distance learning may be less expensive, organizations are justifiably concerned with determining the return on investment associated with its use. For example, IBM noted a 20-fold return on its management training program conducted via distance learning (Vaas, 2001), whereas GE estimated annual savings of $1 million by using distance learning for its geographically dispersed auditing organization (Lohr, 2002).

Although return on investment is an important criterion, organizations are also concerned with the degree to which distance learning facilitates employee learning and skill development. Therefore, organizations may want to evaluate distance learning in terms of Kirkpatrick's (1983) four evaluation criteria, which include reactions, learning, behavior, and outcomes. First, reactions criteria typically refer to trainee reactions to the overall training and might address the question of whether employees react more positively (or negatively) to distance learning than traditional classroom training. Second, Kirkpatrick argues that training should be evaluated in terms of the overall level of learning. Thus, distance learning could be evaluated in terms of the level of declarative or procedural knowledge acquired through such a program. Alternatively, learning acquired through distance learning could be assessed relative to other training methods (e.g., traditional classroom instruction, CD-ROM). In addition, Kirkpatrick contended that training should be evaluated in terms of behavioral criteria, referring to the degree to which training transfers back to the work setting (Hall & LeCavalier, 2000). As a result, organizations may want to assess the degree to which knowledge or skills acquired through distance learning affect on-the-job performance. Finally, Kirkpatrick suggests that training should be evaluated in terms of outcomes, referring to the degree to which training has a positive impact on organization goals. Therefore, organizations may want to evaluate the degree to which distance learning affects important organizational outcomes such as product quality, customer satisfaction, or organization adaptability. Given that Kirkpatrick and others (cf. Kraiger, Ford, & Salas, 1993) encourage the use of multiple criteria to evaluate distance learning, we suggest that organizations move beyond traditional return on investment measures alone and incorporate multiple evaluation criteria to assess the overall costs and benefits of using distance learning programs.

Apart from the advantages associated with using distance learning noted here, researchers (Kosarzycki et al., 2003; Salas et al., 2002) have argued that specific design and implementation issues noted in the following section should be considered by organizations proposing to use distance learning.

Caveats and Implications for Practitioners

Two primary issues facing organizations interested in implementing distance learning are (a) the fragmentation of distance learning systems and (b) the types of training content that can be delivered most effectively via distance learning. First, although distance learning is widely embraced across organizations, distance learning system capabilities vary widely. As a result, training professionals are often forced to focus on identifying and securing those functions that are required for the specific entity. High-quality products are available at lower prices for those willing to expend effort matching products to training need, however (e.g., collaborative capability, student tracking, interoperability with existing hardware and software; Adkins, 2002). In addition, purchasers of distance learning systems must be wary of the disappearance of a preferred vendor and the resulting support problems that might ensue. Furthermore, organizations should be aware that the distance learning industry is currently moving toward consolidation and is striving to establish standards on which to base future growth (Dobbs, 2000).

In light of the industry fragmentation and instability, some training professionals are now looking to a new segment of the distance learning market known as learning management systems (LMS). Designed to coordinate courses across multiple providers, LMS vendors offer management reports, user registration, and tracking capabilities and a framework within which content can be adapted or developed via learning object format to meet the learning needs of a variety of functional groups within an organization. At the same time, learning portals (i.e., Web sites that act as a single contact point for multiple sources of content, courses, and learning information; Mantyla, 2000) are becoming more prevalent. LMS, in concert with the growing number of learning portals, promise increased opportunity and ease of use for distance learning adopters (Kaplan-Leiserson, 2002).

A second issue associated with the design of distance learning systems is the type of training content that can be delivered most effectively via distance learning programs. Although some experts argue that distance learning is suitable for all types of training content (Moe & Blodget, 2000), others (Schreiber & Berge, 1998) contend that training content should be aligned with desired type of learning (e.g., declarative knowledge, procedural knowledge, or strategic knowledge) and the skill level of the trainee. For example, employees with low computer skill levels may find distance learning more difficult and intimidating than those with high computer skill levels.

Acquiring declarative knowledge, with its emphasis on structured domains of facts, with clear "right or wrong" answers, can easily be facilitated by e-learning. Topics include such wide-ranging content as foreign languages, software coding, and mathematics. Similarly, procedural knowledge can also be taught via distance learning (e.g., safety compliance training, business writing; Conners, 2001). As the knowledge being acquired becomes less structured (e.g., strategic planning), however, some researchers (Anderson, 2002) maintain that a combination of methods (e.g., classroom instruction, chat rooms) should be used in conjunction with distance learning to help trainees learn, analyze, and synthesize the material.

Given that e-learning may not be appropriate for all types of training content, some organizations are pursuing a hybrid of instructor-led and distance learning known as "blended learning" (Kaplan-Leiserson, 2002). The hybrid approach seems particularly appropriate for learning interpersonal skills, which are primarily procedural and conceptual rather than declarative. Such a blended approach would include having the trainees review and complete tests on the theory and underlying concepts to be learned (e.g., communication techniques) to prepare themselves for instructor-led classroom experiences (Prentice, 2001). Other researchers have suggested that distance learning can be used to supplement classroom instruction in order to change trainee attitudes and increase motivation (Anderson, 2002). For example, online discussions could be used in conjunction with instructor-led training to advance trainee skills associated with evaluating alternative values and understanding different perspectives (Duckworth, 2001). However, Duckworth (2001) also maintains that training of psychomotor skills will generally require live practice opportunities (e.g., donning safety gear properly, administering cardiopulmonary resuscitation (CPR), flying an airplane), even though some declarative knowledge (e.g., steps in the CPR process) may be obtained via distance learning. Overall, distance learning promises to revolutionize how organizations upgrade competencies in the battle for competitive advantage.

HUMAN RESOURCE PLANNING

Human resource planning is recognized as the link between organizational strategic planning and detailed HR program decisions (Kavanagh et al., 1990). Two primary areas of HR planning affected by the use of Internet and online systems include (a) forecasting and (b) legal compliance tracking.

Forecasting

There are a number of advantages of using the Internet for HR planning in organizations. First, the Internet helps ensure that organizations use employee skills through the use of workforce skills inventories that help HR professionals identify the number and skill levels of current employees (Kavanagh et al., 1990). These analyses assist organizations with filling anticipated vacancies and allow organizations to meet new staffing requirements rapidly. They also provide an important means for increasing the flexibility of organizations and facilitating an organization's ability to adapt to strategic change.

Second, the Internet helps organizations forecast labor supply and demand to project future staffing needs. As a result, Internet systems help ensure that human resources management functions are aligned with the strategic goals of the organization. These systems are also used to assist managers in succession planning, which typically involves identifying and targeting individuals as replacements for key managerial vacancies caused by retirements, promotions, or voluntary turnover. Through the use of succession planning, career plans can be developed for "high potential" individuals to ensure that they are properly trained or prepared to fill important vacancies (Kavanagh et al., 1990).

Legal Compliance Tracking

Another benefit of Internet and online systems is that they are a valuable means of monitoring, tracking, and reporting compliance with government laws and regulations (e.g., EEO, Affirmative Action, OSHA). For example, OSHA compliance reports are required periodically, but information must be available at any time for unannounced inspections or in conjunction with accident investigations. Failure to have up-to-date, accurate data can result in fines or other serious consequences.

In addition, Internet systems make HR data available to managers and help identify deficiencies or problems, allowing managers to formulate corrective action plans. For example, managers can track hiring rates by department and assess the possibility of adverse impact on protected groups. Likewise, managers can analyze turnover rates and uncover potential supervisory or job design problems. Without such systems support, managers may only learn about problems after lawsuits are filed or the organization is subjected to a governmental audit. Thus, Internet systems help managers become proactive in solving problems and avoiding legal sanctions. In general, HR planning can be greatly enhanced through the judicious use of Internet and online systems.

PRIVACY CONCERNS

As noted previously one of the potentially dysfunctional consequences of using the Internet for HR purposes is that employees may perceive such systems as an invasion of privacy. In particular, Stone et al. (2003) have argued that employees are concerned about the extent to which Internet HR systems permit access or disclosure of personal information or contain inaccurate data that may potentially stigmatize individuals or lead to other negative consequences.

Access or Disclosure of Personal Information

Researchers (Stone & Stone-Romero, 1998) have long argued that employees are concerned about the storage of data in HR systems because these systems contain a great deal of personal information about them, including data about their creditworthiness, benefits, performance, medical history, and family background. Thus, employees often fear that HR Web-based systems are insecure, allowing users (both inside and outside the organization) to gain access to their personal information. As a consequence, employees may perceive that if some individuals access their personal data they will be stigmatized or experience other negative outcomes (e.g., embarrassment, loss of job opportunities). Furthermore, employees are often concerned that organizations may release personal information about them to third parties (e.g., credit grantors, courts, potential employers).

Interestingly, there is considerable evidence that employee concerns about organizational access and disclosure of personal information are warranted. For example, surveys suggest that organizations collect and store a great deal of personal information about employees and do release the data to third parties (cf. Stone et al., 2003). In particular, a survey by the Society for Human Resources Management (2000) revealed that 34% of firms collect and store medical and prescription drug information about employees, often releasing such information to insurance companies and potential employers. Similarly, surveys show (Electronic Privacy Information Center, 2000) that 70% of employers disclose information to creditors, 47% release information to landlords and 19% disclose data to charitable organizations. Furthermore, 60% of employers do not inform employees that they disclose such personal data (Society for Human Resources Management, 2000).

Apart from the survey results reported here, findings of studies (Eddy et al., 1999) on employee reactions to human resources information systems (HRIS) revealed that individuals were more likely to perceive that HRIS were unfair and an invasion of privacy when they were unable to control the release of information, when data were released outside the organization, and when employees were unable to authorize the release of information. Similarly, results of a study by Stone, Lukaszewski, and Stone-Romero (2001) indicated that an HRIS was considered most invasive of privacy when (a) employment data were disclosed to supervisors rather than HR representatives, (b) the same data were used for HR planning purposes rather than emergency notification purposes, and (c) employees had no ability to check the accuracy of the data in the HRIS. In addition, results of a study by Lukaszewski and Stone (2001) suggested that employees were more likely to perceive their privacy had been invaded when medical data were collected and stored in an HRIS and when they had no choice about whether the data would be stored in a Web-based system or a traditional paper file system.

Data Accuracy

Another potential concern with the use of Web-based HR systems is that such systems often contain inaccurate data about employees that may stigmatize them or result in negative outcomes (Stone et al., 2003). Consistent with this concern, results of survey research suggest that some data in HR systems may be inaccurate and employees are often unable to access and correct their personal data (e.g., Electronic Privacy Information Center, 2000). For example, a study by Pillar (1993) indicated that 48% of credit data are inaccurate, including the data used for employment purposes. Likewise, a survey by Linowes (Electronic Privacy Information Center, 2000) showed that 72% of firms do not allow employees to access and correct records. Thus, employees may be justifiably concerned that HR systems used to store employment data may contain inaccuracies that can potentially affect their outcomes in organizations.

Caveats and Implications for Practitioners

Given the growing use of Internet-based HR systems, HR professionals and Web site developers must be cognizant that employees are often concerned about the privacy of their personal data. Although recent court cases have affirmed the organization's right to monitor employee e-mails and Internet usage, privacy concerns are likely to receive increasing scrutiny (Stone & Stone-Romero, 1998). Protection of individual information was easier when most records were on paper in the HR department or in legacy systems for which there was no easy external access. With the increased use of Internet HR systems and Web-based portals, access to personal or sensitive information about employees is more of a potential problem than ever before. Thus, organizations must ensure that particular care is taken to safeguard personal information about employees. Although there is no federal privacy law that applies to the private sector, several states have passed legislation giving employees the right to access, review and amend their employment records (cf. Stone & Stone-Romero, 1998). Also, the newly passed European Data Act places restrictions on the transmission of employee data across national boundaries. As a result, HR professionals should be proactive in developing policies to protect employee privacy and ensure that employee data are recorded accurately and handled fairly.

IMPLICATIONS FOR RESEARCH

Although we have described a number of advantages of using Internet HR systems, we indicated previously that little theoretical or empirical research has focused on the effectiveness of such systems. Thus, we believe that future research should be conducted to examine the effectiveness of many of these systems (e.g., Internet recruiting, distance learning, ESS, and MSS). Furthermore, research is needed to assess the degree to which Web-based systems and portals are a more effective means of communicating HR policies and practices than traditional communication systems. Likewise, given that Internet-based HR systems often transfer traditional HR work to employees and managers, research should focus on the reactions of internal customers (e.g., employees, managers, HR staff) to these systems. In particular, employee acceptance may be critical to the success of ESS systems designed to allow employees to change or review benefits. Likewise, managerial reactions to the increased workload (i.e., coproduction) and data provided by MSS systems may also be a key to the successful implementation of the new HR systems. Furthermore, given the widespread use of distance learning in industry and academia, research is needed to examine (a) the effectiveness of these systems in terms of key learning criteria (e.g., trainee reactions, behavior, outcomes), (b) the types of training content that can be effectively delivered through distance learning, and (c) the extent to which trainee individual differences affect the success of distance learning. Finally, research is needed to examine strategies for reducing employees' fears and concerns about the privacy of Web-based HR systems.

CONCLUSION

We have reviewed the impact of the Internet on several key HR processes, including recruitment, selection, performance management, compensation, training, and HR planning. Overall, our review revealed that the use of the Internet promises to (a) reduce the cycle time associated with many HR processes, (b) increase the flexibility and effectiveness of these systems, and (c) provide better service to employees and managers. Despite the many benefits of using Web-based HR systems, we also noted that the Internet may pose a number of new problems for organizations, including negative reactions from employees due to violations of privacy and the increased depersonalization of HR systems.

Although we have attempted to describe the impact of the Internet on HR systems, we must stress that we have only begun to analyze the effects of the Internet on organizational processes. As the Internet grows and develops, we believe it will offer numerous benefits and pose a host of unknown challenges for its users. We also believe, however, that HR professionals should be cognizant of the following issues when implementing and using Web-based HR systems. First, HR professionals should stress the importance of aligning Internet-based HR systems with organization goals. For example, they must consider whether the system selected is appropriate for the type and size of the organization and determine whether the system will help support its mission. Second, HR professionals should ascertain whether the organizational infrastructure will support the new technology. For example, HR professionals will need to ensure that they have financial resources needed to implement Web-based HR systems, including hardware, software, training, and ongoing technical support. Likewise, given that technology evolves rapidly, they may want to determine whether the system is adaptable and can be expanded to meet future needs. Finally, HR professionals will want to ensure that this change is managed effectively, which means that key stakeholders (e.g., employees, managers, HR staff) should be involved in every step of the transition from traditional to Internet-based HR systems.

In conclusion, we believe that our chapter has shed new light on the ways that the Internet will affect the practice of human resources management and hope that it has sparked an interest in scientific research that will help evaluate the effectiveness and acceptability of these new systems.

GLOSSARY

Blended learning A hybrid approach to training that combines instructor-led and distance learning techniques to facilitate types of learning (e.g., interpersonal skills) which are primarily procedural and conceptual rather than declarative).

Digital divide The term used to describe the lack of access to computer and Internet technologies that affects some ethnic minorities and individuals from low socioeconomic environments.

Distance learning The umbrella term used to describe a variety of electronic learning (e-learning) techniques and tools intended to facilitate specific skill and knowledge enhancement efforts.

Electronic learning (e-learning) The term used to describe a variety of Internet- and computer-based learning techniques, including Web-based learning, virtual classrooms, computer-based learning, CD/DVD learning, to facilitate individual and group acquisition of specific skills and knowledge.

Electronic monitoring The process of collecting and using computer-based performance measures as part of individual performance management efforts.

Electronic recruiting (e-cruiting) The term used to identify Internet recruiting as a formal sourcing of online job information.

Employee self-service systems (ESS) Internet-linked, coproduction computer systems that provide firm employees with a variety of human resources program and policy information and access to multiple sources of relevant personal information maintained by the employing firm.

Human resources information systems (HRIS) "Systems used to acquire, store, manipulate, analyze, retrieve, and distribute pertinent information regarding an organization's human resources . . . including people, forms, policies and procedures, and data for the purpose of providing service in the form of accurate, timely information to clients for supporting strategic, tactical, operational decision making (selection, recruitment), evaluating programs, policies or practices (compensation plan comparison, sick leave costs, diversity hiring), and enhancing efficient fulfillment of daily functions (time reports, attendance, performance management)" (Kavanagh, et al. 1990, pp. 29–30).

Learning management systems (LMS) Internet-based computer systems designed to coordinate training course offerings and management across multiple providers.

Management self-service systems (MSS) Internet-linked, coproduction computer systems that provide support to firm managers in fulfilling desired human resources goals and policies, including tracking, analyzing, and organizing data about subordinates.

Privacy the expectation by individual employees that personal information maintained by employers for a variety of legitimate purposes will be closely protected by human resources professionals and will be divulged only under limited circumstances to internal sources.

Realistic job previews (RJP) are one of several ways firms may attempt to manage expectations of job candidates regarding actual job responsibilities and firm working environments prior to job offers as a means of increasing job acceptance, enhancing initial new-hire socialization tactics, and reducing early-stage voluntary turnover.

Stigmatized the term used to describe individual physical, psychological, or sociological marks that may preclude full inclusion and unbiased treatment in organizations.

Three-hundred-sixty (360) degree feedback The term used to describe multiple sources of performance information from supervisors, peers, customers, and subordinates provided to individuals as part of performance management efforts.

Web-based portals Internet sites maintained by firms for the specific purpose of encouraging contact with both internal and external stakeholders.

I

Information Quality in Internet and E-business Environments

Larry P. English, *Information Impact International, Inc.*

INFORMATION QUALITY APPLIED TO THE INTERNET

As organizations move into the e-business arena, failure to address information quality issues can produce garbage-in–garbage-out at the speed of the Internet. Information quality is one of the most important ingredients to a successful Web site whether the site is informational or e-business transactional. Consider the following:

Twenty-nine million U.S. adults stopped using the Internet in 1999, double the number who dropped out the year before (Iwata, 2000).

A UK retail company received and confirmed orders for thousands of television sets for an online mispriced £3 (US$5.00) instead of the actual price of £300 (US $500.00) before discovering the error.

A European telecommunications company failed to charge their customers of Internet services an amount equivalent to 8 million Euros ($7.8 million) for six months before they discovered the "oversight," creating a significant public relations and recovery problem.

A U.S. airline offered trans-Atlantic flights for $25.00 fares over the Web, honoring them at a significant loss of revenue.

A U.S. computer maker offered personal computers online for $1.00, resulting in thousands of sales and legal problems.

One industrial supplier, whose typical orders were $1,000–$10,000, received an Internet order from a fictitious customer, named "Dr. Evil," for $10 million worth of materials. Although this was an obvious prank, intentional falsification is not uncommon on the Web.

A major airline sued one of its Internet business partners for "misleading" information about its flights.

This discussion applies to all aspects of information quality (IQ) on the Internet and e-business, including IQ in Web-provided information and business-to-consumer (B2C) and business-to-business or government (B2B, B2G, G2G) supply chain management.

Information Quality Defined

To define information quality in the context of the Internet, we must first define "quality":

> Quality is a customer determination, not an engineer's determination, not a marketing determination or a general management determination. It is based upon the customer's actual experience with the product or service, measured against his or her *requirements*—stated or unstated, conscious or merely sensed, technically operational or entirely subjective—and always representing a moving target in a competitive market. (Feigenbaum, 1991, p. 7)

Quality, then, is "the total set of product and service characteristics . . . through which the product and service in use will meet the expectations of the customer" (Feigenbaum, 1991).

Information quality is "consistently meeting all knowledge worker and end-customer expectations" (English, 1996, p. 1.4) in all characteristics of the information products and services they deem important. In e-business Web visitors, e-consumers, and e-business partners will assess information as "quality" or not, based on their needs and expectations as they conduct business on the Internet.

Components of Information Quality

Information consumers have quality expectations in three areas of information: *definition, content,* and *presentation* (English, 1999, p. 27–30). Internet and e-business information require the following:

Data Definition Quality

With data definition quality e-customers understand *the meaning* of the information and any underlying policies, such as terms and conditions of business transactions. They know exactly the meaning of information a Web transaction asks them to provide so they can provide the correct data values.

Data Content Quality

With data content quality e-customers *trust* the information they get to be *accurate, complete,* and *current,* and they *trust* that the organization will protect their information (security and privacy). They trust the organization will handle their information properly and will fulfill their transactions accurately, properly, and on a timely basis.

Information Presentation Quality

With information presentation quality e-customers can find the information they need quickly *when* they need it, and the information is *presented* in an *objective,* intuitive way, enabling them to take the right action or make the right decision.

Categories of Internet Information Requiring Quality

There are three categories of information in the Internet environment and the processes that produce and maintain them to which quality principles must be applied:

Web-Based Documents and Web Content

Misleading, inaccurate, or noncurrent information provided to Web visitors can cause harm to the enterprise or drive customers away without even being noticed.

Data "Shared" by Internal Processes and Internet Processes

Disparity in designs between Internet accessible databases and internal databases drives operating costs up and increases points where errors can be introduced.

Information Collected or Created over the Internet

Data created by customers or business partners in e-business are outside enterprise control and introduce new sources of nonquality that must be overcome.

E-business Supply-Chain Management

E-business is not just a new channel to be "bolted on" to existing processes. It demands rethinking and reengineering *how* the organization conducts work. The entire value chain of work from the Web activities to internal business activities, and from originating supply to ultimate distribution to the customer, must be managed and controlled for quality and customer satisfaction.

Quality Processes for Internet and E-business Information

To provide and collect quality information, effective enterprises will implement quality management processes and apply them to the processes that "produce" information in the same way that world-class manufacturing and service organizations applied quality management principles. These processes include the following:

Assess Information Quality

An organization must measure the extent of nonquality information and the costs of process failure and "information scrap and rework" to understand whether its information processes are in control and consistently meet customers' expectations.

Improve and Control Information Processes

Process improvement and control enable organizations to operate at peak performance to meet their customer's needs.

Implement an Information Quality Improvement Environment

Information quality does not just happen. To have sustainable information quality, organizations must embed quality management beliefs, principles, and processes into the fabric of their cultures.

QUALITY PROBLEMS UNIQUE TO THE INTERNET AND E-BUSINESS INFORMATION

While IQ is important in all of business, it is even more critical in e-business. In cyberspace, the information *is* the business, making IQ a *strategic* requirement for successful e-business. Here, organizations expose both their business processes and information to their customers and business partners. Nonquality information and defective processes creates high costs of process failure and information scrap and rework and indirect costs of missed opportunity and lost customer lifetime value.

All customer or supplier interactions and transactions take place electronically without people-to-people interaction. Quality problems occur in *gemba,* the Japanese word that means "the real place." In quality management, *gemba* is where value work happens. In manufacturing, *gemba* is where products are made or the place services are performed (Imai, 1997, p. 13). In the Information Age, Gemba is anywhere information is discovered, created or "produced," updated, moved, or exchanged. Information quality principles and techniques must be employed at each point. On the Internet, *gemba* is a virtual place, unlike the shop floor or at a sales counter where people can see when problems occur. Internet IQ problems include the following:

General Internet Information Quality Problems

Unscrupulous and unreliable Web sites have driven potential e-customers off the Internet. Anyone can create a Web site and place any kind of information on it with little concern to its accuracy. The "quality" Web site must establish its credibility for its e-customers to trust both the information and the organization that provides it.

The ease of posting information to the Web coupled with the emphasis on accelerated cycle times to publish on the Web has had the impact of decreasing quality control of the content (Calvert, 1999).

Nonquality information in cyberspace can go unnoticed—except by the visitors—for much longer periods of time than in a store, where staff can recognize and adjust for obvious IQ problems.

Internet information sources can be unreliable with pages being modified without documentation, or moved or removed without notice. According to DeletedDomains.com, there were 29,335,210 currently registered domains and 19,052,261 deleted domains as of May 2, 2003.

Misinformation, complaints, and rumors can be spread globally quickly and easily over the Internet, increasing risks and damage caused by nonquality Web information.

Business-to-Consumer (B2C) Information Quality Problems

On the Internet, customers who have a "complaint" are just a few clicks away from competitors. If they cannot find something easily or perceive noncurrent, missing, inaccurate, or biased information on the Web, they only have to click to the competition.

Staff no longer control information captured. E-customers are the new *information producers* in e-business. Organizations cannot "train" e-customers in the same way they train point-of-sales staff. Complex transactions produce higher error rates.

The anonymity of the Web increases the potential for misinformation, maliciously provided information, and fraud.

Privacy laws impose additional minimum "quality" requirements on data.

Mistrust of e-businesses has created a new IQ problem—deliberate falsification of data by e-customers to protect their privacy. An increasing number of Web visitors provide false information when registering with Web sites. According to a Georgia Tech Research Corporation study, 46.2% of 4563 respondents said they falsified information at least once when they registered on Web sites, with 12.3% saying they falsified information more than 50% of the time (GVU, 1998; the most recent study on this topic known to the author at time of publication). See Figure 1.

Business-to-Business (B2B) Information Quality Problems

The exchange of information among businesses or organizations (business, government, etc.) exposes risks of errors, omissions, and duplication. Overloaded data elements (multiple fact types) may be handled by the source organization's immediate operational application.

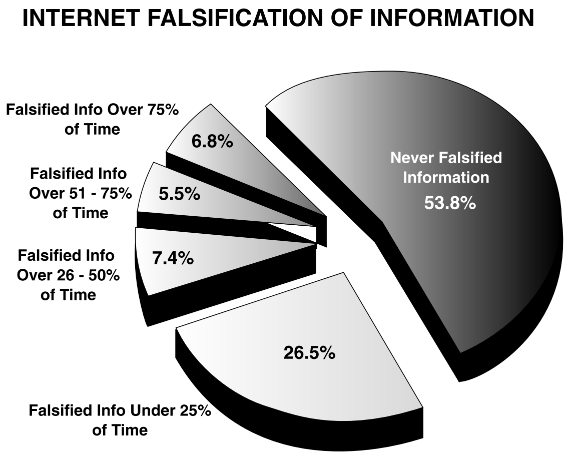

Figure 1: Web site registrants frequently falsify information.

However, that same data can cause business partner processes to fail.

Nonquality information passed can expose embarrassing information or breach regulation or confidentialities.

Subtle differences in the data definition, domain value sets, and business rules across organizations can cause interorganizational processes to fail. Effective communication requires partners to understand the precise definition of the data and the business rules constraining it.

XML by itself cannot solve data definition problems. XML, as a language for information exchange, addresses only part of the problem by passing a label (not a definition) of the values passed. However, XML by itself will no more solve communication problems across organizations than DBMS by itself solved the data-sharing problem within an organization. Cross-organization and even cross-industry data standards and common information models are required to eliminate communication (data definition) problems in B2B communications.

QUALITY PRINCIPLES APPLIED TO INTERNET AND E-BUSINESS INFORMATION

To solve the IQ problems inherent to the Internet, an organization must understand e-customers' quality expectations, the fact that information itself is a "product," and how to implement quality principles and processes into the organization culture.

The Internet "Customer"

Quality management has taught us that business success depends on how well an organization meets or exceeds customer expectations. E-business is the same. "Visitors" to a Web site are not unempowered "users." They are, first, information "customers" and knowledge workers who gather information for their purposes and, second, they are product/service "prospects" who hopefully become satisfied "customers."

Successful e-businesses will understand the quality expectations of its market and will measure "customer satisfaction" as part of its balanced scorecard. Increased customer satisfaction results in "customer lifetime value" of return visits and repeat business.

An effective e-business leverages its information content, especially information about its existing customers and their relationships. It analyzes its information to understand its customer behavior and needs, and uses it to plan, design, and implement its Web site and e-business processes.

The Internet "Product"

On the Internet, the information *is* the "business." Whether an organization is providing information or selling products or services, the only commodity that exists is the information. There are no tangible goods for the customer to feel, try on, or try out. Because e-customers are not able to *physically examine* products, they must *trust* the information.

Only after e-customer expectations are understood can the organization design (or enhance) a Web site to provide "quality" information that "consistently meets information customer expectations." Only then can it design the e-business transactions that enable the customers to conduct business in ways that satisfy their requirements.

The E-business "Processes"

Three categories of processes and information require quality management:

Providing information, including Web site design, Web content, and information produced by internal business processes;

Collecting information from e-customers or business partners about themselves; and

Conducting business over the Internet, including B2C and B2B transactions.

Quality principles applied to each of these processes are described in subsequent sections.

THE CUSTOMER-CENTRIC E-BUSINESS VALUE CHAIN

A customer-centric e-business value chain, illustrated in Figure 2, identifies the cycle of activities of an e-customer's request for information or services and their satisfaction from benefits received. Successful e-businesses must understand this cycle and manage and control the activities across the value chain, not just the individual functions to meet e-customer expectations.

Customer Focus

World-class e-businesses, like world-class brick-and-mortar businesses, focus on customer satisfaction for success. The first of Deming's 14 Points of Quality confirms that an organization must "create constancy of purpose

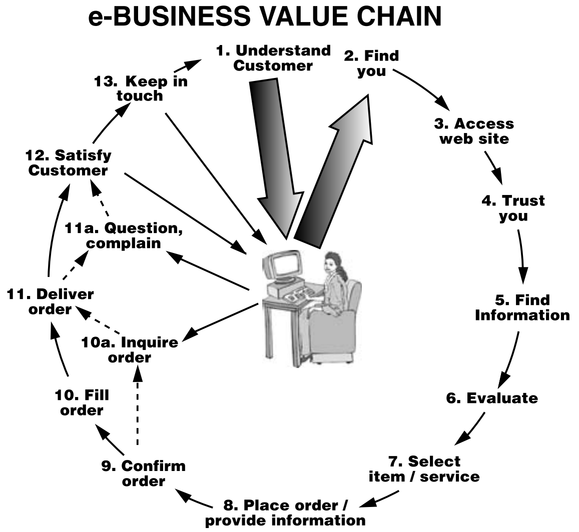

Figure 2: The e-business value chain. From English (2000). © 2000. Reprinted with permission.

Table 1 Customer Satisfaction: Why E-customers Return

Quality Requirement	E-customer Expectation
Valuable content	Meets my need to know and my purposes.
Accurate	I do not waste time or make costly mistakes as a result.
Complete	I have all the data I need for my purposes.
Current	Updated frequently; new things of interest to me.
Objective	I can trust the information because it is not misleading; I easily draw the right conclusion.
Concise	I do not have to waste time in "information overload."
Fast	Fast downloads and few clicks minimizes my time to use.
Easy to use	Minimizes my time to learn; I don't get lost.
Timely	Conduct business on *my* time table.
Reliable	I get goods and services that meet my expectations.
Meets expectations	Makes my life easier or more successful.

Note. From English (2000). © 2000. Reprinted with permission.

for improvement of product and service," an obligation to the customer that never ceases, for "the consumer is the most important part of the production line" (Deming, 1986, p. 26). A Web site, whether informational only or B2B or B2C, will succeed or fail based on the e-customers' experiences. Table 1 illustrates why e-customers return to a Web site.

E-business Value Chain Steps

Success in e-business requires an organization to understand the complete value chain of e-business from the request of a prospective e-customer to a satisfied e-customer. The 13 discrete value chain steps are illustrated in Figure 2.

This section introduces the quality requirements required for each value chain step. Specific quality techniques are described in the subsequent sections:

Step 1: Understand Customer Expectations

The first step of the e-business value chain is central to quality management: Understand and define customer expectations in order to design quality into information, products, and services that meet or exceed them.

Steps 2–6: Provide Quality Information

A Web site must first be found *easily* by prospective e-customers. Both general information and product/service information must be found *easily* and enable e-customers to evaluate the right products and information for them. The site *must contain* information that e-customers find valuable and engender *trust* for them to conduct e-business.

Steps 7–9: Provide Quality Products and Services

As e-customers conduct business over the Internet, they become *information producers,* directly providing personal information and transactional data. Error-proofing techniques must be applied to *information collected from and provided by* the e-customer to prevent inadvertent errors, such as transpositions, unreasonable values, or deliberate falsification.

Steps 10–12: Meet/Exceed Customer Expectations

These steps fulfill the e-business requests for information, or orders for products or services, or requests to conduct business transactions, whether online, such as software upgrade download or bank account transfer, or physical product delivery, such as office supplies or custom-made products. The e-business must meet delivery and quality expectations, communicating to e-customers any delivery problems, handling questions, and resolving any complaints. E-customers judge e-business' quality with the simple criteria: "I got what I expected in the way I expected it with value for my time and money."

Steps 13 and 1: Continually Improve

Customer-focused organizations will understand their customers better by analyzing all customer contacts. Through an *appropriate* level of contact with e-customers and analysis of customer experiences, customer loyalty and customer lifetime value can be increased.

E-BUSINESS VALUE SYSTEM AND CODE OF ETHICS

With myriads of unscrupulous and unreliable Web sites along with growing incidents of identity theft, reputable e-businesses must establish credibility and trustworthiness in their Web sites and e-business operations (Alexander & Tate, 1999; Ciolek & Goltz, 1996; English, 2000).

The quality organization will differentiate its Web site as a reputable place to find reliable information and successfully transact business. An organization with a customer-centered value system can translate that into a customer-centered code of ethics that instills e-customer confidence. A code of ethics contains statements of commitment to the following:

Integrity, Credibility, and Legality

This establishes professional credibility or authority (Alexander & Tate, 1999, p. 11) and a commitment to compliance to an industry or professional group code of ethics that the e-customer can verify. For example, Rite Aid and drugstore.com display their VIPPS certification provided by the National Association of Boards of Pharmacy. To be VIPPS certified, a pharmacy must comply with NABP criteria, including quality assurance, patient privacy rights, state licensing and inspection, security of prescription orders, and provision of meaningful consultation between patients and pharmacists (NABP, 1999).

Security

The highest level of security must be provided relative to the nature of the information exchanged to assure no accidental disclosure of or unauthorized access to personal data or confidential or sensitive business data. Data must be classified as to its security requirements, including regulatory and privacy, and implemented with the proper level of security control, such as firewalls, secure servers, effective log-in ID and password techniques, and encryption.

Privacy and Confidentiality

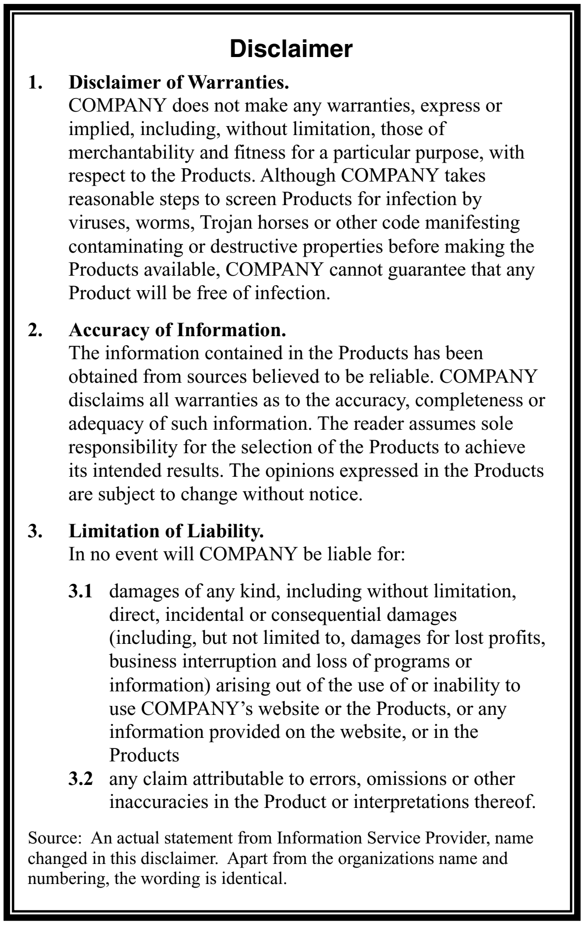
Consumers are increasingly frustrated with what they perceive as "intrusive" invasion of their privacy. The UK and EU Data Protection Acts and the U.S. Gramm–Leach–Bliley Act require organizations to take a more customer-focused stance on privacy. These laws confirm customer "rights" as to what data may be collected about them and how it may be used.

Conforming to the letter of the law is only the *entry point* for privacy. A quality organization understands its individual customer's privacy expectations and honors them. Reputable organizations develop customer-centric privacy policies and have third-party certification of their privacy statements through organizations such as TRUSTe (1997) or BBBOnline (1996).

Information Quality

Credible Web sites will *not* just post a *disclaimer* disavowing responsibility for the completeness, accuracy, or currency of the information they post. Rather, they will *claim* what they *are* doing to assure quality information. See the upcoming section Quality Principles for Web-Based Documents, Web Content, and Information Presentation. Only after they communicate what they are doing to provide quality information will they describe any disclaimer for legal purposes.

Figure 3 illustrates an actual disclaimer on an information provider's Web site. There is no statement as to what, if any, quality management controls are applied.



Disclaimer

1. **Disclaimer of Warranties.**
   COMPANY does not make any warranties, express or implied, including, without limitation, those of merchantability and fitness for a particular purpose, with respect to the Products. Although COMPANY takes reasonable steps to screen Products for infection by viruses, worms, Trojan horses or other code manifesting contaminating or destructive properties before making the Products available, COMPANY cannot guarantee that any Product will be free of infection.
2. **Accuracy of Information.**
   The information contained in the Products has been obtained from sources believed to be reliable. COMPANY disclaims all warranties as to the accuracy, completeness or adequacy of such information. The reader assumes sole responsibility for the selection of the Products to achieve its intended results. The opinions expressed in the Products are subject to change without notice.
3. **Limitation of Liability.**
   In no event will COMPANY be liable for:

   3.1 damages of any kind, including without limitation, direct, incidental or consequential damages (including, but not limited to, damages for lost profits, business interruption and loss of programs or information) arising out of the use of or inability to use COMPANY's website or the Products, or any information provided on the website, or in the Products

   3.2 any claim attributable to errors, omissions or other inaccuracies in the Product or interpretations thereof.

Source: An actual statement from Information Service Provider, name changed in this disclaimer. Apart from the organizations name and numbering, the wording is identical.

Figure 3: Example of an Information Quality Disclaimer with a nonquality focus.

Describing what the organization is doing to *assure quality* information increases customers' trust in their information. U.S. federal law requires federal agencies to ensure and maximize the quality, objectivity, utility, and integrity of the information (including statistical information) they disseminate. "Agencies must issue their own implementing guidelines that include 'administrative mechanisms allowing affected persons to seek and obtain correction of information maintained and disseminated by the agency' that does not comply with the OMB guidelines" (OMB, 2002). The National Science Foundation Web site illustrates its "warranty" and procedures for how to communicate an information complaint and how the complaint will be handled (NSF, 2002). Information consumers can identify suspected nonquality information and describe how the information consumer uses the information, how they are "hurt" by the information in error, and reasons for correcting the suspected error.

This law may be a forerunner of laws requiring *warranties for information quality* and customer recourse in the private sector if consumer well being becomes at risk.

Customer Satisfaction

Credible e-businesses post customer satisfaction policies and product/service warranties. It is even more important when conducting business without prior physical evaluation of goods and services. See Table 1 above.

QUALITY MANAGEMENT PROCESSES FOR E-BUSINESS

Like manufacturing quality, information quality must be planned with assessment and improvement processes defined. Quality must be designed into the business processes for quality information products. Because information is a product, the same principles that apply to manufacturing quality apply to information quality (English, 1999; Huang, Lee, & Wang, 1999; Redman, 2001).

Information Quality Assessment

This process measures the quality of data definition, data content, and information presentation to assure information meets customers' expectations. Assessments measure the level of quality in important characteristics, such as accuracy, completeness, and currency of the information. Measuring the costs of nonquality information establishes the economic impact of nonquality information and prioritization of information quality improvement and error-proofing initiatives (English, 1999, pp. 199–236).

Information Process Improvement and Control

Without process definition, improvement, and control, processes will produce a(n)—often high—degree of error. A process improvement technique, such as the Shewhart Cycle of PDCA or Plan–Do–Check–Act (Deming, 1986; English [PDCA applied to information processes], 1999; Imai, 1997) or the Six Sigma DMAIC or Define–Measure–Analyze–Improve–Control (Brue, 2002), is used to apply various quality techniques to improve processes. The goal is to error-proof processes and prevent *errors* or *omissions* in information created by the enterprise for its Web site content or information collected from the e-customers. Processes must be in place to maintain *currency* of information subject to information quality decay.

Error-proofing techniques must also be applied to B2B and B2C processes that collect information from e-customers, whether consumer or business-to-business, to assure its *completeness, validity* to allowed values *and* correctly defined business rules, *accuracy,* and *nonduplication* (multiple records about the same customer). Accuracy cannot be "guaranteed" with edit and validation routines electronically for most data elements, such as birth date, name (spelling), address-to-person matching, and product price. Accuracy requires additional error-proofing techniques to prevent digit or character transpositions, deliberate falsification, and reasonable but inaccurate data entry.

Planning and Implementing an Information Quality Improvement Environment

Producing quality products or services is not a one-time project. It requires a culture of process excellence and customer focus in tangible goods and information products. This requires management accountability for information quality, training in information quality principles and methods, and implementation of key performance measures of customer satisfaction of information products.

Planning for quality requires management to understand the costs of nonquality information. Costs include *direct* costs of process failure and "information scrap and rework" caused by nonquality information as well as *opportunity* costs of lost and missed revenue caused when missing or inaccurate data cause the organization to miss an opportunity or drive customers away. Especially important in e-business, e-customers who cannot find easily what they are looking for, find suspect data, or cannot trust the organization can, and will, go elsewhere. E-customer complaints can go unnoticed and, therefore, unresolved, while the e-customer clicks off to the competition.

Deming's 14 Points of Quality describe the 14 components of management transformation to create a quality culture. The 14 Points must be implemented to sustain a habit of continuous improvement to "do jobs right the first time" and eliminate the high costs of process failure and scrap and rework, whether in manufactured products or information (Deming, 1986, pp. 24–96; English, 1999, pp. 337–399; English, 2000, pp. 6.10–25):

1. Create constancy of purpose for *improvement* of *information* product and service. The obligation to the customer never ceases. Planning, designing, and operating the e-business for e-customer success leads to e-business success.
2. Adopt the new philosophy of quality information, for "reliable [quality] shared information reduces costs." Improving processes to error-proof them is less costly than the direct costs (alone) of process failure and information scrap and rework due to defective data.
3. Cease reliance on mass data inspection as a means of quality: design quality into the processes that create, update, distribute, and deliver information to knowledge workers. This applies to internal processes creating Web content and to processes that capture data from Web visitors.
4. End the practice of "on-time" and "within-budget" alone as measures of information systems' delivery of success. The collapse of the Internet revolution taught us that it is not who is first into the Internet space who will win, but those with *quality* information, products, and services that satisfy e-customers. Of the three project objectives "quality, cost, and speed," sacrificing quality always drives up costs of maintenance and scrap and rework, and prevents optimizing time-to-market in the long term.
5. Improve constantly and forever the system of information production and service. Information quality is not a one-time data "cleanup" initiative. World-class organizations make a habit of continuous improvement.
6. Institute training. Content and information producers within the organization require training to know how to provide quality information and how to improve their processes. They must know how their customers use information and the costs and consequences of nonquality. "Training" of e-customers requires intuitive site and business transaction design, providing online training and help mechanisms for ease of use, including intuitive clear labels, glossaries and definitions, search engines, easy site navigation, and help where necessary.
7. Institute leadership for information quality. IQ does not just happen. Someone must lead the enterprise into implementing the principles, policies, and

processes of IQ management. Management must accept accountability for the information produced by its staff. Managers of the Internet processes must be held accountable for the quality of information captured. Managers must implement processes that prevent defective data.

8. Drive out fear. E-customers will NOT conduct business with an e-business if they "fear" for their privacy, or they will be motivated to falsify information.
9. Break down barriers between staff areas, including between information systems areas and business areas, between application and e-business development staff and information resource management, and between business areas and business areas. Enterprise failure occurs when business areas operate to their own autonomous goals. When they do so, they create problems for their downstream information "customers," forcing them to spend time in scrap and rework instead of value work. World-class organizations manage *across* the e-business and other value chains.
10. Eliminate *slogans* and exhortations for quality, and replace them with *actions* for IQ improvement. An organization cannot just *tell* people to do a quality job, it must provide people with the training, resources, and tools, such as a process improvement method, to *do* a quality job.
11. Eliminate quotas of "productivity" and replace them with metrics of customer satisfaction that keeps customers coming back, increasing customer lifetime value and profit.
12. Remove barriers of pride of workmanship. Empower and involve information producers to improve their processes. They know the barriers, and given an opportunity will improve processes to eliminate waste, for people want to be able to say, "we have provided valuable work."
13. Institute a vigorous program of education and self-improvement. The organization that learns tomorrow's skills will be the organization that leads tomorrow's markets. In the Information Age, information is the new currency. We must learn that information management is a core competency, manage information and improve the processes that produce it with quality, and exploit it for the benefit of its customers and its internal and external stakeholders.
14. Management must organize itself to make the other 13 Points happen. To do so, senior management must understand—and feel the pain—of the costs of information scrap and rework. Senior management must communicate to a critical mass of people why change is necessary. Management must put *everybody* to work to make information quality happen as a proactive reality, and not as a reactive, scrap-and-rework consequence of not producing information systems, databases, and data right the first time.

A methodology for Total Information Quality Management (TIQM) is represented in Figure 4, and documented in English (1999). Other quality methods describe information quality assessment (Huang et al., 1999) and data quality tracking and control (Redman, 2001).

TOTAL INFORMATION QUALITY MANAGEMENT (TIQM®)

TIQM® is *not* a program; it is a *value system, mind set,* and *habit* of continuous improvement of:

1. Application and data development processes

2. Business processes

By integrating *quality* management *beliefs, principles* and *methods* into the culture

QUALITY PRINCIPLES FOR WEB-BASED DOCUMENTS, WEB CONTENT, AND INFORMATION PRESENTATION

Quality management principles must be applied to information, both Web pages and database data, made available to e-customers on the Web site and disseminated electronically. These principles address e-business value chain steps 1–6 (Figure 2).

Quality Principles for Web Design and Information Presentation Quality

This section seeks not to describe Web site design, but to describe the *quality principles* for "designing quality into" Web site and document information presentation. Quality principles include the following:

Quality Design Principles

Quality Function Deployment (QFD) techniques are used to involve e-customers in the *design* (*redesign*) of the Web site and presentation style as a "product." QFD techniques link the needs of the customer with design, development, engineering, manufacturing, and service functions. QFD helps organizations discover the spoken needs ("Voice of the Customer") and unspoken needs, translate them into actions and designs, and focus the various business areas developing products and services that exceed normal customer expectations (QFD Institute, 1995).

Web sites should be designed for simplicity and ease of navigation to prevent casual e-customers from getting lost (Alexander & Tate, 1999; Nielsen, 2000; Useit, 1996). As many as two out of three customer complaints are caused by confusing marketing and inappropriate customer use (nonquality information presentation) (TARP, 2000).

Site search capability allows e-customers to quickly find specific information.

Document design techniques like Information Mapping help chunk information and documents into structured formats that make it easy for readers to scan and find pertinent information quickly (Infomap, 1995).

Pictures or graphic representations should clearly and accurately represent products. Allow pictures with enlargement options for increased clarity to minimize returns.

A "minimalist" approach to text information, using standards for meaningful titles and descriptive abstracts, enables e-customers to evaluate content efficiently and reduces downloading of inappropriate documents.

Provide e-customer-friendly error messages. Intercept cryptic system error messages and restate them to be meaningful.

Design and test for the most common denominator for the browsers and intended access platforms, such as laptops, PDAs, and e-mobile devices.

Assure all hyperlinks correctly link each time a page is updated. Periodically check hyperlinks to assure currency. If linked pages are moved, links should be updated. If 6,000 e-customers link to a moved page with a 10-s timer redirecting it, 10 hours of e-customer time is wasted.

Quality Feedback Principles

E-customers need an easy way to provide feedback or "complain" about nonquality site information, products, or services. Feedback is critical to detect broken processes early, as well as to prevent losing customers.

Clickstream quality analysis and customer satisfaction surveys (TARP, 2000) help understand e-customers' experiences in the *gemba* of The Internet, especially to identify prospective customers who drop out of a site after starting a business transaction. The pages people drop out from may identify causes of e-customer dissatisfaction.

Quality Principles for Web Data Definition

Because e-customers have different backgrounds and range from casual to experienced, labels and terms used must be intuitive and unambiguously named and defined with help mechanisms as necessary for ease of understanding:

Use universally accepted names and terms.

Provide glossary with hyperlinks to technical terms, or terms that might be misunderstood. If multiple definitions may apply to a term, define all pertinent meanings and the context in which each definition applies (English, 1999, p. 97).

Develop guidelines for descriptive key words and metatags to facilitate indexing and search engine management.

Quality Principles for Electronic and Web Document Management

Information management includes all forms and formats of information, not just electronic databases or files. This is even more important when documents, such as product literature, may be produced in multiple physical formats, such as glossy brochures, plain paper copies, and HTML or Web documents and presentation media format.

A document management process, such as illustrated in Figure 5, provides consistent control of document and distribution (ISO 9001, Standard 4.1).

Assure updates are made to a single record-of-reference document with revisions or revised document published or propagated to secondary copies.

Maintain document "expiration dates" or "review-by dates" as well as revision numbers and dates, requiring review and approval. This enables proactive management of content subject to "information quality decay" to maintain currency. These documents can be automatically deleted if not updated, or marked to advise readers they are no longer current.

Quality Principles for Web Content Creation and Maintenance

Because on the Internet, *the information is the business,* information created for the Web must be subject to rigorous quality management processes. Standards for Web content include criteria of authority (credibility), accuracy, objectivity, currency, and adequate coverage to meet

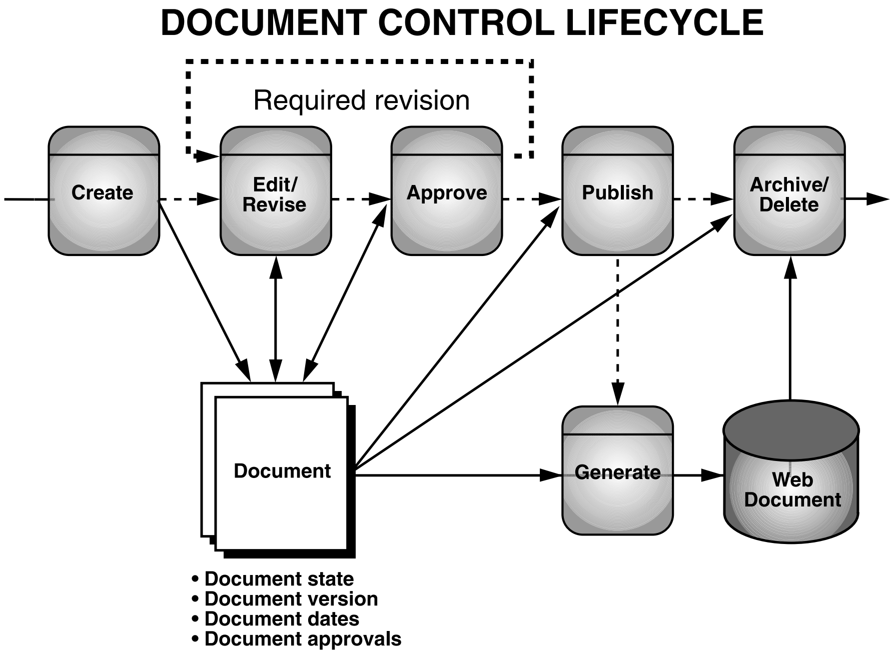

Figure 5: Document control lifecycle. From English (2000). © 2000. Reprinted with permission.

the needs of the intended audience (Alexander & Tate, 1996, 1999; Beck, 1997; Ciolek & Goltz, 1996; English, 2000; Virtual Chase, 1998).

Implement accountability and training:

- Implement management accountability for information content. Documents and information created within a business area are the responsibility of that business area manager. In the same way managers are accountable for their budgets and personnel, they *are* also accountable for the information produced in their area, as managerial information stewards (English, 1999, p. 406).
- Provide training to managers and information and Web content producers in quality principles and defect prevention techniques.
- Develop contracts for quality standards with third-party information sources.

Implement standards for site and page design that establishes the authority and credibility of the information (Alexander & Tate, 1999):

- Clear identification of organization responsible for the content, parent or sponsoring organization, and editorial or oversight board, if any.
- Name of copyright holder.
- Method to contact organization.
- Content author name and qualifications.
- Source(s) of information not produced by the host organization and how obtained.

Implement standardized processes which help content producers to provide quality information:

- Confirm accuracy of details with reliable sources.
- Corroborate information provided by external sources to assure accuracy.
- Verify summary or calculated data.
- Assure consistency of redundant data, such as to source data, between data in body and abstract or introduction, or in tables or figures.
- Conduct periodic IQ assessments of information content from both internal and external sources and process improvement initiatives as necessary.

Implement standardized procedures for all content producers to keep data current:

- Establish review or expiration dates for pages containing time-sensitive data.
- Provide dates when data were first provided to the site and date last updated.
- Use international date format (dd month yyyy) to avoid ambiguity; for example, 11/12/02 could be 11 December 2002 or 12 November 2002 or either date in 1902.
- List frequency of update for volatile information, such as prices.

Implement reasonability tests in data created for or migrated to the Web. This would have prevented the magnitude of error in the UK retail company's £3 television sets cited earlier.

- Assure information coverage is complete for the needs of the intended audience.
- Use the "who, what, where, how, when, why" checklist to assure all relevant data are included
- Include links to supplemental or support data.
- Provide definitions or links to glossaries of technical terms for understanding.
- If the content also exists in print format, identify any inconsistencies, such as if parts are missing, or if some content is updated from the print version.
- Provide legends, footnotes, or explanations for anomalies. If e-customers doubt data that appear "wrong" but are actually correct, they may lose trust in the entire Web site and not come back.

Present information objectively:

- Avoid bias that may lead the reader to a wrong decision. Although marketing information is inherently biased, there is a fine line between acceptable marketing bravado and deception. When e-customers feel misled, they can become vociferous complainers through chat rooms, consumer action Web sites, and e-mail.
- Differentiate informational, advertising, and editorial pages.
- Present both sides of issues fairly, even if the recommendation is for one point.
- If providing a survey or sampling to create summary information, assure the use of sound statistical sampling techniques and communicate the survey or sampling techniques used and the confidence level of the results. Present the questions as asked, especially if presenting a short form of the question in graphics.
- Publish IQ assessment results with assessment dates, so knowledge workers know the degree of error and omission, if any. Knowledge workers may not need zero-defect data, but they need to know the degree of inaccurate and missing data, to factor into their decisions or use.

QUALITY PRINCIPLES FOR DATA SHARED BY INTERNAL AND INTERNET PROCESSES

Data integration of Internet and internal data is best achieved by accessing data from a commonly defined database. If, for security or real performance reasons, the Internet databases must be physically separate from the internal databases, they must have *controlled* processes that keep the data, such as product and product price or customer name and address, equivalent.

Information Architecture and Internet Applications

Databases that house an enterprise's data must be designed, just as a building must have a sound blueprint. For shared business data maintained in an enterprise database such as product and product price or customer name and address, the quality principle is to design and define the data so they can be shared directly from a single database or be controlled replicated copies or partitions. Data designed for direct sharing eliminates the need for disparately defined and redundant databases for different functional uses. In this way only a single copy, or controlled replicated copies, needs to be maintained, reducing the costs of maintenance and data transformation.

Database architecture has quality design, resulting in databases that are

Stable—new applications, such as Web applications, are added with only the addition of new date elements or files and no destructive change is required,

Flexible—processes and applications can be reengineered with minimal modification to the database design, and

Reusable—minimal redundant databases are required, and where they are, they have consistent definition and domain value sets for common data elements, reducing development and maintenance costs and points of potential error introduction.

Develop standards and guidelines for the use of XML consistent with enterprise information architecture. XML as the basis for information exchange among businesses is often misunderstood and misused. It is a tool that *can be* used to help IQ if it is used effectively. Although XML allows passing data along with a label of the data, it is generally insufficient to completely define the meaning of that data. XML cannot be used as a substitute for complete definition of data elements and entity types, nor of rigorous data modeling. Standard XML labels should be consistent with the standard data names for data elements, and they must be backed up with complete, correct, and clear definition. Clear and precise business rule documentation should be available to business partners.

Managing Consistency of Redundant Data

When redundant databases must be developed, strict quality controls on data creation, updates, and data movement must be implemented. The quality principles for controlling redundant, disparately defined data in application software packages or in non-architected legacy systems include the following:

Define data with a standard name, single meaning, and valid data value set enterprise-wide. In this way data values need only to be replicated and not transformed. See below the principle for controlling data transformation when it is required.

Develop single-application programs or callable modules that maintain information about a specific entity type, such as product. Where there are subtypes of a given entity type that have unique attributes (data elements) not common to the supertype, then develop a unique callable module to capture unique attributes for each subtype. For example, all insurance products, regardless of whether they are life insurance or homeowners insurance, will have common attributes, such as product id, product name, product description, product first available date, product retired date, and product type (life or homeowners). Life products will have some unique attributes not applicable to homeowners and vice versa. Each subtype of product should have an application module dedicated to capture its unique attributes. This is the principle of single source supplier (Deming, 1986, pp. 35–38; English, 1999, p. 356). Having only one application module to capture common product information, rather than one application for each business area (life, homeowners, etc.), simplifies common data capture and reduces the costs of data capture and maintenance.

Define a single authoritative record-of-origin for each information type, or set of occurrences within one information type (partitioned database) to which data of that type will be created or updated.

Propagate data in one direction, from the record-of-origin to the record-of-reference database from which the data can be published or replicated where distribution is required.

When application software packages are *required* and/or when non-architected legacy systems must be interfaced with enterprise standard databases, the enterprise data model should control the data transformation and interfacing as a hub for information exchange. Controlling data transformation in data movement requires defining and implementing appropriate audit and control routines to assure proper extract, handling, and loading. Data transformation requiring control includes attributes with different data definitions (Web visitor to customer), different formats (person name [free form] to person first name, middle name, first surname, last surname), and/or different data value sets (M [male] and F [female] = 1 and 2, respectively). Most extract, correct, transform, and load (ECTL) software handles record counts satisfactorily, but few handle control total balancing and value transformation control balancing well. Content control audits generally must be defined and built as separate controls embedded in the ECTL job streams. Data control, tagging, or tracking techniques (Redman, 2001; Segev, 1996) assure data are moved and transformed properly across redundant databases.

Periodically assess information quality characteristics of timeliness (of data propagation) and consistency of data that should be equivalent in the multiple databases. Assess information quality by extracting sample records in the record-of-origin database. Assess them for completeness, accuracy, and nonduplication. Then extract the counterpart records in the downstream databases and measure for "equivalent" values, (gender code value of "M" in one database is a value of "1" in the downstream database) to assure that no corruption has taken place in the data movement (English, 1999; Redman, 2001).

QUALITY PRINCIPLES FOR INTERNET-COLLECTED INFORMATION

As Web sites matured from static read-only sites to registering e-customers and to conducting business, new information quality problems emerged. Capturing customer or business partner data and their business transaction data shifted from internally trained staff to the e-customers and e-business partners themselves. External customers and suppliers became direct information producers. Information quality became subjected to new factors:

E-customer lack of "training";

E-customer typing ability;

E-application design intuitiveness and ease of use;

Lack of strong e-application edit and validation capabilities;

Lack of e-application help capabilities; and

E-customer trust and deliberate falsification.

This set of IQ principles centers on the e-business value chain steps 7–9. Processes must have quality designed in to error-proof them such as check digits for numeric identifiers, double entry of critical data, and real-time look up of address and other verifiable data, to prevent inadvertent keying transpositions, to prevent deliberate falsification, and to verify the data using IQ software or internal edit and validation.

Understanding E-customer Expectations Regarding Their Personal Information

E-customers will provide quality information if they trust the organization and understand how their information will be used or why it is important.

Customers are increasingly concerned about their privacy and have fears about how their information might be used.

A customer-focused privacy policy helps customers trust an organization, minimizing deliberate falsification.

Cookies should be used from a customer-care focus to customize screens, offerings, and prevent re-entry of data already provided or known.

Defer to an e-customer's preferred form of (valid) address should that be different from the official postal address.

Allow e-customers to omit providing optional information not required for the processes. Create a "customer does not wish to provide" attribute along with their privacy requests.

Designing Quality into Electronic Forms

To minimize errors, forms must be intuitive, easy to understand and use, and error-proof.

Form labels and data names should be intuitive and clear from the reader's perspective with an accessible glossary of terms, to prevent misinterpretation by the readers and to prevent readers from providing the wrong information.

Information collection forms and procedures should be simple and clear. If procedures are required, use a well-defined set of procedure guidelines with prompts. Procedures should be written in a style readable by two grade levels below the target audience education level. Indices such as the Gunning Fog Index (1999) can assist in readability analysis. The goal is to eliminate or minimize errors due to misinterpretation or complex procedures.

E-customers should not have to re-enter data they have already provided. Propagate e-customer previously provided data into the forms, with opportunity for them to confirm or update inaccurate or changed information.

Pull-down menus and selection boxes minimize e-customer keystrokes in providing data and standardize data values.

Pull-down menus and selection boxes should have all possible options, with an "other" category to capture rare or unexpected, but real, values.

Designing Quality into Internet Processes That Collect Information

Design quality by defining the process, defining the data to be produced, and implementing error-proofing techniques. Techniques include the following (English, 1996, 8.35–36; English, 2000, 5.8; Redman, 2001):

Implement IQ software with "defect prevention capability" or edits in the source transactions of e-customer data creation. Several IQ software products provide defect prevention capability for e-business applications (Infoimpact, 1996, particularly the IQ Products page: http://www.infoimpact.com under the Tools and Resources Section, and IQ Products. Understand the strengths and limitations of IQ software tool functionalities (English, 1999, chap. 10).

Implement appropriate edit and business rule validation routines in data capture applications. Use intelligent edits. For example, avoid simply testing for an "@" to test for a "valid" e-mail address.

Defect prevention software and edit and validation tests should be performed in real time. If not possible, execute tests "near real time," before the data are acted on by subsequent processes to minimize process failure from defective data.

Do not overvalidate data. Correct values may fall outside expected limits. Allow e-customers to provide correct data and provide a reason. Then re-evaluate the validation rule tests.

Maintain assessment attributes to allow anomalistic data that are correct to be maintained without unintentional "correction" to a wrong value. For example, both George D. and Sam M. are women whose gender codes tend to get changed to "male" by "gender-assignment" software. Assessment attributes include the assessment type ("AV" = accuracy verified, or "CA" = corrected to authoritative source) and assessment date.

Periodically assess information quality characteristics of completeness, validity, accuracy, and nonduplication (English, 1999; Huang et al., 1999; Redman, 2001).

Provide feedback of acceptance of transactions to prevent the resubmissions that create redundant transactions.

Notify e-customers of data "corrections" for their confirmation. Even reputable defect prevention software can have errors in their databases or in their business rules.

Provide data "corrections" or suspect data back to the e-customer, such as address, product characteristics (such as an illegal color or size), or quantity for confirmation or correction.

IQ problems should be prevented by conducting an information quality improvement initiative, using the Shewhart PDCA Cycle (Deming, 1986; English, 1999; Imai, 1997) or the Six Sigma DMAIC technique (Brue, 2002). In PDCA, the "plan" phase seeks to discover the root cause(s) and define an improvement that eliminates recurrence of the defects. The "do" phase implements the improved process in a controlled way, enabling a "check" to confirm its effectiveness. If the improvement has accomplished the quality goal with no negative side effects, "act" standardizes and institutionalizes that improvement, putting the process into control.

QUALITY PRINCIPLES IN E-BUSINESS SUPPLY-CHAIN MANAGEMENT

Once e-customers have visited a Web site, liked what they have seen (e-business value chain steps 2–6), and placed their order or conducted their business (steps 7 and 8), the e-business must deliver the goods and services or complete the business transactions to meet expectations (e-business value chain steps 9–12). See Figure 2.

Early e-business failures often resulted from a rush to get into the Internet revolution with "bolt-on" processes to conduct business on the Web. Lack of thought-out process design and control can result in nonquality service delivery. E-business requires the enterprise to reengineer how it performs business.

Reengineer Business Processes

The Internet is not just a new channel for organizations to conduct business. It represents an opportunity to "rethink" *how* it can perform its business. Quality principles include the following:

Reengineer business processes; do not just "bolt-on" e-business processes.

Minimize developing applications that create redundant and disparately defined databases that must be integrated by "interfaceation." Define and develop integrated, commonly defined, and shared operational databases.

Eliminate activities that add only costs and focus on processes that add value. The more interface programs an organization has, the more opportunity for error in data movement and the more the costs of "scrap and rework" of maintaining the redundant databases and applications—and the lower the profit margin.

Develop contracts with service/product providers that specify quality requirements to satisfy your e-customer expectations.

Deliver as Promised

Whether delivering products from one's own or third-party warehouses to fulfill order distribution, e-customers will hold the e-business accountable for any failure. The entire order fulfillment value chain must be managed, not just the online portion.

Confirm the e-customer order. The communication loop is not completed until the sender is assured the receiver has understood accurately their request. Information quality means providing feedback to confirm correct understanding of their order, business transaction, or request. Feedback should include specific dates or times e-customer should receive their order or have the business transaction completed.

Enable e-customers to have personal contact with help staff when they need it.

Reply to e-customer inquiries and complaints in a timely fashion to minimize lost customers.

If there are hitches in delivery, proactively and quickly communicate the delay and rescheduled delivery, confirming whether this is acceptable to the e-customer.

Maintain a customer-friendly returns policy. Analyze return reasons to identify quality problems, such as the item "did not look like the picture."

UNDERSTANDING E-CUSTOMERS' EVOLVING QUALITY REQUIREMENTS

Because there is no *physical* interaction with e-customers in e-business, new ways to understand e-customer behavior and their needs must be found.

Keep in Touch with E-customers Appropriately

While keeping in touch with customers is easier than ever, it is also easier to alienate them. Avoid the appearance of spam and exploitation. Quality principles include the following:

Use appropriate forms of contact with e-customers. This includes new ways of segmenting customers based upon their preferences for forms and nature of contacts.

E-mail periodic reminders to e-customers to verify their personal data if you have not had recent contact. (Always provide value when sending such reminders.)

Customize content options based on learned preferences of e-customers.

Provide varied ways for e-customers to communicate, such as newsletters (always with value-adding content), surveys with results going back to respondents in ways that add value to them, discount opportunities, and ways to "complain" and communicate how your e-business can improve.

Use appropriate e-customer satisfaction surveys to gather likes and dislikes (TARP, 2000). Make them easy to complete. Analyze and *act* on the feedback.

Clickstream Quality Analysis

One way to "see" e-customer behavior is through their clickstream "trail" of the pages they have visited. Quality principles include the following:

Where do e-customers come from (third-party site links; banners, search engines, etc.)?

What terms are used to access a site via search engines? This indicates subjects of interest or customer terminology to enhance finding the site.

What terms do e-customers look up on the site search engine. This identifies areas to expand content and offerings.

What glossary terms do the e-customers tend to look up? This identifies possible ambiguous terms and labels to improve or define.

What inner pages are "bookmarked" and linked to? This indicates content of interest for continuation or expansion.

What pages do e-customers leave from? This may indicate potential complaints, especially if they were in midst of a transaction, such as going through the checkout process with one or more items in the shopping cart, or from a registration page or the privacy statement page. Analyze and understand the following:

- Did they have to go through too many pages?
- Does the privacy policy not engender trust?
- Did they get lost in the site navigation?
- Were the pages ambiguous or too complex?

How long do people stay on various pages? This may identify where they find value. However, excessive length generally indicates interruption.

Limitations of clickstream analysis must be understood to maximize planning and analysis:

Spiders access all pages and should be filtered out.

Masked IP addresses and IP proxies provide anonymity.

Caching of Web pages prevents accurate page trails. The use of dynamic pages increases better page trail data by causing pages to be regenerated each time.

Statistics of average time on a page can be skewed by visitor interruptions.

Time of visits represents the site time of access and does not adequately reflect global e-customer local time of access. Mapping local transaction time, when known, to site access time compensates for this to understand e-customer behavior. Mapping organizational IP addresses to local time zones can provide some adjustment, but cannot compensate for traveling e-customers.

Individual e-customers may access a site from different IP addresses (office, home, and laptop) and single IP addresses may have many individuals accessing a site (library or shared machines).

Focus on Making the E-customer Successful

Because customers measure quality of products and services in terms of how well those products and services help them to be successful, world-class organizations concentrate on the customer's success. The Internet provides new ways to help customers to be more successful:

Use e-customer knowledge to help people avoid making mistakes.

Customize instructions for customers given their unique environment, such as customized installation instructions for a car CD player based on the specific make and model of the automobile.

Use customized e-mail early warnings. Some airlines customize e-mail and e-mobile communications for canceled or delayed flights to their frequent flyers.

Use renewal or reminder notices. Pharmacies send e-mail remainder notices for regular prescriptions before the patient's supply runs out, especially helpful for patients with failing memories.

Contacts with the e-customer should always provide value. E-customers can be alienated if they perceive that they are being contacted only for "selling" purposes.

CONCLUSION

Creating and collecting quality information on the Internet and in e-business transactions has additional complexities and challenges beyond internally controlled information production. This increases the importance of implementing quality management principles, processes, and systemic changes into the culture of the enterprise.

Key components of quality e-business include implementing a customer-centric code of ethics that focuses on understanding e-customer expectations and implementing improvement and quality control in processes that create Web content to engender trust in the e-business and its information. Additional techniques for error-proofing processes in which the e-customers—the new information producers—provide information with quality, both to minimize inadvertent error and to discourage deliberate falsification, are required.

Organizations that do not apply quality management principles to their Internet information and e-business will suboptimize their investment at best or fail at worst. Those organizations who apply quality management principles will reduce the costs of information scrap and rework, reduce the instances of e-customer dissatisfaction and lost business, and will increase opportunity gains and customer lifetime value.

GLOSSARY

Accuracy A characteristic of information quality measuring the degree to which a data value (or set of data values) correctly represents the attributes of the real-world object or event.

Corrective maintenance The process of correcting or reworking defective products to an acceptable level of quality, i.e., correcting defective data, such as missing, inaccurate, or duplicate data; also called scrap and rework, data cleansing, or data scrubbing.

Clickstream quality analysis The activity of using data-mining techniques to analyze patterns of e-customer behavior to identify possible points of dissatisfaction, such as leaving a retail Web site with items in their shopping cart, or frequent links to a site map from a specific page (from which they might be confused).

E-customer Persons or organizations who access information or conduct business over the Internet, including both prospects and purchasing customers.

Gemba Japanese for "the real place"; in information quality, where information is exchanged, gathered, or created in the course of conducting business (adapted from Imai, 1997).

Information producer The role of individuals in which they originate, capture, create, or maintain data or knowledge as a part of their job function or as part of the process they perform; they create the actual information content and are accountable for its accuracy and completeness to meet all information stakeholders' needs. In e-business, the external consumers and business partners are the new information producers.

Information quality (IQ) Consistently meeting all knowledge worker and end-customer expectations in all the characteristics of the information products and services they deem important; the degree to which information consistently meets the requirements and expectations of the knowledge workers in performing their jobs.

Information quality characteristic An aspect of information that an information customer deems important in order to be considered "quality information"; includes completeness, accuracy, nonduplication, timeliness, conciseness, understandability, objectivity, and presentation clarity, among others.

Information quality decay The characteristic of data such that formerly accurate data will become *inaccurate* over time because the characteristic about the real-world object will change without a corresponding update to the data applied; for example, a John Doe's marital status value of "single" in a database is subject to information quality and will become inaccurate the moment he becomes married.

Kaizen Japanese for "improvement," including continuous improvement in all aspects of life, including personal, social, professional, and work. In work, kaizen means continuous improvement involving everyone in the organization, both managers and workers. Trademark of the Kaizen Institute.

Knowledge worker (1) The role of individuals in which they analyze or apply information in any form as part of their job function or in the course of performing a process or making a decision; also referred to as an *information consumer* or *customer*. Accountable for work results created as a result of the use of information and for adhering to any policies governing the security, privacy, and confidentiality of the information used. (2) Coined by Peter Drucker no later than 1973 and refers to business persons or workers in the Information Age as opposed to the term "user."

Overloaded data element A data element that contains more than one type of fact, usually the result of the need to know more types of facts growing faster than the ability to make additions to the data structures, which causes process failure when downstream processes find unexpected data values.

PDCA (Plan–Do–Check–Act) A closed-loop process for planning to solve a problem, implementing suggested improvements, analyzing the results, and standardizing the improvements. Also called a Shewhart cycle after its developer, W. A. Shewhart.

Preventive maintenance The activity of process improvement to error-proof a process and eliminate the causes and occurrences of defects.

Quality Function Deployment (QFD) The methods and techniques to actively involve customers in the design of products and services to better understand and capture customer requirements, and design and develop products and services that better meet their needs on initial product or service delivery.

Record of origin The first source or artifact, such as a paper document, audio or video recording, or electronic recording, in which data are captured or recorded.

Record of reference The single, authoritative document or database for a collection of data elements for a set occurrences of an entity type, representing the most reliable source of operational data for these data elements. In a fragmented data environment, a single occurrence may have different collections of data elements whose record of reference is in different files. Synonyms include database of record and system of record.

TIQM (Total Information Quality Management) A complete methodology for assessing IQ, measuring the costs of nonquality information, correcting data and controlling data transportation and movement, improving processes, and implementing IQ management principles into the culture of the enterprise. TIQM® is a registered trademark of Information Impact International, Inc.

User A term used by many to refer to the relationship of a person to information technology, computer systems, or data, implying dependence on something, or one who has no choice, or one who is not actively involved in the use of something. The term is inappropriate to describe the role of information producers and knowledge workers who perform the work of the enterprise by employing information technology, applications, and information in the process. Thus, the role of business personnel to information technology, applications, and data is one of information producer and knowledge worker, and their relationship to information systems personnel is not as users, but as partners. If Industrial-Age personnel were (machine) "operators" or "workers," then Information-Age personnel are "knowledge workers," a term coined by Peter Drucker in or before 1960 and used by him since then to refer to business persons.

Value chain An end-to-end set of activities that begins with a request from a customer and ends with specific benefits for a customer, either internal or external; also called a business process or value stream.

Integrated Services Digital Network (ISDN): Narrowband and Broadband Services and Applications

John S. Thompson, *University of Colorado at Boulder*

INTRODUCTION

A common topic of discussion in telecommunications today is the notion of converged networks in which one infrastructure is used to carry voice, data, and multimedia content. This concept is often presented as novel and unique to the Internet era. Although the emphasis in today's discussion is on a common transport technology set, converged networks also must include common interface and operational technologies as well. In this sense, integrated services digital network (ISDN) and broadband ISDN (B-ISDN) represent two earlier attempts at converged telecommunication networks.

Although the deployment of ISDN in the world's public telecommunication networks has not reached the levels its developers had anticipated, the technologies that underlie it have had an impact far beyond the number of terminals and switches based on these standards. In fact, the very body of standards that define ISDN and B-ISDN represents a realization that a coherent, standards-based approach to telecommunications technology is the only way to ensure consistent progress and provide fair access to the market for all customers, equipment vendors, and service providers.

The development of standards for ISDN may also represent one approach to this process that can be contrasted with the approach that has characterized that for the Internet. In the ISDN model, based in the International Telecommunications Union (ITU) body of multinational technology experts, standards are created and agreed in total before any deployment generally occurs. This normally means that there is a considerable development period before information is available for guidance on products and services. In the Internet model, managed by the Internet Engineering Task Force (IETF), standards are developed, tested, and deployed incrementally, which allows the process to track more readily rapid changes in technological capability. This latter approach, however, does not always reflect the full impact of new concepts and will often result in the need to render previous standards obsolete with some resulting disruption in the market.

It can be argued that ISDN and B-ISDN are both victims of a slow-paced, deliberative standards process that was overtaken by evolving technology and comprehensive attempts to codify the methods of providing telecommunications to end users that has identified virtually all of the needs of multimedia communication and provided stability to the market. Neither side of the argument is willing to concede much to the other. Perhaps ISDN, especially the narrowband version, is a victim of bad timing. When it was initially defined in the 1970s and 1980s, no one could conceive of a need for end user capabilities as high as 64,000 bits per second (kbps) data communication; once it was ready for full deployment in the 1990s, and the Internet was upon us, no one could imagine a need for such a low rate!

History and Origins

By the end of the 1960s, it was clear that the transition from telephone networks based on analog technology to those based on digital technology was inevitable and would be complete within a few decades. It was equally clear that digital technology options were much more diverse than the analog predecessors and progress could only occur if broad agreements could be reached among all parties with a significant stake in the future of the industry.

The ITU formally assigned the question of how to develop international standards for digital telecommunication networks to study groups in this period, and over the next 24 years a series of standards documents were

Table 1 Principles of ISDN

1.1	The main feature of the ISDN concept is the support of a wide range of voice and nonvoice applications in the same network. A key element of service integration for an ISDN is the provision of a range of services using a limited set of connection types and multipurpose user–network interface arrangements.
1.2	ISDNs support a variety of applications including both switched and nonswitched connections. Switched connections in an ISDN include both circuit-switched and packet-switched connections and their concatenations.
1.3	As far as practicable, new services introduced into an ISDN should be arranged to be compatible with 64 kbit/s switched digital connections.
1.4	An ISDN will contain intelligence for the purpose of providing service features, maintenance, and network management functions. This intelligence may not be sufficient for some new services and may have to be supplemented by either additional intelligence within the network, or possibly compatible intelligence in the user terminals.
1.5	A layered protocol structure should be used for the specification of the access to an ISDN. Access from a user to ISDN resources may vary depending upon the service required and upon the status of implementation of national ISDNs.
1.6	It is recognized that ISDNs may be implemented in a variety of configurations according to specific national situations.

Note: Source ITU-TI.120. Reprinted with permission.

produced that progressively defined the details of design and operation of ISDN. The principles of this work are provided in ITU-T Standard I.120 (1993) and are shown in Table 1.

The standards developers also recognized that the movement to full deployment of ISDN would require a considerable period of time and defined several principles of "evolution" to guide it (ITU-T, 1993). Unfortunately, they did not recognize that the Internet "revolution" would overtake many of their principles. This first effort can be considered narrowband ISDN (N-ISDN) because it is based on a synchronous time division multiplexed structure consisting of increments of communication "bandwidth" of 64,000 bits per second (64 kbps).

ISDN developers also recognized the need for greater transmission rates that could not be accommodated by integral multiples of 64 kbps only and for communication that did not require continuous and dedicated access to any fixed bandwidth value. As a result, broadband ISDN (B-ISDN) was conceived and based on the notion of asynchronous transport using fixed-size data cells (ITU-T, 1997). This asynchronous transfer mode (ATM) is contrasted with the synchronous transfer mode (STM) approach of N-ISDN. ATM held the promise of being the foundation for all digital communication regardless of speed or other characteristics. In fact, it can be considered the second attempt at a common converged infrastructure for telecommunications.

Current Deployment and Significance in Today's Markets

Narrowband ISDN (N-ISDN) is now deployed in almost 60% of the countries of the world, having grown from just over 4% since 1990. This deployment is uneven, however, with the less developed countries generally having little or no ISDN deployment and the wealthy ones having the greatest penetration. The countries of Europe have the greatest ISDN deployment, and the highest proportion of ISDN channels as a fraction of all telephony access channels reaches more than 49% in Norway (other examples include Germany at 35.7% and Netherlands at 30%). Japan (29.7%) and the Republic of Korea (10.7%) are the exception to relatively low deployment in Asia, and the United States (6.7%) and Canada (4.4%) are at the top of the list for the meager deployment in the Western Hemisphere. Nevertheless, these are important, if not overwhelming numbers (ITU, 2002). N-ISDN is certainly a player today in the world telecommunications market, but this is not the end of the story.

When first conceived, N-ISDN, especially the BRI version (described later in the chapter), was designed to provide multichannel, high-speed (64-kbps) connection over single subscriber loops. This, it was argued, would serve the needs of any single-line customer who wanted simultaneous voice and data communication. Since that time, the slow pace of N-ISDN deployment and the development of 56-kbps analog modems drove the market for second-line service in many areas. Furthermore, broader band services such as high-speed asymmetric digital subscriber line (ADSL) on local loops and cable modems on the ubiquitous cable networks have presented a significant challenge to the 64- or 128-kbps capability of N-ISDN for those customers demanding broadband access.

The existence of N-ISDN standards and services also helped support the development and deployment of multimedia communications that includes voice, video, and simultaneous data sharing in a single connection. The ITU-T standard H.320, titled Visual Telephone System, specifies the use of N-ISDN services for such calls. This standard, and others related to it, have helped advance this higher function form of communication in both the switched channel telephone network and in the packet-based Internet.

Although N-ISDN was developed and initially deployed as a service set supported by the conventional, but evolving, public telephony networks, the access technology for it has also seen life as one of a host of digital subscriber line (DSL) services that provide end users with both traditional telephone service and simultaneous wider band data service for Internet access on a single copper wire pair. This service, known as IDSL, uses the same line coding techniques and frame format as the N-ISDN basic rate interface (BRI) service and provides 144 kbps of data communication bandwidth between a user's premises and the central office (CO). At the CO, the connection is diverted directly to an Internet service provider's (ISP) network. IDSL does not provide any switched service, including and in particular, voice service, as found in N-ISDN BRI. This is just the latest of a series of derivative uses for ISDN technology.

N-ISDN also sees service in the video teleconferencing market. The first of a series on ITU-T standards, H.320, defined a Visual Telephone System that operates on multiples of 64-kbps bearer channels up to 1,920 kbps using ISDN call control and management. This standard specifies video, audio, and data services for multimedia communication and also defines the concept of a multipoint control unit (MCU) that permits more than two parties to participate in a conference using all three communication modes. This work has also served as the foundation of one option for call control standards in multimedia communication in packet communication networks such as the Internet.

The significance of ISDN today derives both from its deployment, principally as a narrowband offering, and from the foundation of standards it has spawned in call signaling, frame relay and ATM transport services. For example, frame relay service access ports, as a percent of all commercial broadband access in 2001 was about 35% and was exceeded only by traditional private lines leased largely from traditional telephony providers (38%; E Dunne, 2002; information available at http://www.verticalsystems.com). ATM access service is only a small fraction of this market (less that 1%), but this figure does not begin to represent the importance of the role ATM plays in core networks. The signaling protocols of ISDN not only are redeployed in these derived services for connection setup and management, but they have also been adopted in one of the leading techniques for packetized speech services in the Internet protocol (IP) networks that are taking hold in telecommunications networks today (ITU-T Standard H.323, 1999).

Standards and Organization

Standards development for ISDN was initiated by and has remained largely in the hands of the ITU-T. The "I-series" of standards of that organization are devoted to ISDN issues and include eight categories: general structure, service capabilities, overall network aspects and functions, user–network interfaces, internetwork interfaces, maintenance principles, and B-ISDN equipment aspects (ITU-T Standard I.120, 1993). These standards, and those from other series documents associated with them, generally serve most of the countries of the world for purposes of product and service definition.

In North America, however, regional supplements to international standards were required both to complete definitions left open at the international level and to provide for specific needs in the United State and Canada. These standards are provided through the American National Standards Institute (ANSI). The most significant of these is perhaps that for the physical layer definition for two-wire communication for basic rate service between the customer premises and the attached central office—ANSI T1.601.

Despite all of the intense effort to develop standards, there were still many unanswered questions that had to be resolved before broad-based deployment could occur in North America. The Bell Operating Companies and Bellcore (now Telcordia, see http://www.telcordia.com) developed a series of plans to complete this work and called it National ISDN. Known as NI-1 through NI-4 (for National ISDN-1, etc.), these plans specified details for access, call control, and signaling, uniform interface configurations for basic rate interface, uniformity of BRI services, primary rate interface (PRI) capabilities, data capabilities, operations support capabilities, and billing capabilities (Telcordia, 1995). The National ISDN agreements were crucial to deployment in North America but also introduced yet another delay in the process for that region.

NARROWBAND ISDN

The evolution from analog to digital telephony was based on the concept of synchronous time division multiplexing in which each communication channel was provided a fixed amount of bandwidth suitable to carrying a single, band-limited voice conversation. The standard for such conversations were established with the first digital carrier systems deployed in the early 1960s at an 8 kHz sample rate with 8-bit digital samples based on a nonlinear, compressed code. The basic voice channel rate thus became 64 kbps. Narrowband ISDN is based on providing various combinations of these "bearer" channels between the customer premises and a central office (CO) switch over copper wire access loops.

Basic Rate and Primary Rate Interface Common Features

N-ISDN defines two classes of service and interface: basic rate interface (BRI) and primary rate interface (PRI). Both interfaces include some number of 64-kbps bearer channels and a common signaling and service channel. The bearer channels are called B channels, and the signaling channel is known as the D channel. Both interfaces have a time division multiplexed line format based on a fixed frame structure that has an underlying repetition rate of 8,000, or some submultiple of 8,000, frames per second. This means that the bearer channels, when used for voice transmission, can be synchronized with the telephone network by placing one or more samples in each frame. This supports the end-to-end synchronization of voice communication from one customer premises terminal to another.

The BRI frame has two 64-kbps B channels and one 16-kbps D channel, whereas the PRI has either 23 or 30

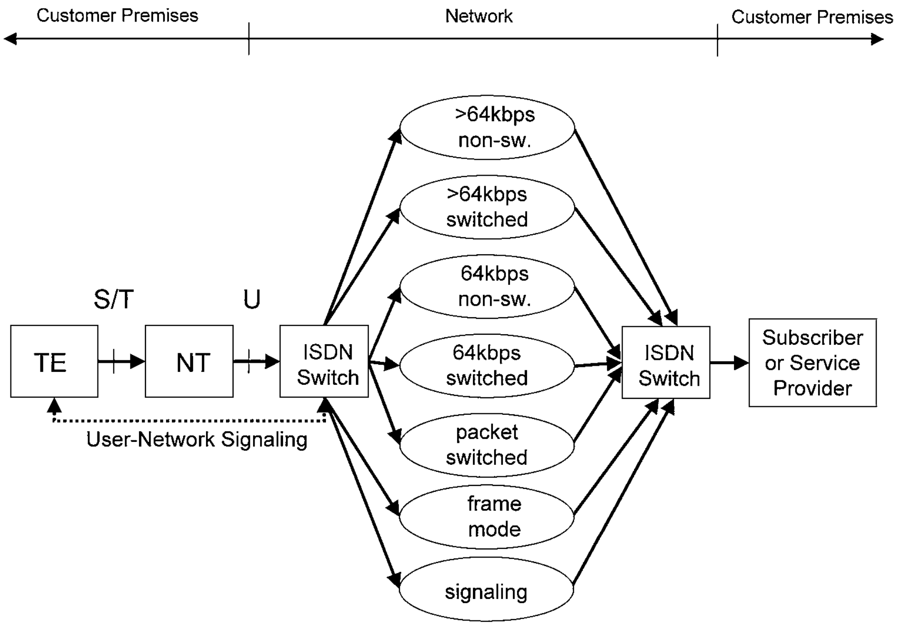

Figure 1: ISDN architectural elements and reference points.

B channels and one 64-kbps D channel. The difference in PRI B channel support depends on the underlying physical layer bit rate of 1.544 Mbps or 2.048 Mbps (derived historically from the T1 or E1 digital hierarchy carrier systems developed in North America and Europe) respectively. BRI service is commonly used for individual subscriber needs, whereas PRI service typically is used to support customer premises switching equipment such as a private branch exchange (PBX).

D channel operations for both BRI and PRI are primarily for signaling to establish and disconnect calls on the B channels associated with the interface. This signaling supports both origination and termination of calls and specifies how the associated B channels will be used including such characteristics as voice coding technique or data multiplexing functions. D channel operations also support direct data communication services as well (see Data Link Layer and Operations later in the chapter).

Physical Layer and Operations

Because BRI is intended to serve as a high-function alternative to conventional analog single-user service, it must be provided on the single wire pair access loop now connecting most users to the central or end office of the public switched telephone network (PSTN). Because BRI service must support at least a $2 \times 64 + 16 = 144$ kbps rate in both directions, this means that the access loop must be capable of supporting a bandwidth much greater than the 4 kHz normally associated with an analog voice connection and that some means must be established to keep the signals traveling in the two directions from interfering with each other.

PRI service is defined as using two wire pairs, but again, this will generally be the same physical wire plant used for single-user service and must support 1.544 or 2.048 Mbps rates. In fact, both BRI and PRI are examples of the general class of access services known as DSL services. All of these services take advantage of the fact that telephone access lines have a much greater effective bandwidth than that needed for simple analog telephone service. The rates that can be carried and the information formats used, however, depend on loop length and a variety of potential impairments that can only be fully determined by direct measurement by service providers.

BRI

Basic rate service is defined in ITU standards to have several reference interfaces both on the customer premises and at the point between the customer premises and the central office (see Figure 1). The “U” reference point is the two-wire connection point and operates at a 160 kbps rate using the 2B1Q (two binary, one quaternary) multilevel line. (This is the line coding used in North America. Different techniques are used in other parts of the world.) This results in an 80-kilobaud signaling rate and minimizes the bandwidth requirement on the local loop. The difference between 160 kbps and minimum 144 kbps occurs because 16 kbps of framing and maintenance information is included in the BRI U reference frame format.

The U reference point is converted to the “T” reference point at the customer premises through the network termination 1 (NT1) functional device. Among other functions, the NT1 device converts two-way, single-pair transmission to one-way, two-pair transmission. A network termination 2 (NT2) device may be realized separately and further defines an “S” reference point where ISDN compliant terminals can be connected. Alternatively, a terminal adapter (TA) device can connect at the “S” reference point to permit support of conventional analog telephones and data communication gear.

The data format at the S/T reference points operates at 192 kbps using a pseudoternary line code. Once again, the difference between 144 kbps and 192 kbps is accounted for by the addition of framing and maintenance information included in the frame format at this point. This physical level detail is specified in the ITU-T Standard I.430.

There is a variety of BRI wiring arrangements that permit up to eight compatible ISDN terminals to connect in parallel at the S/T reference point. Each of these terminals can be assigned its own directory number and operate independently within the limitation that only two B channels are available for use at any one time. It is most common, however, for only a single terminal to be deployed for ISDN BRI service and for that terminal to be a combination telephone hand set and data communication termination for a PC or local area network or as data network router capable of automatic connection to a remote site.

PRI

Because the PRI in North America, Europe, and the rest of the world is already defined to use existing physical level signals currently in place in the digital hierarchy, introducing this capability into the telephone physical plant was somewhat easier than BRI. The specific details for the electrical interfaces and the frame structure are defined in ITU-T standards G.703 and G.704 respectively. As in the case of BRI, the data rate for PRI is slightly greater than the sum of the B and D channel rates to allow for framing and maintenance features.

Regardless of the physical format of the communications link, BRI or PRI, the physical connection must be complete, and end-to-end, bit-level synchronization must be established before any data link level communication can proceed. This step-by-step initialization moving up the levels in the open system interconnection (OSI) reference model is common to all data communication systems, including ISDN.

Data Link Layer and Operations

N-ISDN represents the first time telecommunications standards identified separate, general-purpose user and control "planes" within a single physical transmission facility. Although this notion is now so common within data communication networks such as the Internet that we don't think much about it, in the 1960s, it was quite novel. Within N-ISDN control and user planes exist in separate portions of the transport frame, the B and D channels, but there is also a further separation within the D channel itself that allows that system component to serve as both a signaling and a transport channel.

8	16	Variable	8/16	16	8	bits
Flag	FCS	Information	Control	Address	Flag	

Figure 2: LAPD packet format.

ISDN services, both narrow- and broadband, are most extensively defined at the user–network interface (UNI). This means that while end-to-end information may flow unchanged through the network (e.g., 64-kbps pulse code modulated (PCM) encoded speech), the precise physical, data link, and network level definitions for carrying this information may only be defined at the UNI. Typically, then, ISDN access links terminate at the central office where B channels will be synchronously switched into the larger time division modulated public switched telephone network (TDM PSTN), and the D channel will terminate on CO software control functions that determine when, and how, those B channels will be switched. ISDN standards also define terminations to a variety of other services (see Figure 1), but 64-kbps channelized service is the most common.

The D channel, then, operates as a point-to-point, synchronous data communications link between the customer premises and the CO. At the data link level, the 16- or 64-kbps channel functions as a continuous bit stream even though the individual bits are partitioned and carried in separate frames in the underlying physical layer frame format of BRI or PRI. Information in the D channel is carried in packets delimited by a unique start and stop pattern of bits called a flag (see Figure 2). The structure of this packet, including the flag, is taken from the high level data-link control (HDLC) format that has been used in synchronous data communication from its earliest days (e.g., X.25 and various other standard and proprietary systems).

The D channel packet structure and its operation are known as the link access protocol—D channel, or LAPD, and is one of a class of protocols that has evolved over a number of years to support reliable transport of information across a single data communications link. The key features of the LAPD packet format are, in addition to the delimiting flag patterns, the address, control, information, and frame check sequence (FCS) fields. LAPD is defined in the ITU-T standard Q.921.

The information field is variable in length and carries the actual control information that is interpreted at the network and higher layers of the ISDN protocols and services. The FCS field is a 16-bit cyclic redundancy check code that serves to detect single-bit errors in the overall LAPD packet that can then be used to trigger error control procedures.

The address field is divided into two subfields: the service access point identifier (SAPI) and the terminal endpoint identifier (TEI; see Figure 3). The SAPI value determines what functional service the packet will perform. For example, SAPI = 0 is the value for call control procedures used to set up the use of associated B channels.

10-16	9	3-8	2	1	bits
Terminal Endpoint Identifier	1	Service Access Identifier	C/ R	0	

Figure 3: LAPD address field format.

Other significant values are 16 for X.25 communication on the D channel, 32–61 for frame relay communication on the D channel, and 63 for D channel management functions. The SAPI field is the way LAPD multiplexes the D channel for different functions. Although call control information clearly must terminate on the CO, X.25 and frame relay information would likely terminate with another end user and this implies that the CO would have to include a packet forwarding capability if this service is to operate (see Figure 1).

The TEI field supports the concept of multiple terminal end points at the user premises as in the case of BRI. TEI values can be manually assigned but more likely the CO will automatically assign them as part of an initialization procedure when the ISDN equipment is first connected. Note that the TEI does not relate to B channel use but to specific terminals that may use a given B channel that is established at the time of call setup. The TEI value of 127 is used as a broadcast value when no specific value has been assigned or appropriate.

The control field has several formats depending on the type of information being exchanged. Seven bit send and receive sequence numbers are used to support reliable communication in LAPD by means of acknowledged transfer in which each end of the link is able to track the last packet that was successfully received at the far end and announce what was last successfully received at its end. This technique is used in the basic "information" transfer mode. The "supervisory" mode is used when only one-way acknowledgment is required and the "unnumbered" mode is used when unreliable communication is appropriate, as in the case of the link initialization required when LAPD communication is first established on the D channel. Initialization for LAPD includes assigning a TEI value using the unnumbered information packet type and the set asynchronous balanced mode extended (SABME) packet type in the unnumbered control mode. The D channel is now ready for network layer communication (e.g., call setup).

Network Layer and Operations

The connection-oriented communication model is fundamental to all ISDN services (narrow- and broadband). This means that communication has three distinct phases—setup, information transfer, and disconnect—and that there is some notion of a system resource being reserved for the duration of the communication. The principle resource being reserved in N-ISDN is a B channel. D channel network layer operations serve to exchange information between user end points and the network to establish this reservation for the duration of a call, and the designated B channel resources are then used for communicating information between end points.

Therefore, call control communication in the D channel must be able to identify both the B channel resources in question and the particular call instance of concern. It is also important to be able to describe how the network is to treat the B channels during end-to-end communication in terms of any special coding or other manipulations. All of this capability is contained in the protocols defined for ISDN network layer services (see Figure 4).

Figure 4: ISDN protocol and service model.

ITU-T standards Q.930, Q.931, and Q.932 are the principal specifications for N-ISDN call control. These standards and the call management model they represent not only define ISDN but have also provided a call management model for network-wide signaling using Signaling System 7, are the foundation for connection management for B-ISDN (ATM) and frame relay services, and have also been incorporated into one of principal competing standards for voice and multimedia services on IP networks, H.323.

The basic Q.931 call control message is carried as the payload in a LAPD packet between the user end point and the CO (see Figure 5). These messages have four common features:

1. A protocol discriminator that uniquely identifies the payload as a Q.931 defined message
2. A call reference value that uniquely associates all information about one call for its entire duration
3. A message-type indicator that determines which of a defined set of call control messages is being invoked
4. A set of one or more information elements that carry all of the call management detail required, realizing the particular call control message

A typical call control procedure will include a number of common message types. For example, in ISDN, some end user on customer premises equipment always initiates calls. That user's terminal equipment will begin

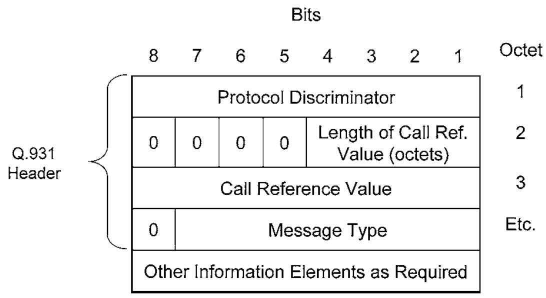

Figure 5: Q.931 call control message format.

by issuing a SETUP message type to the CO. This message must contain a Bearer Capability information element that describes the required bearer channel needs and how they are to be used in the call. The message may also contain such important information elements as calling and called party numbers, call progress information, and display information useful to the human end users.

SETUP messages are acknowledged, as are most ISDN messages, and provide a means to indicate success or failure of the original message. PROGRESS and CALL PROCEEDING messages are included in the Q.931 protocol repertoire to allow the network and terminals to signal that things are progressing as expected. The ALERTING and CONNECT messages allow end points and the network to signal that a connection is being attempted and is complete, respectively.

Finally, either end of a two-party call can initiate termination. This is done with a DISCONNECT message. Recall that Q.931 messages includes a call reference value, and it is this value that allows the terminal equipment and the CO to agree that they are each referring to the same connection at any given time. This value can also be used by terminal and network equipment to maintain records for billing and other purposes, although these features are not defined in the standards. All of the details of call processing in both terminal and network switching equipment beyond the Q.931 protocol definitions are the subject of software that is proprietary to specific equipment vendors.

Extended Bearer Channel Operations

The simplest and most common use of ISDN service is to provide a clear 64-kbps channel to transport either voice or data information between two end points. In such cases, the SETUP message, and its bear capability information element, will define how the B channel will be used. The ISDN standards, however, anticipated a number of other, more complex uses of connection bandwidth.

For example, 64 kbps may not be enough capacity for certain services, such as data or video communication. In this case, capabilities are defined to support fixed multiples of B channel capacity in one connection. A common service might be 2 × 64 kbps to allow the use of both B channels in BRI service to provide a broader band connection for terminating LAN routing gear that must communicate with a remote network location.

Other examples of "$n \times 64$" service are defined for PRI service in which specific aggregations are defined, such as $H_0 = 384$ kbps ($n = 6$), $H11 = 1536$ kbps ($n = 24$, 1.544 Mbps PRI), and $H12 = 1920$ ($n = 30$, 2.048 Mbps PRI). Standard services also support the case for a general value of n for applications in which one of the fixed bandwidth services is not appropriate. In all cases, however, the network resource, in terms of B channels, is reserved for the duration of the call, and this is one of the basic criticisms of N-ISDN: It may not make efficient use of network bandwidth resources for information transport in which the data rate may be irregular during the period of connection.

At the other end of the speed spectrum, there is also a need to provide communication channels with data rates less than 64 kbps. Although this is not as common today as when the ISDN standards were first developed, considerable attention went into creating standard mechanisms for multiplexing several data signals into one 64-kbps B channel. Terminal adaptors at the user premises are responsible for the multiplexing function and, because of the nature of N-ISDN service, individual data signals multiplexed into one B channel must originate and terminate together—there is no "add–drop" capability defined.

Drivers in General Telephony and Data Services

N-ISDN standards developed at a time when there was tremendous growth in digital telephony around the globe. This growth drove an increasing need for uniform and reliable techniques for long distance network signaling. The development of Signaling System Number 7 (SS7; see ANSI standard T.110) almost exactly parallels that for N-ISDN and complements the end user to CO signaling support of ISDN with network to network signaling needed to complete calls between arbitrarily different customer premises.

Even though common channel signaling required for conventional analog telephony represented a major advance in long-distance calling reliability and flexibility, ISDN represented a new richness in call features that placed new demands on the networks. It makes little sense to allow an ISDN end office to support a complex call initiation by an end user if the detail of the required end-to-end connection cannot be communicated across the network to the other party and facilities needed to support it cannot be reserved within the network itself.

An equivalent network layer protocol has been defined in the SS7 protocol system, called ISDN user part (ISUP; ANSI Standard T1.113), for just this purpose. ISUP is not only capable of supporting, through translation, all of the Q.931 messages required in ISDN but it is also a sufficiently significant advance of the earlier SS7 protocol, telephone user part (TUP), that it is becoming the dominant signaling protocol for all service, conventional and ISDN alike.

Signaling is not the only area in which ISDN standards have affected telecommunications beyond the actual deployment of the service itself. Recall that part of the D channel LAPD specification included the ability to support end user to end user data communication using something called frame relay. The 30 values from SAPI = 32 to SAPI = 61 can each designate a unique logical communication connection on the ISDN D channel. Because LAPD operates at Layer 2 of the OSI reference model, frame relay service provides a basic point-to-point transport for arbitrary packet information.

The value of frame relay services is so great that separate distinct standards have been developed by the ITU-T, including Q.922 which is the specification for frame mode bearer services, Q.933, the frame relay call control procedures, and I.122, the overall framework for frame mode bearer services. From a commercial perspective, however, these international standards were not adequate. As a result, the Frame Relay Forum was formed and has provided a set of implementation agreements that has guided the industry since the early 1990s. Details on the forum and the agreements they have produced can be found at http://www.frforum.com.

BROADBAND ISDN

Even as the narrowband ISDN standards were being completed and deployed in the 1980s, standards developers recognized that the restriction of assigning multiples of 64 kbps to connections would not be adequate for the indefinite future. It was also recognized that dedicating transport bandwidth, no matter what amount, to a connection for its entire duration was also not appropriate for a great many, nonvoice services. As a result, development began on standards for broadband ISDN (B-ISDN) as a complement and possible successor to N-ISDN. A basic definition of terms and the overall aspects of B-ISDN can be found in ITU-T standards I.113 and I.121, respectively.

Rationale and Worldview

When measured in bits per second, the total amount of information passing along the world's telecommunications networks that represents voice has continuously decreased, as a proportion of the total, relative to that for other forms of information. At some point in the late 1990s general data began to exceed voice communication as the dominant form of traffic. It is only reasonable to assume that the underlying network for telecommunications would be optimized for the principal type of traffic. In a sense, this was the design principle behind B-ISDN.

Even if one takes a coarse view of classification of telecommunications traffic consisting of voice, data, and video, it is possible to identify several distinct ways to characterize each traffic type and its potential impact on the underlying transport network (DuBoise & Kim, 1992). For example, in addition to the basic average bandwidth required, there is a simple binary distinction of whether the signal requires continuous or time-variable access to this bandwidth. If variable access is required, one can further define the signal in terms of how (proportionately) often access is needed (burst ratio) and how long that access persists (burst length).

Finally, information flows can be characterized in terms of the quality and reliability of the transport they require. Such measures include data loss and error tolerance and overall delay in transport from end to end. The ranges in all these measures are considerable: bandwidth from a few kilobits per second to a few gigabits per second; burst ratios from 1 (continuous transmission such as voice) to 1,000 (Internet World Wide Web access); burst lengths of up to 100 megabits (digital images); loss tolerance from one error in 10^4 bit (speech) to one error in 10^{12} (high-resolution graphics); delay tolerance from less than 10 ms to more than 10 s or more. The B-ISDN standards developers attempted to address this entire spectrum of needs and, in this mission, set about creating a second generation of converged services network.

The B-ISDN Services Vision

Despite the expansive worldview taken in B-ISDN standards development, there is recognition that some form of backward compatibility with and migration from N-ISDN is essential. The vision is that B-ISDN can coexist with N-ISDN and that some subscribers will choose one or the other according to their needs. There is some similarity between the high-level views of architecture for the two classes, however (see Figure 6).

The same concept of architectural reference points exists in B-ISDN to help delineate functions in the network and on the customer premises and help ensure interoperability of service and product components from different providers. A set of standard access capabilities connecting the user to the CO is also provided for B-ISDN as well. In this case, however, the fundamental rates are 150 and 600 Mbps and the access medium is optical fiber instead of copper wire pairs.

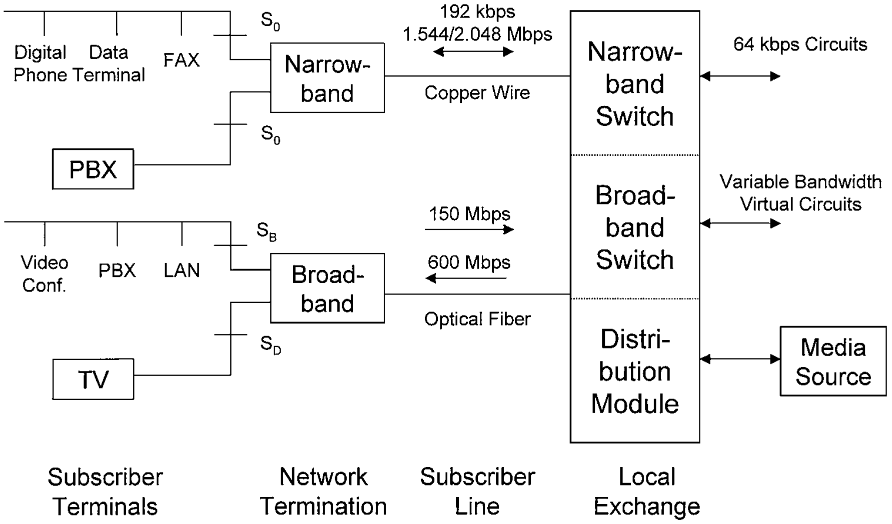

Figure 6: User-network alternatives for broadband ISDN.

B-ISDN services extend from the traditional narrowband functions of telephony to the distribution of entertainment functions we currently associate with cable or satellite television broadcasting. In other words, B-ISDN is to fulfill the promise of N-ISDN by supporting the remainder of telecommunication services not adequately or efficiently supported by 64-kbps transport.

The Decision for Cell Transport and ATM Overview

Perhaps the most significant decision in the design of standards for B-ISDN is the one to abandon STM operation. In STM, all connections, whether single or multiple channels of 64 kbps, are transported and switched in a synchronous manner end to end. This means that every connection has a fixed delay for the duration of the connection. It also means that the entire network must be effectively synchronized to preserve the underlying, common 8-kHz sample rate that is the foundation of the basic B channel service.

B-ISDN had to support not only a wide range of data rates but also the burst ratios that implied that network bandwidth was not continuously required throughout the connection. The solution was to build B-ISDN transport not on a fixed unit of constant bandwidth but to use a fixed unit of information transport size, called a cell. A further decision was made to abandon network-wide synchronization and adopt and ATM of transmission. Actually the two decisions are linked once one considers the network behaviors necessary to switch cells across different network nodes on their way between end points.

In STM, the addressing of channels across the network is separate from the transport of information and switching points preserve the temporal order of the share of time devoted to each connection. In ATM, even though a source may generate information for cells at a constant rate (e.g., voice), other cells for other connections will be inserted and removed as the streams progress through the broadband network. This means each cell must be labeled to associate it with a particular connection.

The cell size chosen was 53 octets of which 5 octets form the header of the cell, which includes the connection identification, and 48 octets contain the information being transported. B-ISDN standards (ITU-T Standard I.121, 1991) define a layered structure in which the physical layer can be a variety of capabilities ranging from 25 Mbps on up. Layer 2 is divided into the ATM sublayer that carries the basic ATM cells and the ATM adaptation (sub-)layer (AAL; see Figure 7). The AAL takes data from higher layers in the OSI reference model and "adapts" it for transport in ATM cells. Currently there are four basic AAL protocols in general use, AAL1, AAL2, AAL3/4, and AAL5, and each one is designed to support a particular class of service including a circuit emulation service (CES in AAL1) that emulates the N-ISDN 64-kbps B channel.

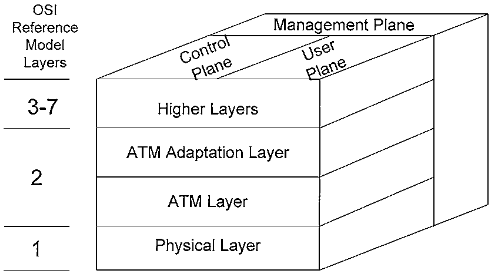

Figure 7: ATM protocol architecture.

An ATM connection is a virtual circuit connection, which means that, although there is no dedicated and reserved bandwidth as in STM systems, there still are logically reserved resources assigned to it. This is accomplished by assigning virtual connection identifier to each ATM cell associated with a connection. This virtual connection identifier actually consists of two parts: the virtual path identifier (VPI) and the virtual channel identifier (VCI) (see Figure 8). This two-part structure gives a logical feel to ATM service similar to the individual trunks (VCI) and trunk groups (VPI) familiar from traditional telephony. In fact, the B-ISDN standards note that ATM switching, maintenance, and other operations can occur at either or both the VCI and VPI logical level.

Because each cell is uniquely identified with its associated connection, it is possible to treat different connections in such a way as to provide better service to one over another. The ATM standards define how this can be done and how switches and call management functions must operate to support the requirements of different types of communication service.

ATM defines both permanent virtual circuits (PVC) and switched virtual circuits (SVC). PVCs are manually administered between end points and are intended to provide dedicated transport for customers. As with frame relay service, which has the same two circuit forms, PVC service is the overwhelming form of ATM service provided today. In effect, ATM service is a private line, dedicated service in the current market (see the following section, Development and Deployment of ATM and B-ISDN).

SVC service, as the name implies, uses standardized call setup and management procedures to establish a virtual circuit. The call management protocol is very similar to the Q.931 standard used for N-ISDN but is sufficiently enlarged that it is defined in a separate set of standards beginning with Q.2931. One other difference in ATM over N-ISDN is that the control channel for signaling is not

physically distinct the way the D channel is but, instead, is simply a dedicated virtual circuit (VCI–VPI value pair) that is only used for this purpose.

Because ATM and B-ISDN were to be carried on optical fiber connections from the beginning, it is logical to assume that one other set of standards being developed at this same time, synchronous optical network (SONET) and the synchronous digital hierarchy (SDH), would also be closely related to this service. SONET/SDH is an 8-kHz framed optical transport system with multiple physical bit rates extending from approximately 50 mbps/ 150 Mbps (OC-1/OC-3) to (currently) nearly 40 Gbps (OC-768) and which can support both STM services as well as ATM (ATM Forum, 2000). As such, it has become the backbone optical service for traditional telephony service providers and customers alike.

Development and Deployment of ATM and B-ISDN

B-ISDN, like N-ISDN, was seen primarily from the perspective of the user–network interface and was driven by an expected flood of demand for new broadband services by end customers. As the market developed, the demand came first from telecommunication service providers who saw ATM (and the conveniently available SONET/SDH physical transport technologies) and not the entire B-ISDN model, as a desirable internal structure for their networks. Just as in the case of frame relay, the demand for completed standards outstripped the capacity of the ITU-T standards development process and the industry turned to a consortium of equipment manufactures, service providers, and customers. This consortium, the ATM Forum, has become a principal source of ATM standards for this service today (http://www.atmforum.com) through a set of implementation agreements that are aligned with ITU-T standards where they exist and are complete.

Although B-ISDN, as such, has not really been deployed, ATM service, including direct customer access service, has been widely deployed. ATM service and networks, based on ITU-T and ATM Forum standards, is used primarily for core network service for service providers, including those providing frame relay service to end users. Direct access to ATM, however, remains at only a few percent of the market for customer service (E. Dunne, personal communication, 2002).

ISDN APPLICATION TO THE INTERNET AND E-COMMERCE

The relationship between ISDN and the Internet divides along a narrowband–broadband fracture line. N-ISDN, with its 64-kbps dedicated bandwidth service, now serves as the low end of the digital access services available to customers who cannot be satisfied with (dial-up) analog modem service. B-ISDN, through the deployment of ATM technology and services largely through traditional telecommunication service providers, makes up a significant, and still growing, part of the backbone transport for ISPs (E. Dunne, personal communication, 2002).

Whether the 64-kbps (or 128-kbps) bandwidth seems to be a limitation, of course, depends on the end user's requirements and the alternatives that are available. The assumption that bandwidth demand for Internet access can only continue to grow dramatically seems to have been challenged a bit by the reverses in the telecommunication industry in 2001 and 2002, but even a resumption of this growth does not necessarily mean an end to N-ISDN BRI service demand. To begin with, both conventional ISDN BRI service and IDSL direct Internet access service using the same line signaling formats can extend to greater distances from the CO than other DSL techniques. This means that ISDN is the only way for some wire-line access customers to gain even modest digital communication rates.

For small commercial offices, ISDN service for local area network routers that can automatically dial central and home office sites have provided a cost-effective alternative to dedicated private lines or other services. In some circumstances, the public network connection flexibility of ISDN is the right solution. In addition, most local and regional ISPs offer ISDN termination options for subscribers to permit direct access to the Internet. For now, this flexibility may be difficult to obtain through other services.

Even though ATM service is a relatively small proportion of the total dedicated data service market, its broadband character and its use internal to networks (as opposed to premises access) promises to position it well for the next few years. Revenue from these applications is expected to grow at a cumulative annual rate of 34% (E. Dunne, personal communication, 2002). Even some of the services competing with N-ISDN, like ADSL, use ATM core network transport to link CO access line terminations to Internet access points. The legacy of B-ISDN lives on in this way.

CONCLUSION AND THE FUTURE OF ISDN

In some sense, one can argue that ISDN has both enabled the Internet and been overrun by it. The core and edge network technologies of ATM and frame relay are outgrowths of ISDN standards efforts and represent both a current and future portion of the transport solutions that connect people to the Internet. Call connection signaling standards for ISDN have been absorbed into at least one solution for converged services using a single, IP-based network. Finally, the comprehensive approach to defining connection management for services like telephony that are inherent to the ISDN standards represents a minimum threshold of excellence that all competing approaches must address.

It is equally clear that neither the narrowband nor the broadband ISDN perspectives for end user service are adequate for the indefinite future. Compared with purely packet-based alternatives, 64-kbps communications channels are simply too restrictive or wasteful. Although an early attempt was made to position ATM services to the general user premises and to individual desktops, this technology has found its place firmly in the core of communications networks. Furthermore, ATM and

B-ISDN are not the same thing; B-ISDN will never see deployment beyond the use of its link layer technology as it is currently applied.

The future of ISDN and its associated technologies is not in question. Eventually it will be displaced, application by application, by the technologies of the Internet. The question is, how long will this take? It is a sound wager that N-ISDN will survive at least as long as the PSTN and will slowly grow as the proportion of service in it. ATM and frame relay continue to have healthy growth rates (E. Dunne, personal communication, 2002) and present some advantages in places where IP-based networks continue to struggle (e.g., Quality of Service guarantees).

For those who would like to explore N-ISDN and B-ISDN and their derivative services in greater depth, there are several resources. Stallings (1999) provides a good, integrated view of all the topics covered in this article in much greater detail. Black (1997) provides a comprehensive view of ISDN and SS7, and Black and Waters (1997) consider SONET and T1 in detail. Miller (2001) considers the issues associated with the protocols in actual application.

GLOSSARY

American National Standards Institute (ANSI) A private, nonprofit organization that administers and coordinates the U.S. voluntary standardization and conformity assessment system. One particular role is to ensure that international standards are complete and appropriate for deployment in the United States and to sponsor additional standards development when necessary. A committee designated as T1 coordinates telecommunications standards. Standards from this committee are designated with the form T1.xxx, where the “xxx” is the specific standard number. Further information is available at http://www.ansi.org.

Asynchronous transfer mode (ATM) A form of physical layer information transport based on fixed length data cells with a 48-octet payload. ATM networks consist of a series of transport links connected through switches that do not retain bit or cell rate synchronism between input and output switch ports. End points in an ATM network are not able to synchronize directly with each other and must use embedded information or an external means to do this. ATM is the transport basis of broadband ISDN standards.

Basic Rate Interface (BRI) The narrowband ISDN user–network interface for individual subscribers. BRI provides two 64-kbps bearer (B) channels and one 16-kbps signaling and control (D) channel in each direction between the subscriber and the ISDN central office.

Broadband integrated service digital network (B-ISDN) The set of international standards that define both the network and operations to support end-user services with both uniform and irregular data rates at speeds up to 600 Mbps between the end user premises and the network. B-ISDN is the extension to (narrowband) ISDN services for broadband applications.

Digital subscriber line (DSL) A generic term that applies to a set of technological solutions for carrying voice and data over the (generally) two-wire subscriber line between a customer premises and the telephone central office. Narrowband ISDN is considered a member of the class and uses strictly digital techniques for transport. Asymmetric DSL (ADSL), another technique commonly available today, provides support for both existing analog telephone service and for simultaneous, broadband digital data service. The term xDSL is often used to reference a member of this class without specifying any one in particular.

International Telecommunications Union Telecommunications Standardization Sector (ITU-T) The ITU, headquartered in Geneva, Switzerland, is an international organization within the United Nations system in which governments and the private sector coordinate global telecom networks and services. The Telecommunications Sector is organized into study groups associated with different aspects of the field. ITU-T standards are designated by an initial letter that identifies a technology area and a three- or four-digit number designating the specific standard (e.g., Q.931). More information is available at http://www.itu.int

Link access protocol (for the) D channel (LAPD) A protocol used on the narrowband ISDN D channel for both BRI and PRI. It is based on high-level data link control protocol and provides the open system interconnection Layer 2 transport for signaling and control for N-ISDN.

Narrowband integrated services digital network (N-ISDN) The set of international standards that define digital, time division multiplexed access for subscribers to a uniform set of telecommunications services based on dedicated 64-kbps bearer channels (often called simply ISDN).

Primary rate interface (PRI) The narrowband ISDN interface definition typically used by enterprises to manage either 23 64-kbps bearer (B) channels and one 64-kbps signaling and control (D) channel (1.544 Mbps) or 30 B channels and one D channel (2.048 Mbps) between the customer premises and the ISDN central office.

Signaling System Number 7 (SS7) The set of international standards to provide out-of-band signaling for the global telecommunications network. In addition to supporting the signaling needs of traditional analog telephony and both digital and analog trunk technology, SS7 has a particular set of signaling capabilities designed especially to interconnect ISDN end offices and support services for ISDN and non-ISDN end points.

Synchronous transfer mode (STM) The time division multiplexed transport technique in which each communication channel on a link is allocated a particular time interval, called a time slot, in a strictly periodic information frame. Time division multiplexed switches that maintain synchronism between input and output ports interconnect links in an STM network. End points in an STM network can thus be directly synchronized with eachother.

Intelligent Agents

Daniel Dajun Zeng, *University of Arizona*
Mark E. Nissen, *Naval Postgraduate School*

INTRODUCTION

This chapter is about intelligent agents and their applications in e-commerce. The term *intelligent agents* has many connotations. At one extreme, one can envision competent humans performing in some agent capacity (e.g., real estate, stock transfer), while at another extreme, the term conjures up images of sophisticated software that interfaces with their human users in a natural language and helps them manage various aspects of their personal and professional life (e.g., booking vacation packages and answering business e-mails). The kinds of intelligent agents we discuss in this chapter certainly fall in between these extremes, but articulating a precise, universally accepted definition is infeasible at this early stage of agent development. Nonetheless, drawing from the agent-research literature, we can outline a number of properties generally associated with intelligent agents. For instance, despite ambiguity arising from the term *agent,* we refer to intelligent agents solely in terms of software applications; that is, we exclude all references to people performing in some agent capacity. However, not all software constitutes agents, and not all agents are considered "intelligent."

To be considered an agent, researchers have proposed a number of characteristics, including autonomy, networked interaction, reactivity, and persistence. By "autonomy," we mean the software should be endowed with goals and the mechanisms to pursue such goals without sustained human intervention; some software application that needs to be told what to do each time it is invoked is unlikely to be characterized as an agent. Agents are generally viewed as interacting with other agents in some networked environment; some software that operates alone in some monolithic manner is unlikely to be characterized as an agent. By "reactivity," we mean the software has the capability to sense its environment and respond with different behaviors depending upon the kinds of environmental stimuli received; software that exhibits only a fixed set of behaviors is unlikely to be characterized as an agent. Agents are generally viewed as being persistent in their pursuit of goals and operating for long periods of time if necessary; some batch or user-interactive software that terminates immediately after completing some task is unlikely to be characterized as an agent.

To be considered "intelligent," agent software must exhibit behaviors similar to those that would be exhibited by a person, who is considered to be intelligent, in the same situation. Some well-accepted characteristics of intelligence from a software perspective include goal-oriented automated problem solving, integration of problem solving and execution of decisions, self-awareness, bounded rationality, adaptivity and the ability to learn, flexible exception handling and robustness in an open and distributed environment, proactivity in identifying goals to be accomplished, natural and easy interaction with human users, and long-livedness in a networked environment (Jennings, Sycara, & Wooldridge, 1998; Russell & Norvig 1995).

If these characterizations of an intelligent agent appear somewhat vague, it is because the field of agents research has yet to come to exact terms with aspects such as these. However, the characterizations above are well rooted in the literature (Weiss, 2000), and most researchers would be likely to identify with the majority of them.

Now that we have discussed what it means to be an intelligent agent, we address the e-commerce context of such agent applications. As described elsewhere in this book, recent developments in networking and Internet-related technologies are leading to the emergence of a digital economy. As with agents, many different definitions for e-commerce are possible. For purposes of this chapter, however, we adopt a fairly restrictive definition: e-commerce refers to commercial activities conducted over the Internet. In this sense, we use the terms e-commerce and Internet commerce interchangeably. Given the key role of networks in our characterization of agents above, with the convergence of e-commerce and Internet commerce in this view, it should be clear that intelligent agents represent inherently capable technological enablers.

However, like any software application, agent development consumes precious resources (e.g., development, infrastructure, maintenance), and despite their technological capability, in the commercial setting intelligent agents must also make economic sense. In some respects, this requires considerable scale, for agent development may not be economically viable for small (electronic) marketspaces or those in which the inherent capabilities of software (e.g., processing speed, memory capacity) do not convey sufficient advantage over the fundamental capabilities of people (e.g., flexibility, tolerance of ambiguity). In other words, for intelligent agents to be viable for e-commerce, their domains of application must have sizeable scales in terms of users, transactions, and information content. Otherwise, agents for e-commerce will not produce sufficient return on investment. Despite periodic shakeouts in the "dot-com" industry, even widely differing estimates (Lindberg, 2002) suggest global e-commerce will remain an area of continuing growth through the foreseeable future.

Additionally, we note several reasons why agent technology offers particularly high potential to drive further e-commerce growth. First, as software implementations, agents process information very quickly; hence, they can search through and filter huge information spaces (e.g., e-catalogs, potential customers) much faster than people can. As business, customer, product and service information is increasingly stored online and made Web-accessible, the potential of intelligent agents in this respect will become increasingly pronounced. Second, once a basic agent design has been developed and implemented via software, the capability of one such agent can be replicated by cloning and adapting other agents to perform similar functions; hence, a massively parallel system of intelligent agents can be established quickly and efficiently by replicating agents. Even where the "intelligence" of a particular software agent remains limited (e.g., in human terms), launching a thousand such agents to tackle a search or problem-solving task in parallel can effect great economies in terms of time and other resources.

As an example in the business-to-business (B2B) e-commerce domain, agents for a supplier could perennially monitor sales forecasts of its primary customers and use the results from such monitoring to develop aggregate production schedules. Based on such schedules, another set of agents could in turn interact with lower-tier suppliers and order the necessary parts and supplies, all automatically, without human intervention. Gauging from prototype supply chain agent systems such as the Intelligent Mall (Nissen, 2001), this latter agent scenario is not too distant in terms of realization. Other examples can be envisioned as well—some more futuristic than others—but the applicability and potential of intelligent agents to enable, automate, and enhance e-commerce is profound.

Other e-commerce applications include automation (e.g., performing tasks such as bank transfers without human intervention), decision support (e.g., setting up product comparisons based on consumer preferences; automatic bidding on online auctions), disintermediation (e.g., using agents to replace market intermediaries such as real estate agents), re-intermediation (e.g., using agents to implement new intermediaries in markets such as online information brokers), and others.

Following this Introduction, the balance of the chapter is organized as follows. The next section briefly reviews intelligent agent technology from a technical perspective. E-commerce Agents for Knowledge- and Information-Intensive Processes focuses on the use of agent technology in e-commerce to manage knowledge- and information-intensive processes, and Agent-Based E-commerce Decision-Making discusses agents that can be used to make or aid both operational and strategic e-commerce decisions. In Agent-Based E-commerce System Development and Evaluation, we revisit system development and integration issues related to building effective e-commerce agents, and Roads Ahead concludes the chapter with a summary and look at roads ahead for agent applications in e- commerce.

INTELLIGENT AGENT TECHNOLOGY

The purpose of this section is not to provide a comprehensive survey of agent technology. Such surveys already exist in the agent literature (Jennings, Sycara, & Woodridge, 1998; Weiss, 2000). Rather, we intend to provide a brief overview of various technical aspects of agent technology that have particular relevance to e-commerce applications and e-commerce system development. Whenever appropriate, we suggest further readings that provide detailed in-depth technical discussions.

Intelligent agent technology is highly interdisciplinary and has benefited from a wide spectrum of academic disciplines, including but not limited to philosophy, logic, linguistics, ecology, economics, operations research, distributed systems, computer programming languages, software engineering, and computer networks (Weiss, 2000). However, the main throttle behind the recent rapid development of intelligent agent technology comes from ideas and innovative research originated by the artificial intelligence researchers (Russell & Norvig, 1995).

Here, we briefly summarize the main connections between intelligent agent technology and its related (supporting) disciplines by considering artificial intelligence (AI), emergent computation, distributed systems, economics, and game theory. AI provides the basic automated reasoning capabilities for an agent to be "intelligent." In particular, AI planning techniques, motivated by the needs to achieve intelligent goal-driven behavior through automated construction of an action sequence, are being heavily used in developing agents. In addition, AI equips agents with a logic-based representation framework to model the environment and behaviors of agents.

Recent work in emergent computation is interwoven with intelligent agent research. The basic idea behind emergent computation is that interactions of some simple behaviors in a localized context can lead to sophisticated system-wide behaviors and desirable outcomes. Some best-known examples of emergent computation are genetic algorithms, artificial life, and market-oriented programming (Wellman, 1995).

Regarding distributed systems, many issues occur when a system is composed of a distributed collection of entities and a centralized control mechanism is absent. Distributed systems research provides analytical tools and coordination protocols that facilitate the design and implementation of multi-agent systems.

Finally, a significant portion of economics and game theory studies noncooperative interactions between self-interested decision-making entities (Fudenberg & Tirole, 1991). Many agent-based systems, in particular multiagent systems that consist of a distributed collection of software agents, typically involve agents that represent independent parties that do not necessarily share a common goal. Consider, for instance in a supply chain setting, the buyer's agent and the seller's agent represent their own respective owners whose preferences are in direct conflict when negotiating prices. The models and market mechanisms (as distributed resource allocation mechanisms) developed by economists and game theorists can guide the design of agent-based systems (Wellman, 1995). In effect, the relationship between economics, game theory, and agent technology can be fairly complex and goes in both directions. For instance, intelligent agent technology is also being viewed as a major enabling technology that can reduce economic transaction costs and make various types of markets more efficient.

Because of the highly interdisciplinary nature of intelligent agent technology, it is not surprising to see much confusion concerning the agent-related terminology and many different views on what agent technology can offer. Next, we summarize some of the widely accepted views particularly relevant to e-commerce applications.

Agents as a System Analysis Tool

Agents can be used as a system analysis tool in the conceptual design phase of a software development project. They are particularly useful for applications that involve a distributed set of autonomous decision makers/execution units. In an agent-based system analysis approach, autonomous entities are modeled as agents. Interactions among these entities are modeled as interagent communications in the syntactical level, and as agent coordination protocols in the semantic and application level. Depending on the nature and complexity of the target application, the inner structure of an agent can be modeled recursively as another team of agents or an atomic decision-making unit or data source. Compared to traditional system analysis tools, this agent-based approach has many advantages such as providing a natural mapping of the distributed nature of data and control; providing a powerful abstraction and encapsulation mechanism to model complex and dynamic behavior; and facilitating modeling of scenarios that involve parties with conflicting goals.

Agents as a Programming Paradigm

Agents represent a natural evolution from object-oriented programming (OOP) as a programming paradigm (Shoham, 1993). Software engineering research has recognized that interaction among software modules is the most important aspect of complex software systems. Agents provide a richer, more independent software building block than OOP to achieve better data independence, control independence, interaction independence, behavior encapsulation, and software reuse. Agents can be particularly useful in developing interorganizational applications where decisions on various aspects of software development such as the computing platform and programming environment are made independently. Agents also operate in a robust manner in "open" computing environments, which are characterized by interaction between diverse computational artifacts (e.g., computer hardware, operating systems, agent designs) and dynamic agent participation. This highlights a particularly challenging aspect of an open environment, in that agents might join and leave some virtual environment (e.g., marketspace) or organization (e.g., supply chain federation) repeatedly and without notice.

Agents as a Distributed Decision-Making Paradigm

In many applications, decisions must be made in a distributed manner. For instance, in a supplier/buyer negotiation case, the selling price of the product under negotiation must be jointly decided by all parties involved. These parties are self-interested and have conflicting goals. In situations like this which involve strategic interactions, a distributed decision-making paradigm is a must, and agents provide a convenient modeling alternative that is flexible and extensible.

In another example of a more collaborative nature, an online retailer is making inventory decisions for its regional warehouses. These inventory decisions can be potentially made by a centralized decision-making mechanism or jointly by all regional warehouses. Although this type of decision-making does not involve self-interestedness, a distributed paradigm still offers many potential advantages over its centralized counterpart. For instance, a centralized approach needs access to centrally maintained data sources that consolidate data from all regional centers, whereas a distributed approach does not have this data requirement. In addition, from a pure computational standpoint, an agent-based, distributed decision-making model can solve satisfactorily (in a heuristic sense) some problems that are too large for centralized approaches (e.g., Liu & Sycara, 1997).

E-COMMERCE AGENTS FOR MANAGING KNOWLEDGE- AND INFORMATION-INTENSIVE PROCESSES

In this section, we discuss agents for information and process management, address key technical issues associated with such agents, and feature one real-world implementation of e-commerce agents developed specifically for managing knowledge- and information-intensive processes. Each of these three topics is discussed in turn.

E-commerce Agents for Information and Process Management

Despite inexpensive electronic access to information, effective use of the Internet by people and decision support systems has been hampered by some dominant characteristics of the Web. First, information available from the Web is typically unorganized, multimodal, and distributed on servers all over the world; that is, the right information can be difficult to find. Second, the number and variety of data sources and services are increasing dramatically every day, and the availability, type, and reliability of information services are constantly changing; that is, once found, accessing and retrieving information can be challenging. Third, the same piece of information can be accessible from a variety of different information sources, but with varying degrees of "freshness"; hence, understanding how much confidence to place in specific information content requires judgment. Thus, information can be quite difficult for a person or machine to collect, filter, evaluate, and use, so the critical problem of locating, accessing, filtering, and integrating information in support of e-commerce has become a very challenging task.

Alternatively, intelligent agent technology provides a novel and promising approach to address this e-commerce challenge. For instance, e-commerce agents can act on behalf of their human users in order to perform laborious information gathering tasks. Examples include locating and accessing information from a wide diversity of online information sources, resolving inconsistencies in the retrieved information, filtering out irrelevant or unwanted information, integrating information from heterogeneous information sources, and even adapting over time to their human users' information needs (Sycara & Zeng, 1996).

Consider a specific application—comparative shopping—to illustrate how agent technology is being applied to address this e-commerce challenge. Recent years have seen a blossom of shopping agents that facilitate consumer and organizational purchasing activities (e.g., mysimon.com, shopper.com, bizrate.com). Most of these agents are hosted by third-party e-commerce information intermediaries. Given one or several user-provided keywords, these systems search through an internal, dynamically maintained database for potential vendors. Information items such as real-time price quotes, vendor ratings, product reviews, and shipping costs are then displayed to the user. Such e-commerce agents are providing increasingly impressive services to potential buyers, because they make sophisticated use of many underlying information technologies.

For instance, information technology has developed considerably in the area of knowledge representation and domain ontologies; that is, formally or heuristically defined domain knowledge enables shopping agents' intelligent behavior (e.g., resolving synonyms, tolerating user-input errors, suggesting relevant products and search terms). Another instance pertains to information retrieval and digital library technologies; that is, Web-based information collection, storage, and search capabilities have advanced greatly. Further, technologies associated with natural language understanding and content parsing have recently come of age in terms of e-commerce agent applications, as some agents apply sophisticated language understanding techniques to parse vendors' Web pages directly and extract fresh information on the fly. Additionally, machine learning and personalization technologies now enable some shopping agents to learn user preferences and present personalized interfaces and information search experience. In addition, collaborative information retrieval and recommendation technologies enable several shopping agents and recommendation systems to leverage information gleaned from prior user sessions when performing new tasks.

Technical Issues

As with any software development, technical issues associated with agents for e-commerce abound. However, such issues are particularly demanding in terms of intelligent agent development. One reason for this technical difficulty is that the agents field is comparatively young with respect to other software areas (e.g., transaction processing systems, database applications, client/server architectures). However, another reason stems from the power of intelligent agents and their focus on knowledge. Two key technical issues must be addressed: (1) how to represent process knowledge via agents, and (2) how to develop capable agent applications for managing knowledge- and information-intensive processes.

Knowledge representation (KR) has long attracted the attention of AI researchers, and a wide variety of KR tools and techniques have been developed over the past three decades (e.g., rules, frames, scripts, semantic nets). One aspect of KR for agents that leads to difficulty stems from our discussion above, in that agent applications are generally composed of many individual agents that operate together in some networked, organized manner. Thus, the representation of knowledge via agents must be distributed.

One approach to this distributed KR problem is the use of agent-development tools. Although specific tools come and go, the use of tools in general has proven effective in addressing the distributed-KR problem. For instance, Nissen (2001) employs Grafcets to define the structure and behavior of intelligent agents. Grafcets are derived from work on Petri Nets and have been accepted as an international standard (IEC 848 and IEC 1131–3) for specification of programmable logic controllers (David, 1995). Grafcets are used to outline the key steps and transitions associated with process performance, along with internal rules and procedures, external events and alternative system states that affect reasoning, decisions, and behaviors represented for a process. This technique facilitates mapping between the knowledge and activities required for effective enterprise performance, at the process level, and the behaviors of an agent application, at the technology level. As a method supporting abstraction and successive refinement, it facilitates agent design by allowing the developer to concentrate on high-level process knowledge and activities before diving into details of objects, messages, and code.

Nissen (2001) approaches the technical issue of agent development by using a research application called ADE (Nissen, 2000). ADE is a layered application that runs on top of G2, an environment for developing real-time intelligent systems (http://www.gensym.com). It provides integration between the activities and required knowledge captured from an enterprise, at the process level, and the technology-level transitions and steps that define agent behaviors and communications. These latter agent behaviors and communications are in turn implemented through objects, methods, messages, and rules; that is, below the agent level of abstraction, familiar object-oriented analysis, design and programming approaches and techniques apply. ADE provides its own environment for simulation and execution of agents, and it contains a translation mechanism for implementing agents in Java.

A number of other agent-development tools are also available, but as discussed in greater detail in the section Agent-Based E- commerce System Development and Evaluation, the relative value of agent-specific tools appears to be diminishing. Regardless of the specific tool (e.g., agent-specific, general) used, however, perhaps the greatest technical challenge associated with agent development is anticipating the emergent behavior of many agents operating simultaneously. Because of the properties from above generally ascribed to agents (e.g., autonomy, persistence), each individual agent is often developed to pursue its own goals (e.g., those specified by the agent's user/principal), and the aggregate of such goal-oriented behavior by many agents can be very difficult to anticipate during the agent-design stage of development.

For instance, in the Intelligent Mall discussed in the next section, agents for the same enterprise (e.g., different procurement agents of the same company) can find themselves competing with one another to purchase high-priority parts or supplies from a particular vendor, which can have an adverse impact of driving up prices. We label this behavior as "emergent," because it is not specifically designed into the agents; rather, it simply emerges through the interaction of networked agents working toward individual goals. Alternatively, if this emergent behavior can be anticipated (e.g., through networked-agent simulation), then more appropriate behaviors—such as agents combining their orders to negotiate price discounts—can be defined through Grafcets or whatever agent- development approach is being employed.

Feature: Real-World Agent Implementation

A number of different agent systems for managing knowledge- and information-intensive processes have been developed and implemented in the modern enterprise. For instance, Nissen (2000) developed an agent system to aid the design of business processes in a reengineering context. This process-design agent was implemented and then tested through laboratory experimentation, in which its performance surpassed that of people in terms of process-design efficacy and efficiency. As another instance, the Intelligent Mall (Nissen, 2001) was developed to automate and support the procurement and order fulfillment processes of the supply chain, and this agent system was later adapted to match people with jobs in an e-employment market. Further, the ADEPT system (Jennings, Norman, & Faratin, 1998) makes a good case for an agent-based approach in this domain, showing how agent technology can improve efficiency by ensuring that business activities are better scheduled, executed, monitored, and coordinated. Here, we briefly feature the Intelligent Mall, characterizing its role and operation in the context of knowledge-work required for performing supply chain processes. As an operating e-commerce application, its discussion provides a concrete exemplar of current agent technology applied to this area.

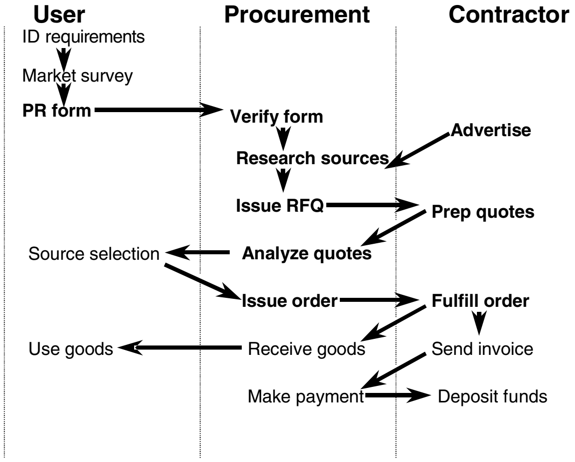

Figure 1: Integrated supply chain process.

The Intelligent Mall was developed to automate and support two complementary processes of the enterprise supply chain: procurement and order fulfillment. Specifically, the enterprise procurement process pertains to work done by the supply department at a medium-size government facility in the United States. The commercial order fulfillment process pertains to work done by a leading-edge U.S. technology development company.

To help understand the Mall application, the associated supply chain process activities and flow are presented in Figure 1. Note that this process involves three participants: the user, a procurement organization, and a vendor/contractor. This represents a representative link of the supply chain, as the same kinds of structures, relationships, and process flows exist between the vendor/contractor and its lower tier suppliers, between the latter's still-lower tier suppliers, and so forth to the end of the chain. Of the major process activities diagrammed in the figure, 16 activities (e.g., advertise items for sale, request vendor quotations, analyze quotes, pay for items) are automated through a small federation of agents that cooperate in a virtual mall environment.

In this environment, sellers establish agents to advertise and sell products, and buyers establish agents to search for and purchase products. Once the agents—both seller and buyer—have been launched, they operate autonomously and persistently until they either accomplish their goals (e.g., purchasing a specific item) or are halted by their users/principals (e.g., when an item is no longer offered for sale).

A screenshot of the Intelligent Mall interface is presented in Figure 2. This figure shows a number of animated agents for visualization as they perform procurement and order fulfillment process activities. For instance, the animated agents labeled "shopper" represent buyers in this virtual mall environment and seek out purchase items specified by their users/principals. Likewise, the animated agents labeled "shop" represent sellers and offer items for sale in the Mall. In terms of behavior, shop agents

advertise items for sale (see example in upper right corner of the figure) that the Mall makes available through electronic Yellow Pages (i.e., what is for sale; see example on left side of the figure) and White Pages (i.e., what customers and vendors are participating in the Mall). Shopper agents take their lists of items to purchase (i.e., "shopping lists"; see example in lower right corner of the figure) and send messages requesting price quotations from all shop agents that offer such items for sale. When quotation requests are received, shop agents respond with individualized messages back to each shopper agent indicating the price (and any other pertinent terms) of each item. Each shopper agent then analyzes all quotations received from shops and selects the best buy (e.g., based on lowest price). Shopper and shop agents then pass several successive messages (e.g., with payment information, a purchase receipt) to one another to complete the purchase transaction.

Each shopping agent is capable of interacting with many different shop agents, and each shop agent can interact with many different shopper agents. Additionally, all shop and shopping agents behave autonomously and independently, and processes that require several hours—or even days and sometimes weeks—to perform through people in the enterprise can often be completed in a minute or less. Further, the Intelligent Mall environment is truly virtual, so the physical locations of various shops and shoppers are irrelevant; only a computer and Internet connection are required to launch agents that participate in the Mall.

The architecture of this agent federation is flat and distributed. It is flat in that all agents and hosts operate at the same, nonhierarchical level in the federation and on a network. It is distributed in that diverse agents in a federation can operate, communicate, collaborate, and move across various host machines and locations. Agents communicate and collaborate through messages in a peer-to-peer manner, but some communication support and like services (e.g., agent registry, Yellow Pages, message forwarding) are provided by a specialized class of agents across distributed hosts. These specialized agents help balance the low overhead achievable through a flat architecture with the need for organization and structure among agents as a distributed application scales to a large enterprise federation.

AGENT-BASED E-COMMERCE DECISION MAKING

At the present time, the use of agent technology in the realm of information and knowledge management dominates agent application in e-commerce. We believe, however, that the next wave of innovation will rely heavily on using software agents in making and executing e-commerce decisions in an automated or semi-automated (e.g., in the decision-aiding context) manner. Agent-based e-commerce decision making and automated execution can lead to significant improvement in decision quality and reduction in commerce transaction costs. This argument is essentially in line with the vision behind the Semantic Web, XML, and more recently Web services: the Web should be not only a medium through which human users can obtain and publish information but also a distributed, scalable, interoperable platform for software programs to exchange information and leverage each other's capabilities.

Many types of decisions need to be made in e-commerce practices. We use a simple criterion to divide them into two groups: operational and strategic decisions. By operational decisions, we mean the set of intraorganizational decisions that in principle can be made by a single decision-making entity. Examples of this type of decisions are coordinating an internal fleet of delivery trucks, deciding whether an order request made online should be accepted, and making a production schedule for a floor shop. By strategic decisions, we mean the decisions that cannot be made without explicit involvement from other self-interested parties. Obvious examples of decisions of the strategic nature include online auctions and negotiations where binding economic deals are made jointly by several active parties, each of which may have conflicting interests.

Agent-Based Operational Decision Making

Enterprise operational decisions are currently made largely in a centralized manner. Mathematical models and decision-making frameworks proposed in operations management, industrial engineering, and management information systems serve as the theoretical foundation for this type of centralized operational decision making. Existing enterprise-computing platforms such as ERP systems provide the corresponding IT infrastructure and execution environment.

Many facets of today's enterprise management in the e-commerce context, however, pose significant challenges to this centralized approach and promote a distributed framework to which agent technology contributes as both a system analysis and implementation methodology, as well as an effective computational paradigm. For instance, the modern enterprise comprises a network of distributed decision entities, both manual and automated. These entities usually have their own unique information channels, perspectives, and incentive structures. Furthermore, the supply chains and trading partnerships consist of many loosely connected companies and consumers with completely different objectives and constraints. In this case, it is unlikely that one can impose some common decision structures as necessary in a centralized data management and decision-making approach.

As another instance, it has been a clear trend in many industries that enterprises or production units focus on their respective core competencies (Kalakota & Robinson, 1999). They are agile organizations that may dynamically team up to form virtual enterprises to deliver value. In this type of setting, centralized mechanisms fail to capitalize on agility, flexibility, and quick response provided by this type of organization. Dynamic teaming and efficient coordination are also difficult to come forth in centralized frameworks.

From the viewpoint of implementing enterprise decision support systems, high modularity, incremental system development, and evolutionary deployment are usually preferred. Given the open nature of the environment, it is important for a system to expand and grow in various dimensions. These extensibility issues are difficult to resolve in traditional frameworks.

Further, the size of the decision problems that an enterprise system must face increases dramatically given the new development on the e-commerce front and growing interdependencies among supply chain partners. Scalability issues regarding the problem size are a major stumbling block for centralized systems based on traditional optimization formulation and computation.

Moreover, quick responsiveness is viewed as one of the key success factors for an enterprise due to the high degree of uncertainty and rapid advances of technology. It is difficult to develop a monolithic and responsive system given the size and the complexity of the problems and decision scenarios that a total enterprise system is designed to deal with.

An agent-based, distributed approach offers many advantages that alleviate the problems already mentioned. Each agent corresponds to a real entity, such as a decision-making unit, an activity, a resource, and so forth. This provides closer management of an entity in its situated environment and therefore facilitates potential real-time responsiveness. Each agent can make decisions based on its own strategies and its local situation. This provides modularity for constructing the system. As well, such an agent-based model provides the ability to decompose the system into appropriate levels of granularity, to disentangle the problem interdependencies, and to analyze how they interact with each other at each of these levels.

From a computational standpoint, an agent-based approach promotes the idea of "emergent" computation. Instead of attacking a problem directly in its entirety from first principles, an agent-based approach first uses an appropriate decomposition scheme that divides various aspects of the original problem into relatively independent components. This scheme uses different criteria (e.g., decision variables, constraints, resources, data access, control structure) to decompose the problem depending on its nature and characteristics. Each component is then assigned certain designed behaviors. The problem solving is in turn accomplished through iterated, structured interactions of these components according to the selected agent coordination protocols (Weiss, 2000). Effectiveness of agent-based decision making is largely decided by the appropriateness of problem decomposition and agent interaction design.

Significant progress has been made in the development of agent-based decision making for enterprise and e-commerce applications. Examples include distributed agent-based production scheduling and constraint satisfaction (Liu & Sycara, 1997), and agent-based supply chain management (Swaminathan, Smith, & Sadeh, 1998; Zeng & Sycara, 1999).

Agent-Based Strategic Decision Making

Agent-based systems that aim to facilitate practical strategic decision making are starting to emerge. Well-known examples include systems that provide strategic decision support in international trade negotiation, labor negotiation, and bargaining (Jennings, Sycara, & Wooldridge, 1998). Most of these current systems are programmed with rules-of-thumb distilled from intuition about good behavioral practice in human strategic interactions.

Positive conclusions regarding effectiveness of these systems have been reported in the literature. Nevertheless, almost all these evaluative studies were conducted via computer simulation with limited, rigid problem scenarios. Significant research efforts are called for to address issues relating to how to prevent one's agents from being badly exploited by aggressive new agents that have been programmed to take advantage of their weaknesses (Binmore & Vulkan, 1999). Another interesting and important research challenge in this area is to explore the dynamics of human/agent and agent/agent interactions.

In this section, we first briefly discuss the theoretical foundation for making e-commerce strategic decisions. We then summarize three common types of e-commerce strategic decision-making agents offering varying degrees of decision-making sophistication, modeling, and computational capabilities. We conclude this section by presenting several emerging research topics closely related to the development of these e-commerce agents. These topics are been actively pursued by researchers.

It is not surprising that the academic discipline most relevant to the study of e-commerce strategic decision-making is economics, and more particularly, microeconomics, a branch of economics focusing on the interaction of individual economic entities such as consumers and firms through well-defined market mechanisms. Although consumers and firms' commercial behaviors in the e-commerce realm may be significantly different from those in traditional, nonelectronic settings, underlying market mechanisms (i.e., the communication and transaction protocols governing selling and buying activities) remain largely the same in both electronic and nonelectronic settings. In addition, there are no fundamental changes in the end goals of market participants' involvement (e.g., profit and utility maximization). Thus, the basic analytical framework developed in microeconomics is still largely applicable to e-commerce. This framework includes expected utility theory, risk preferences, mechanism design, Nash equilibrium and its refinements, and their applications in various types of markets including auctions among others (Fudenberg & Tirole, 1991; Pratt, 1964). We caution the reader, however, that although we argue that microeconomics provides an underlying modeling framework and a wide choice of relevant models, we are not stating that e-commerce strategic decision-making is a solved problem. On the contrary, it poses many new challenging problems of practical significance to a number of related fields including economics, and in recent years has motivated fruitful collaboration and synergetic research efforts among economists, artificial intelligence researchers, and applied mathematicians, some of which are discussed at the end of this section.

We choose auction theory to illustrate the applicability of microeconomics theory to e-commerce strategic decision making. This choice is made because not only auction theory is a leading, mature field of microeconomics but also online auction is currently the most important form of market mechanism used in e-commerce. For instance, most of online auctions are the ascending price, real-time action, called English auction, in which the bidder with the last highest bid buys the auctioned item at a price equal to his or her bid. Auction theory has a lot to say about how bidders should (or are predicted to) behave in various auction types including the English auction and what the expected seller payoff should be (McAfee & McMillan, 1987). A prevalent solution concept is the Bayesian-Nash equilibrium in which each bidder adopts a bid function that is the best strategic reply to the bid functions adopted by rival bidders. Following such a strategy, a bidder will bid "straightforwardly" in any English auction selling a single item: This bidder will outbid any standing bid that another bidder holds by the smallest allowable bid increment so long as the new bid does not exceed his or her valuation of the item for sale (also called reservation price). In effect, this strategy is a dominant strategy in the sense that it does not depend on how other bidders behave or the bidder's risk preferences. In other common types of auctions such as first-price sealed-bid auctions (every bidder submits his or her bid in a sealed envelop, and the highest bidder wins and pays the highest bid) and Dutch auctions (the auctioneer announces descending prices, and the first bidder buys the auctioned item at a price equal to the accepted price), which are being practiced mostly through traditional means rather than through an electronic marketplace, figuring out the optimal bidding function can be significantly harder. This is because in these auctions, optimal bidding hinges on information regarding other players, typically in the form of probabilistic distributions of their valuations as well as the bidder's risk preferences. However, in principle, the defining mathematical properties of optimal bidding are known and sometimes closed-form solutions can be derived under certain restrictive assumptions regarding value distributions and risk preferences. The reader is encouraged to read (McAfee & McMillan, 1987) for an excellent introduction to basic auction theory that can serve as a foundation for analyzing and designing online market mechanisms.

Agent technology can be applied to facilitate strategic decision making on online markets in several ways. From an implementation standpoint, agents can be used to automatically collect information necessary to make informed decisions (e.g., comparative shopping agents as discussed under E-commerce Agents for Knowledge- and Information-Intensive Processes and auction information and consolidation agents such as http://www.auctiontamer.com). From a computational perspective, agents can be used to "crunch" the numbers as significant computational support is needed to solve for some of the auction-theoretic (and in general game-theoretic) solution concepts relevant to e-commerce. From the point of view of transaction, agents can also be a major technology enabler in automating many aspects of e-commerce transactions, freeing people's time and reducing related information and cognitive overload. Last but not least, from an evaluation standpoint, agents can be used as part of the simulation and experimental framework to evaluate at both individual and overall societal levels the effectiveness and efficiency of the bidding strategies under study.

We now discuss three common types of e-commerce strategic decision-making agents:

1. *Simple execution agents*. This type of agent does not have an explicit model of the underlying strategic

decision task. Nor does it provide active decision support. The sole functionality of a simple execution agent is to automatically execute its human user's trading strategies, which are fully specified by the user at the beginning of trading through a limited number of parameters. Popular proxy bidding agents (e.g., the eBay proxy bidder) that function on online markets operated under English auctions fall into this category. These agents are initialized with their user's reservation price. Then without user intervention, they will monitor the progression of an auction and place a bid when the current highest bid is below the prespecified reservation price and is held by another agent. For other types of online markets, such as bargaining, some simple analogous strategy exists where a proxy negotiation agent submits its price proposals based upon a simple function specified by the user at the outset of the negotiating process (e.g., Kasbah; see Chavez & Maes, 1996).

2. *Behavioral agents.* This type of agent possesses explicit knowledge of the e-commerce trading institutions and provides active decision support. Computational models of auctions and negotiations from the economics and AI literature (e.g., the auction-theoretic ones already mentioned) serve as the basis for constructing such agents. To be computationally feasible, these models typically ignore certain aspects of strategic interaction. Examples of the models that have been utilized to develop behavioral agents are optimization-based strategies for competitive bidding that assume known distributions of values and the number of bidders (McAfee & McMillan, 1987), AI logic and rule-based negotiation strategies (Kraus, Sycara, & Evanchik, 1998), automata play, and adaptive auction and bargaining strategies using machine learning techniques (Wellman & Hu, 1998).
3. *Agents with human-like properties.* All the decision-making models already mentioned assume that the sole purpose of the agent is to maximize its user's utility or profit. In commercial and other social activities conducted through either traditional or online channels, however, rich patterns of interaction among participants cannot be fully captured by this utility-maximizing, self- regarding assumption. This prompts recent studies aimed at modeling other regarded properties and developing agents with such human-like properties. For instance, theoretical models proposed by Cox and Deck (2001) readily serve as the foundation for programming the behaviors of agents that demonstrate properties such as seeking fairness and being cooperative. Recent work has also started to equip such agents with human-like appearance and communication capabilities such as natural language input/output and facial expressions.

We conclude this section by pointing the reader to two ongoing lines of research driving the current development of strategic decision-making agents for online markets.

Purchasing bundles of goods is much more common than purchasing one unit of a single item in real-world applications, especially in industrial procurement. Different mechanisms have been proposed and studied in the literature. For instance, there has been a substantial interest in a particular class of auctions called combinatorial auctions that allow the bidders to submit bids for a bundle of goods as opposed to single items. Selecting a winning bid from these bundle offers turns out to be nontrivial. Significant effort from researchers in a number of related fields including economics, operations research, and multiagent systems has been invested to study combinatorial auctions in recent years (Sandholm, 2002). Another mechanism called the simultaneous ascending auction has also been proposed to deal with bundle purchases and shown to have a number of desirable properties (Milgrom, 2000). In effect, the simultaneous ascending auction was successfully applied to sell licenses to user bands of radio spectrum in the United States.

The third approach is a "meta-auction" based on a collection of simultaneous single-item auctions. In this approach, each auction is conducted according to its own rules and run independently from one another. Bidders who may need to purchase a bundle are responsible for coordinating their own bidding activities across these independent markets to achieve the best overall profit. Since there is no theory prescribing bidding strategies in this heterogeneous market environment, heuristic or expert system-based approaches are being actively developed. These approaches are agent-based e-commerce strategic decision-making systems in the strong sense. One significant issue with developing such agents is evaluation: How would different strategies fare against each other in this meta-auction context? In response to this evaluation issue, the multiagent systems research community has been organizing an annual tournament called "Trading Agent Competition." In this tournament, agents, designed and implemented by different research teams using a common programming interface, function like a human travel agent and attempt to purchase travel packages that include airline tickets, hotels, and entertainment (baseball, ballet) tickets, sold through independent auction markets. These agents are matched against each other in the profits they are making by finding the right packages for a given set of customers with specific (randomly generated) travel needs (Greenwald & Stone, 2001).

Another important research direction concerns the multidimensional aspect of the goods or services being auctioned or sold through other markets. By multidimensional, we refer to product characteristics besides price, such as delivery method and quality among others. It has been shown that multidimensional auctions, among other multidimensional markets, are hard to design in principle. Computing bidding strategies for such markets is also particularly hard, making an agent-based approach a viable modeling, computational, and implementional alternative (Zheng, 2000).

AGENT-BASED E-COMMERCE SYSTEM DEVELOPMENT AND EVALUATION

In this section, we discuss system architecture and development issues and evaluation of agent-based e-commerce systems.

System Architecture and Development Issues

In the early years of agent technology, software development tools and communication protocols specifically designed for agents received a lot of attention. For instance, KQML, which was developed prior to the Web protocols, coupled with KIF, had been accepted as one of the de facto agent communication languages. Integrated agent development environments had also attracted considerable attention from both the research community and industry.

In recent years, however, the use of agent-specific development tools and protocols has been waning. Alternatively, generic software development environments, especially those that have been motivated for Web-based applications, are being increasingly used to develop agent-based systems. We suspect the following reasons contribute to this interesting phenomenon.

First, due to lack of industry support, none of the agent-specific tools and protocols has become sufficiently stable and feature-rich to be adopted widely. Second, more and more applications are starting to adopt some aspects of agent-based computing ideas, although they remain far from being full-fledged intelligent agents. Using an environment motivated for the development of sophisticated agents is an overkill and can cause serious system maintenance and integration problems. Third, because of the significant academic and commercial interest in distributed Web-based computing, mainstream programming environments are now equipped with sophisticated support for knowledge representation and manipulation (such as XML), messaging, mobility and basic distributed coordination mechanisms (such as JavaSpace and Web services). Fourth and last, as agent ideas are being applied in highly specialized decision making, it is unlikely that any programming environment will provide readily reusable software modules. We envision that this trend of relying on generic programming platforms and toolsets will continue, and the role of agents as a system design methodology and a distributed decision-making framework will increasingly dominate the role of agents as an implementation environment.

Evaluation of Agent-Based E-commerce Systems

Existing research on agent-based e-commerce systems remains largely in the technological realm. Evaluation of such systems is also confined to a large extent in the algorithmic and technical contexts. For instance, in the Trading Agent Competition discussed previously, performance and efficiency of trading agents employing different meta-auction algorithms are evaluated through a simulation-based tournament.

As these systems are maturing and being accepted increasingly in practice, issues beyond technology development such as adoption and evaluation are also becoming more pressing and warrant significant research efforts. In this section, we emphasize evaluation of agent-based e-commerce systems in light of human–agent interactions as opposed to agent–agent interactions, which have been extensively discussed in the multiagent systems literature (Weiss, 2000). We also ignore a large body of literature studying human bidding behavior in both laboratory environments and real-world online markets, since software agents do not play a pivotal role there.

Studies on the evaluation of comparative shopping system designs based on research methodologies ranging from marketing, consumer behavior, human—computer interaction, and industrial psychology are starting to emerge. Also, the literature on general technology adoption has significant relevance to such evaluative studies, not limited to comparative shopping. Historically, experimental economics has focused almost exclusively on human decision making. Smith (1982) explains the theory underlying the method of experimental economics and how microeconomics can be an experimental science. In the laboratory, the experimenter controls the environment (e.g., the costs to a seller and the values for a buyer). The experimenter also controls the institutions or the rules by which the human agents can take actions and send messages in the marketplace. Controlling these two components of the microeconomic system, we then observe the behavior of the human agents. By holding the environment constant in the laboratory but altering the institution, behavior may change such that the resulting market outcomes are markedly different.

One overlooked characteristic in agent-based e-commerce is the human-agent interaction and the mixing of human play with agent play. Direct human behavior may change in a nontrivial way if mixed with human-to-agent play on the same side or other side of the market (i.e., buyer or seller). Zeng, Sheng, and Wilson (2000) followed an experimental economics-based research methodology to evaluate agents for Web-enabled auctions. In their pilot study, they focused on proxy bidding agents, used by many auction sites such as eBay. Using these proxy agents, bidders specify the maximum bidding amount, which is kept private. The proxy agents then automatically bid as the auction proceeds, bidding only enough to outbid other bidders. Although these bidding agents sound very straightforward, the interactions between agents and their human users are intriguing.

To explore the behavior of markets with a proxy-bidding agent, Zeng et al. recruited 20 University of Arizona undergraduates to participate in a one-hour experiment using Java applet auction software that they developed. As is standard in laboratory auction experiments, the subjects were informed that if they purchased a unit for less than their value, they would earn the difference as profit, which would be converted into cash. One bidder in each market was first instructed to submit a single proxy-bidding agent to the market. Once submitted, the remaining three bidders were free to bid in real time for the next two minutes. The theoretical prediction is that the highest value bidder will win the auction, paying a price equal to the second highest value. In their experiments, however, they observed that the presence of a proxy bidder consistently leads to prices on average less than the second highest value. One possible explanation is that the presence of the proxy-bidding agent changes the nature of the auction (e.g., from an English auction into a last second first price auction). The implication of this behavior is that the auctions can be inefficient when a simple automatic execution mechanism is introduced. Although preliminary, this study argues strongly that deploying agent technology in e-commerce settings does not necessarily lead to more efficient and effective outcomes. Similar experiments have been conducted at the IBM T. J. Watson Research Center for other types of auctions more commonly seen in stock exchanges. In summary, agent behavior could inadvertently change the nature of the market mechanism and thus result in unexpected inefficiency. Careful examination, possibly through controlled experiments, is called for before the deployment of any agent-based e-commerce systems.

ROADS AHEAD

This chapter discusses the application of agent technology in e-commerce applications. We argue that agent technology has great potential in guiding e-commerce systems analysis, design, and implementation. We focus on specific applications of agent technology in two major types of e-commerce tasks: managing knowledge- and information-intensive processes, and operational and strategic decision making. Interested readers are encouraged to browse a comprehensive agent technology portal at http://agents.umbc.edu for a wide array of ongoing agent research projects and industrial applications including e-commerce.

Agent-based e-commerce systems are still in their early stage of development. Significant technological advances need to be made to make agent-based e-commerce a reality. In the area of managing knowledge- and information-intensive processes, knowledge representation challenges related to building complex product and service catalogues and resolving vocabulary ambiguities need to be addressed. Challenges also exist in the area of user interest solicitation and system personalization. In the area of decision making, issues such as supporting scalable, real-time operational decision making and providing computational support for strategic decision making (e.g., for coordinating bidding activities across markets as discussed under Agent-Based E-commerce Decision Making) call for new breakthroughs.

Agent-based e-commerce systems do not exist in isolation. Challenging system integration issues need to be addressed in interoperating agent-based and non-agent-based (such as transactional) parts of the system. Other significant technological challenges include, but are not limited to, how to architect and implement agent-based systems in a wireless and mobile-commerce setting; how to make the system scalable and robust in an open environment; how to address security and authentification issues (e.g., a shopping agent may possess all kinds of sensitive information including credit card numbers); and how to resolve the real-time issues (e.g., an auction site needs to decide how and when to end an auction in face of network delays). Nontechnological issues such as legal implications (e.g., when automated execution systems make deals on behalf of their organizational users), adoption, and possible organizational changes also warrant significant new research efforts. These are exciting times in terms of intelligent agents for e-commerce.

GLOSSARY

Agent-oriented programming A special case of object-oriented programming where computer programs are written as a collection of interacting agents, which in turn are programmed directly using generic constructs such as belief, desire, and intention.

Auction A market institution with an explicit set of rules governing selling and buying activities including the determination of trading prices, given the bids from buyers and/or sellers.

Combinatorial auction An auction that sells many assets or goods simultaneously by allowing buyers to bid for asset or good bundles.

Distributed artificial intelligence A subfield of artificial intelligence studying intelligent agents and multiagent systems.

Electronic commerce The application of information and communications technologies to facilitate all or some aspects of commerce-related activities, including but not limited to online marketing and trading, products and services delivered through electronic means, and business transaction automation.

Electronic marketplace A technology-enabled virtual market through which sellers and buyers share information, trade, and conduct other business transactions. Internet and other communications technologies such as wireless technology are the main driving forces behind the development of the electronic marketplace. Examples include online auction sites.

Emergent computation A distributed computing paradigm where solutions to the problem under study emerge as a side effect of multiple autonomous computational entities interacting with one another following certain social norms.

Experimental economics A branch of economics studying the principles of using experimental methods (including both laboratory and field experiments) in economics and testing the validity of underlying economic theories. A significant portion of experimental economics focuses on the study of different forms of market mechanisms including auctions.

Intelligent agent A computational entity that is capable of autonomous actions, manifests nontrivial behavior, is self-aware, and can improve its performance through experience.

Knowledge representation The art and science of making knowledge explicit and amenable to automated inference through computational models.

Multiagent system A distributed computational system consisting of multiple autonomous agents that operate asynchronously, interact with one another through well-defined protocols, and may represent conflicting interests.

Process management The activities associated with planning, organizing, and monitoring systems of recurring processes composed of a set of interdependent tasks in the enterprise.

Proxy bidding A simple automated bidding service available from many online auction sites. After receiving a user-specified maximum willingness to pay, the proxy bidding system monitors the ongoing auction session and automatically increases bids (if needed) till the maximum willingness to pay is reached.

Supply chain management Coordinating enterprise activities concerning order generation, order taking, order fulfillment, procurement, and distribution of products, services, and information, across organizational boundaries.

Interactive Multimedia on the Web

Borko Furht, *Florida Atlantic University*
Oge Marques, *Florida Atlantic University*

INTRODUCTION

Personal computing, multimedia, and computer networks have experienced a tremendous boom during the past decade. From expensive, stand-alone MPC-1-compatible PCs that landed in the marketplace in the early 1990s to the popularization of the Internet, particularly the World Wide Web, the production, archiving, and distribution of multimedia has evolved from a few, technologically limited devices to a plethora of hardware and software available for these tasks. It is now possible to develop higher quality multimedia content, in less time, and distribute it to a much wider audience (using the Web as opposed to CD-ROMs) than anyone could have imagined a decade ago.

The Internet has become ubiquitous and is quickly extending its arms to the wireless arena. The hunger for multimedia-rich content over the Web has fostered developments in many fields, from the technological infrastructure necessary to carry multimedia data, to the tools used to create, manage, and distribute multimedia content. Interactivity is the key concept in many such applications, such as games, maps, and distance learning applications.

In the first part of the chapter, we define the concepts of multimedia and interactivity, particularly on a Web-based context, and present a summary of the network technologies that enable transmission of interactive multimedia information over the Web. In the next section, we show the process and related languages and tools for creating interactive multimedia Web pages. Finally, we present an overview of current interactive multimedia applications and services.

WHAT EXACTLY IS INTERACTIVE MULTIMEDIA?

We start by conceptually defining "multimedia" and "interactivity" in the context of Web-based applications. The term multimedia has been frequently used to mean the combining of text, graphics, images, sounds, and video on one page or presentation. According to this definition, most of the pages currently available on the Web are inherently multimedia. For the discussion that follows, it is important to know the following. (a) Multimedia content that combines only text, images, and animations (for which there is a built-in HTML support) is different from applications that use video clips, animations, and sounds (for which third-party products—usually available as browser plug-ins—are required). A multimedia-rich HTML page consisting exclusively of text, JPEG images, and animated GIFs would belong to the first category, whereas a page that loads a Macromedia Flash movie would belong to the second group. (b) Multimedia information that is delivered without user interaction is different from multimedia contents that change dynamically in response to the user's inputs. The streaming of a prerecorded video clip would be classified under the first group, whereas the constant updating of a screen in a multiplayer Web game would qualify as an example of the second case.

MULTIMEDIA NETWORK TECHNOLOGIES

There are five main types of communication network technologies used to carry multimedia traffic (Halsall, 2001): telephone networks, data networks (including the Internet), broadcast television networks, integrated services digital networks (ISDN), and broadband multiservice networks, such as B-ISDN. In this chapter, we focus mostly on the Internet. Besides enabling a number of interpersonal communication tools, such as e-mail, the Internet also hosts a large number of interactive multimedia applications stored in Web servers.

Characteristics of Multimedia Traffic

Interactive multimedia may be real-time or non-real-time information. Real-time, or *continuous,* information is transferred from source to destination as it is generated and is played out at the destination as it is received. This mode of operation is commonly known as *streaming*. Audio and video streaming over the Web have become very popular over the past few years. Examples include radio and TV broadcasting over the Web. In non-real-time, or block-mode, media, the information is generated and stored in a way that is not time sensitive and is downloaded by request by interested users.

Multimedia traffic can be classified into two main types: *constant bit rate* (CBR) and *variable bit rate* (VBR). Audio streams, for example, are typically generated at a constant rate, determined by the sampling frequency and number of bits per sample used to convert the audio information into digital format. Video streams, on the other hand, exhibit VBR, even though the frames that make up a video program are generated and displayed at a constant rate. This is due—among other things—to the fact that most video compression algorithms use differential techniques that employ fewer bits on frames that resemble previous frames.

The transfer of multimedia information streams between any source and destination of can occur in a number of different ways.

Simplex: Information flows in one direction only.

Half-duplex: Information flows alternately in both directions.

Full-duplex: Information flows in both directions simultaneously.

Unicast: Information flows from the source to a single destination.

Multicast: Information flows from the source to multiple destinations, comprising a subset of the nodes connected to the network.

Broadcast: Information flows from the source to all destinations connected to the network.

In the case of half- or full-duplex communications, the flow of information can be *symmetric,* where each party sends a comparable amount of information to the other, or *asymmetric,* where the flow of information is much higher in one direction than in the other.

The Internet uses packet-switching techniques to transfer information between two end computers using intermediate nodes—routers—along the way. This mode of operation is also sometimes referred to as *store-and-forward,* indicating that there is a built-in delay in the process that occurs every time a packet arrives at a router and waits for the router's decision (upon looking at its routing tables) as to where the packet must be forwarded next. The sum of the store-and-forward delays in each router contributes to the overall end-to-end delay between source and destination. The average of this delay is known as *mean packet transfer delay* and the variance is usually known as *delay variation* or *jitter*. The inevitability of these delays is one of the technical challenges behind enabling interactive multimedia applications on the Web.

Besides the delay limitations, the Internet has another characteristic that makes for less-than-ideal conditions for carrying multimedia traffic: It offers a best-effort service to its end users, which means that the TCP/IP-based transfer of packets is subject to errors (damaged packets, lost packets, timeouts, etc.), and the typical way to handle such errors is to discard packets and (optionally) request/wait for retransmission. Because much of multimedia traffic may be sensitive, retransmissions are usually not desired, because they add up to traffic inside the network and also because by the time the retransmitted packet arrives, it is no longer needed. A common way of handling with lost/retransmitted packets while providing the user with the illusion of continuous flow of information is the use of buffers at the receiving side.

Designers of networked multimedia applications usually specify the minimum network requirements that must be met to enable the application to work. These requirements are collectively known as network *Quality of Service* (*QoS*) parameters. Examples of QoS parameters are maximum packet size, average bit rate, average packet error rate (PER), mean packet transfer delay, worst-case jitter, and transmission delay. In addition to the network QoS parameters, the application itself has QoS parameters associated with it, such as the required bit rate or mean packet transfer rate, the maximum start-up delay, the maximum end-to-end delay, the maximum jitter, and the maximum round-trip delay. To simplify the process of determining whether a network meets the QoS requirements of a particular application, several *service classes* have been defined, each of which contains a specific set of QoS parameters. A network may support two or more service classes, in which case different classes are usually assigned different priorities.

Standards for Multimedia Communications

Multimedia information is typically transmitted in compressed form over the Web. Many standards have recently been developed for image, audio, and video compression and transmission. The most important standards are as follows.

MPEG-1: The first widely deployed standard proposed by the Motion Pictures Expert Group (MPEG). It aims at audiovisual encoding at a bit rate of 1.5 Mbps, which allows for VHS-like video with stereo audio to be encoded and which is stored in a CD-ROM. The best-known contribution of the MPEG-1 standard is its layer III audio compression, popularly known as MP3, which caused an entire revolution in the music industry.

MPEG-2: Enables the transmission of audio and video over broadband networks. It aims at encoding digital TV (and HDTV) signals and has been widely used in the consumer electronics field, from delivery of TV programming via personal satellite (dish) systems, to DVDs, to personal digital video recorders such as TiVo.

MPEG-4: Follows an object-based representation approach to audiovisual scenes, where each scene is composed of objects, both natural and synthetic. MPEG-4-based systems are not yet fully deployed at a consumer level at the time of this writing. It is expected, though, that the object-based nature of the standard will significantly enhance interactive multimedia applications.

MPEG-7: Standard that describes multimedia content, enabling users to search, browse, and retrieve multimedia

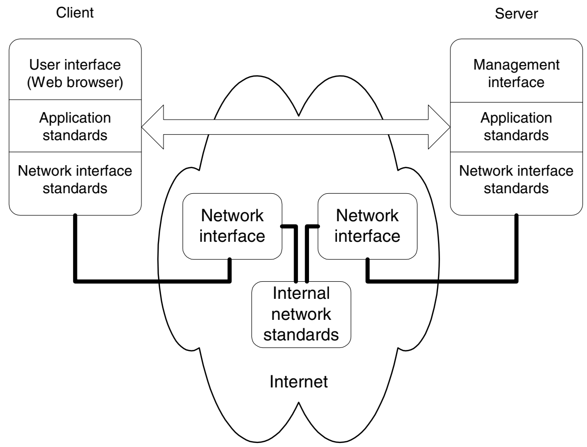

Figure 1: Standards requirements for interactive multimedia applications over the Internet.

contents more effectively than current text-based methods allow.

MPEG-21: The latest effort of the group focuses on providing a multimedia framework that should enable transparent use of multimedia resources across a wide range of networks and devices.

JPEG and JPEG 2000: The JPEG (Joint Photographic Experts Group) compression standard for still images was developed in the late 1980s and has become tremendously popular. JPEG 2000 is a new standard that uses Wavelet subband coding techniques and allows for numerous compression options. It has recently been approved and is starting to enjoy some popularity among Internet imaging users.

In the context of interactive multimedia applications on the Web (Figure 1), standards are required both at the application and at the networking level. Examples of application-level standards include the JPEG and MPEG compression standards and the hypertext transfer protocol (HTTP) implemented by all Web browsers to allow HTML pages to be displayed at the client's side. Network-level standards include the TCP/IP protocol suite.

CREATING INTERACTIVE MULTIMEDIA WEB PAGES

Contemporary tools for designing Web pages (such as Macromedia Dreamweaver and Microsoft FrontPage) allow the inclusion of multimedia objects, such as videos, images, animation, and audio, in Web pages. To play sound, animation, and video, the user system may require plug-ins, which are small programs that work in cooperation with a Web browser. Some plug-ins have become very popular, so Netscape and Microsoft browsers have built them into their latest versions. Popular multimedia plug-ins include RealNetwork's Real Audio and Real Video, Apple's Quick Time, and Macromedia Shockwave and Flash.

Besides plug-ins, which allow multimedia objects to be included in Web pages, more sophisticated Web pages also include Java Applets and VRML (virtual reality modeling language) three dimensional (3D) images. *Java Applets* are programs embedded in Web pages (in HTML code) and used to create multimedia Web pages that include animation, sound, images, and videos. The Applet runs locally on the client machine, which is running a Web browser. *VRML* is a generic text-based language used to construct 3D images and 3D text for Web pages. A VRML document is an ASCII file, much like an HTML document. In VRML, the Web designer specifies objects—called *nodes*—that define shapes and their attributes. These nodes create 3D scene graphs, which a VRML browser renders. Examples of nodes include cube, sphere, cone, cylinder, rotation, and scan.

Although including all these components makes Web pages multimedia rich, it does not make them interactive. The complete process of creating interactive multimedia Web pages, and the related tools and languages, is shown in Figure 2. This process is described next.

The original (home) Web pages, hosted at a server, include multimedia objects (such as music, sound, images, animations, and video clips), Java Applets, and VRML images. To provide interactivity, a Web designer should also apply client-side and/or server-side scripting.

Client-side scripting includes CGI (common gateway interface) scripts that provide interactivity by processing and responding to user inputs. When a user submits an HTML form, a program that resides on the server system receives and processes the form's content. This program then creates an HTML document dynamically, which the server displays back to the user on the client machine. CGI scripts are usually created using Perl, JavaScript, or VBScript.

Perl is an interpreted scripting language for processing data collected from HTML forms, which is well suited for text manipulation. Its features include flexibility, compact, form, security, and support for file and database operations.

JavaScript is another scripting language that is used to create and process Web pages with HTML forms. However, the browser, and not a program on the server, executes JavaScript, adding interactivity and dynamic content to Web pages.

Java Media Framework (JMF) tools provide the integration into Java applications and Applets of a wide range of audio and video formats, advanced imaging, animation, 2D and 3D graphics and modeling, as well as speech and telephony support. The JMF consists of a suite of Java media APIs (application programming interface).

JMF player API is used by applications and Applets to create and control media playback. Java 2D API (J2D) and 3D API (J3D) provide sets of classes for writing 2D and 3D graphics applications and Applets, respectively. Java Advanced Imaging API allows sophisticated image processing to be incorporated into Java Applets and applications.

VBScript is a scripting language from Microsoft that is based on Visual Basic, which is used to create interactive multimedia Web pages. Like JavaScript, VBScript statements are embedded in an HTML code, which a browser executes. VBScript provides access to OLE (object linking and embedding) objects, called ActiveX controls.

ActiveX is an OLE object, which is a class library that contains a complete set of functions for manipulating an

object. The code for an OLE object already exists, so programmers can include the objects in applications quickly and easily. ActiveX controls provide programmers with a way to extend browser capabilities and create a wide range of Web site capabilities. Some examples of ActiveX controls include button (control to display various frame sequences), chart (enables the programmer to draw various types of charts with different styles), and gradient (shades the area with a range of colors).

Server-side scripting provides an effective way to dynamically build documents in response to client (or user) requests. As shown in Figure 2, server-side scripting uses information sent by clients, information stored on the server, and information from the Internet to dynamically create Web pages (in XHTML or XML), which are then sent back to the client.

Active Server Pages (ASP) is a popular server-side technology from Microsoft, which is processed by an ActiveX component (server-side ActiveX control) called a scripting engine. An ASP file has an extension .asp and contains XHTML tags and scripting code. The VBScript is most widely used for ASP scripting, but other languages, such as JavaScript, can be also used.

Scalable Vector Graphics (SVG) is a Web standard that specifies the language for describing two-dimensional graphics in XML. It will provide the next-generation Web browsers with native support for multimedia. SVG allows for three types of graphic objects: vector graphic shapes (e.g., paths consisting of straight lines and curves), images, and text. Graphical objects can be grouped, styled, transformed, and composited into previously rendered objects. Text can be in any XML name space suitable to the application, which enhances searchability and accessibility of the SVG graphics. The feature set includes nested transformations, clipping paths, alpha masks, filter effects, template objects, and extensibility. SVG drawings can be dynamic and interactive. The Document Object Model (DOM) for SVG, which includes the full XML DOM, allows for straightforward and efficient vector graphics animation via scripting.

In summary, a number of tools, languages, and components, which are introduced in this section, are used to create contemporary and effective interactive multimedia Web pages.

TOOLS, SERVICES, AND APPLICATIONS

Today, there is a wide range of interactive multimedia services and applications on the Web. In this section, we discuss the basic services and applications as well as related tools. The list of these services and applications is given in Table 1.

Multimedia Portals

Market environment is changing rapidly and therefore new functionality is important for gaining competitive advantage. Time-to-market is critical, and businesses need to integrate systems, automate processes, and provide each other with access to key functionality. Recently, Web portals evolved as a single, integrated point of access of information, applications, and people. Web portals are Web sites that offer a great deal of

Table 1 Interactive Multimedia Services and Applications on the Web

APPLICATION	DESCRIPTION
Multimedia portals (sample URL: http://www.eUniverse.com)	Give users single, customizable access to multimedia services, including video, audio, animation, interactive banners, etc; can be classified as entertainment, educational, and information portals.
Interactive e-learning and distance learning (sample URL: http://www.click2learn.com)	Applications include a wide variety of media files to interactively explain complex concepts; distance learning allows customers to subscribe to online courses taught at remote sites.
Media sharing (sample URL: http://www.ic.media.mit.edu)	Provides collaborative music and video production by a group of artists from dispersed locations.
Interactive multiplayer games (sample URL: http://www.sierra.com)	Games in which multiple players participate over the Internet.
Web 3D virtual environments (sample URL: http://www.parallelgraphics.com)	3D content that allows users to fly through virtual space.
Participatory publishing	Web content that users, along with authors, can contribute to and influence.
Interactive Web maps (sample URL: http://www.archaeology.usyd.edu.au/research/time_map)	Time-enabled maps that typically display archeological and historical data.
Multimedia search over the Web (sample URL: http://www.fastsearch.com)	Web-based search systems that provide search results as images and audio and video files on a single result page.
Integration of the Web with traditional media (sample URL: http://www.broadcast.com/television)	Applications include radio and television broadcasting on the Web, video-on-demand, and interactive TV applications.

content and services. They integrate new content with existing content, server-side applications, and Web-based services. There are two basic Web portals: (a) public portals, such as Yahoo, which bring together information from various sources, applications, and people, and which offer personalized Web sites; and (b) enterprise, or usiness, portals, which give employees access to organization-specific information and applications.

In another classification, a horizontal portal provides a gateway to a broad range of information, whereas a vertical portal provides in-depth information about a specific topic.

Multimedia portals are special Web portals that offer multimedia services, such as streaming video, audio, interactive banners, and animation (Dimitrova et al., 2000). Multimedia portals can be classified as belonging to one of the following groups. (a) *Entertainment portals* typically provide customizable music, television, and movie news. For example, a portal from Warner Brothers, shown in Figure 3, provides features such as an e-mail center; customizable access to music, DVD videos, television, and movies; entertainment news; a chat room; and interactive advertiser banners. (b) *Educational portals* include online learning applications that provide access to diverse sets of content. An example of a tool for developing educational portals is the Aspen Learning Content Management Server from click2learn (http://www.click2learn.com), which allows a team of instructional designers, media developers, subject experts, and content reviewers to work together effectively through project management, workflow, and collaboration. (c) *Information portals* provide users with the means to find information on any topic (such as Yahoo).

Interactive E-learning Tools and Distance Learning Applications

The Web coupled with multimedia content has the potential to change how people are educated. Contemporary e-learning tools allow the development of online interactive learning applications. An example of such a tool is ToolBook Instructor and Assistant (http://www.click2learn.com), which supports a wide variety of media files, including sound, animation, streaming media, and still images. Some interactive learning applications using ToolBook include innovative technical and maintenance training, electronic service manuals, and software training courses. Figure 4 shows a screen from the interactive Boeing 777 course, showing how skilled aircraft mechanics share techniques for installing safety hardware in confined spaces.

Distance learning allows remote participants to receive classes over the Internet. Advanced distance learning systems include a real-time interactive virtual classroom, which allows a remote participant not only to receive a live class feed but also to interact in a live class using audio and video over the Internet (Deshpande & Hwang, 2001).

Media-Sharing Applications

Media sharing includes the design of tools that support collaborative music or video production by a group of artists from geographically dispersed areas. A sharable media project team at MIT Media Lab, led by Glorianna Devenport (http://www.ic.media.mit.edu), has developed a set of tools that allows online groups of filmmakers to collaborate on the same film project by contributing

and sharing material, and to comment on one another's creations (Kelliher et al., 2000). An example from this project is PlusShorts application, which is implemented as a Java Applet, and which allows distributed groups of users to contribute and collaborate in the creation of shared movie sequences.

RocketNetwork (http://www.rocketnetwork.com) has developed a tool for online musicians that provides simultaneous access to audio files and allows the collaboration of musicians and producers. This system, referred to as "global production network," allows the dynamic updating of files from anywhere in the world. Applications include sound track production for film, TV, and radio, and sound tracks for broadcast media.

The system is based on a RocketNetwork's central server, which coordinates sharing, dynamically updates, and distributes audio and MIDI (musicial instrument digital interface) files.

777 leading edge lockwire installation

The lockwire installation consists of three steps. Look at the diagram below. Click on each of the steps in the diagram in sequence. Read the key points to remember for each step.

Key points:

1. Insert the wire, break the 90, proceed to twist.

2. Continue to twist until the wire aligns with the slot that provides positive tension. Pull the wire through the slot, break the 90 and complete the 7-8 twists.

3. Apply the wire pliers and perform one full twist. Cut the wire leaving 4-6 twists. Bend down the sharp wire ends to prevent a safety hazard.

Click on the numbers above to vi

Figure 5: Half-Life from Sierra.com—illustration of a multiplayer Web game (from http://www.sierra.com).

Multiplayer Web Games

Interactive multiplayer games allow multiple players to participate in games over the Internet. The challenge of Web-based multiplayer games is in the quality of the connection and the ability of the designer to implement the plot in a cyberspace way. Real-time games also require that players visit a chat room and register and that all clients be synchronized. Figure 5 illustrates an example from the game Half-Life, created by Sierra.com (http://www.sierra.com).

Web 3D Virtual Environments

Support for VRML in Web browsers allows developers to present their content in 3D rather than just as documents. The user can "fly" through virtual space and experience a real car, house, or town. The browser requires a plug-in, a Web browser that provides complex VRML rendering. Figure 6 illustrates the Cortona VRML plug-in, by ParallelGraphics for a 3D model of a sport car.

The same company, ParallelGraphics, offers Outline3D, an interior design application that enables users to quickly customize a virtual environment specific to their design needs (http://www.parallelgraphics.com). Potential applications include (a) a 3D room for potential buyers to view the finished interior design of an office or a home, and (b) real estate applications, for real estate agents to show customers the look of their future home.

Participatory Publishing

Participatory publishing refers to Web pages where readers can contribute and influence the content along with authors.

An example of participatory publishing is WebTour, an application developed by the Siemens Research Center in Princeton, in which viewers can make verbal comments and dynamic annotations or drawings to illustrate some points. The system is capable of recording, playing back, storing, searching, and distributing personalized dynamic multimedia annotation on Web documents in the form of guided Web tours.

Potential applications of participatory publishing tools, including WebTour, include the following.

E-commerce: When a customer enters the Web site of a retail store, a Web clerk greets the customer and guides him/her through various Web pages explaining key products and adding advertisements when necessary.

Corporate Intranet: Different users, such as employees and/or customers, can make annotations on the same Web document and share ideas.

Distance learning: A teacher can make annotations on Web pages explaining complex problems. The annotations could then be retrieved by students and played back.

WebTour is implemented using open Web technologies described earlier—standard browsers, Java, dynamic HTML and JavaScript, and Active Server Pages.

Interactive Web Maps

Interactive Web maps are time-enabled maps created from distributed databases. Interactive maps typically display archaeological and historical data, such as historical maps and images, the growth of cities, the spread of dynasties and empires, or the distribution of archeological sites. However, there is a wide range of other applications, which could include time-stamped data. Interactive Web maps could also link map objects to images, other Web pages, multimedia, or a database. In addition, interactive

features include zooming and panning, temporal filtering, data-driven hotlinks, and other functionality.

An example of a tool for creating interactive Web maps is TimeMap, from the University of Sydney (http://www.archaeology.usyd.edu.au/research/time_map). Figure 7 illustrates an interactive map developed by the TimeMap team for the international Dunhuang project and the British Library. By selecting an area and clicking the mouse, the viewer can access another interactive screen (Figure 8). This interactive map allows the viewer to select and view archeological sites, monumental remains, routes, and so forth.

Multimedia Search Over the Web

Today, there are more that 275 million multimedia files on the Web. On average, Web surfers interact with sites containing multimedia content up to 25 times longer than with sites with static content.

FAST Multimedia Search (http://www.fastsearch.com) is currently one of the largest integrated multimedia search products on the Internet, allowing users to receive results for image, audio, and video files on a single, results page. Users simply search by keyword, and as a result, all retrieved multimedia files are accessible from the results

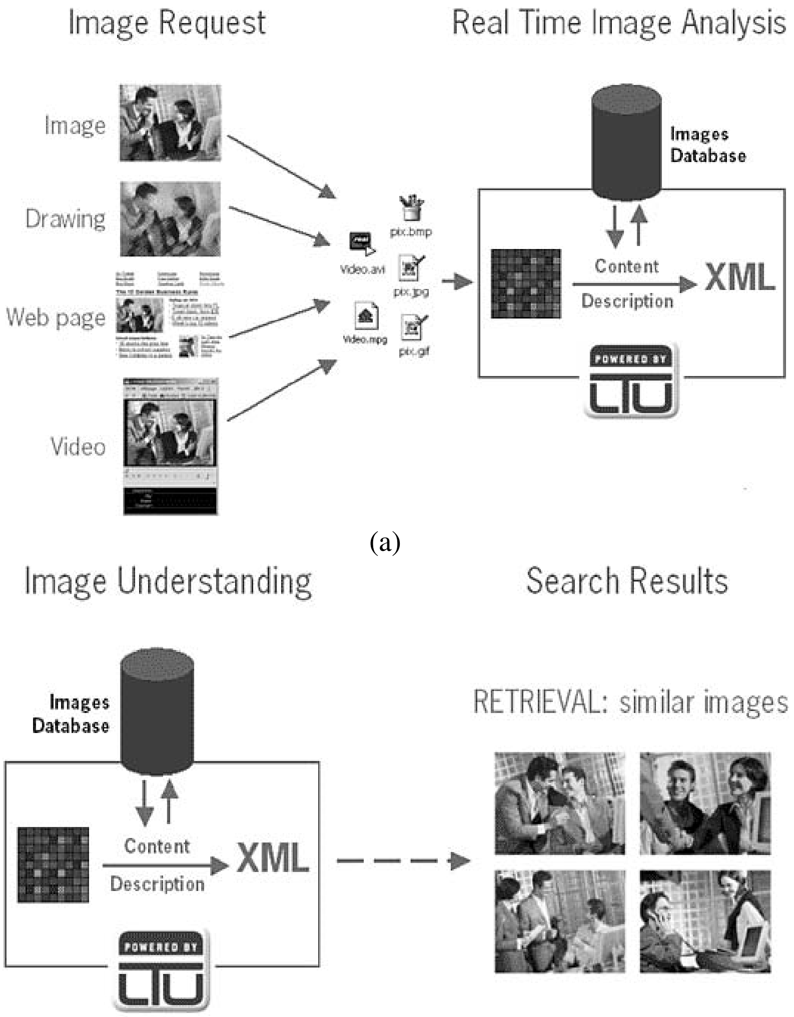
Figure 9: Lycos offers the largest integrated multimedia search engine on the Web. It includes 60 million images, sounds, and videos (from www.multimedia.lycos.com).



(a)

(b)

Figure 10: (a) An image is presented to the system and real-time image analysis is performed by extracting features of the image. (b) The system then matches these features with the features of images in the database and retrieves similar images (from http://www.ltutech.com).

page. This tool has been used by Lycos to create their multimedia search engine (http://www.lycos.com), which is illustrated in Figure 9.

Another, more advanced search of the multimedia repository is content-based retrieval, where the user provides information about the actual contents of the image, audio, or video data, rather than just keywords (Marques & Furht, 2002). A content-based search engine translates this information to query the multimedia database and retrieve the candidates that are likely to satisfy the user's request.

An example of a commercial content-based image retrieval system is a product suite from LTU Technologies (http://www. ltutech.com), which includes five products: Image-Filter, Image-Indexer, Image-Seeker, Image-Shopper, and Image-Watcher. The core of the system is a high-level perceptual image analyzer that is capable of indexing, recognizing, and describing images according to their visual features. Figure 10 illustrates the operation of the system.

Integration of the Web With Traditional Media

There is a growing trend in integrating the Web with traditional media, such as radio and television. As the streamed multimedia protocols for audio and video have matured, a number of radio and television stations have begun offering live and near-live audio and TV content over the Web. Examples include Yahoo! Broadcast radio and television Web sites (http://www.broadcast.com/radio and http://www.broadcast.com/televsion).

In addition, some programs are capable of supporting active user feedback, and even participation, so we can expect a number of new video-on-demand and interactive TV applications.

CONCLUSION

The synergy between new multimedia technologies and the Web have brought new delivery mechanisms and new types of applications. We are still in the first phase of this marriage, where we are faced with such technical challenges as how to efficiently transmit multimedia data over the Internet and how to best use our new tools. However, the focus is already moving to new areas, such as a new way to refer to publishing, how mass media can better reach and involve their audiences, and how to users can better access the Web's wealth of multimedia information (Wynblatt et al., 2000).

GLOSSARY

Active Server Pages (ASP) Server-side technology from Microsoft that is used to dynamically create documents in response to user requests.

ActiveX An OLE object, which is a class library that contains a complete set of functions for manipulating an object. It is used to create a wide range of Web site capabilities.

Client-side scripting Scripts embedded in Web pages that provide interactivity by processing and responding to user inputs.

Constant bit rate (CBR) A type of network service in which the amount of network traffic follows a regular pattern, proportional to the amount of information that is being transferred.

High definition television (HDTV) An imaging system with a resolution of approximately twice that of conventional television in both the horizontal and vertical dimensions, and a picture aspect ratio of 16:9.

Java 3D (J3D) API Provides a set of classes for writing 3D graphics for Java applications and Applets.

Java Applets Programs that are embedded in Web pages and can be used to create multimedia Web pages.

Java Media Framework (JMF) Tools that provide the integration into Java applications and Applets of a wide range of audio and video formats, advanced imaging, animation, 2D and 3D graphics and modeling, as well as speech and telephony support.

JavaScript A scripting language that can be used to create interactive multimedia Web pages.

Jitter Refers to the variance of the overall end-to-end delay between source and destination in a packet-switched network.

Joint Photographic Experts Group (JPEG) Responsible for definition of a standard widely adopted for encoding and compression of digital images.

Mean packet transfer delay The average value of the overall end-to-end delay between source and destination in a packet-switched network.

MPC-1 Part of a set of standards that defined minimum hardware and system software specifications for PC hardware for the earliest multimedia PCs. MPC-1, particularly, was based on Intel's 386SX processor. The last MPC standard published was MPC 3. There are currently no plans for the publication of any additional MPC standards.

Motion Pictures Expert Group (MPEG) Responsible for definition of several standards widely adopted for encoding, compression, and description of audiovisual contents.

Packet switching Refers to a switching technique by which the information to be transferred between two end computers is divided into packets and relayed through intermediate nodes (routers) along the way.

Quality of service (QoS) A collection of application and/or network requirements that must be met to enable an application to work on a specific network.

Server-side scripting Provides a way to build Web documents in response to user requests on the server side. Besides the information sent by users, it also uses information stored on the server and from the Internet to dynamically create Web pages.

Streaming Refers to the continuous transfer of information from source to destination.

Transmission control protocol/Internet protocol (TCP/IP) A standard network protocol stack used on the Internet and on many private networks.

Variable bit rate (VBR) A type of network service in which the amount of network traffic may follow an irregular pattern, mainly because of the nature of compression algorithms used at the source.

VBScript A scripting language from Microsoft that is based on Visual Basic. It is used to create interactive multimedia Web pages.

Virtual reality modeling language (VRML) A text-based language used to construct 3D images and 3D text for Web pages.

International Cyberlaw

Julia Alpert Gladstone, *Bryant College*

INTRODUCTION

The economic benefits that can be derived from business transactions conducted on the Internet have been recognized for several years. Cyberspace has evolved from a basic network established to accommodate the needs of government and academic researchers to a domain of glitzy advertisers and international financial machines. Some forecasters estimate business-to-business e-commerce will generate $8.5 trillion by the end of 2004 (Pastore, 2002). The true potential of the Internet as a commercial venue remains elusive, however, because of the legal uncertainty surrounding what laws are appropriate for governing cyberspace activity.

Questions arise as to whether land-based laws should apply to cyberspace or whether regulations that account for the borderlessness, or the virtual nature, of the medium are more appropriate (Gladstone, 2000). Cyberspace is global; therefore transactions cross national borders. As each nation seeks to protect its citizens and preserve its sovereignty, the nation establishes its own set of rules and regulations that it applies to cyberspace. This creates a conflict as to which nation's laws to apply to a global Internet transaction. This chapter reviews the major national and international laws in the areas of jurisdiction, privacy, electronic signatures, and encryption as well as copyrights and patents that presently impact cyberspace activity, and suggests that there is an incongruence between nations in many areas and that global attention must be focused to harmonize the laws in these areas to provide certainty and consistency. These particular topics of law were selected for examination because they create the foundation of the legal structure of the Internet upon which other, more-country-specific legal issues, such as consumer protection, taxation, gambling, and obscenity, are derived. Predictability and reliability are critical for the growth of commerce, and the law can play a key role in providing this element of certainty.

This chapter begins by exploring the fundamental question of who, if anyone, has the legal authority to regulate the Internet. In the context of transnational law, this is, in essence, the issue of personal jurisdiction. The author reviews the challenges that are often raised against a nation's exercise of power beyond its borders and moves on to review the current status of jurisdiction jurisprudence for cyberspace. Concern about the protection of personal information threatens the growth of commerce on the Internet. In the section on privacy, the author examines the national laws and international laws and treaties that loosely form a privacy policy in cyberspace. Commerce is the major growth area on the Internet that depends on reliable contracts. The use of encryption and digital signatures, which can insure the enforceability of electronic contracts, is discussed in the section on encryption, which also analyzes the current global status of electronic signature legislation.

Our definitions and understanding of rights to ownership in intellectual property have been challenged in response to the movement of information onto the Internet, and nations have responded to these changes in various ways. The section on intellectual property reviews the principal international and national rules in the areas of patent and copyright infringement as they have been influenced by and responded to the activity in cyberspace. Trademark issues are not included because this is a matter that is closely tied to the issue of registration of domain names, which with the development of the Internet Corporation for Assigned Names and Numbers (ICANN) has become its own specialty, and it is best left for a separate chapter.

The lack of uniformity in approach to legislation in many substantive areas is evident from the analysis presented in this chapter, and the author suggests that policy makers remove their national blinders in order to foster e-commerce.

JURISDICTION

Jurisdiction—An Overview

An essential element for the profitable evolution and efficiency of electronic commerce is for business and consumers to be able to act with confidence, knowing the laws that will apply to transactions in which they are engaging. Compliance with rules is impossible without an understanding of whose law is applicable, and the corollary to this is where the legal dispute, if it arises, will be resolved (ABA Project, 2000). These are questions of personal and prescriptive jurisdiction, which a century and a half ago were resolved easily when people lived and died in small geographic areas and the law of that place applied. The sovereign power of any state, which legitimizes the enforcement of its laws, is based upon territoriality. A general correspondence exists between borders drawn in physical space and those drawn in law space. National borders have formed the sovereignty paradigms for regulatory authority and decision making. When parties to the action lived, and the activities in dispute occurred, in a single state, that state's courts and laws were the only obvious and uncontested jurisdictional choice (Mody, 2001).

Long before the Internet, however, social changes challenged the territorial jurisdictional principles across all borders, and the concept of contacts between a foreign defendant and the foreign state was invoked to establish principles of fair and just jurisdiction. The additional jurisdictional challenges that the Internet has presented are due to the perception of the Internet as its own distinct "cyber sovereignty," which would thus make it impervious to real-world legal rules. Some people have argued that the lack of geographical borders in cyberspace turned cyberspace into its own distinct sovereignty beyond the scope of territorial law (Johnson & Post, 1996). However, for the purpose of applying the law, these separate realties need not be seen as distinct. The technology does change how the parties communicate and their state of mind, but it does not change the fact that the parties still exist in physical space, which is the critical point for jurisdictional analysis.

In order to proceed with determining jurisdictional issues on the Internet, the question of whether the law should view cyberspace as a place, a means of communication, or a technological state of mind needs to be resolved. Initially, the number of participants were small, the activities were limited, and the view of cyberspace as a state of mind or a place beyond the rule of law was appealing and even plausible, but in the year 2002, the number of cyberspace transmissions are diverse and they extend well beyond a technological phenomenon and into the real world. Cyberspace, or the Internet, represents merely another means of communication, where a terrorist can promulgate bomb making or kidnapping tips, merchants can conspire to fix prices by e-mail, a corporation can issue fraudulent securities, or a pornographer can sell child porn. Simply stated, there is a tremendous amount of previously unavailable information that is now available free of charge, which makes the Internet susceptible to real-world legal rules.

Generally speaking, a state can only enforce its laws against a defendant when there is a local presence or when there are assets within the local jurisdiction (ABA Project, 2000). The Internet's architecture allows information to flow without bounds, and therefore, the individual or organization supplying the information cannot control where that content will end up. There are no physical barriers or cues to notify the provider; therefore, an activity that may be lawful in Belize, for example, may be easily accessed in New York where it is unlawful (Mody, 2001). Individual states invest time, money, and effort to protect the welfare of its citizens and, naturally, legislate accordingly. There is an apparent conflict between a state's sovereign interest to protect its citizens and a foreign content provider's ability to carry on its lawful activity. Imposing the state's law on the content provider, or transnational regulation, raises objections regarding the violation of jurisdictional norms. The main criticism regarding transnational cyberspace breaking jurisdictional rules is based upon the notion that a state may not act beyond its own territorial borders.

Fundamental Jurisdictional Principles Under International Law

Jurisdiction can be broken into two categories: prescriptive jurisdiction, which addresses the authority of a state to apply its own laws to regulate conduct; and enforcement jurisdiction, which is the executive's authority to compel compliance with these laws. The focus of this chapter is on prescriptive jurisdiction, although issues of enforcement jurisdiction will be raised in the discussion of the Yahoo! case (*Yahoo! Inc., v La Ligue Contre Le Racisme Et L'Antisemitisme,* 2001).

The threshold matter of "jurisdiction to prescribe" means that the substantive laws of the forum country are applicable to the particular persons and circumstances (Restatement, 1987).

When a country has jurisdiction to prescribe, it can appropriately apply its legal norms to conduct. Simply stated, a country has jurisdiction to prescribe law with respect to (a) conduct that, wholly or in substantial part, takes place within its territory; (b) the status of persons, or interests in things, present within its territory; (c) conduct outside its territory that has or is intended to have substantial effect within its territory; (d) the activities, interests, status, and relations of its nationals outside as well as within its territory; and (c) certain conduct outside its territory by persons who are not its nationals that is directed against the security of the country or against a limited class of other national interests (Restatement, 1987).

Jurisdiction to adjudicate or to enforce means that the tribunals of a given country may resolve a dispute to enforce a judgment where the country has jurisdiction to prescribe the law. The exercise by a country of jurisdiction to enforce is subject to the requirement of reasonableness. States exercise jurisdiction to adjudicate on the basis of various links, including the defendant's presence, conduct, or, in some cases, ownership of property within the country. Exercise of judicial jurisdiction on the basis of such links is on the whole accepted as "reasonable"; reliance on other bases, such as the nationality of the plaintiff or the presence of property unrelated to the claim, is generally considered "exorbitant" (Restatement, 1987).

A country may employ judicial or nonjudicial measures to induce or compel compliance or punish noncompliance with its laws or regulations, provided it has jurisdiction to prescribe. Thus, a country may not exercise authority to enforce a law that it had no jurisdiction to prescribe. A country may employ enforcement measures against a person located outside its territory (a) if the person is given notice of the claims or charges against him and they are reasonable in the circumstances; (b) if the person is given an opportunity to be heard, ordinarily in advance of enforcement; and (c) where enforcement is through the courts, if the country has jurisdiction to adjudicate (Restatement, 1987).

The extraterritorial objections to cyberspace regulation reflect a basic misunderstanding of modern jurisdictional doctrine. Although historically a sovereign's power was tied to its geography, a state's power to regulate activity that originates outside the country but causes local harms has been recognized for many years. One of the first cases to recognize that a state's regulatory authority may extend to an extraterritorial activity was decided in the Permanent Court of International Justice (PCIJ) in 1927. In the case of *S. S. Lotus,* (Fr.v. Turk.) 1927 P.C.I.J. (Ser A) No. 10 (19227), the court held that the state of Turkey could apply its criminal law to a foreigner who acted outside of Turkey when committing the offense so charged and which prejudiced Turkey and its citizens, provided the foreigner was arrested in Turkey. This was an application of the law to a person or act outside the territory of Turkey that had an effect on and/or in Turkey. This early case applied the "effects principle" to expand the authority of a state. This is a logical extension of control by a state outside its territory to protect its citizens from actions taken by a defendant that had an "effect" or impact within the state. A state's territorial borders were no longer the sole determination of rule-making authority.

In the more famous case of the *United States v. Aluminum Company of America* (ALCOA), 148 F.2d 416 (2d Cir.1945), the United States Second Circuit Court of Appeals considered whether the United States could apply the antitrust provisions of the Sherman Act to a Canadian company. The anticompetitive acts took place in Canada, but the material effects were experienced in the United States, and the Court did apply United States rules to this Canadian company. Thus, with the ALCOA case, the presumption of extraterritoriality had been overcome.

Fundamental Principles of Jurisdiction Under European Law

In the European Union, the primary source of jurisdiction law has been the Convention on Jurisdiction and the Enforcement of Judgments in Civil and Commercial Matters, September 30, 1968 (the Brussels Convention). In general, jurisdiction is based upon the defendant's domicile, and alternative jurisdictional grounds are available if there is a close link between the court and the action or if the "sound administration of justice" would be facilitated. In contract matters, the place of performance would govern the jurisdiction decision. In tort matters, jurisdiction would lie in the place where the harmful event occurred or where there was a risk of it occurring.

The Brussels Convention was modified, effective March 2002, as the European Union issued the so-called Brussels Regulation (the Brussels Regulation). In contrast to a convention or directive, a "regulation" of the European Union becomes binding immediately after its adoption by the 15 member states without the need for further implementation. The economic drive of electronic commerce created the need for certainty and uniformity of jurisdictional rules early on; therefore, the European Union found it efficient to proceed quickly with a mere regulation. Although the Brussels Regulation does not alter the main structure of the Brussels Convention, it effectuates certain changes that take account of the new technological developments that result from e-commerce. Most important, the Brussels Regulation, which is consumer centered, establishes the fact that the courts of the consumer's domicile will have jurisdiction over a foreign defendant if the latter "pursues commercial or professional activities in the Member State of the consumer's domicile or, *by any means,* directs such activities to that Member state . . . and the contract falls within the scope of such activities." This language expands the range of situations in which the consumer can sue in his or her place of domicile.

The phrase "by any means" was included to broaden the scope of jurisdiction to reach internet-based transactions (Explanatory Memorandum, July, 1999). The Brussels Regulation equates doing business or offering goods and services via the Internet with an invitation or with advertising by businesses that "by any means" directs their activities toward that member state.

In essence, the Brussels Regulation stipulates that an unintended effect in a member state can be the basis for jurisdiction. Because jurisdiction in European countries is not limited by U.S. constitutional principles of due process, as it is in the United States, the Brussels Regulation does not require notice or "minimum contacts."

The Brussels Regulation was controversial; the negotiations reflected the tension between business and consumer groups. Industry groups claimed that it would hinder the growth of e-commerce, by making small- to medium-size businesses reluctant to set up Web sites for fear of being subjected to the jurisdiction of the courts of too many countries. Alternatively, the EU Commission believed that without strong consumer protection, the negative impact on consumer confidence would hurt the unified European market (Explanatory Memorandum, October 2000). If, as a result of reluctance to venture into the World Wide Web to shop, consumers were to stay within their own country, the Commission believed the EU e-commerce sector would be put at a significant competitive disadvantage to the United States; this is based upon the belief that the United States has stronger consumer protection laws.

The EU Parliament has also passed its Electronic Commerce Directive, which applies a more restrictive jurisdictional doctrine to legal disputes, restricting plaintiffs to a "country of origin" approach. Under the Electronic

Commerce Directive, "the law of the country of origin (which is the seller's place of business) would govern the cross-border disputes." Although this may provide more certainty for businesses, it provides consumers with much less confidence in their business dealings (Boam, 2001). There are several exclusions from the Electronic Commerce Directive including "contractual obligations concerning consumer contracts;" therefore, it is not know how these exclusions will work with the Brussels Convention as amended, and in the short run, case by case examination of jurisdictional issues will be required.

Classic United States Jurisdiction Principles

In the United States, assertion of jurisdiction over a person must satisfy the standard of constitutional due process. States exercise jurisdiction over nonresidents under their respective long-arm statutes. First, to establish personal jurisdiction over a defendant, a United States court will apply the relevant long-arm statute to see whether it permits the exercise of personal jurisdiction. Second, the court will apply the precepts of the Due Process Clause. A standard inquiry for whether due process has been satisfied focuses on whether the defendant has "minimal contacts" within the forum such that assertion of jurisdiction does not offend the "traditional notions of fair play and substantial justice" (*World-Wide Volkswagen Corp. v. Woodson,* 444 U.S. 286, 1980).

Under the Due Process Clause of the Constitution, one must look at the relationship between "the defendant, the forum and the litigation" (Rice, 2000). Physical presence is not required; rather the plaintiff must show that the defendant has purposefully directed its activities toward the forum state, or otherwise "purposefully availed itself of the privilege of conducting activities within the forum State, thus invoking the benefit and protection of its laws" (*Hanson v Denckla,* 357 U.S. 235, 1958).

Questions of jurisdiction in cyberspace have generated lengthy court decisions and caused much global debate because of the unique nature of Internet information dissemination. The current global jurisdictional case law suggests that two principal tests are being used to ascertain jurisdiction (Rice & Gladstone, 2002).

One is the "Zippo test," which is named after the case that first articulated it (*Zippo Manufacturing Co.v Zippo Dot Com,* Inc., 952 F. Supp. 119, W. D. Penn., 1997), and the other is the "effects test," which is based upon a standard developed from a U.S. Supreme Court case that arose in the context of print media (*Calder v Jones,* 465 U.S. 783, 1984). Both of these tests constitute a course correction from the earliest U.S. decisions which had based specific personal jurisdiction over a nonresident defendant on mere accessibility in the forum state of the defendant's Web site.

The Zippo test establishes jurisdiction over a nonresident defendant based upon the degree of interactivity between the Web site and the forum. Mere access to the nonresident's Web site is the least interactive; under the Zippo test, a passive Web site is not sufficient to establish specific jurisdiction. The district judge explained that the decision of whether jurisdiction could be properly asserted in a case was to be based upon the nature and quality of the commercial activity that an entity conducted over the Internet. Jurisdiction cases fall somewhere on a "sliding scale" or "spectrum," where the likelihood that personal jurisdiction can be constitutionally exercised is directly proportionate to the nature and quality of the commercial activity that an entity conducts over the Internet.

The primary difficulty in applying the Zippo sliding-scale standard to jurisdiction cases in cyberspace has been determining the degree of "interactivity." Similar fact patterns have led to different jurisdictional findings in different courts. In addition, determining whether a Web site has been integral in a forum often hinges more on a court's perception than on real differences in the manner in which the user employs the Internet. For example, in the year 2000, a judge in the Southern District of New York found that the mere availability of the defendant's Web site in New York made it "intuitively apparent" that defendant's services were used by New York residents (*Cable News Network, L. P. GoSMS.com, Inc,* 2000 WL 1678039, Southern District of New York).

The judge, therefore, found grounds for jurisdiction even though he acknowledged the plaintiff's allegations that the defendants' mobile telephone and two-way e-mail services allegedly used in New York were "factually unsupported."

Jurisdiction Based on "Effects"

The first instance when "purposeful direction" arose was in the context of traditional media, and it has become the basis for all United States cases applying the "effects test." In *Calder v. Jones,* 465 U.S. 783 (1984), Florida residents who had essentially no physical contact with California wrote and edited an article in the *National Enquirer* that defamed Jones, who was a well-known movie actress residing in California. The *Enquirer* had greater circulation in California than in any other state, and the material was based upon California sources. The U.S. Supreme Court found jurisdiction holding that California was the focal point both of the story and the harm suffered. The court held that the defendants' acts were intentional, that they were aimed at California, and that its effects took place in California.

The first use of the effects test in asserting jurisdiction against a defendant in an Internet context was in *Panavision Int'l. L.P v. Toeppen,* 141 F.3d 1316 (9th Cir. 1998), which was a "cyber-squatting" case. Toeppen, an Illinois defendant, had intentionally registered the California plaintiff's trademark as his domain name, namely Panavision. When attorneys for Panavision contacted Toeppen to demand that he stop using the name, he responded by offering to sell the name for $13,000 and promising not to acquire any other, similar names. Unwilling to be bribed, Panavision sued Toeppen in California District Court, where Toeppan objected on jurisdictional grounds. The district court found jurisdiction appropriate under the effects test because the defendant had intentionally directed its conduct toward California, knowing that the effect of his registering the domain name would be felt in California. The Ninth Circuit agreed, analogizing cyber-squatting to an intentional tort and found that "the brunt of the harm to Panavision was felt in California."

In a recent Australian libel case, the effects test was applied to assert jurisdiction to protect a Melbourne citizen. The Victorian Supreme Court found jurisdiction over Dow Jones, a United States company, based upon its *Wall Street Journal* Web site, which carried an allegedly libelous article about Joseph Gutnick, an American businessman who lived in Melbourne, Australia. The Australian Court found that the publication occurred and, thus, had its impact whenever the article was downloaded, thereby dismissing the defendant/Dow Jones' argument that the court lacked jurisdiction because the information was not published in Australia. Again, the impact/effect was felt in Australia (*Gutnick v. Dow Jones,* VSC 305, 2001).

Several leading cyberspace commentators have suggested that the effects test is a more useful mechanism than the Zippo test for establishing jurisdiction in Internet cases. In fact, the effects test has been refined into two parts: a "strict effects" test, which looks to the intent of a defendant acting outside the jurisdiction to establish a connection, and a looser, "soft effects" test, which focuses more simply on the impact within the jurisdiction (Rice & Gladstone, 2002). The former use of the effects test has been employed mostly in tort and intellectual property cases. Indeed, cases of defamation lend themselves easily to finding jurisdiction under the strict effects test because intent to harm is an essential element of the underlying cause of action. Currently, it is likely that a court dealing with the issue of jurisdiction over a nonresident based on his online activity will start its inquiry by using the Zippo test but will continue the analysis by applying the effects test. Therefore, attorneys who advocate jurisdiction in a particular forum would be best advised to use both tests, because the effects test may apply where the Zippo test does not.

Enforcement Jurisdiction and the Yahoo! Case

The recent lawsuit by the International League Against Racism and Anti-Semitism and the Union of French Law Students against Yahoo! (the Yahoo! Case), which has received so much attention in the popular press, summarizes many of the fundamental principles and issues that remain to be resolved in the area of international jurisdiction. In April 2000, two French groups, namely the Union of French Law Students and the International League Against Racism and Anti-Semitism, filed suit against Yahoo! for hosting auctions that displayed and sold Nazi propaganda. The memorabilia auctions were accessible only via the English language site, Yahoo.com. Direct access through Yahoo.fr was not possible. Yahoo! argued in French court that the French court did not have jurisdiction over Yahoo!. That plea was denied, and in November 2000, a French court ruled that Yahoo! must put filtering systems in place to block users in France from access to the Nazi-related goods area or pay fines of approximately $13,000 per day. Only a watered down version of the soft effects test could be seen to apply to the French court's decision in this case, and because Yahoo! was not targeting France, which is a key element in the effects test, the assertion of jurisdiction arguably violates the due process requirement of U.S. law (Rice & Gladstone, 2002).

Yahoo! chose not to appeal the French court's judgment. Rather, it challenged the enforcement of the order in the United States. In December 2000, Yahoo! filed a lawsuit in the United States District Court of Northern California, seeking a declaratory judgment that any final judgment of a French court would be enforceable in the United States. Before the California court could address the merits of the case, in a bit of an ironic twist, the French defendants motioned the California court to dismiss the declaratory judgment suit due to lack of jurisdiction. The U.S. court denied the motion to dismiss, finding jurisdiction based upon the effects theory. The court ruled that the defendant knowingly engaged in the activities and intended to have an effect on United States citizens (e.g., the use of U.S. Marshals to serve Yahoo! officers in California). Clearly, the French citizens purposely availed themselves of the benefits of the United States.

A state can only enforce its laws against a defendant in a forum where the defendant can be found or where there are assets belonging to the defendant. Enforcement of a judgment rendered by another forum requires its recognition by another court to enforce it. If it is the judgment of a court in a state in the United States, the Full Faith and Credit Clause of the Constitution requires that it be recognized by another state. Recognition sought in the United States of a judgment of a foreign court depends on the principle of "comity" (ABA Project, 2000). Comity is not a matter of absolute obligation. It is the recognition that one nation allows within its territory the legislative, executive, or judicial acts of another nation (ABA Project, 2000). National procedures required for recognition and enforcement of judgments vary widely around the globe. In the United States, comity is upheld unless doing so would violate due process, personal jurisdiction, or some public policy.

In trying to determine the enforcement jurisdiction of the French court over Yahoo!, the Federal District Court for the Northern District of California found the issue to be whether it was consistent with the Constitution and the Laws of the United States for another nation, namely France, through their court order, to curtail the Yahoo! Web site. The French, thereby, would be regulating the speech of United States' residents within the United States on the basis that such speech could be accessed by Internet users in France. The court was mindful of the extent to which the United States is governed by the "comity of nations" but did not believe that comity was a matter of absolute obligation. The court decided the case in accordance with the Constitution, finding that the French Order violated the Constitution of the United States, thereby recognizing that it was necessarily adopting the position that given "certain judgments embedded within this enactment including the fundamental judgment expressed in the First Amendment that it is preferable to permit nonviolent expression of offense viewpoints than to impose viewpoint based government regulation upon speech."

The court rendered judgment in favor of Yahoo! in a summary judgment motion that Yahoo! requested on the declaratory judgment action to find the French Order in violation of the First Amendment. This finding of a threat to Constitutional rights by the court was the grounds by which it effectively rendered the Order unenforceable, and which demonstrates the limits of perspective jurisdiction. This case suggests the disharmony that continues to exist among nations on questions of jurisdiction.

It appears that courts and legislatures have found legitimate grounds for asserting prescriptive jurisdiction over defendants based upon actions taken in cyberspace, but that may have little importance when the plaintiff seeks a restorative remedy. Enforcement jurisdiction, which requires the injured party to attach either the defendant or his tangible assets, becomes an issue of comity or state's recognition of its obligation to enforce a law. Questions of comity have not been resolved sufficiently to assure smooth enforcement on the Internet. Policy makers and governments will need to address this higher level of enforcement jurisdiction to foster the predictability and certainty necessary for the growth of commerce on the Internet.

PRIVACY

The technological efficiencies that characterize the Internet, namely transparent dissemination, collection, and aggregation of information, have not previously been experienced by society. Although the facility of data collection has economic benefits, it compromises the individual's right to privacy. During the past half decade, many sectors of the global community have been directing time and resources to resolve the inherent tension that has developed between seeking the economic benefits from modern data collection practices and ensuring human dignity, which is threatened by modern surveillance (Gladstone, 2000). The Internet is the largest electronic infrastructure that allows public access to a nearly infinite resource of information, and it holds the current greatest threat to personal privacy.

The mechanisms used to protect that information fall into three categories, reflecting either a self-regulatory, statutory, or technology approach. The self-regulatory, or market-dominated, approach, which is adopted in the United States, is based upon industry-developed norms, policies, and contracts, rather than statutory legal rights, to protect the privacy interests of its citizens. The statutory, or rights-dominated, approach, which was developed in the European models and recently adopted in Asia, New Zealand, and India, relies on statutory and common laws to establish rights to information privacy (Reidenberg, 2000). Technology is used globally in varying degrees in different sectors. Data flows on the Internet are international, and these divergent data protection policies and rules confront each other with increased frequency. Attempts at harmonization have been enacted, most notably the International Safe Harbor rules, or Safe Harbor Rules, which were adopted to implement the EU Privacy Directive, but further work toward uniformity is needed.

This section begins with a description of two examples of how one's privacy is threatened on the Internet. The first example reviews data collection practices that threaten consumer privacy. It is followed by a review of the laws in the United States that have been passed to prevent inadvertent exposure to pornography on the Internet. The section continues by exploring the differences that underlie the approach to privacy of the United States versus that of other nations, which suggests reasons for difficulties in finding a common ground. The section on EU privacy discusses the background and scope of the Council Directive 95/45/EC (the EU Privacy Directive), including a discussion of the strategies for U.S. compliance, namely the Safe Harbor rules, the Model Contract Terms, and derogations, or exceptions, allowed under national law. The technology that drives the Internet is based upon an open architecture, the natural default of which exposes information about people's actions on the Internet, whether through the World Wide Web or e-mail. Several surveillance initiatives, or technologies, by the U.S. government have drawn on this open architecture to retrieve personal information about citizens. The recent enactment of the Uniting and Strengthening America by Providing Appropriate Tools to Intercept and Obstruct Terrorism Act of 2001, Pub. L. No. 107–56, 115 Stat 272., (the USA PATRIOT Act), which has broadened the surveillance powers of the United States, is reviewed toward the end of this section. The passage of the USA PATRIOT Act suggests that the differences in the data protection policies between the United States and Europe may be getting wider.

Data Collection, Pornography, and Privacy Invasions

The expansion of digital computers and networking technology, with the Internet being the most prime example, has moved much of our social, educational, and commercial activities into an electronic environment. The technology that has enabled integrated global networks facilitates the creation of digital records showing what people spend time looking at, how much time they spend at particular sites, what messages they send, and what purchases they make. This "electronic footprint" is created by a variety of processes that can be generated by simply browsing the Web (Piera, 2001). Activity of the user within the Web site provides "click-stream data," which includes the time spent on each page and the information retrieved. There is technology that can collect and organize all this information into data packets; these are referred to as "cookies" and they are stored on the user's hard drive. The cookie is assigned a unique identifying code, and each time the user goes back to the Web site, the cookie is retrieved. It then tailors that visit to the previous behavior at the Web site. This invisible data collection is primarily conducted by business. The warehousing of transaction information and profiling of online users has become a critical component for e-commerce business models. The behavioral information enables sites to characterize users and offer them content of personal interests. Internet revenue is generated through target advertising that has become especially efficient as a consequence of the design of technological infrastructures that enables the global network.

This economic efficiency comes at the cost of lost privacy to the consumer. Studies indicate that Internet users do choose not to make online purchases because of privacy interest issues. In fact, some people argue that consumers have lost total control over their personal privacy choices.

Inadvertent exposure to online pornography presents another example of how privacy is threatened by the borderless and anonymous world of cyberspace. Internet pornography is big business, comprising 11% of the entire $9 billion e-commerce revenues in 1998, with industry experts projecting that e-porn will generate over $3 billion by 2003 (Alexander, 2002).

Many of the sites are free and serve as teasers to lure people to commercial sites. Consequently, children and adults alike may enter a pornographic Web site inadvertently. Such accidental exposure is common, particularly because users inputting Web site addresses often misspell them. In addition, the very open architecture of the Internet, where all material is equally accessible, means that sex-related materials are not segregated, as they may be in the material world. This exposure violates one's right to be let alone. Sexually explicit materials on the Internet range from the commonplace pornographic still frame, to live broadcasts of couples losing their virginity.

The general public in the United States has voiced a desire to restrict the dissemination of pornography on the Internet, and Congress has responded with at least three major legislative reforms. Congress' top-down attempts to regulate have not been successful, because in each instance a federal court has invalidated the statute based upon constitutional grounds.

The first and most significant act that Congress passed to eradicate online pornography was the Communications Decency Act (CDA), which covered a wide variety of activity. The operative provisions found in Section 502(a) prohibited the "knowing transmission of obscene or indecent messages to any recipient under 18 years of age" and criminalized the "knowing, sending or displaying of patently offensive messages in a manner that is available to a person under 18 years of age." In *ACLU v Reno,* 521 U.S. 844 (1997), in upholding the decision of the three-judge panel, the Supreme Court found that provisions of the CDA were impermissible content-based restrictions on speech. In addition, the court found that the language was facially overly broad and vague, which would create an unacceptable chilling effect on the speech of adults using the Internet.

The subsequent two laws that Congress passed were more specifically directed toward children. The Child Online Protection Act (COPA) followed the tone of the CDA by criminalizing Web publishers who used the World Wide Web to make harmful material available to minors. COPA provided broad affirmative defenses for Web publishers with restricted access to minors regarding the use of credit cards or other age verifying technology.

COPA was found to be unconstitutional because of the impermissible burden placed on protected adult speech. The district court found that COPA was neither narrowly tailored nor was it the least restrictive means used to protect children from harmful materials. Finally, the Children's Internet Protection Act (CIPA) required that all public schools and libraries with Internet access install filtering software to block access to sexually explicit Web sites. A U.S. District Court in Philadelphia found the CIPA unconstitutional because the filtering software would "block access to a substantial amount of speech that was both constitutionally protected and fails to meet even the filtering companies' own blocking criteria."

As of the time of this writing, the regulation of Internet pornography continues to present a challenge to Congress that remains unresolved. Access to the Internet, which is truly a unique marketplace of ideas, presents tensions among several fundamental rights. Our freedom of expression must be protected while one's right to be let alone or one's right to privacy must also be respected. In order to balance the right of privacy against other rights or practices, such as data collection, one must first examine a much more important question: What is the value of the right to privacy?

Views of Privacy

The American approach to privacy has evolved as one of restraint, whereas many other nations take an omnibus approach, giving the state a proactive and preventative role. The fundamental difference in the American versus the European conception of privacy can be seen most basically in the words used to describe data privacy. Americans use the term "privacy," which can refer to the right to be free from the gaze of a "peeping Tom" or the right not to disclose one's name on a Web site. Europeans use "data protection," which very specifically addresses information generated by an individual's overt activity. In the entire history of the United States, the position of Chief Counselor for Privacy lasted for 2 years only, whereas in Europe there are entire parliamentary departments and "privacy czars"devoted to data protection and privacy concerns.

As colonies of individuals who fled the tyranny of a controlling government, Americans feared a strong central government and established a Constitution that grants primary power to the states. The first ten Amendments (Bill of Rights) assure Americans additional freedoms, which they covet. The protection of privacy, which is not a fundamental right stated in the U.S. Constitution, can impose restrictions on other fundamental rights. In nearly every country within the European Union, the right to privacy is expressly stated in a constitution.

The First Amendment free-speech guarantee limits government regulation of the flow of information, including personal data. Indeed, by securing the freedom of speech, the First Amendment limits the protection of privacy. The American reluctance to grant power to the government in this area is also reinforced by the country's laissez-faire market economy. The recent threats to national security that resulted from the September 11, 2001, bombings of the World Trade Center in New York and the Pentagon in Washington, D.C. resulted in the passage of legislation, namely the USA PATRIOT Act, which suggests that Americans continue to not recognize the importance of privacy (Godwin, 2001).

The first major international accord that addressed personal data protection was the Organization for Economic Cooperation and Development Privacy Guidelines of 1980 (the OECD Privacy Guidelines). The OECD Privacy Guidelines have been adopted by all twenty-five member nations, and although they are not binding, they serve as suggestions for member countries and others in developing their domestic legislation. The OECD Privacy

Guidelines established eight basic principles that govern the handling of personal information, which are referred to as "fair information principles." They are collection limitation, data quality, purpose specification, use limitation, security safeguards, openness, individual participation, and accountability.

These are internationally accepted principles, which pertain to all types of data processing by both the public and the private sector. Application of the OECD Privacy Guidelines is based upon a loose reciprocity model of enforcement whereby personal data can flow freely between countries that provide equivalent protection.

EU Privacy Directive Explained

The most recently enacted and extensive statement of information privacy principles is the EU Privacy Directive. The EU Privacy Directive is a fully fledged system for the protection of personal data, which requires the establishment of rights for data subjects and obligations for those who process personal data. It also provides monitoring by an independent body and sets out sanctions for offenders. The goal of the EU Privacy Directive is to increase the free flow of information, and it is designed to allow personal data to be sent or processed on the same terms within the European Union and throughout the world. Each of the 15 member countries has had to pass its own legislation to implement the EU Privacy Directive, and to date, only France, Ireland, and Luxembourg have not passed such laws. The EU Privacy Directive is broken into seven chapters, which contain a total of 32 articles. The following overview of key provisions of the EU Privacy Directive illustrates the intensive focus on information privacy taken by the member states and also reflects a concern for data protection greater than that typically found under United States law.

Article 2 of the EU Privacy Directive contains the operative definitions of the EU Privacy Directive, which include personal data, processing of personal data, personal data filing systems, controllers, processors, third parties, and recipients. The EU Privacy Directives employs the terms "controller" and "data subject," which creates a top-down assumption of computer networks, not necessarily personal or individual use of computers. These assumptions are less applicable or useful in a world of personal computers where persons are browsing on the Internet.

Articles 6 and 7 of the EU Privacy Directive provide the general rules on the lawfulness of the processing of personal data. Article 6 establishes data quality principles by requiring that personal data must be processed fairly and lawfully and that such data be accurate and kept up to date and in a form that permits identification of data subjects for no longer than necessary. Lawful and fair processing is further defined by requiring that the data be collected for explicit, legitimate purposes. In addition, there can be no "secondary use" or "sharing" of data. Affiliate sharing or secondary use of personal data is allowed in the United States under the Financial Services Modernization Act of 1999 (Gramm-Leach-Bliley Act, Pub.L.No. 106–102, 113 Stat 1338, 1999), which provides the most comprehensive privacy protections for consumers to date (Gladstone, 2000). Once again, this highlights the differences in privacy policies between the United States and Europe.

There are provisions in the EU Privacy Directive that allow data processing if the data subject "unambiguously gives consent." A data subject can give his consent either by "opting in" or "opting out." A data processor may disclose on its Web site that personal data disclosed by the consumer may be further distributed for purposes of research or marketing. The Web site may offer the viewer a choice of not allowing the Web site to engage in this practice. This is called opting out. It is unclear whether opting out satisfies the criteria of "unambiguously giving consent" or whether only an opting-in alternative, whereby the Web site disseminates the data only if the viewer clicks "yes" to such a practice, is sufficient (Gladstone, 2000).

Article 7 also allows the processing of data that is needed in order to execute a task carried out in the public interest or for the exercise of the official authority vested in the controller. As in Article 3, the focus of the EU Privacy Directive is to protect data from abuse by private hands: The EU Privacy Directive deference to the government or an official authority is unlike the American approach, which seeks to minimize government involvement.

Articles 25 and 26 govern the transfer of personal data outside the EU to third countries such as the United States. The EU Privacy Directive bars the export of European personal data to countries that do not have "adequate" personal data protection regimes. The EU Privacy Directive sets out specific derogations whereby personal data may be exported despite adequate protection. These exemptions include situations where there has been consent by the subject, where it is necessary to the completion of a contract, and where it is in the public interest or in the vital interest of the subject (EU Privacy Directive). Information on the Internet crosses geographical and political borders on a continuous basis; therefore, all countries connected to the Internet are subject to the extraterritorial application of the EU Privacy Directive. Many U.S. companies have been concerned about the impact of the EU Privacy Directive's "adequacy standards" on their privacy policies and practices.

Safe Harbor Compliance

The initial response of the United States to comply with the "adequacy standards" of the EU Privacy Directive resulted in the establishment of the International Safe Harbor Principles. After protracted negotiations, the U.S. government and the European Commission jointly agreed to satisfy the "adequacy standards" of the EU Privacy Directive. Organizations that seek to benefit from the Safe Harbor Principles must self-certify their compliance with the U.S. Department of Commerce, thereby agreeing to terms of data handling practices, compliance, and dispute settlement. The Safe Harbor mechanism allows voluntary commitment by U.S. companies, which builds on the self-regulatory approach the United States takes toward privacy. To date, only 148 firms have joined the Safe Harbor Program (Aaron, 2002).

The Safe Harbor Principles are composed of two documents: a list of seven "critical" elements dealing with data processing, and a list several frequently asked questions

(FAQs). Organizations may choose to precisely adhere to the specific provisions of the Safe Harbor Principles to obtain the benefits of the Safe Harbor and publicly declare that they do so. Alternatively, organizations may develop their own self-regulatory privacy program, provided it conforms to the Safe Harbor Principles, or join a self-regulatory privacy program that adheres to the Safe Harbor Principles. Organizations that have agreed to comply with the Safe Harbor Principles are subject to the Section 5 "unfair and deceptive" practices of the Federal Trade Commission Act. Air carriers are subject to the equivalent statute of the Department of Transportation. There are several industries, such as the telecommunications and financial services industries, that are not eligible for the Safe Harbor or whose business practices are incompatible with the provisions.

The seven critical elements of Safe Harbor are notice, choice, onward transfer, security, data integrity, access, and enforcement. At least five of the critical elements directly address the provisions in Articles 2 through 14 of the EU Privacy Directive. From the perspective of assuring the same high level of privacy protection as the EU Privacy Directive, the Safe Harbor Principles appear to fall short in several areas, which again reflects the tradeoff between privacy and other fundamental rights in the United States. Under the Safe Harbor criteria of providing notice, individuals must be informed in clear and conspicuous language of the following: (a) the purpose for which an organization collects and uses information; (b) the types of third parties to which an organization discloses the information; and (c) how to make inquiries or complaints. This Safe Harbor requirement follows the requirements of Articles 10 and 11 of the EU Privacy Directive, but Articles 10 and 11 require that information be given to the subjects *before* the collection of personal information. The Safe Harbor notice requirement provides more leeway, because it stipulates that such notice may be given before personal information is received or "as soon thereafter as practical." This delayed notice was undoubtedly fashioned to encourage easy compliance with the EU Privacy Directive, but abuse of this option could effectively negate one of the key privacy protection mechanisms of the EU Privacy Directive. If an organization finds that prior notice is too costly, under the Safe Harbor Principles, they may opt routinely for giving notice after the fact. In addition, the Safe Harbor notice requirement does not require that data subjects be explicitly informed of their right of access to personal data (Gladstone, 2000). This, again, presents a disparity with the EU Privacy Directive, and it diminishes the underlying goals of the EU Privacy Directive.

Article 14 of the Directive grants the data subject rights to object to the processing of data that the controller anticipates as being processed for direct marketing and is incompatible with the purpose for which it was collected. The Safe Harbor Principles give individuals the opportunity to opt out in deciding how personal information will be disclosed to third parties for a purpose other than that for which it was originally collected. Under EU Privacy Directive, the data subject must be given the opportunity to object before the data is disclosed for the first time to a third party. The Safe Harbor opt-out choice falls short of the prior choice requirements in Article 14 of the EU Privacy Directive (Gladstone, 2000). Article 6 of the EU Privacy Directive sets out the principle of the quality of the data that may be collected and prohibits further processing of that personal data in a way that is incompatible with the "legitimate purpose for which it was collected." A parallel provision of Safe Harbor Principles entitled "Data Integrity" allows an organization more freedom in collecting and maintaining data, because it stipulates that an organization is not prohibited from the further processing of data as long as the organization takes "reasonable steps to ensure the data is accurate, complete and current."

Article 25 of the EU Privacy Directive prohibits the transfer of personal data to a third country that lacks an adequate level of protection, and Article 26 offers certain limited exceptions to this prohibition. The onward transfer provision of the Safe Harbor requires that disclosure of personal information to a third party be consistent with the principles of notice and choice; an organization is liable if it knows or has reason to know that a third party will process the information improperly. Under the Safe Harbor Principles, however, an organization is in compliance when transferring data to a third party even if the third party does not subscribe to the Safe Harbor Principles or the EU Privacy Directive as long as that third party signs an agreement to protect the data. This flexibility could easily create of a data haven and effectively subvert the EU Privacy Directive even if one were to comply with the Safe Harbor, thereby essentially directly frustrating the purpose of the EU Privacy Directive (Reidenberg, 2000).

Model Contract Clauses

In an effort to offer more flexibility for compliance with the EU Privacy Directive, in December 2001 the EU Commission adopted the Commission Decision 2002/16 (Contract Clause Decision), which sets out standard contract clauses for the transfer of personal data to processors in non-EU countries that have not been recognized as providing "adequate protection" for data. Under these standardized contract clauses, an EU company exporting data can and must treat the data with the full respect of the EU data protection requirements. The terms of these standard privacy contract clauses can be appended to existing licenses or contracts and offer a guarantee that the necessary security measures for privacy protection are in place.

The companies that choose to comply with the Safe Harbor provisions are subject to the enforcement jurisdiction of the U.S. Federal Trade Commission. Under the standard contract clauses, an entity becomes subject to the European Data Authority and the standard contract creates a private right of action in Europe. In addition, the terms of the standard contract are rigid and may impose criminal penalties.

The EU Privacy Directive, which has set the standard for privacy protection for international transfer of data, can be satisfied in several ways. The means of compliance that is adopted, and which can vary from joining the Safe Harbor to drafting model contract clauses, will depend on the nature of one's organization and how one's data is collected.

Technological Responses to Privacy Protection

For the part they play in the effort to protect privacy, the legal and self-regulatory instruments described above have legitimately received substantial public support. The fundamental flaw with these privacy programs and legislations is that most users of the Internet lack an understanding of the premise underlying the technological structure of computer networks, in particular the Internet. Loss of control over one's personal data or relinquishment of one's privacy is a direct result of the technology or infrastructure of the Internet. Network computer systems are designed to have identifiable transactions; every time a user logs onto the Internet, an electronic record is created (Lessig, 1991).

The ease with which privacy is sacrificed as a result of the openness of the infrastructure of the Internet was recently brought to the attention of the public, as the FBI has widely implemented a very efficient surveillance technology, Carnivore, that captures Internet conversations. Carnivore is a software technology that was developed to intercept e-mail messages based upon code words (Electronic Privacy Information Center, 2000). Carnivore is the term used for an entire system: a computer running on a Microsoft's Windows 2000 operating system and software that scans and captures packets, the standard unit of Internet traffic, as they travel through an Internet service provider's network. The FBI can install a Carnivore unit at the network station of an internet service provider (ISP) and configure it to capture e-mail going to or from the person under investigation. Under the USA PATRIOT Act, discussed below, in order to obtain a court order to install Carnivore, a law enforcement agent must simply certify to a judge that the information is "relevant to an ongoing criminal investigation." In addition to the fact that under the USA PATRIOT Act the warrant requirements are lowered, the packet-switching technology that drives the Internet has allowed the FBI to gather more information than a prescribed search warrant would allow. This compromises the privacy of all persons who have any interaction with the targeted suspect. Questions have been raised regarding the mechanics of the Carnivore system. When the Electronic Privacy Information Center filed a Freedom of Information Act (FOIA; 5 U.S.C. 552 1994 & Supp. 1999), request for Carnivore's source code, the inner workings of how the device functioned, the FBI refused to disclose information about how Carnivore worked. The persistent refusal for full disclosure by the FBI has led to several lawsuits against the them, which has created the impression in the eyes of the public that law enforcement is taking away rights rather than protecting them (Van Bergen, 2002).

Any discussion of privacy must recognize that a balance must be struck between interest of privacy and security. The swiftness with which the USA PATRIOT Act recently passed through Congress illustrates that Americans do not highly value their privacy when national security is threatened. The U.S. Department of Justice has been arguing with civil liberties groups and privacy advocates for several years over amendments to federal statutes that would expand law enforcement wire tapping and electronic surveillance operations. Congress had been reluctant to expand law enforcement surveillance activities with respect to the Internet, usually citing privacy concerns. After the September 11, 2001, terrorist attacks, congressional reluctance and public opposition, as measured by consumer polls, to expanded surveillance diminished.

The USA PATRIOT Act is a long and complex statute that made changes to over 15 different statutes, several of which directly impact Internet communications. Section 216 of the Act addresses pen/trap orders, which were initially defined under the Electronic Communications Privacy Act (ECPA) (18 U.S.C. 3121–3127) as including a device attached to a telephone line to trace and trap telephone numbers. Since about September 2000, the FBI had been routinely applying pen/trap devices to computer communications, and thus, under the USA PATRIOT Act, the pen/trap provisions apply to computer communications so that all e-mail addresses, Web addresses visited by a target, Internet protocol addresses, and other routing information can be obtained. The contents of the messages have never been retrievable under a pen/trap order, but while telephone numbers can be easily separated from a telephone message, e-mail addresses are not so easily separated from e-mail contents or e-mail subject headings in particular, and therefore pen/trap orders may be misused in the e-mail context.

The USA PATRIOT Act amends the Foreign Intelligence Surveillance Act (FISA) (50 U.S.C. 1841–1846), which historically had separated domestic criminal investigations from foreign investigations. Domestic surveillance was governed by Title III of the Omnibus Crime Control and Safe Streets Act of 1968 (18 U.S.C. 2510–22), which provided for adequate safeguards for basic constitutional rights, such as the Fourth Amendment probable cause requirements and judicial review. Foreign intelligence, which was governed by FISA, granted the attorney general the power to treat an alien as an agent of a foreign power, which meant that person was not entitled to constitutional rights. The boundaries between these two laws are blurred under the USA PATRIOT Act, which is most evident from the expanded definitions of "terrorist." Consequently, under the USA PATRIOT Act's pen/trap provisions, an ISP must respond to a court order as long as the law enforcement agent certifies that the surveillance "is relevant to an ongoing investigation." The Fourth Amendment requirements of probable cause when conducting wiretaps have been lowered. In addition, pursuant to the same lowered standard, any business may now be served with an order for the production of "any tangible thing," not just a business record. Clearly, ISPs, cable subscribers, and businesses in general ought to review their privacy policies and confidentiality agreements to ensure that they accurately reflect their new obligations under the USA PATRIOT Act.

There are significant differences in the regulations surrounding the protection of personal information in the United States and in Europe. These differences will likely impede global e-commerce and international agreements, and negotiations are needed to enable nation states' policies to develop in harmony. Reidenberg (2001) has suggested the promotion of negotiations for a General

Agreement on Information Privacy (GAIP) in connection with the World Trade Organization (WTO). He recommends this type of a treaty organization because it places data protection in a trade arena rather than a political arena, and by placing GAIP within the WTO, it would add social protection norms to a trade treaty. The GAIP would include many signatory countries and would focus on an institutional process of norm development to facilitate easily implemented standards for informational privacy. The WTO could define cost standards for data protection that could be incorporated into a multilateral trade agreement (Reidenberg, 2001).

ENCRYPTION AND ELECTRONIC SIGNATURES

The expansion of Internet technology has allowed people to use the Internet as a platform for worldwide business, and therefore, contracts are being formed among parties with no prior relationships. Parties want to rely exclusively on online communications; therefore, a reliable system of authentication is needed to ensure the success of e-commerce (Winn, 2001). The ability to transmit information secretly over distances has been accomplished for decades using cryptography. Digital signatures and encryption are the two key aspects of cryptography that have been recognized as essential tools for security and trust for e-commerce. This section begins with an explanation of the current global regulation regarding the control of exportation of encryption. The most popular form of encryption in use today is public key asymmetric cryptography (PKI), which is used in digital signatures. *Electronic Signatures-Technical Overview* distinguishes digital signatures from electronic signatures before offering an overview of the PKI technology. *Regulatory Models* explains the three legislative models that have been developed for the regulation of electronic signatures.

Cryptography is the art of using code to keep information secret, and encryption is the technique of encoding or scrambling communications. Most nations regulate the exportation of encryption technology because of the fear that abuse of the technology by terrorists or criminals would impede the ability of national security and law enforcement to do their jobs. Privacy advocates and free speech proponents in the United States agree that restrictions on exports of encryption infringe on individuals rights to informational privacy, Fourth Amendment and First Amendment rights. Members of the high-tech and software industries complain that such restrictions are anticompetitive vis-a-vis foreign nationals.

Encryption Exportation Regulation; United States Law and International Treaties

Under the Arms Export Control Act of 1978 102, 22 U.S.C.S. 2799aa-1 (2000; the Arms Export Control Act or the Export Administration Act [EAA]), the U.S. State Department decides whether an item is dual purpose, a category that includes such things as commercial products with military application. Control over the licensing and export of dual-purpose products is transferred to the Department of Commerce (DOC; Paik, 2000). The DOC under the EAA now regulates the export of all general-purpose encryption devices and software. The DOC Export Administration Regulations 15 C.F.R. 730–74 (2000) include source code and object code in the definition of software subject to regulation and exportation, which includes "downloading or causing the downloading of such software . . . or making such software available from electronic bulletin boards . . . " (Paik, 2000). During the Clinton Administration, there was significant discussion regarding the requirement that software companies create key recovery systems. One that was recommended by the government was known as the Clipper Chip. That requirement was not adopted, and current regulations allow U.S. citizens to ship any retail encryption product around the world to commercial concerns after a one-time technical review by an interagency panel (Paik, 2000).

The Wassenaar Agreement is an international agreement that addresses controls on encryption exports, and to which 33 countries, including the United States, subscribe. The Wassenaar Agreement, which was designed to promote cooperation among its members, was amended in 1998 to impose export control on export software for keys above 64 bits and to eliminate record keeping for low-level encryption. Several countries, including Israel, South Africa, India, and China, however, are not members. Thus, there is not harmonization in the global encryption export market (Paik, 2000).

Electronic Signatures—Technical Overview

An electronic signature is any method that logically associates an electronic representation of the identity of a person with the content of an electronic document or record. It implies acknowledged authorship or agreement, but there are times, with e-mail programs for instance, where an electronic signature can be applied automatically. Generally, with electronic records the goal is to protect the integrity of the content, and a generic electronic signature provides very low assurance that documents have not been altered. Digital signatures, a special subset of electronic signatures, can provide this assurance (Ballon, 2001).

Digital signatures serve three essential functions: authentication, integrity, and nonrepudiation. Authentication means that the party is who she says she is. Integrity is assurance that the communication has not been tampered with (i.e., it is in its original form), and nonrepudiation prevents the party from retreating from the transaction in the event a dispute arises. A digital signature denotes "an electronic imprint" that is created using PKI. PKI is also referred to as asymmetric encryption because two keys are used, a private key and a public key. The two keys are mathematically related, so when the message is encrypted with the private key and sent to the recipient, the recipient must use the sender's public key to decrypt it. Each user has a different public/private key pair (Berman, 2001).

A digital signature is not a digitized version of a person's handwritten signature; rather, it is a "message digest" of the document that is being encrypted, or sent. The message digest is created by processing the document through a unique computer-generated code known as a "hash."

Once the hash is created, the signer types in a personal identification number (PIN) that allows the private key to generate a long series of numbers and letters, which is the digital signature. The sender uses a one-way hash function to encrypt the message he wants to sign and then sends it. The computer-generated signature and the hash result are unique to the message. Every time the message passes through the hash function, the same message digest will be produced. To verify the signature of a digitally signed message, the receiver reverses the process with the public key (Berman & Biddle, 2001).

In order for a digital signature system to function, the parties must be assured that the public keys they obtain actually belong to the person it is purported to be from and not to a forger. The way to achieve this confidence is with a Certification Authority, which is an entity either public or private that attests to the integrity of the system. Certification Authorities issue certificates of authenticity as to the ownership of the keys. There have been several proposals as to the best solution to the problem of authentication (Zemmick, 2001). Currently, several banks offer this service.

The intention in all jurisdictions that have enacted electronic signature laws is to encourage the development of e-commerce, but there is a large disparity in their treatment of electronic signatures. According to Smedinghoff and Bro (1999), "predictability is a watch word for the growth of commerce and law can play a role in providing this valuable commodity," and yet the most striking feature of the various electronic signature laws enacted around the world is their lack of uniformity (Fischer, 2001). As we saw with the various privacy policies, failure of policy makers to remove national barriers will hinder successful global e-commerce and possibly widen the digital divide.

Regulatory Models

Electronic signature legislation can be seen as based on one of three models. The first of the three models is known as the mandatory or prescriptive model because it mandates a specific technology (Fischer, 2001). Alternatively, the minimalist legislative approach is technology neutral, and the third hybrid approach suggests a favored technology that affords presumptions under the law. Proponents of the prescriptive model, which include Germany, Italy, Malaysia, and Russia, mandate specific technology when authorizing electronic signatures as an alternative to pen and paper. Public key infrastructure, or a digital signature, which is currently the most sophisticated technology, is required. In addition, this mandatory or prescriptive approach often outlines specific criteria for the trusted third party, or Certification Authority. The rationale given for this approach is that the requisite security for e-commerce can only be obtained with these constraints. In addition, it is believed that these requirements will assure legal certainty, which is essential for public trust. Critics of this approach point out that this not only grants economic advantages for a particular existing technology, it is shortsighted because although the "best" technology in 2002 may be PKI, there is no guarantee that better, more sophisticated techniques will not become available.

In addition, this mandatory or prescriptive approach often outlines specific criteria for the trusted third party (CA) and usually overly limits the liability of the CA. Typical prescriptive digital signature laws place the burden for loss or theft of a private key on the consumer if there was a failure to exercise reasonable care. The consumer will bear the entire loss, thus insulating the CA from any liability. This structure of liability seems to unfairly burden the consumer in an effort to create a less risky role for the CA, whereas the CA could more efficiently protect itself.

The hybrid model, adopted under the EU Signature Directive of 1999 by the European Union, is often referred to as a two-tier model because it grants basic validity to all electronic signatures but provides special treatment to certain advanced signatures. Under this hybrid approach, an electronic signature cannot be denied legal effectiveness solely because it is electronic, but some technologies are given presumptions of authenticity if the signature meets certain requirements. Currently, the only technology that meets these heightened standards is PKI.

The rights and duties set out for the parties to an electronic transaction under the hybrid model reflect a market-driven philosophy. Unlike under the prescriptive approach, CAs will be found liable in damages for harm caused to someone who has reasonably relied on a certificate for the accuracy of the information, unless it can be proven that the CA was not negligent. The presumption is in favor of the consumer. Under the hybrid approach, CAs can limit their liability by contract, however, prior to entering into the transaction.

The minimalist, wholly technology-neutral approach provides that no electronic signature of whatever type may be denied legal effect, validity, or enforceability because it is in electronic form. The U.S. Electronic Signatures in Global and National Commerce Act of 2000 (E-SIGN), 15 U.S.C. 7001–06, 7021, 7031, endorses this approach. Australia and the United Kingdom have also enacted minimalist legislation, and New Zealand is considering a law similar to that of Australia (Fischer, 2001). The philosophical principles upon which it is based foster technological advancements by allowing the market to decide which technology is best. It also allows several systems to be developed simultaneously. E-SIGN was drafted and enacted swiftly in the United States, which was in part a response to the factious division among the several states within the U.S. in adopting various versions of electronic signature legislation.

The major criticism of E-SIGN is that it is too vague and that its lack of certainty will hamper electronic commercial growth. Critics of E-SIGN suggest that the nonrestrictive legislation might lead to parties being held liable for contracts they did not actually authorize, for example if a party somehow failed to protect the security of his signature device. Although the liability may be severe, the "liberty to contract" concept prevails, which leaves the parties free to be bound or reject the contract.

The electronic signature legislation that has been passed in countries around the world reflects the contrasting views of the minimalist and the prescriptive approach. The global initiative by the United Nations Commission on International Trade Law (UNCITRAL) working group on electronic commerce is not expected to have a significant impact on existing or proposed legislation, because business lost confidence in the proposal during negotiations as a result of the parties' insistence on a prescriptive approach mandating a public key infrastructure (Fischer, 2001). The future of commerce will not take place on paper, and it is important for the law to grow to facilitate the development of e-commerce. Attention needs to be given to harmonize the differences between nations that exist in the area of electronic signatures, possibly through a revising of the work previously produced by UNCITRAL.

INTELLECTUAL PROPERTY

Technology has had a profound impact on the perception of intellectual property and the appropriate distribution of the rights traditionally attached to trademark, patent, and copyright in the global context. Although technological advances have created unprecedented opportunities for economic prosperity in the area of intellectual property, legal systems have had to adapt to maintain firm standards while fostering financial growth. Consistency in legal paradigms across national borders, which is crucial to establishing the Internet as a reliable conduit for successful global commerce, has been relatively successful in the area of intellectual property. International intellectual property conventions have been consolidated under the auspices of Convention Establishing the World Intellectual Property Organization (WIPO). The Agreement on Trade Related Aspects of Intellectual Property (TRIPs) has formed a WTO–WIPO union by integrating much of WIPO's law into WTO's trade regime (Mort, 1997). Trends in practice also suggest a tendency toward uniformity. This section reviews substantive provisions of the WIPO Copyright Treaty, key terms of the Digital Millennium Copyright Act (DMCA), the European Copyright Directive, and the Electronic Commerce Directive, particularly as they reflect the guidelines for ISP copyright liability. Digital transmissions allow infringers to obtain and disseminate information quickly without being detected. The Internet presents difficult challenges for copyright owners, who want to identify and stop infringers. Locating a financially sound ISP to end the copying activity is the surest route for the copyright owner. This section further examines the discrepancies that exist between the United States and the EU's approach to database protection and business method software protection.

ISP Liability for Third-Party Copyright Infringement

Intellectual property conventions, which predated WIPO's creation in 1967, historically operated independently without institutional oversight (Mort, 1997). WIPO, which was designed as a specialized agency to administer major international conventions under the leadership of the United Nations Director General Secretariat, had difficulty enforcing rights and resolving conflicts. Serving as the sole international authority for over two decades, WIPO lacked the necessary enforcement powers to eliminate piracy of intellectual property. In 1986, as part of the Uruguay Round Negotiations, intellectual property protections were integrated into the General Agreement on Tariffs and Trade (GATT). In 1994, TRIPs was established and a symbiotic institutional relationship between the WTO and WIPO was formed (Mort, 1997). There was a simple integration of intellectual property protection into a trade-based sanction regime. In 1995, a cooperative agreement was signed between the two bodies to coordinate their efforts.

In 1996, WIPO concluded two treaties covering the protection of copyright and rights in digital environments, and the names of those treaties are WIPO Copyright Treaty and WIPO Performances and Phonograms Treaty. The WIPO Copyright Treaty established a distribution, rental, and communication right in creative works to the public. This distribution right under the WIPO Copyright Treaty may be accomplished through sale or other means of transferring ownership, but the right is limited to fixed tangible copies capable of circulation (Soma & Norman, 2000). There was no agreement between the delegates as to the scope of the doctrine of exhaustion for "first sale" rights, so that was left to be defined by each adopting nation. Another important provision of the WIPO Copyright Treaty related to the exhaustion of rights is that the right of public communication permits copyright holders to make their works available by wire or wireless means. Included in this right is the ability to make works available to the public so they can access them as they choose. In the event communication permits recipients to reproduce a tangible copy, national law must define liability for infringement.

The implications of this broad access right is that ISPs could be liable for direct and contributory copyright infringement causes of action that may be brought by the copyright owner against the ultimate recipient. The right created in the WIPO Copyright Treaty leaves details about liability for third-party copyright infringement to the contracting parties. This has caused much concern among telecommunications companies and ISPs, because such a broad interpretation of the treaty could lead to lawsuits from copyright owners (Mort, 1997).

Under case law in the United States, the issue of determining ISP liability for third-party copyright infringement starts with an examination of the type of service the ISP provides in relationship to the infringement claim. The categorization of the ISP is based upon the level of knowledge the ISP had of infringing activity, the control of the ISP, the length of time the material is stored on the ISP server, and any financial benefit received by the ISP. When defined according to function, one will analyze and apply liability to the ISP based upon the traditional common carrier versus publisher/distributor model (Soma & Norman 2000).

In the United States, the Digital Millennium Copyright Act limits ISP liability for third-party copyright infringement where the ISP complies with a detailed system of notice and removal. Where an ISP acts as a mere conduit for data, the DMCA will limit liability of the ISP relating to these transitory communications.

The recently passed EU Copyright Directive follows a logic similar to that of the DMCA in that it exempts ISPs from liability where they play a passive role as a mere conduit of information from third parties. An ISP cannot modify the work in any manner; must comply with industry standards for transmission and storage, and must remove infringing materials expeditiously in order to avoid copyright infringement liability. A third-party copyright infringement case would not be successful unless the ISP had been warned to remove it and did not do so (McDonald, 2001). Finally, the Electronic Commerce Directive, which is similar to the DMCA and the EU Copyright Directive, sets out guidelines for liability for ISPs where they play a passive role as a mere conduit of information from third parties. Similarly, the Electronic Commerce Directive limits ISPs from liability for other intermediary activities, such as storage of information or caching.

Databases

Database protection presents a controversial area of legislation in the global arena. A database, which is a compilation of information, is not protected under copyright law in the United States unless the arrangement or selection rises to a sufficiently high level of originality or uniqueness in its selection or arrangement. Database protection was limited by the United States Supreme Court in *Feist Publications Inc. v. Rural Tel. Serv. Co*., 499 U.S. 340 (1991), where the court held that a white pages directory, which consisted of preexisting factual material, lacked the requisite originality in selection coordination and arrangement of data to garner copyright protection. The simple listing of subscribers in alphabetical order by surname lacked originality, despite the excessive time, effort, and energy expended to organize it. Feist struck down the "sweat of the brow" doctrine, which some U.S. courts had used to find copyright protection. Opponents of greater legal protection for databases believe that the balance between control over information and allowing information into the public domain is best met with few legal restrictions imposed. "Information is meant to be free" is the ideology expressed in support of a reduced role of government. The European countries believe that there are sound economic justifications for affording protection to owners of databases based upon the "sweat of the brow" theory and in 1996 passed the EC Directive No. 96/9, on the Legal Protection of Databases (the Database Directive). The sui generis protection granted to databases is based under the Database Directive on a property concept, which bestows exclusive rights of ownership to the database compiler. The provisions to afford database protection was dropped from the WIPO Copyright Treaty over objections by members of the academic and scientific community, but in the United States, debate over this issue remains. Several legislative bills have been introduced in Congress based upon the belief that such protection would make the United States more competitive in foreign markets. None of these bills has passed as of the time of the this writing.

Software Patents

The topic of patenting software and, in particular, business methods has received a lot of attention from the pubic due to the economic success of several e-commerce entrepreneurs (Gladstone, 2002). The EU and American approach to protection of software has traditionally been reported as divergent, but on closer examination, the two policies appear to be converging, particularly in light of the decline of the heated electronic commerce boom. Historically, intellectual property and software was limited to copyright protection on the grounds that it was written in code, thus it was a literary work, and hence copyright protection was appropriate. In *Diamond v. Diehr,* 450 U.S. 175 (1981), however, the U.S. Supreme Court held that a process for monitoring the temperature inside a synthetic rubber mold using a computer and the Arrhenius equation for measuring cure time as a function of temperature and other variables was patentable subject matter. The court focused on the "postsolution activity" that resulted from the computer program (Cohen & Lemley, 2001). The lesson from the Diehr decision was to include a physical element or step in any future patent application that might recite a "mental process." This theory was adopted and clarified by the Federal Circuit in *In re: Alappat,* 33 F.3d 1526 (1994), which established that an "otherwise statutory process or apparatus requirement may be satisfied by drafting claims to include a general purpose computer or standard hardware or memory element that would be necessary for any useful application of the algorithm." The logic of these cases did not include claims reading on computer programs themselves, as opposed to programs implemented in a machine or system (McDonald, 2001). This obstacle was overcome in the *In re: Boureguard,* 53 F.3d 1583 (Fed Cir., 1995). While an appeal was pending, the U.S. Patent and Trade Office established that software stored in memory media is patentable as an article of manufacture.

Article 52 of the Convention on the Grant of European Patents, October 5,1973, 13 I.L.M. 270, the European Patent Convention (EPC) indicates that computer programs "as such" are not patentable and that programs for computers shall not be regarded as inventions. The European Patent Office (EPO) estimates, however, that they have issued over 20,000 patents on computer programs. In late 2000, there was a diplomatic conference to revise the EPC to change Article 52, bringing it in line with actual practice and with TRIPs, making it clear that patent protection would be available to technical inventions of all kinds (McDonald, 2001). This measure did not pass, however. The reversal and decision to hold onto the old position is interesting in that it reflects a rebellion against the rushed commercialization reflected in the e-commerce boom.

Critical to any discussion of intellectual property rights is finding the correct balance between creating incentives to encourage innovation by inventors and the public's right to access to information and knowledge. The trend in the United States to grant exclusive patent rights to software involving Internet technology continued unabated to the point where the U.S. Patent Office was granting patents on "how to get a business method patent." Beginning with the case of *State Street Bank & Trust vs. Signature Financial,* 149 F.3d 1368 (Fed Cir., 1998), where Signature Financial was granted a patent for a data processing system to implement an investment structure, the court endorsed business methods providing they comply with other requirements for a patent, thus laying to rest "the ill conceived exception to the law" that business methods were not patentable. U.S. patents have been issued on numerous technological processes; the "single click" patent covering a method and system for placing purchase orders via a commercial network that was granted to Amazon.com and contested by Barnesandnoble.com, Inc is one of the more controversial and publicly known cases to be litigated. Although Amazon.com initially was granted an injunction to prevent Barnesandnoble.com, Inc from using the process, the patent is still being challenged (Shulman, 2000).

The trend in the United States to grant patents on software for business methods informed the discussion within the Diplomatic Conference of the European Commission regarding their policy toward granting patents on software. It is likely that the concern over the inseparability of business methods from software patents in general may have encouraged no change in the EPC. Proponents of LINUX, the open source software, which encourages sharing of ideas to promote innovation, began campaigning against software patents in general in Europe in the late 1990s. This development may also have influenced the change in the EPC outcome (Mcdonald, 2000).

The economic downturn of the late 1990s that hit technology companies and Internet startups particularly harshly may have contributed to the slowdown in Internet-related business method patent filings, but the curtailment of the public's endorsement of companies whose sole or main asset was a business method patent was also a key factor. Empirical evidence, which demonstrates the withdrawal of funds from these "idea factories" (Shulman, 2000), suggests that the flurry of business method patents may not have been based on solid economic grounds. The multibillionaire entrepreneur Jay Walker, whose company, Walker Digital, claimed 70 business method patents, with 400 pending before the U.S. Patent Office, needed to lay off 80% of its workforce within a few short years of establishing itself (Shulman, 2000). The profusion of new software business method patents was exciting, but, in fact, they had a chilling effect on e-commerce, and when put to the Wall Street test, most of these companies did not fare very well. Although business method patents are still often being applied for, these are offensive or defensive acts taken to prevent others from gaining market share, rather than with an expectation of employing the patent. The recent decline in enthusiasm of business method software patents in the United States suggests that the EU position, which has been to proceed cautiously before modifying laws to broaden the individuals rights at the expense of the public's access to information, may be the better approach to follow (Gladstone, 2002).

CONCLUSION

The Internet reaches around the globe and it may be unrealistic to expect symmetry between nations, but policy makers must continue to strive for a common ground. There is sufficient legal and empirical evidence to support a nation asserting jurisdiction and enforcing its laws beyond its borders, but enforcement jurisdiction and questions of comity present additional difficulties, as we have seen recently with the internationally recognized Yahoo! case. In the areas of privacy and electronic signatures, discrepancies between countries remain apparent, and these variances are rooted in fundamental cultural, social, and philosophical differences. The Internet has become a medium for widespread commercial activity, but further growth will require agreement regarding mechanisms to regulate in all areas of human activity. Global consensus to limit ISP liability for copyright infringement, the reduction in the business method patent application surge, and the reluctance in the United States to pass a sui generis database protection law suggest a concerted global effort to not limit public access to information and to allow the Internet to serve as a conduit of knowledge dissemination. There is a clearly a trend toward common ground in several areas of intellectual property law in cyberspace. Harmonization in all areas of the law is the goal to strive for, because without seamless predictable systems, businesses and consumers will be reluctant to enter into transactions.

GLOSSARY

Cyberspace Where messages and Web pages are posted for everyone in the world to see. In Reno v. ACLU, 117 S.Ct. 2329 (1997), the first opinion about the Internet by the United States Supreme Court, it was stated that "[t]aken together, these tools constitute a unique medium—known to its users as 'cyberspace'—located in no particular geographical location but available to anyone, anywhere in the world, with access to the internet."

Cybersquatting Where a person or an entity registers a domain name with no intention of using the name for any purpose but to thwart the ability of the rightful owner or trademark holder to obtain the name.

Data Protection The right provided for under the Council Directive 95/45/EC of the European Parliament and of the Council of the European Union of Oct. 24 (1995); also know as the EU Privacy Directive.

Encryption The conversion of data into cipher text, a form of text not easily understood by unauthorized people.

Electronic Signatures in Global and National Commerce Act (E-SIGN) A U.S. law that was passed in 2000 that recognizes the legal effect of an electronic signature in whatever form it is made.

International Safe Harbor Principles The regulatory response of the U.S. government to the "adequacy standards" of the EU Privacy Directive agreed on by the European Commission.

Privacy The right to be left alone.

International Supply Chain Management

Gary LaPoint, *Syracuse University*
Scott Webster, *Syracuse University*

INTRODUCTION

The term "supply chain management" is open to alternative interpretations. We view a supply chain as two or more parties linked by a flow of resources—typically material, information, and money. Supply chain management deals with managing flows of resources among departments within a firm and among independent enterprises.

Some believe there are fundamental differences between supply chain management and logistics management. We disagree. Writings on logistics management have long stressed the importance of a total systems perspective, although there has been a gradual shift of emphasis from a single enterprise focus to a broader multienterprise view today. For example, more than 25 years ago, Bowersox (1974, p. 1) defined logistics management as the process of managing all activities required to move raw materials, parts, and finished inventory strategically from vendors, between enterprise facilities, and to customers.

Approximately 10 years later, Houlihan (1985) stressed the strategic importance and opportunities of interenterprise logistics issues, and introduced the term supply chain management to emphasize this point. This broader view is now reflected in the Council of Logistics Management's (2002) definition of logistics:

> Logistics is that part of the supply chain process that plans, implements, and controls the efficient, effective forward and reverse flow and storage of goods, services, and related information between the point of origin and the point of consumption in order to meet customers' requirements.

In summary, the systems perspective of logistics management has become richer over time, in part because of advancing information technologies that reduce barriers to interenterprise supply chain planning and coordination. In the next section, we discuss how these technologies in combination with new trade agreements are driving rapid growth in international supply chains. There are many laws, processes, and service providers that are unique to international supply chains. The main lesson from this section is that a basic understanding of these laws, processes, and service providers can be essential for a firm's survival, let alone success. This provides the backdrop for a section that reviews laws, processes, and service providers specific to international supply chains. We provide sources for more detailed information and also discuss barriers that are limiting further growth in international supply chains. Finally, we conclude with a chapter summary.

TRENDS IN INTERNATIONAL SUPPLY CHAIN MANAGEMENT

International Trade

The volume of material, information, and money flowing through international supply chains is significant and expanding at a rapid pace. In the United States, for example, import and export trade has been growing faster than the U.S. economy, with this trend expected to continue over the foreseeable future. More than $2 billion worth of cargo is imported into the United States, every day (Toran, 2002). Imports to the United States are expected to grow at an average annual rate of 7.9% between 2000 and 2010 (Su, 2001). Similarly, U.S. exports are expected to grow at an average annual rate of 7.8% between 2000 and 2010 (Su, 2001). About $3 billion of goods and services are exported from the United States every day, with the dollar volume doubling about every 7 years between 1970 and 2000 (Testimony of Under Secretary of Commerce, 2001).

Outsourcing

A closely related trend is the growth in outsourcing in recent years. A 1999 survey found an increasing number of companies are contracting noncore business processes to an outside provider as a means to improve performance

(Global study finds, 1999). In another survey, 50% of executives viewed outsourcing of noncore functions to be critical to improving supply chain performance (Chabrow, 2002).

Outsourcing began to pick up pace in the early 1990s. The main motivation was to reduce cost, although this is less the case today when time-to-market, access to high-quality employees, and workforce flexibility can take precedence (Outsourcing Institute, 2002). Common early outsourcing targets included ancillary activities such as janitorial and cafeteria services. We have since seen a growth in third-party logistics companies as an increasing number of firms have outsourced transportation, warehousing, order fulfillment, and import–export functions. Similarly, a growing number of components and subassemblies that were once produced in house are now being sourced from low-cost regions such as Latin America, the Far East, and Eastern Europe. In 2000, for example, the average contribution of exports of goods and commercial services to the gross domestic products of developing nations was 26%, which represents a 53% increase since 1990 (World Trade Organization, 2002). Today, relatively low-value items requiring fairly simple production methods dominate most offshore sourcing. The capabilities to design and produce sophisticated products requiring skilled labor and complex processes are rapidly advancing in low-cost regions of the world, however. This trend is especially evident in the developing high-tech industrial sectors in the Far East. Original design manufacturers (ODMs) provide design and manufacturing services; in the consumer electronics industry, ODM revenues are expected to increase from $4.5 billion (in U.S. dollars) in 2001 to $77.8 billion in 2005 with most ODMs in Taiwan (Carbone, 2003).

What explains these trends of growing international trade and outsourcing, and what are the implications for management? Let us begin with the first question. Although there are arguably many contributing factors, the Internet and related information technologies in combination with the general lowering of trade restrictions in recent years stand out. The Internet is reducing the costs in both time and money of finding and initiating profitable business ventures, and in realizing efficient collaborative relationships among new supply chain partners. At the same time, the pool of viable business partners is continuing to expand as trade restrictions are being relaxed. We explore both of these factors in the following sections.

Internet and Related Information Technologies

Initially the Internet was a new source of communication; then it became a source of information. Today businesses use the Internet to advertise, take orders, manage inventories, provide information to customers, locate suppliers, and negotiate. The Internet has helped turn a planet of individual economies into essentially one global economy. Buyers and sellers from around the world come together in a virtual market place. Manufacturers are finding suppliers they never knew existed in locations never considered to be a possible source. Likewise, suppliers are finding buyers they never knew existed. A survey found that more than 70% of executives view the Internet as a key factor in fostering greater collaboration with business partners through increased supply chain visibility (Chabrow, 2002). Online purchases are estimated at more than $1 trillion in 2002 (Vigoroso, 2002) and predictions for global business-to-business (B2B) e-commerce range between $4.5 trillion and $8.5 trillion by 2005. International B2B e-commerce is predicted to grow annually at a rate of more than 70% between 2000 and 2005 with the fastest growth in Western Europe and Asia–Pacific (International B2B, 2001). For example, the European Union's online trade represented less than 1% of their total business trade in 2001 and is expected to grow to 22% by 2006. The increase in online trade spurs continued growth as adopters pressure other trading partners to accelerate their use of the Internet for commerce.

There is a wide range of Internet-based technologies and software applications that support the planning, buying and selling, and control associated with the movement of resources through supply chains (see http:// www.freightworld.com/software.html for a list of nearly 200 supply chain management software vendors). Many of these technologies and software applications are discussed elsewhere in this book (see chapters on related topics, such as B2B and B2C electronic commerce, collaborative commerce, customer relationship management, data mining, electronic data interchange, e-manufacturing, enterprise resource planning, e-procurement, extensible markup language, intelligent agents, supply chain management, online analytical processing, and online auctions). Our purpose in this section is to highlight software applications and related Internet-based technologies that are specific to international trade. As the following sections show, the movement of materials across international borders requires extensive and detailed documentation. There are also many (less than obvious) costs associated with steps in import–export processes. These two complexities unique to international trade have given rise to software applications that help streamline document preparation and exchange and that facilitate cost analysis of international sourcing alternatives. Examples of such software applications are briefly motivated and discussed here.

In the wake of September 11, 2001, security has been tightened, and international shipments are more heavily scrutinized. Customs agents in many countries are placing an even greater emphasis on compliance to import–export laws. Even the slightest of errors in paperwork can delay shipments at gateway ports. Bolero.net (Bolero.net, 2002) is an example of a software application that provides tools for preparing requisite international trade documents and for secure electronic document transfer over the Internet. By sending the complete documents ahead of the physical goods, customs clearance and ground handling can be prepared at the destination before arrival of the freight (Global Logistics Group, 2002). Electronic documentation also helps eliminate mistakes in paperwork that can result in significant delays. Other examples are Tradex2000 and ExportDoc Worldwide, which assist shippers in preparing export documentation. The software ensures that shippers enter required information and that all the necessary documentation is prepared. NAFTAssitant is a related software application with a more narrow focus on documents required under NAFTA and on being in compliance with NAFTA regulations (NAFTAssistant, 2002). NAFTAssitant maintains large databases of information on a firm's products such as the country of origin, harmonized tariff schedule numbers, descriptions, and part numbers.

As companies venture into the global marketplace, many lack even basic skills required to import and export. Obviously, making a decision to outsource a component from an international supplier based solely on the unit cost and not the total landed cost per unit would be foolish. But what costs should be included in the analysis? Determining all the costs associated with importing can be elusive, even for experienced importers. Costs may include value added tax, general service tax, duties with possible adjustments for duty drawback, ocean charges, inland transportation and terminal handling fees, to name just a few. Of equal concern is being in compliance with import and export laws. This is particularly difficult because of the myriad regulations and the continual updates to documents such as the Denied Parties List, Specially Designated Blocked Persons List, and the Commercial Control List. Xporta Solutions provides software that enables supply chain managers to compare all the costs associated with various sourcing alternatives. Their software also ensures that imports and exports comply with government regulations.

Extensible markup language (XML) is an example of an Internet-based technology that facilitates electronic document exchange. It is a technology that goes much beyond the realm of international trade and is discussed elsewhere in this book. There is a technology that builds on XML (known as ebXML), however, that is relevant for software applications of the type discussed here. ebXML is an evolving XML-based standard for global e-commerce. It defines computer-to-computer information exchange protocols in an XML framework enabling a standard to exchange business messages, conduct trading relationships, communicate data in common terms, and define and register business processes. ebXML is sponsored by United Nations Center for Trade Facilitation and Electronic Business (UN/CEFACT) and OASIS (ebXML: Enabling, 2002). Both of these organizations were formed to develop and establish e-commerce standards. Many of the software applications for international trade are designed to be ebXML compliant.

The technologies discussed here facilitate buying and selling over the Internet through efficient information sharing, transaction processing, and cost analysis. These technologies are advancing and becoming more widely accessible, reducing barriers to international trade and accelerating import–export processes.

Trade Agreements

New trading blocks have emerged throughout the world during the last decade. Trading blocks are countries that have established trade agreements between one another for the purpose of increasing trade. Trading blocks are typically regional. The primary means of increasing trade is to lower the tariffs on items traded between the countries. There are six trading blocks in the Western Hemisphere alone. Of these six, the North American Free Trade Agreement (NAFTA) is by far the largest in terms of trade. There are, however, discussions on the creation of a South American Free Trade Agreement (SAFTA). Other large trading blocks include the European Union (EU) and the Asia–Pacific Economic Cooperation (APEC). There are many smaller trade agreements throughout the world as well, all designed to ease tariffs and increase trade between selected trading partners (see, e.g., http://intl.econ.cuhk.edu.hk/rta/).

Implications for Supply Chain Managers

Trade barriers are lowering, supply chain management information technologies are advancing, and these technologies are becoming more widely available throughout the world. These factors are behind a long-term trend toward increased international trade and, in particular, supply chains that span an increasing number of countries. The challenge for a firm is to develop the management talent and harness the technologies to exploit this trend. The importance of this challenge is further heightened by the opportunities to penetrate emerging markets. Approximately 83% of the world's population resides in countries comprising 17% of the world's combined gross domestic product (GDP), but the economies in many of these countries are the fastest growing in the world (International gross domestic, 2000). The Far East, Eastern Europe, and Africa, in particular, are emerging as high-growth markets that will likely be a focus of marketers for at least the next two decades. The largest construction projects taking place in the world today are in China and other Far East countries. Companies that are adept at establishing and managing international supply chains will be well positioned to take advantage of these growth markets.

In summary, a firm's ability to identify, establish, and manage relationships effectively among multinational supply chain members has become a strategic core competency. Excellence in this area (a) provides cost, quality, and agility advantages through effective sourcing; (b) increases revenues as a firm is able to quickly move into high growth foreign markets; and (c) is not easily duplicated by others. In the next section, we outline the rudiments of what every manager should know about buying and selling across international borders. We cover the types of international service providers that are frequently used in international trade, and we cover the basic import–export laws and processes. Our coverage of laws and processes is from a U.S. perspective, but many of the features are common to other countries.

ELEMENTS OF INTERNATIONAL SUPPLY CHAINS

International Service Providers

Understanding the roles of key international service providers and establishing strong relationships with such firms is essential for effectively managing international supply chains. The service providers discussed in this section specialize in the movement of materials across international borders. International trading has many more variables than domestic trading, and these added variables increase the chances that orders or shipments can be delayed or assessed fines. Aside from the obvious complications such as distance, time, and language, other notable differences include government restrictions, different currencies, additional handling, different modes of transportation, additional paperwork, customs requirements, and trade terms. There are four commonly used international service providers: (a) customs brokers, (b) international freight forwarders, (c) international carriers, and (d) international banks.

Customs Brokers

Although not required by law, the services of a licensed customs broker are commonly used when importing. Thus, although it is true that individuals can clear their own import through customs, the complexity and periodic changes in requirements dictate a high level of specialized expertise and knowledge. Given the complexities of U.S. import regulations and potential ramifications of improperly importing merchandise, licensed customs brokers are essential players when importing. Being licensed affirms that the broker meets a certain level of competence as required by U.S. Customs to make entry of merchandise into the U.S. and permits a broker to clear freight on behalf of others.

Customs brokers operate on behalf of the importer of record. The importer of record is ultimately accountable for the import. U.S. customs brokers provide preentry services such as preadvance clearing, filing formal entries for shipments valued greater than $2,000, classifying material, paying duty, and performing postentry services (e.g., filing protests on behalf of the importer, filing for duty drawback). Brokers are responsible for maintaining their own records, but contrary to belief among some importers, brokers are not responsible for maintaining records for the importer of record. Federal law requires that the importer of record maintain all documentation used in the importation of material for 5 years. The law is specific as to how these records are to be maintained, including for example, how records are to be filed in a filing cabinet. Rules and regulations pertaining to customs brokers can be found at www.access.gpo.gov/nara/cfr/waisidx_02/19cfrv1_02.html, and general information can be found at the National Customs Brokers and Forwarders Association of America Web site (http://www.ncbfaa.org) and at http://www.customs.gov.

International Freight Forwarders

International freight forwarders act as a middleman between the exporter–importer and the carrier. Freight forwarders can work either on behalf of the shipper (the exporter) or the consignee (the importer). A freight forwarder's business is to move freight as quickly as possible at prices lower than what their client could generally receive on their own. Few exporters–importers ship enough volume to deal directly with an international carrier such as a steamship line or a commercial airline. Freight forwarders contract for space on these carriers by committing a certain level of business based on the total shipping volume of their customer base. By doing so, they can obtain lower rates than what the average shipper could obtain on their own. Although freight forwarders make international trade viable for the smaller to medium size company, even the largest of shippers use them. Having a presence at the ports of entry and contacts at these ports of entry is critical when moving freight internationally. When imported merchandise reaches a U.S. gateway, the slightest discrepancy or question places the merchandise on hold until the question is resolved. Many times the issue is easily resolved if someone is at the port of entry working on behalf of the importer. Otherwise, it can be difficult to make the proper contacts to get the problem resolved in the time frame in which the importer would like it resolved. Without a presence at the ports of entry, there is little urgency for resolution. Most companies cannot afford to maintain this presence with their own staffs.

Some international air freight forwarders are certified by the International Air Transport Association (IATA; http://www.iata.org). The air-freight industry is not regulated, and as such, air freight forwarders do not have to be certified. Air freight forwarders certified by IATA, however, are issued an IATA number. Many commercial airlines will ask for an IATA number before they will accept any freight from an air-freight forwarder.

In 1998 the Ocean Shipping Reform Act deregulated ocean shipping. The Act became effective on May 1, 1999. Part of the Act consolidated ocean freight forwarders with non-vessel-operating common carriers (NVOCCs). The consolidated group is now known as Ocean Transportation Intermediaries. Both ocean freight forwarders and NVOCC's are required to have a bond demonstrating financial stability, but only the ocean freight forwarder is required to be licensed by the Federal Maritime Association. In all practicality an NVOCC, also referred to as an NVO, acts as a carrier with the only difference being they do not operate a vessel. Although an NVO may seem like a freight forwarder, they are not the same. An ocean freight forwarder prepares all the documentation required for shipment and negotiates freight rates, among other activities. The difference is that the paperwork prepared by the forwarder is in the name of the forwarder, not the carrier, whereas, the paperwork prepared by the NVO is essentially in the name of the carrier. Freight forwarders are sometimes the largest customers of NVOs.

From a shipper's standpoint, freight forwarders act as a common carrier. A shipper must be careful to understand that international forwarders limit their liability, however. The prudent shipper will carefully review the liability limitations of an international freight forwarder prior to signing any contract or tendering any shipment.

Two organizations are involved in setting standards and practices in the freight forwarder industry. The first is the International Federation of Freight Forwarders Association (http://www.fiata.com), based in France, and the second is National Customs Brokers and Freight Forwarders of America Association (http://www.ncbfaa.org).

International Carriers

Truck, rail, air, and water are all used for international freight, and multiple carriers are often employed between origin and destination. This even occurs between contiguous countries due to restricted access to foreign carriers. In these cases, which are not uncommon, cargo must be transferred at the border to a carrier based in the country.

Carriers, whether domestic or international, may act as a common carrier or contract carrier. By law, common carriers must accept business from anyone who tenders them business (although there are ways carriers can discourage certain types of business and customers). A contract carrier, on the other hand, has a formal relationship with a shipper, the terms of which are spelled out in a negotiated contract. For situations in which there is a specific need (e.g., critical time frame, cargo requiring special handing) or significant ongoing volume, a shipper may be able to achieve better service or pricing (or both) through a contract carrier than a common carrier.

Shippers can work directly with international steamship lines and air carriers. Most international carriers presell their cargo space to freight forwarders, however, and with the exception of firms with significant volume on a continual basis, it is generally difficult for a shipper to book space. Most shippers do not deal directly with international carriers, other than perhaps UPS and FedEx, which operate their own aircraft. Even integrated carriers such as these will act as a forwarder for some of their international freight. Additional detail on issues relating to international steamship lines and air carriers can be found at the Federal Maritime Commission Web site (http://www.fmc.gov) and the International Air Transport Association Web site (http://www.iata.org).

International Banks

Financial risks are present in nearly every international transaction (e.g., buyer credit risk, political uncertainty, documentation errors, currency fluctuations, interest rate fluctuations). International banks may play a role in reducing financial risk by providing a letter of credit, more commonly known as an LC. An LC provides assurance of the buyer's ability to pay for a shipment, and a shipper may require an LC prior to shipment. This means that a shipper requires the buyer to deposit an amount equal to the value of the commercial invoice in the buyer's bank. When the material arrives, shipping documents are presented to the buyer's bank, which in turn transfers the funds to the shipper's bank to collect funds on behalf of the shipper. LCs can also be used to protect against fluctuating currency and interest rates by setting a value for each and holding those values for a specific period of time. As a word of caution, an exporter should always verify that an LC is in accordance with UCP 500. UCP 500, which stands for Uniform Customs and Practice, is the international convention that governs the actions and obligations of the bank involved in an LC transaction.

International Commercial Terms

International trade requires a thorough understanding of international commercial terms, or Incoterms. Incoterms are analogous to what is known domestically in the United States as free-on-board (FOB) terms. Ignorance of Incoterms can be costly; it is not uncommon for those unfamiliar with Incoterms to be taken advantage of by those who do.

There are 13 Incoterms. A listing and description of each Incoterm can be found at http://www.iccwbo.org/incoterms/wallchart/wallchart.pdf and http://www.ltdmgmt.com/incoterms.htm (see http://www.incoterms.org for more detailed information). Incoterms were created by the International Chamber of Commerce to standardize the terms used for international trade. Great care should be used in selecting the proper Incoterm. Although Incoterms may appear to be written in a manner that is specific and precise, their meaning is often subject to interpretation. Buyers and sellers must clearly define in their sales or purchase contract who has insurable interest and where the insurable interest is assumed. In particular, insurable interest should be clearly defined and detailed when shipments are consigned to a third party, such as a third-party logistics firm or a bank. Each party to a transaction must be well versed in the Incoterm specified in the purchase contract. A shipper or consignee may think the other party has insurable interest in a shipment only to find out after a loss that they did as well.

Another hazard of selecting the improper Incoterm is that a seller can unknowingly be made the importer of record on an order when exporting to another country. For example, suppose the buyer in a foreign country purchases material from the seller who is located in the United States. The U.S. seller exports the shipment to the buyer. One may think that the buyer would become the importer of record. The buyer, however, may have selected an Incoterm that essentially makes it appear to foreign customs that the seller, not the buyer, is the importer of record. The seller is now responsible for clearing the shipment through foreign customs and for paying any foreign duty and taxes that would have otherwise fallen on the buyer. In addition, the seller can be subject to other fees or duties as described by the law in the foreign country.

The 13 Incoterms fall into four groups that correspond to the first letter of the term (i.e., C, D, E, and F). E and F Incoterms minimize a seller's risk and cost and are least favorable to the buyer. C terms create a little more risk and cost for the seller and less for the buyer, and D terms create the most risk and cost for the seller. A seller, for example, should not accept a D Incoterm without a thorough understanding of its implications. The delivered duty paid (DDP) Incoterm, in particular, is the most dangerous from the seller's perspective. DDP can, depending on the country, make the exporter a nonresident importer of the country to which they are exporting. This means the exporter would be responsible for all transportation, duties, and taxes from the point of origin to the customer's dock, as well as any other costs that might be incurred along the way.

U.S. Export Laws and Processes

A shipment is considered an export if the destination of the shipment is outside the United States and its origin is within it. Specific documents are required to export material out of the United States. The particular documents required will depend to some degree on the nature of the product being shipped, the value of the shipment, the type of service required and the destination. A representative list is identified later in the chapter (general references for further information relating to exporting include http://www.tradeport.org/ts/trade_expert/infobase/basic/ and http://www.cia.gov/cia/publications/factbook/).

Transport Documentation

Every shipment must travel with some form of manifest. These are typically referred to as a bill of lading for ground and ocean shipments and an airway bill for air shipments. The bill of lading and the airway bill serve as a contract between the shipper and the carrier. Most international shipments use both a domestic and an ocean (or airway) bill of lading. These documents are typically nonnegotiable, which means that they do not convey title. As such, the carrier can deliver the order without the consignee presenting an original copy of the bill of lading. An order bill of lading, however, is negotiable and is often used in international transportation. If the shipment includes an order bill of lading, then the consignee must pay the value of the invoice to receive the original bill of lading from the shipper. The carrier will not tender delivery unless the consignee can present the original bill of lading to the carrier. Only then does title of the merchandise pass from seller to buyer. In essence, an order bill of lading is similar to a domestic cash-on-delivery (COD) shipment.

Shippers Export Declaration (SED)

Unless specifically identified as an exception in the export administration regulations, an SED will be required for every export shipment in which any individual line item is valued at $2,500 or more. For example, if an order consists of 10 line items and the value of each line item is less than $2,500, then no SED is required, even though the value of the entire shipment may exceed $2,500. A shipment is defined as all merchandise moving from one exporter to one consignee on one exporting carrier. Separate SEDs are required for each shipment.

The shipper or their designated agent prepares the SED. The person who signs the SED must be in the United States at the time of signing. The person who signs the SED, whether exporter or agent, is responsible for the truth, accuracy, and completeness of the SED, except insofar as that person can demonstrate that he or she reasonably relied on information furnished by others. As of November 1, 2001, SEDs must be filed electronically with U.S. Customs. If the shipping location is not capable of electronic filing, then a forwarder, agent, or the carrier must file the SED. The forwarder, agent, or carrier's authority to sign the SED must be executed by a formal power of attorney.

Commercial Invoice

A commercial invoice is required for every export shipment. Unlike SEDs, there are no exceptions. Foreign customs offices use the commercial invoice to determine the duty rates for imported merchandise. The commercial invoice contains the following information: (a) Country of origin for each item, (b) seller's name and address, (c) buyer's name and address, (d) description of the items being shipped, (e) schedule B number (this number, which is referred to as a harmonized tariff schedule number on imports, is a code that is used to determine the duty rate), (f) extended value of each individual line item, stated in U.S. dollars.

For customer orders, the value used on the commercial invoice must reflect the transaction value for that merchandise. If a U.S. company conducts business with its foreign subsidiaries on an arm's-length basis, prices charged to their foreign subsidiaries are to reflect the competitive conditions in the market and be comparable to prices charged to large unrelated customers.

Packing List

A packing list must accompany every export shipment. The packing list contains the (a) description of the material being shipped, (b) quantity, (c) shipper's reference number, and (d) customer purchase order number.

Certificate of Origin

Some export shipments may require a certificate of origin. This is not a requirement of U.S. export law but a request on the part of the buyer or a requirement of foreign customs. The certificate of origin is a document, usually signed by an officer in the company, attesting to the country of origin of merchandise described on the commercial invoice.

Export License

Export licenses are required if a shipment is consigned to anyone or any country identified on restricted trade lists maintained by the U.S. government. These lists are discussed in more detail later (see Other Considerations).

Miscellaneous Documents

In some circumstances, other export documents may be required. Some examples are listed in the following sections.

Fumigation Certificates or Declaration. Some countries require U.S. shippers to produce a fumigation certificate or a declaration stating that the packaging or crating material is made from nonconiferous wood. If the packaging or crating is made of coniferous wood, then the wood must either be fumigated or heat treated to kill any insects that may inhabit the wood. These requirements are country specific. If crating, packaging, or fumigation is performed by an outside service, the service will be required to complete and sign the fumigation certificate or declaration.

Inspection Certificates. Some customers may require inspection by a certified inspector prior to shipment. Upon inspection, the inspector will complete an inspection certificate that is typically faxed to the buyer before the shipment takes place. The certificate states that the shipment meets the requirements of the importer or the importer's country.

Hazmat Documents. In the event that a product is hazardous, a hazmat bill of lading or hazardous airway bill is required. Many air carriers will not accept international shipments of hazardous material, so any such shipments will require investigation to see which, if any, air carrier will accept the shipment.

Consularization. Some Middle Eastern and Latin American countries require export documents to be consularized, or stamped, by their foreign consulate prior to export. Consularization is a formality that certifies the shipment to be exported to that foreign country. A certificate of origin and a commercial invoice must be presented to the foreign consulate. Some consulates will stamp the documents with an official stamp, whereas others will issue a consular invoice. If a consular invoice is generated, then the original document must travel with the shipment and be presented to the foreign customs.

Destination Control Statement. A destination control statement (DCS) is required for all exports from the United States for items that are restricted for export by the U.S. government. Lists of restricted persons and countries are discussed later (see Other Considerations). The DCS is a statement to the consignee (receiver of material) that they cannot forward this shipment on to another party without the permission of the shipper.

ATA Carnet. One little-known tool that can be useful for exporting equipment or material that needs to move around while in a foreign country is the ATA carnet. (ATA stands for admissions temporary admissions.) The ATA carnet is like a passport for merchandise that allows temporary importation of products free from duties, taxes, and security deposits. It permits material to move freely within a foreign country for the duration of the carnet. Material traveling under an ATA carnet enters a foreign country duty free; when the material returns to the United States, it enters the U.S. duty free as well. The ATA carnet is particularly useful for trade show or exhibition materials. Carnets are not universal. They are currently accepted in 58 countries and 27 territories (Advincula, 2001). See http://www.uscib.org for a list of countries that accept carnets.

Other Considerations

During the 1990s, and particularly since September 11, 2001, the U.S. government has intensified its scrutiny of both import and export shipments. Specific individuals within the customer service organization process export orders in many medium size to large size companies. Prior to releasing an export order to the warehouse or the factory, these individuals must review several government alerts to ensure that the countries, individuals, or organizations receiving these materials either directly or indirectly are not restricted by the U.S. government. The following items must be reviewed prior to release of every export order to the warehouse or the shipping floor to ensure that the order is not in conflict with established regulations.

Denied Persons List (DPL). The DPL is maintained and updated by the Bureau of Industry and Security, formerly known as the Bureau of Export Administration (BXA). U.S. law prohibits exports to individuals and businesses on the DPL. The DPL is available at http://www.bxa.doc.gov/dpl.

Commerce Control List and Economic Control Commodity Number (CCL/ECCN). The CCL is maintained and updated by the Bureau of Industry and Security. The list identifies all commodities that are restricted for export by the U.S. government. Every item on the CCL is assigned an economic control commodity number (ECCN). If an item is listed on the CCL, then proper authorization must be received from the U.S. Department of Commerce prior to export. Authorization is typically in the form of an export license. The CCL is available at www.access.gpo.gov/bis/ear/ear_data.html.

Embargoed Nations List. The U.S. government has identified nations with which it strictly forbids conducting business, either directly or indirectly. This list is maintained and updated by the U.S. Treasury Department, Office of Foreign Asset and Control. The embargoed nations list is available at http://www.treas.gov/ofac.

Special Designated Nationals and Blocked Persons (SDNB). The SDNB is maintained and updated by the U.S. Treasury, Office of Foreign Asset and Control (OFAC). The SDNB contains the names of individuals, organizations, and business concerns whose assets have been frozen by the U.S. government. Conducting business with those who appear on the SDNB is prohibited unless approval in the form of a license is received from OFAC. The SDNB list is available at http://www.treas.gov/ofac.

In addition to reviewing these issues, the export manager must also be familiar with the International Trade on Arms Regulations (ITAR) and the Antiboycott Regulations. ITAR defines the regulations associated with the exportation of products that can be used as a weapon or in conjunction with a weapon such as a component or as part of a weapon system. Items of concern are identified on the U.S. Munitions List in part 121.1 of ITAR (see http://www.pmdtc.org/reference.htm#itar).

Antiboycott laws prohibit U.S. citizens and U.S. firms and their subsidiaries from participating in foreign embargoes that the U.S. government does not sanction. The effect is to prevent U.S. firms from being used to implement foreign policies of other nations that run counter to U.S. policy. For example, it is in violation of antiboycott regulations for a customer in a foreign country to require that a particular airline of a specific foreign country not be used to ship their order. Antiboycott regulations are maintained by the Bureau of Industry and Security (BIS) and can found at http://www.bxa.doc.gov/antiboycottcompliance.

Foreign subsidiaries of U.S.-based companies are required to comply with the same U.S. export laws. The penalties for violating these restrictions can be harsh. Criminal and civil penalties can be assessed against violating companies, including revoking a company's export privileges. Additionally, individuals who were associated with the violation can be held personally responsible and can be subject to personal fines or imprisonment depending on the severity of the offense.

U.S. Import Laws and Processes

A shipment is considered an import if the destination of the shipment is the United States and its origin is outside of the United States. The party responsible for the import is referred to as the importer of record. The importer of record is responsible for U.S. Customs clearance, and duties and taxes associated with the import. Generally the importer of record is the buyer of foreign merchandise. With the exception of the shippers export declaration, the documents required for importing are the same as for exporting. Mandatory items include a manifest, commercial invoice, packing list, and either a bill of lading or airway bill. The same miscellaneous documents used in exporting can also be found in importing.

For the most part, an importer requires a licensed U.S. Customs broker to clear the shipment through U.S. Customs and an import bond. The bond ensures that U.S. Customs gets paid the duty it is owed. Bonds can be purchased individually as imports arrive or a company can purchase a continuous bond, which is also known as a surety bond. A continuous bond permits a large importer from having to purchase a bond each time it receives an import.

Another form of bond is the temporary import bond, commonly referred to as the TIB. The TIB allows an item to enter the U.S. duty free on a temporary basis with the requirement that the item will be exported out of the U.S. within 1 year. During that year, the item cannot be sold or transferred. If at the end of a year the material is not ready to be exported, the importer can apply for a TIB extension. If the item fails to be exported during the term of the TIB or if the item is sold, then U.S. Customs can, and generally will, levy fines and penalties on the importer.

There are two key areas for U.S. import compliance. The first is known as the entry. When an import arrives at a U.S. gateway, it must be cleared to enter the United States. This is where the customs broker comes in. The customs broker will prepare an "entry" that will permit U.S. Customs to process the shipment and allow it to enter the country. The entry form contains four main pieces of information pertaining to the shipment. First, the entry form identifies the origin of the shipment to ensure the material is not originating from an embargoed nation or a specially designated national and blocked person. Second, the entry form identifies the harmonized tariff schedule (HTS) classification number used to describe the item(s). The HTS classification determines the duty rate of an item. Also, certain items are subject to countervailing or antidumping duties, so proper classification of an item is critical. Third, the entry form identifies the value of the shipment so a duty can be calculated. Fourth, the entry form identifies whether or not the two parties involved in the transaction are related. It is unlawful for an importer to take advantage of a related party by having it assign a value to a product that is unreasonably low for the purposes of lowering the duty. Because duty is based on the value of a good, a lower value would result in a lower duty assessment. It is the broker's responsibility to ensure that the information on the entry is accurate.

The second key area of U.S. import compliance is record keeping. In 1993, the 103rd congress passed the Customs Modernization Act also referred to as the Mod Act. The Mod Act shifts the legal burden to exercise "reasonable care" in conducting international trade onto the trade community (Linet, 2002). Prior to the Mod Act, U.S. Customs had assumed the responsibility of ensuring that imports were in compliance. U.S. Customs requires all importers to maintain records of their import activities. "Any owner, importer of record, consignee or their agent who imports or knowingly causes goods to be imported into the customs territory of the United States shall make and keep such records in accordance with U.S. Customs regulations" (Tariff Act, 2002). Many U.S. companies unknowingly think that because they use a customs broker that the broker is responsible for maintaining the importer's records. This is a serious misjudgment on the part of the importer. The broker is only required to maintain its own records, not those of the importer.

U.S. Customs may audit the records of any U.S. company at any time. The North American Free Trade Agreement (NAFTA) also permits the Canadian government to audit the records of a U.S. company that has shipped goods from the U.S. to Canada under NAFTA. Importers should conduct a self-assessment of their import procedures to determine if they are in compliance with U.S. Customs regulations (see http://www.customs.gov/xp/cgov/import/regulatory_audit_program/ for self-assessment guidelines). In addition, a firm should keep a record of all inquiries made to U.S. Customs. Inquiries can be in the form of requests for a ruling or requests for assistance in classifying an item. Finally, internal import and export procedures should be documented.

Assists

An assist is when a U.S. firm provides assistance to a foreign supplier to produce or provide merchandise that will eventually be sold and exported back to the United States firm. An assist can be in many forms. Common forms of assists are financial assistance, manufacturing equipment, tools, dies, molds, technical drawings, intellectual property, and some forms of technical advice.

The U.S. firm, which in this case is also the importer of record, is accountable for the duty on the value of the assistance given to the foreign supplier at the duty rate applicable to the finished product being imported. For example, suppose a U.S. firm provides $100,000 in startup capital to a foreign concern to make a product that the U.S. firm will in turn purchase and import back into the United States. Additionally, the U.S. firm also sends the foreign supplier tools and dies totaling $250,000 in value, and the finished product, when imported into the United States will be subject to a 5% duty rate. This means that the U.S. firm, in addition to the normal duty on the finished product, will have to pay $17,500 ($350,000 × 5%) on the value of the assist.

Often a U.S. company will purchase foreign merchandise through a purchasing agent, even material they have arranged to have made for them as just described. This removes the responsibility of arranging transportation and customs clearance from the U.S. firm. It does not, however, remove the obligation of paying for the assist. The U.S. firm is responsible for notifying the purchasing agent of any assists so that the purchasing agent can pay the assist when the merchandise is imported. The purchasing agent would in turn charge the U.S. firm for the amount paid to U.S. Customs.

Foreign Trade Zones

Foreign trade zones (FTZs), also known as free trade zones and enterprise zones, are specific areas within a country that have been designated as a duty free zone. For customs purposes these zones are considered to be outside the country, and thus, no duties are paid when merchandise enters an FTZ. Merchandise leaving an FTZ for domestic use must go through customs and duties must be paid. FTZs offer a number of advantages for importers and exporters (Ballou, 1999), including the following:

- Deferral of duties until the point in time when product is needed within the host country.
- Imported goods may be temporarily stored or modified and assembled in an FTZ, then shipped to another country with no duties or customs processing.
- Errors in documentation can be corrected in an FTZ prior to going through customs, thereby avoiding fines.
- Product subject to spoilage, damage, and loss do not incur duties on the amount lost.

The main disadvantage of an FTZ is reduced revenue from import duties by the host country.

In the United States, FTZs fall under the supervision of the U.S. Customs Service and the Foreign Trade Zone Board. There are two types of FTZs in the United States: (a) general purpose and (b) special purpose subzones. A general purpose FTZ is typically licensed to a municipality, public agency, port authority, or industrial park to operate on behalf of the general public. A subzone, on the other hand, is a site authorized by the Foreign Trade Zone Board to operate as an FTZ but is generally not physically located in an FTZ. Subzones are usually licensed to specific firms, frequently as a manufacturing site or distribution center. They are designed to permit companies to receive the benefits of a FTZ without being physically located in the FTZ. At present there are 256 general purpose FTZs and 438 single company subzones operating within the United States. Web sites maintained by the Foreign Trade Zone Board (http://www.ia.ita.doc.gov/ftzpage), the National Association of Foreign Trade Zones (http://www.naftz.org/body_what.htm), and U.S. Customs (http://www.customs.gov) contain additional detail on FTZs.

Barriers to Growth

There remain several barriers limiting faster growth in international trade. First, although progress is being made (e.g., ebXML), there are no widely accepted and used standards for global e-commerce. Different countries and companies operate using different protocols. The United Nations has created UN/CEFACT, the United Nations Centre for Trade Facilitation and Electronic Business, to help develop a global standard in conjunction with other standards organizations.

Another barrier is currency. At present there are hundreds of currencies each with their own valuations. Large and unpredictable variations in currency value make it difficult to trade in some regions of the world. Much discussion is beginning to take place on the merits of common currencies. To increase international trade, there will invariably have to be a reduction in the number of currencies used in trade, either by combining currencies, such as in the case of the Euro, or through the use of currency unions or currency boards. Barter is still used in some instances, but that does little to improve local economies and can only be used on a limited basis. In the not too distant future, there may only be a few key trading currencies. This is emerging today. The Euro currently includes 12 European countries and will surely spread to others. The U.S. dollar is already used as the primary currency in many countries, and many others have linked their currencies to the U.S. dollar. It is conceivable that as trading blocks merge to form super trading blocks, each trading block will develop a common currency. Frankel and Rose (2002) found that common currencies increase bilateral trade by a factor of three. As we have seen with the Euro, however, creating common currencies is difficult.

Security measures for U.S. imports are tighter today than before September 11. In January 2002, U.S. Customs initiated the Container Security Initiative (CSI) as a means to ensure the integrity of container shipments entering the United States. The initiative requires inspection of ocean container contents, either through direct physical examination or via noninvasive methods, at the foreign port of embarkation. In addition, all ocean carriers and NVOCCs are now required to send an electronic manifest 24 hours prior to the loading of the vessel at a foreign seaport. Depending on where a shipment is originating, it has been estimated that this new requirement will delay a shipment from 2 to 4 business days (TDC Trade.com Business Alert, 2002). As a result, shippers need to have material at the seaport at least 1 week earlier, resulting in approximately 20% more inventory in the pipeline. Increased security by U.S. Customs at U.S. ports of entry is also causing delays. Companies can reduce delays by participating in the Customs Trade Partnership Against Terrorism (C-PAT), however. By participating in C-PAT, a company agrees to conduct a comprehensive self-examination of its supply chain security using guidelines established by U.S. Customs and by the trade community (U.S. Customs, 2002). The primary benefit to companies who participate in C-PAT is less scrutiny by U.S. Customs on inbound shipments, which translates to lower processing times at ports of entry and border crossings.

CONCLUSION

We argued that the Internet and related information technologies in combination with a lowering of trade restrictions are driving growth and opportunity in international supply chains, and that these conditions are likely to extend into the foreseeable future. The primary implication being that a firm's ability to effectively identify, establish, and manage relationships among multinational supply chain members is becoming increasingly attractive as an area for top management attention and investment. It is not a simple endeavor to develop this ability into a strategic core competency because of the breadth and complexity of international trade. If attained, however, such competency is not easily duplicated and as such presents significant opportunities with respect to both supplier and customer markets. Strength in this area exposes opportunities for cost, quality, and agility improvements through sourcing and for revenue growth because a firm is in position to move quickly into high-growth foreign markets.

GLOSSARY

Assist A relationship in which a U.S. company provides assistance to a foreign supplier to produce or provide merchandise that will eventually be sold and exported to the U.S. company in the United States. Duties are paid on the value of the assist.

Carrier A term denoting the firm providing transportation services to a shipper.

Commercial invoice A document required for every export and import shipment. It contains such information as country of origin, buyer and seller names and addresses, descriptions of products being shipped, harmonized tariff schedule codes, and product values.

Consignee The receiver of a shipment.

Duty drawback The recovery of duty paid on an import when the item is later exported out of the United States.

Foreign trade zones (FTZs) Specific areas within a country that have been designated as a duty-free zone.

Free-on-board (FOB) terms U.S. domestic shipping terms that determine when title and risk passes between the seller and buyer.

Freight forwarders Entities that provide domestic and international shipping services. Most do not operate their own vehicles. They obtain lower rates by acting as a consolidator and contracting with common and contract carriers.

International commercial terms (Incoterms) Trade terms used in international commerce (e.g., international equivalent of FOB terms). They define the costs, risks, and obligations of buyers and sellers in international transactions.

International freight forwarders Entities that act as middlemen between the exporter and importer and the carrier.

Harmonized tariff schedule (HTS) Used by governments to classify material and to determine duties. The schedule contains classification numbers for products. For U.S. imports these numbers are called HTS numbers, for U.S. exports these numbers are called schedule B numbers. The first six digits of the HTS number are universal. The remaining digits are country specific.

Import bond A certificate insuring that U.S. Customs gets paid the duty it is owed. Import bonds are required for imports to the United States. An import bond is also known as a surety bond.

Importer of record Generally the buyer of foreign merchandise that has the merchandise imported into its country.

Non-vessel-operating common carriers (NVOCCs) Found in ocean shipping only, these are considered common carriers, but they do not own or operate a vessel. NVOCCs and freight forwarders are similar in function and process except a freight forwarder cannot sign paperwork on behalf of the carrier whereas an NVOCC can.

Packing list A document that must accompany every export—import shipment. It identifies what is being shipped, the quantity, the shipper's reference number, and the customer purchase order number.

Shipper A term used in transport documentation to denote the seller of the merchandise.

Third party logistics firms Entities that provide comprehensive logistics services (e.g., transportation, ware housing, order processing), thus representing a significant third party complementing the parties of buyer and seller.

Trading block A group of countries that have established trading agreements for the purpose of increasing trade between the participating countries. A trading block is also known as a regional trading agreement.

U.S. customs brokers Brokers licensed to clear imports into the United States that ensure all the necessary paperwork for entry is in order.

Internet Architecture

Graham Knight, *University College London, United Kingdom*

INTRODUCTION

The Internet is a rather loose assemblage of individual networks; there is little in the way of overall administration. The individual networks are owned by a huge number of independent operators. Some of these are major corporations with large, high-capacity networks; others are private individuals operating tiny networks of two or three computers in their homes. Between them these networks employ just about every networking technology yet invented. The great strength of the Internet is that it allows these diverse networks to act together to provide a single global network service.

The interactions between a network and its neighbors are, in essence, both simple and robust. This makes for easy extendibility and fuelled the early growth of the Internet. New participants needed only to come to an agreement with an existing operator and set up some fairly simple equipment to become full players. This was in great contrast to the situation within the world of telephone networks, where operators were mostly large and bureaucratic and where adding new interconnections required complex negotiation and configuration and, possibly, international treaties.

This chapter is organized into four main sections. I begin with a discussion of network interconnection and how a new service, the IP service, enables it to be achieved. In the second section, I look at how useful applications can be built on the IP service. Next I take a more detailed look at how the IP service is provided in practice. Finally I take a brief look at how the Internet is developing into a "multiservice" network capable of carrying many types of traffic.

NETWORK INTERCONNECTION—THE IP SERVICE

The Internet story began in the early 1960s with the invention of the idea of sending data through computer networks in discrete lumps (called "packets") rather than as continuous streams of bits. In general, large objects such as computer files would need to be chopped up into several packets and reassembled at the destination. A major early experiment in packet-switching was the ARPANET instigated by Leonard Kleinrock, Lawrence G. Roberts, and others and sponsored by the U.S. Department of Defense. By the end of 1969, the ARPANET was up and running, with four computers connected. The network grew over the next few years and began to support applications such as file transfer and electronic mail. In 1972, Bob Kahn, who had been influential in ARPANET design, began to turn his attention to network interconnection or "internetting." One of Kahn's key insights was that there would, in the future, be many independent networks, each based on a different technology. He recognized that it would be impossible to require all these networks to be compatible with the ARPANET way of doing things. Instead he designed an open "Internetworking Architecture." Essentially, networks could do what they wanted internally, but if they wanted to interwork with other networks they would need to implement the interworking architecture as well. Kahn, in collaboration with Vint Cerf, went on to flesh out these basic ideas. They devised a set of rules called the "transmission control protocol" (TCP), which specified how two computers should cooperate to provide reliable delivery of data across the internetwork. Shortly after, it was recognized that not all applications would want the same levels of reliability guarantees, so TCP was split in two: one part provided reliability and retained the name TCP; the other part dealt with the delivery of packets and was called the "Internet protocol" (IP). TCP and IP have survived, unaltered in most important respects, until today—a tribute to their designers in the early 1970s.

The ideas of Kahn and Cerf were soon put into practice in a three network "internet" consisting of the ARPANET itself, a packet radio network and a packet satellite network. The latter gave the internetwork, an international reach with a node at University College London in the United Kingdom run by Peter Kirstein. Originally it was thought that one day there might be perhaps 100 participating networks. The invention of local area networks (LANs) in the 1980s changed all that and brought an explosive growth in the number of participating networks which, today, are numbered in hundreds of thousands. In 1986 the U.S. National Science Foundation funded a backbone network linking five supercomputing centers. This network (NSFNET) grew into the first real Internet backbone with connections to many countries around the world. By 1995 it was clear that the Internet, for many years a research and academic network, had a major commercial future, and NSFNET's backbone role was handed on to a set of linked commercial network providers.

Network Technologies and the Services They Provide

The fundamental components of the Internet are "packet networks" (called simply "networks" for the remainder of this chapter). This term indicates any technology that is capable of transferring data packets from one computer to another; Figure 1 shows an abstract view of such a network. Usually many computers are attached to the network, which consequently provides them with "addresses" that can be used to specify the source and destination of packets. Most of the computers connected to networks are classified as "hosts." These are computers than run programs; desktop PCs and servers come into this category. A few computers provide functions related solely to network operation. For example, "gateways," "routers," or "bridges" relay packets between networks.

There is a huge variety of technologies that fit into this general model. For example, LANs such as Ethernet (Metcalfe & Boggs, 1976) use so-called medium access control (MAC) addresses. These are 48-bit addresses allocated by the manufacturers of the interface cards that are plugged into the hosts. The "network service" provided by a LAN is simple: a computer constructs a packet including a destination MAC address and asks the network to deliver it—exactly like posting a letter. This is termed a "connectionless" (CL) service. A rather different style of service is provided by, for example, asynchronous transfer mode (ATM) (Vetter, 1995) networks. In these networks, there is an initial negotiation phase during which the computer tells the network what kind of data it wants to send and the address of the destination. This gives the computer the opportunity to specify the quality of service (QoS) it requires (bounds on throughput, transit delay, etc.). The network must decide whether it can meet the request. If it can, it tells the computer that a "connection" has been established to the destination and that data transfer can begin. This is similar to making a telephone call in which one dials a number and establishes a call before speech can begin and is termed a "connection oriented" (CO) service. Addresses in CO networks are used only during the connection set up phase.

Interconnection via "Convergence"

Virtually all networking technologies provide services similar to those just described, even though the mechanisms they use to implement the service may be radically different. Within these broad categories, however, there are many awkward differences: Each technology imposes its own limit to the size of packet that may be sent, each has its own idiosyncratic addressing scheme, some technologies allow subtle control of QoS others do not, and so on. These differences pose difficulties for network interconnection. We cannot simply take a packet from one network and forward it onto the next; all sorts of subtle transformations would be needed. The solution

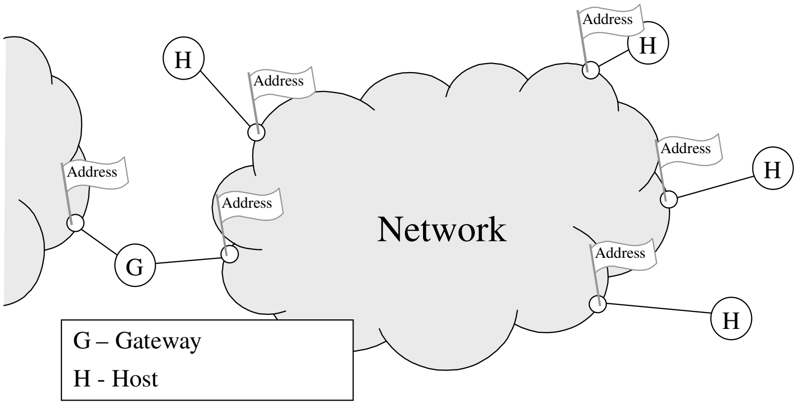

Figure 1: An abstract view of a network. Computers, termed "hosts" have physical interfaces to the network. These interfaces have addresses. The network is capable of delivering packets to hosts identified by their addresses.

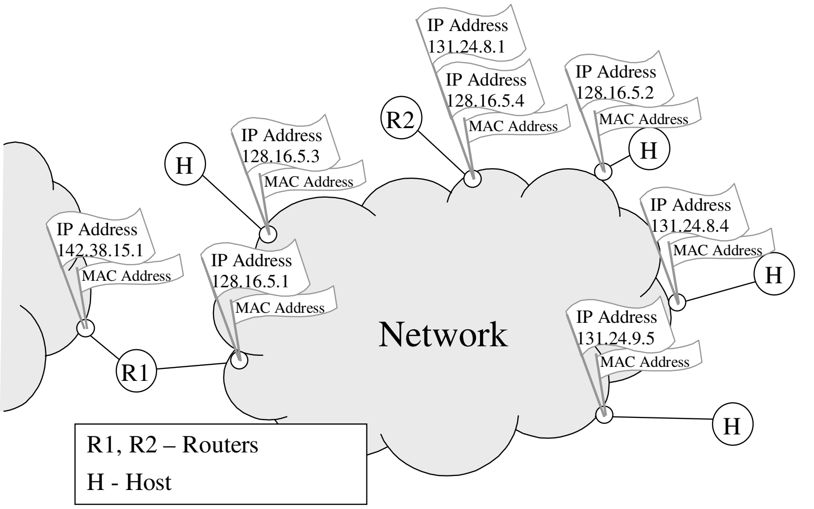

Figure 2: Internet protocol addresses allocated to network interfaces. In this case, the first 16 bits of the IP address identify the "IP Network." Thus there are three IP networks: 142.38, 128.16, and 131.24.

is "convergence." We invent an abstract network service and, for each networking technology, we provide "convergence functions" to implement the abstract service. Through these means we make all networks look the same and the interconnection problem becomes manageable.

The Internet Protocol—A Convergence Protocol

The IP provides a convergence function. Version 4 of the protocol (still the most widely deployed) and the abstract network service it implements are specified in RFC 791 (Postel, 1981a) published in 1981. (Many Internet RFCs, or Requests for Comment, are cited in this article. All are available online on the Web site of the Internet Engineering Task Force: http://www.ietf.org/rfc.html.) The service is a simple CL one that allows single packets (called IP datagrams) to be sent to destinations identified by "IP addresses." An IP address is a 32-bit quantity that is divided into two portions. The first portion, the "network prefix," identifies an "IP network" (sometimes now called an "IP subnetwork"). The second portion identifies an interface on that network. The 32 bits are normally written as four decimal bytes separated by dots (e.g., 128.16.5.2).

Hosts, IP Networks, and Routers

Figure 2 shows the network from Figure 1 set up to implement the IP service. Each interface has now acquired an IP address in addition to its original "technology-based" address. To make things a little more concrete, we will assume the networks are LANs, in which case the "technology-based" addresses will be MAC addresses. An important point is illustrated here: An IP network is an abstract thing and does not necessarily correspond one-to-one with a physical network. In Figure 2 we see one physical network partitioned into two IP networks (128.16 and 131.24). The reverse is also possible with several physical networks operating as a single IP network. Traffic is relayed between one IP network and the next by devices called "routers" (the term "gateway" was used in early Internet documents and survives to some extent).

The basic algorithm for delivering an IP datagram to its destination is broadly as follows:

```
If (destination network prefix = = "my"
  network prefix),
  send datagram direct to its destination
  across the local physical network
else
  choose a suitable router
  send datagram to router across the local
  physical network
```

This algorithm is executed by the source host and, if necessary, by a succession of routers along the path to the destination. Thus a datagram sent from host 128.16.5.2 in Figure 2 to host 128.16.5.3 would be sent directly while one to host 150.23.4.1 would probably be sent to router interface 128.16.5.1. Note that this router interface belongs to the same IP network as the source host, a requirement of classical IP operation. To make the configuration in Figure 2 complete we have had to add a second router (R2) so that the hosts in the 131.24 IP network can communicate with the rest of the world. This router is mandated solely by the Internet routing architecture; it provides no additional physical connectivity.

The step in the algorithm "choose a suitable router" is easily stated but less easily implemented. Sometimes there will be several possible routers, and hosts and routers must maintain "routing tables" indicating which router is the best one to use as the "next hop" on the path to a particular IP network. Because there are hundreds of thousands of IP networks in the world, maintaining such tables can be a problem. In practice, most tables contain

entries for just a few "local" IP networks. Datagrams for all other networks are sent to a single "default" router which, it is hoped, will know what to do with them.

IP Addresses

We have assumed that the network prefix part of the IP address is 16 bits. This means we can have 16 bits to identify the individual interfaces on each network a total of $2^{16}(= 65{,}536)$, which is a large number of interfaces to have on one network. Therefore, the IP designers decided there should be three classes of IP address to suit the requirements of small, medium, and large networks. For small networks, the network prefix is 24 bits and the host part 8 bits, allowing 256 hosts (in fact, it is 254 because one is used for "this host" and another for local broadcast). Obviously routers need to know how many bits there are in the network prefix because these are the bits they look up in their routing tables. This information is encoded in the first few bits of the address according to the following scheme, where N indicates the network prefix and H the host part:

Class A	0NNNNNNN	HHHHHHHH	HHHHHHHH	HHHHHHHH
Class B	10NNNNNN	NNNNNNNN	HHHHHHHH	HHHHHHHH
Class C	110NNNNN	NNNNNNNN	NNNNNNNN	HHHHHHHH

The Internet Assigned Numbers Authority (IANA) is the top-level authority for allocating IP addresses. IANA delegates authority over blocks of addresses to regional authorities who, in turn, allocate blocks to Internet service providers (ISP). Finally ISPs assign IP addresses to end users.

The IP Datagram and the Service It Offers

The basic IP service is simple; a host constructs a packet of data and gives this to the IP service along with the IP address of the destination. The IP service then makes its "best effort" to deliver the datagram. The service offers no guarantees of success, however. It may lose the datagram without informing either the source or the intended destination, delivery may be subject to arbitrary delay, two datagrams dispatched to the same destination may be misordered on arrival—it may even deliver two copies of one datagram. If an application running in a host finds this rather cavalier attitude toward service unacceptable, it is up to the application to do something about it. For example, many applications exploit the TCP (Postel, 1981b), which keeps track of wayward datagrams, retransmits missing ones, and ensures sequenced delivery. (More details on TCP are provided later.)

In fact, simplicity is the IP service's greatest strength and one of the main reasons for its considerable success. A simple convergence protocol is easy to implement, which encourages its deployment on as wide a range of technologies as possible. Having only minimal features in the network service maximizes flexibility for applications running in hosts. For example, some applications may happily tolerate the occasional lost datagram, especially if this avoids problematic costs and delays imposed by retransmission. If the network service itself took on the responsibility for retransmission these applications would suffer. Thus the design exemplifies the end-to-end argument as propounded in Saltzer, Reed, and Clark (1984).

IP datagrams themselves have a simple structure consisting of a header (typically 20 bytes) plus a "payload," the data the datagram is carrying across the Internet. The header format is shown in Figure 3. The fields are interpreted as shown in Table 1.

Implementing the IP Service

The IP datagram delivery algorithm given earlier includes the phrase "send datagram direct to its destination across the local physical network." We must specify how this is to be done for each network technology. The three main issues involved in this are discussed next.

Encapsulation in "Native" Formats

Each network technology specifies its own packet format. Usually this consists of a header, which often contains addresses, followed by the data payload, perhaps followed by a checksum used to detect errors. In essence, encapsulation means we construct our IP datagram and make this the payload of the packet. Figure 4 shows this in the case of Ethernet (note that it is common to refer to Ethernet "frames" rather than "packets"). Encapsulation would be similar for the other LAN technologies that have been standardized by the IEEE. CRC (cyclic redundancy check) is a checksum intended to discover transmission errors.

It is important to remember the strict division of labor here. The Ethernet technology pays no regard to

Table 1 Meanings of the IP Header Fields

IP Header	Meaning
Internet Protocol (IP) Version	4 for IPv4, 6 for IPv6
IHL	The length of the IP header (normally 20)
Type of Service	This is discussed in the section on quality of service
Total Length	Total length in bytes (including the header)
Identification, Fragment offset	Used to implement fragmentation
Flags	Bits used to mark special status of a datagram
Time to Live	A counter that is reduced by one by each router through which the datagram passes; when it reaches zero, the datagram is discarded, ensuring misrouted datagrams do not circulate forever
Protocol	A number to identify the protocol that this datagram is carrying (transmission control protocol, user datagram protocol, etc.)
Header checksum	Used to pick up transmission errors that might corrupt header fields.
Source/Destination Addresses	Discussed earlier
Options	Rarely used (space precludes discussion here)

the payload; it is interested only in the Ethernet header and the CRC checksum. Likewise, Internet technology—routers and so on—is interested only in the IP datagram and its header.

In practice things may be slightly more complex than Figure 4 suggests. An Ethernet may be carrying other protocols in addition to IP datagrams. Systems processing incoming Ethernet frames need to be able to determine what protocol the frame is carrying. This entails the insertion of another header between the MAC and IP headers. This header will include a "protocol identifier," a "well-known" number indicating "this is an IP datagram."

Some technologies require special treatment. ATM, for example, uses small packets, called cells, each of which carries 48 bytes. An associated standard, ATM Adaptation Layer 5 (AAL5), explains how a larger packet, an IP datagram, for example, can be fragmented into cells and reassembled at the destination.

Address Resolution

Each network technology has its own addresses; in this chapter, these are termed "physical addresses." Obviously a technology understands its own physical addresses; no networking technology understands IP addresses, however. These are processed exclusively by the convergence function. Once the IP delivery algorithm has determined whether an IP datagram can be delivered direct or whether it must be sent to a router, we are left with the problem of determining the correct physical address to use. The business of mapping from an IP address to the corresponding physical address is called "address resolution." Two techniques are used to achieve this:

1. Most LANs have a "broadcast service." All systems attached to the LAN will receive and process a frame sent to the MAC broadcast address. For address resolution a frame is sent to the broadcast address containing an address resolution protocol (ARP) (Plummer, 1982) request for the desired IP address. The host that recognizes the specified IP address as its own replies with an ARP response containing its own MAC (physical) address.
2. For nonbroadcast network technologies it is normal to deploy an ARP server that maintains a table of mappings. Attached systems register their mappings with the ARP server at boot time. Systems that need to resolve a IP addresses send ARP requests to the server and receive ARP responses.

In both cases, mappings are cached by the requesting system for future use.

Fragmentation

Each network technology imposes its own limit on the number of data bytes that may be carried in a frame,

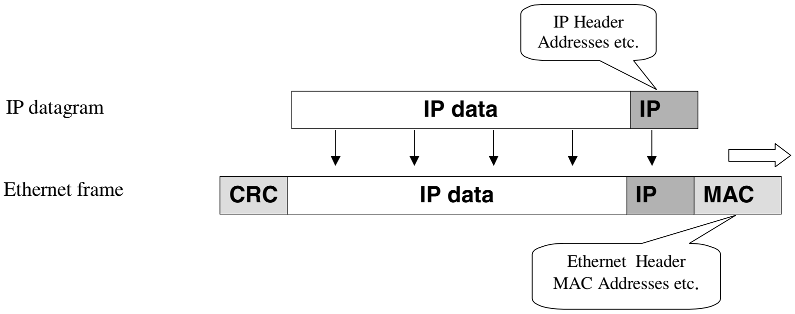

Figure 4: Simple encapsulation of an Internet protocol datagram in an Ethernet frame; the datagram simply becomes the payload of the frame.

referred to as the maximum transfer unit (MTU). These limits pose problems for IP because the path to a destination may traverse dozens of networks and the system that originates the IP datagram knows only the first hop of the route. Consequently, it cannot know the MTU of the complete path (the "path MTU"). In IP version 4 (IPv4), this is solved by allowing hosts and routers to fragment datagrams. An IP datagram that is too large will be split into two or more smaller IP datagrams (each complete with its IP header). The destination host will reassemble the original IP datagram from the various fragments.

Unfortunately fragmentation is not an efficient procedure. Suppose the originating system generates a series of IP datagrams of length 1,600 bytes, and somewhere along the path there is a network with an MTU of 1500 bytes. Every IP datagram will be split into two fragments doubling the work for the remaining routers along the path. If the originating host knew the path MTU in advance, it could have divided its data into 1,500-byte pieces, avoiding fragmentation and causing less work for the routers. A second problem arises if one fragment of a datagram is lost. Reassembly will not now be possible so all the work done by the networks and routers in delivering the other fragments will have been wasted.

The modern approach is to avoid fragmentation in routers by probing the network to discover the path MTU. This can be done by sending IP datagrams with a flag set that means "do not fragment." A router that is unable to forward such an IP datagram because it exceeds the MTU for the next hop network must discard it. When it does so, it sends an Internet control message protocol (ICMP) message (discussed in a later section) back to the originating host explaining what has happened. The originator can then try again with a somewhat smaller IP datagram. This is the approach favored in the latest version of IP, IP version 6 (Deering & Hindon, 1998), which actually prohibits fragmentation in routers.

BUILDING ON THE IP SERVICE

It is clear that the service provided by IP is inadequate for some applications. Several IP datagrams may be needed to carry one Web page. We care that all these datagrams are delivered exactly once and in the right order. There are many applications that have similar requirements. Rather than each of them inventing its own mechanisms to meet them a common protocol—TCP—is used.

TCP—The Transmission Control Protocol

TCP is an "automatic repeat request" (ARQ) protocol; such protocols send packets of data that each include a sequence number. It is up to the receiver to check the sequence numbers, ensure that all packets have arrived, and reorder them if necessary. The receiver sends "acknowledgment" packets back to the transmitter. The transmitter retransmits packets that are not acknowledged sufficiently promptly. In the TCP case, the packets are termed "segments," each of which is carried in an IP datagram. Each segment consists of a TCP "header" (containing the sequence and acknowledgment numbers) that may be followed by a block of data (see Figure 5). At any instant there are likely to be data bytes that have been sent but not yet acknowledged. A limit, termed a "window," is set on the number of these bytes. This window is specified by the receiver in the acknowledgments it sends. By reducing this window the receiver may slow down or even stop the flow of data. This flow control mechanism is essential in preventing a slow receiver from being overwhelmed by a fast transmitter.

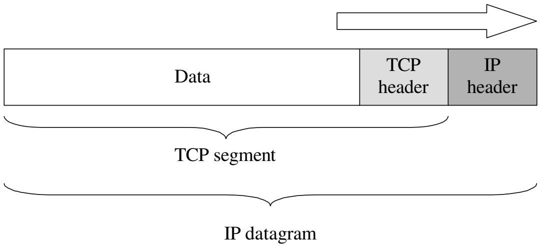

Figure 5: A transmission control protocol (TCP) segment carried in an Internet protocol (IP) datagram. Coincidentally, both the TCP and IP headers are normally 20 bytes long. The data part may be any length subject to a limit imposed by the network technology in use. See also Figure 4.

The TCP protocol, although it uses the IP service, is independent of it. The components that implement the IP service, including all the routers, are interested only in the IP header—the fact that a particular IP datagram is carrying a TCP segment is of no importance whatsoever to these components. The components that are interested in TCP are the pieces of software that implement the logic of the TCP protocol. These exist in the end systems or "hosts"; typically such software is supplied as part of an operating system such as Linux or Windows.

This independence between the TCP "layer" and the IP "layer" is illustrated in Figure 6. TCP is just one possible "transport protocol" and will be used for most applications that require reliable, sequenced delivery. Logically we can think of the two TCP modules in the hosts as exchanging segments and acknowledgments directly with each other (represented by the broken, horizontal arrow). Physically, however, a TCP module must pass its segments down to the local IP module (also a piece of software within the operating system) that will wrap it in an IP datagram and send it on its way. The IP module at the receiver will unwrap the IP datagram, retrieve the TCP segment, and pass this up to the local TCP module. This is represented by the vertical arrows.

TCP's Role in Congestion Control

A weakness in the Internet architecture is the limited control over congestion it affords. Just as in road transport networks, congestion occurs when too much traffic attempts to pass through a particular point. Were the IP layer CO, there would be an opportunity to refuse new connections if these seemed likely to overload some router along the path. The Internet's basic CL service has to accept all the traffic that is thrown at it, however, and do the best it can. TCP can help alleviate this problem. As part of its normal operation a TCP module becomes aware of dropped or delayed IP datagrams because these manifest

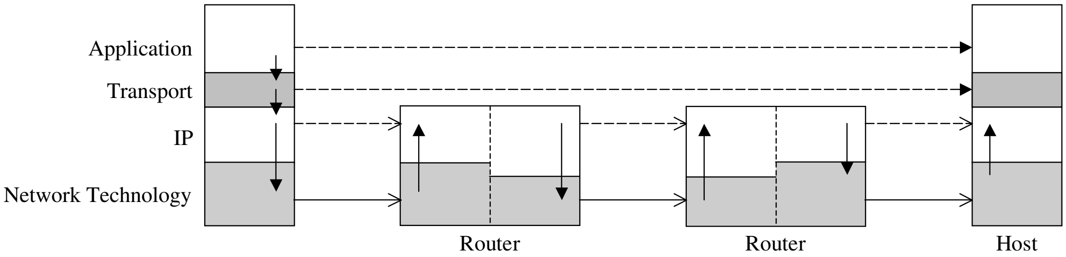

Figure 6: The fundamentals of the Internet architecture. The Internet Protocol (IP) layer provides convergence, allowing many network technologies to take part. It also provides the relaying operation from router to router toward the destination host. Above IP comes the "transport" layer," which is where TCP fits. This layer is entirely the responsibility of the hosts.

themselves as missing or delayed TCP acknowledgments. When these occur, TCP concludes (usually correctly) that congestion is occurring and employs a "congestion control" algorithm attributable to Jacobsen (1988). This algorithm results in TCP temporarily slowing its data transmission rate. If all the TCP connections passing through the congested router behave in this way, the congestion should be relieved.

This mechanism has been observed to work well in practice. Unfortunately there has been a recent growth in real-time applications which, typically, use user datagram protocol (UDP; Postel, 1980) rather than TCP. UDP is almost a null protocol and lacks all of TCP's reliability and congestion control mechanisms, leaving such issues to the applications themselves. Efforts are being made to endow such applications with "TCP-like" behavior, but it seems unlikely that this alone will suffice to deal with the congestion problem. Some kind of resource management inside the Internet seems essential; approaches to this are outlined in the final section of this chapter.

Ports—Identifying Applications and Processes

Hosts are identified by IP addresses. Assuming we know the IP address of our intended recipient, the IP layer will (usually) deliver our IP datagram successfully. We need also to identify a particular application or process present on the host, however. This is the role of transport layer ports. Here one can draw a close analogy with telephone extensions; the telephone number (IP address) identifies the building, the extension number (port) identifies an individual within the building. All Internet transport protocols include source and destination ports in their headers; these are simply 16-bit integers.

A "client-server" model is assumed; the client is the piece of software that initiates requests, the server software waits and responds to client requests as these arrive. Public services usually use "well-known" ports (see Table 2). Thus, when a browser (client) requests a page from a Web server, the TCP segments it sends will have the destination port set to 80 in the TCP header. The operating system on the server host will have a table that tells it that port 80 is the WWW server. It will ensure that the WWW server software receives the incoming data and processes it. The client system chooses a source port. It should choose a value that is not currently in use for any other purpose. This source port will be used as the destination port in any replies from the server.

Other Internet Transport Protocols

Some applications do not need the reliable sequenced delivery provided by TCP, especially because TCP buys this reliability at the cost of delays when retransmissions occur. A great strength of the Internet architecture is that such applications can select a different transport protocol. The simplest is the UDP, which adds nothing to the basic IP service; however, its simple header does include the ports necessary for application selection. UDP is a popular choice for delay-sensitive applications and also for applications that just need to send one message and get one reply. It is sometimes favored by applications that work mostly within a LAN; for example, the SUN Network File System (NFS) can use UDP instead of TCP.

Several other protocols are in widespread use, including the real time protocol (RTP; Schulzrinne, Casner, Frederick, & Jacobson, 1996), which provides sequence numbering and time stamping for applications such as streamed audio and video. Sometimes two transport protocols are used in tandem: RTP is often carried inside UDP datagrams; Transport Layer Security (TLS; Dierks & Allen, 1999), which provides authentication and confidentiality, may be used in conjunction with TCP.

Table 2 Some "Well-Known" Transport Ports and Associated Protocols.

SERVICE	PROTOCOL	"WELL-KNOWN" PORT
HTTP (Web server)	TCP	80
FTP (FTP server)	TCP	21
Telnet (Remote rlogin)	TCP	23
SMTP (e-mail)	TCP	25
DNS (Name and address mappings)	UDP	53

Note. A client wishing to contact one of these services will use these as the "destination port" in the messages it sends. DNS = domain name service; FTP = file transfer protocol; HTTP = hypertext transfer protocol; SMTP = simple mail transfer protocol.

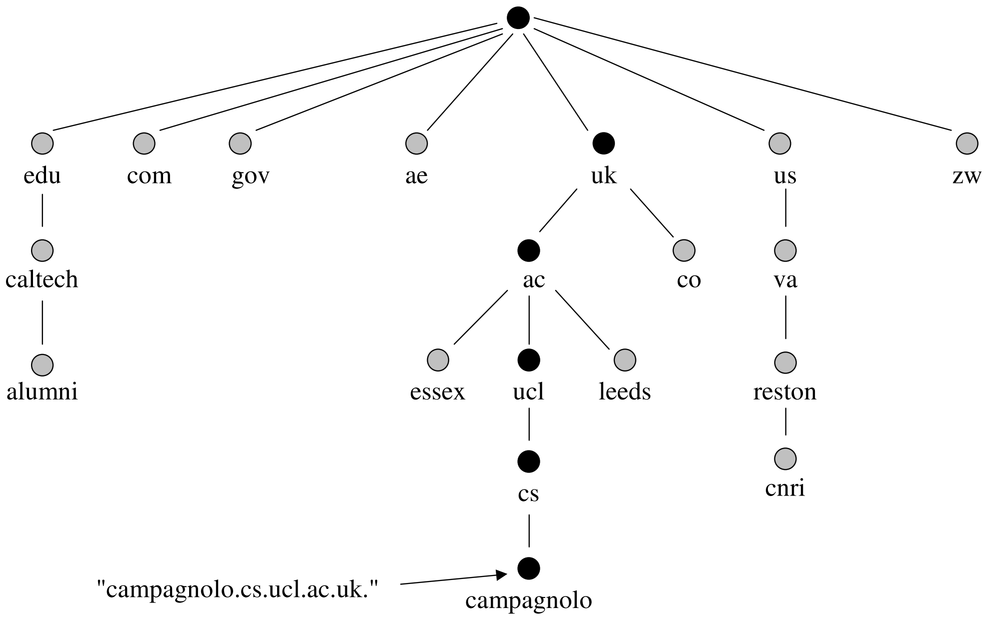

Figure 7: A portion of the domain name tree.

Naming Internet Objects

We have seen that IP addresses provide globally unique labels for the interfaces between computers and the Internet. Such numeric labels, like telephone numbers, are efficient for computers but not especially memorable for humans. They are also liable to change according to technological diktat—for example, when a computer is moved to a new IP network. Furthermore, the Internet makes many other sorts of object accessible—networks, e-mail accounts, files, and so on—and we need globally unique labels for these. Internet domain names (DN; Mockapetris, 1987a) solve these problems by providing a systematic way of generating globally unique and reasonably user-friendly names. Like other schemes with similar objectives the DN scheme relies on a recursive devolution of authority over the namespace.

Figure 7 shows a portion of the domain namespace. Each node (leaf or nonleaf) represents a domain that consists of itself and all the nodes in the subtree beneath it. A fully qualified domain name is a concatenation of the labels on the path from a node all the way back to the root (e.g., *campagnolo.cs.ucl.ac.uk*). The authority for a zone is responsible for ensuring that no two sibling nodes have the same name. The top-level domains include the worldwide generic domains (*com*, *org*, *net*, *edu*, etc.), two U.S.-only generic domains (*mil* and *gov*), and country code domains (e.g., *us* for the United States, *uk* for the United Kingdom, etc.). Each authority has its own rules for name allocation and each may delegate authority over subdomains. For example, in the United Kingdom, the Department of Trade and Industry, which administers the "uk" domain, has allocated an "ac" subdomain and has delegated authority over it to a joint-board of UK universities. This board has allocated domains, and delegated authority, to individual universities.

Although the principal use of DNs is the naming of computers and interfaces, they can be used for any purpose. Furthermore, there are no inherent relationships between domains and IP networks. It happens that the computer named "*campagnolo*" with address 128.16.23.3 belongs to the Computer Science department of University College London, an academic institution in the UK and its DN, *campagnolo.cs.ucl.ac.uk*, reflects this closely. There is nothing to stop the department from allocating the name to a computer on some other network in some other country, however; the name is theirs to use as they like.

The Domain Name System

The domain name system (DNS; Mockapetris, 1987b) is a distributed directory service that supports, among other things, the automatic mapping of DNs to IP addresses. Generally speaking, each domain must provide a computer on which runs a DNS "nameserver" that maintains a table of mappings for the names in its domain. This is termed the primary nameserver for the domain. The DNS protocol allows hosts to query these mappings and so to map names onto addresses. Local DNS servers hold mappings for local machines and answer queries for these directly. Nonlocal names are passed on to other DNS servers. Figure 8 illustrates this when a local nameserver cannot resolve the DN *www.ibm.com*. Steps 2 through 5 show the iterative mode; the query is passed to the *root* nameserver for the *com* domain which refers its questioner to a different nameserver. The local nameserver will cache the result of the query so that, next time around, we will see, at most, steps 1 and 6. As with all caching strategies, there is a danger that the cached information will become out of date, so a timeout is used. In addition to this, nameserver responses always contain a flag to indicate whether they are *authoritative,*

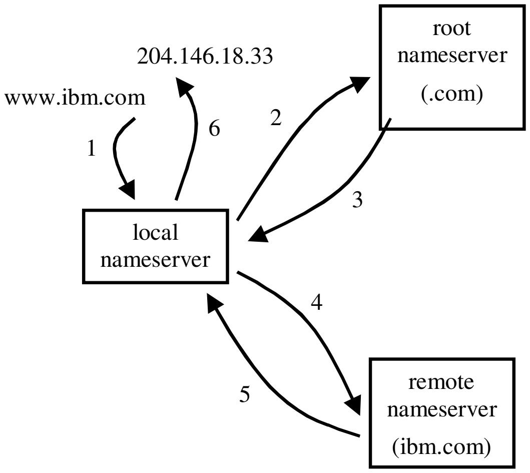

Figure 8: Distributed operations in the domain name system. The name cannot be resolved by the local nameserver, which passes the query to the nameserver for the top-level (com) domain and so on.

that is, whether they come direct from a primary nameserver.

The DNS can answer a number of other queries. Especially important are "MX" mappings. These map a DN used in an e-mail address to the name of a host willing to accept mail for the domain. Thus an e-mail client wishing to deliver a message to *bloggs@cs.ucl.ac.uk* can discover the mapping *cs.ucl.ac.uk* ⇒ *smtp.cs.ucl.ac.uk*.

Universal Resource Locators

Universal resource locators (Berners-Lee, Fielding, & Masinter, 1998) are the familiar URLs used on the World Wide Web. The URL format is flexible; however, most URLs that users encounter have the following format:

```
<protocol>://<domain name>/<local name>
```

The `domain name` is a DN as described in the previous section. It identifies a host on which runs a Web server program that has access to the resource (a file for example) identified by `local name`. Although it is common for hosts used for this purpose to be given a DN starting "WWW," there is no particular need for this, and any name will do. The `protocol` indicates the application protocol to be used when contacting the WWW server. These days this is usually the hypertext transfer protocol (HTTP; Fielding et al., 1999), described in a later section It is still quite common, however, to see FTP, the original Internet "file transfer protocol" (Postel, 1985).

Internet Applications

Like transport protocol modules, applications are implemented by software residing in hosts. Application software exchanges messages across the Internet. In the most widely used applications, these messages are formatted using structured ASCII text. For example, a browser application (Internet Explorer, Netscape etc.) uses HTTP to retrieve information from a Web server. An example of an HTTP "GET" request message is the following:

```
GET http://www.cs.ucl.ac.uk/research/index.html HTTP/1.0
Authorization: Basic QWxhZGRpbjpvcGVuIHNlc2FtZQ==
```

HTTP employs TCP in the transport layer. Therefore HTTP messages like the one above (encoded into binary using ASCII codes) will form the data part of a TCP segment. If all goes well, the HTTP response will include the file "index.html." Typically this is likely to be too big to fit into a single TCP segment, so several will need to be sent. Other familiar applications (e.g., FTP for file transfer and simple mail transfer protocol [SMTP] for e-mail; Klensin, 2001) use similar protocols. Designing such protocols is a matter of deciding what messages need to be sent, under what circumstances each needs to be sent, and specifying the format to be used.

Some application protocols provide generic services on which specific applications can be built. Among this group are the Remote Procedure Call and Remote Invocation protocols such as CORBA and Java RMI. These adopt an object oriented model with one part of the application invoking operations on objects on a remote host. Each operation requires parameters to be sent and results to be returned. CORBA and Java RMI provide general mechanisms for handling these aspects.

In most operating system environments applications exist in user (rather than kernel) space. To operate they need to interact with the transport layer modules that usually reside in the kernel. The operating system will provide a set of system calls to support basic operations such as opening a TCP connection, sending or receiving a block of data, and so on. The so-called socket system calls, which originated with Berkeley Unix, are a widely adopted standard.

MAKING THE IP LAYER WORK

The previous sections established the basic components of the Internet architecture:

- An Internet layer, which allows IP datagrams to be sent to destinations identified by IP addresses;
- A transport layer, which enhances the Internet layer service to provide a service satisfying an application's requirements; A variety of transport protocols exist, each of which resides exclusively in hosts and operates end to end
- An application layer, which includes multiple applications, each of which employs a suitable transport layer

This section considers the operation of the Internet layer in more detail.

IP Routers

I have already described the basic algorithm for IP delivery. Every IP router implements this algorithm and applies it to each IP datagram it receives. The router must make such a "forwarding decision" for every IP datagram it receives. The router must look at the destination IP address, extract the network prefix, and look this up in its routing table. As a result of this look-up, the router will know the IP address of the "best" next-hop router (or host). Once this has been accomplished, all necessary fragmentation, encapsulation, and address resolution can be performed and the IP datagram dispatched. This style of operation is called "incremental routing" because each router concerns itself only with the next hop of the route and not with the complete route.

In this section I take a second look at network prefixes and consider how routing tables can be maintained.

IP Networks, Subnets, and Supernets

Recall that an IP network is a logical entity—a collection of interfaces in which all IP addresses share a common network prefix. The three IP address classes described earlier have proved insufficiently flexible. Class C IP networks (254 hosts) are too small for many organizations, whereas class B IP networks (65534 hosts) are too big. The problem is exacerbated by the fact that there can only be 2^{14} (= 16384) class B IP networks, and most of these have already been allocated. Consequently, most allocations today are for class C IP networks, and large organizations end up with multiple class C IP networks. This causes problems with the "classical" Internet delivery algorithm presented earlier because it insists that an IP datagram sent between distinct IP networks must travel via at least one router. On the face of it, this will force the introduction of many routers simply to satisfy the model assumed by the delivery algorithm. At the other extreme, an organization lucky enough to have a class B network may nevertheless want to install internal routers. These may be needed to allow interconnection between two dissimilar network technologies such as Ethernet and ATM. Another motivation is the desire to partition a large LAN into several smaller LANs; large LANs can suffer from many "collisions" as multiple hosts compete to send traffic. The classical delivery algorithm requires that distinct network prefixes must be used on either side of such routers,–so it is necessary to ask for additional IP networks.

The solution to these problems is to abandon the class-based address scheme and to employ subnets and supernets.

Subnets

Suppose an organization possesses the class B IP network 128.16 and wishes to operate internally as several small networks linked by routers. Using subnetting the organization may decide that, internally, 20 (for example) rather than 16 bits should be used for the network prefix. This allows 16 subnets with network prefixes (in binary) as follows:

10000000.00010000.0000
10000000.00010000.0001
...
10000000.00010000.1111

A new notation is needed to specify an IP subnetwork address under this scheme. Using this notation the second address above would be written 128.16.16.0/20 whereas the original class B address would be written 128.16.0.0/16. An alternative (and obsolescent) way of expressing the same thing is to give a "subnet mask." This is an IP address with 1s in place of all the network prefix bits, 0s otherwise. The mask for the scheme above would be 255.255.240.0 (11111111.11111111.11110000.00000000 in binary).

Table 3 16 Class C IP Network Addresses Sharing the Same First 20 bits.

11010010	00110010	10100000	210.50.160
11010010	00110010	10100001	210.50.161
11010010	00110010	10100010	210.50.162
11010010	00110010	10100011	210.50.163
...	...	...	...
11010010	00110010	10101111	210.50.175

Of course none of this will be effective unless all the routers and hosts involved know that 20-bit network prefixes are in use. They must be told this explicitly—an extra piece of configuration for each participating system.

Note that subnets are an internal matter. To the outside world the network just described still appears as a single class B IP network. This is valuable because it means that external routers need only have one routing table entry for the whole IP network.

Supernets

If care is taken in how one allocates multiple class C IP networks to an organization, they can be made to look like a single, larger IP network. Table 3 shows 16 class C IP network addresses chosen so that they share the same first 20 bits.

This can be treated as a single "supernet" with address 210.50.160.0/20—an example of so-called classless interdomain routing (CIDR; Fuller, Li, Yu, & Varadhan, 1993). Unlike subnets, supernets generally are visible externally. It is important that they are visible because this means that an external router need have just one routing table entry for the supernet rather than 16 entries for the individual class C IP networks.

Routing Tables

Figure 9 shows a configuration of networks and subnets that we can use to illustrate the use of routing tables. (In reality, there would be many more hosts; most have been omitted for clarity). We assume this configuration is operated by a single administration that has decided to partition its class B IP network into several subnets. The main partition is into three 20-bit subnets, two on the main site and one for a set of remote machines which are accessible via ISDN (integrated services digital network). (Note that ISDN is not an IP network, it merely provides links between a router on the main site and those at the remote sites.) The "remote" subnet is further partitioned. This kind of sub-subnetting assists with routing.

Consider the transmission of an IP datagram from host *dharu* on the main site to host *mavic* on remote site B. The routing table on *dharu* can be very simple (Table 4). Our datagram for *mavic* (128.16.23.2) matches the default

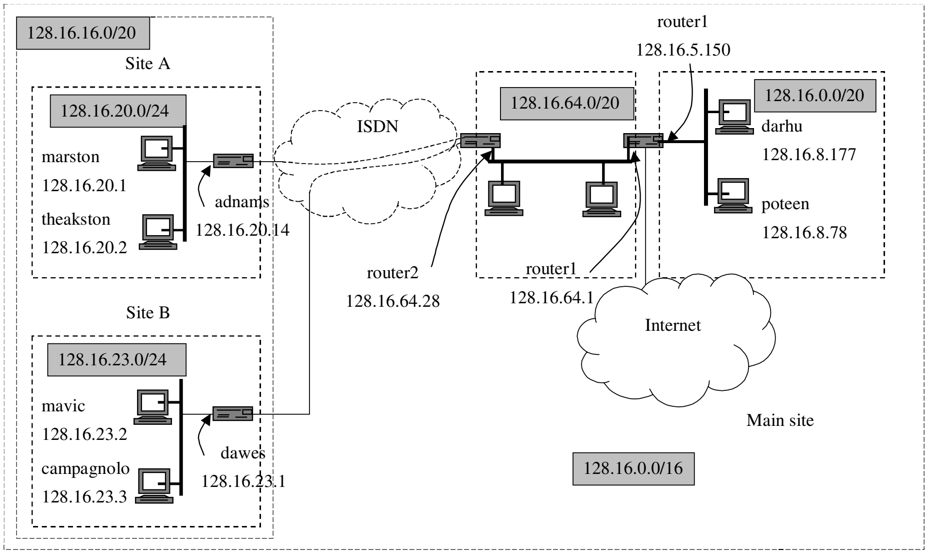

Figure 9: A class B Internet protocol network (128.16.0.0/16) partitioned into two subnets for the main site (128.16.0.0/20 and 128.16.64.0/20) and one for remote sites (128.16.16.0/20). The remote site subnet is further partitioned into two 24-bit subnets.

entry and so will be forwarded to *router1*. *Router1* is the main router giving access to the rest of the Internet. Its routing table could be large but must include at least the entries shown in Table 5. These include entries for the two local subnets and the entire remote subnet; notice that there is no need to have separate entries for each individual remote site. Our datagram matches the first entry and so will be sent to *router2*. *Router2* does need to distinguish between the various remote sites (Table 6). Here ISDN1 and ISDN2 represent the two ISDN calls. These are dial-up calls and would be managed so that they were only set up when data needed to be transferred. Our datagram matches the third entry and so will be sent to the router called *dawes*.

Suppose now that *mavic* is important so that we wish to have a permanent connection to it rather than relying on ISDN; we might lease a line between *mavic* and *router2*. We would now need to modify *router2*'s table (Table 7):

In Table 7 we now have a special entry for *mavic* (note that there is no need to put anything in the "next hop" column because there is only one possible destination at the other end of the leased line). Our datagram now matches two entries; there is a 24-bit match for the third entry and a 32-bit match for the fourth entry. This is a common situation and the tie-break rule is "choose the longest prefix match".

In some cases another factor is included in the forwarding decision a "metric" signifying the cost of a particular route. This can be used to choose between two otherwise equivalent routes to a destination. Many metrics can be used. The simplest is a hop count, an estimate of the number of routers along the route to the destination. Other possibilities are estimates of delay, error rate, or throughput along a particular route. Some systems maintain multiple metrics and choose which one to use according to the QoS to be given to the datagram (this is discussed in more detail in a later section). If we are using a dynamic routing protocol (see next section), the metrics may vary with time to reflect changing network conditions.

It is clear from this discussion that the forwarding decision can be complex. Because this decision must be made for every datagram passing through a router, its efficiency is crucial to router performance. Router manufacturers expend a great deal of effort in devising clever ways of speeding up the forwarding decision and so increasing the throughput of their systems.

Routing Information

It is crucial to Internet operation that information in routing tables is both timely and accurate. If routers have inconsistent information, it is possible for a datagram to circulate among a group of routers without ever reaching its destination—a "routing loop." The problem is compounded by the fact that the Internet is controlled by thousands

Table 4 Internet Protocol Routing Table for Host *dharu*

NETWORK	INTERFACE	NEXT HOP
128.16.0.0/20	Ethernet	Direct
Default	Ethernet	128.16.5.150

Default	Ethernet	128.16.64.1
. . .	. . .	. . .

of independent and autonomous administrations. A section of the Internet run by a single administration is called an autonomous system (AS). An AS is free to decide for itself how to manage routing internally. It may employ "static routing" whereby routes are worked out by hand and the corresponding routing tables are installed in all the administration's routers. Alternatively, the administration may decide to adopt a "dynamic routing protocol" that enables routers to exchange information on the current state of the network and so derive routing tables according to some algorithm. Most routers within an AS have detailed knowledge only of networks and subnets belonging to the home AS. Traffic for a network in "foreign" AS will be sent, by default, to a router that acts as an "exterior gateway," that is, one that has a link to an exterior gateway belonging to a neighboring AS. These exterior gateways exchange information on which networks they can reach. These exchanges enable exterior gateways to learn plausible routes for reaching any network on the entire Internet.

Dynamic Routing and Routing Protocols

The original Internet architects were keen to ensure that, as far as possible, the Internet would be self-managing. For example, if some Internet component failed or its performance was degraded, the network should automatically reconfigure so as to direct traffic away from the problematic component. Dynamic routing protocols can help to achieve this. Early work on the ARPANET adopted a routing protocol of a class called "distance vector." These work as follows.

Periodically each router receives reports from its neighbors containing estimates of the neighbors' "distances" from other networks. The information in these reports is combined with information about local links so as to derive a new routing table. For example, if a router measures its current distance to neighbor X as 10 and X reports its distance as 100 from network Y, this means that Y is reachable via X at a distance of 110. Various measures of distance have been tried. The original ARPANET algorithm used queue length—the number of datagrams awaiting transmission on a link. The routing information protocol (RIP; Malkin, 1998), which is still in widespread use, uses a simple hop count. Changes occurring in network state are reflected in local measurements made by routers. These, in turn, are reflected in the information sent to neighbors in the next periodic routing update. Unfortunately, this means that many periodic updates must take place before all routers become aware of a change in network state. Until this occurs routers will have an inconsistent view of network state and routing loops can occur. This and other problems with distance vector algorithms has led to widespread adoption of an alternative class of algorithm called "link state." The "open shortest path first" (OSPF; Moy, 1998) routing protocol is of this type.

Table 7 Modified Internet Protocol Routing Table for Router 2

NETWORK	INTERFACE	NEXT HOP
128.16.64.0/20	Ethernet	Direct
128.16.20.0/24	ISDN1	128.16.20.14
128.16.23.0/24	ISDN2	128.16.23.1
128.16.23.2/32	Leased	—
Default	Ethernet	128.16.64.1
. . .	. . .	. . .

In a link state algorithm each router measures the state of its local links; again, various measures of "distance" could be used. This information is then flooded to all other routers in the network. The result is that each router receives link state information from all other routers and from this information a routing table is calculated. Because all routers receive the same information, routing loops should not occur. Routing table calculation usually employs an efficient algorithm attributable to Dijkstra (1959).

Routing protocols such as RIP and OSPF are used within an AS and are referred to generically as "interior gateway protocols." Another class of protocol, "exterior gateway protocols," serves to exchange routing information between ASs (e.g., border gateway protocol [BGP]; Rekhter & Li, 1995). These protocols carry "reachability" information—lists of networks known to an AS and for whom it is prepared to carry traffic. Many issues, including commercial and security issues, have an impact on what is included in such lists.

The Physical Structure of the Internet

The Internet has a loose structure. Its topology is mainly a consequence of perceived commercial need being satisfied by a network service. The result is a broadly hierarchical structure, however, with some operators concentrating on providing "core" networks, others concentrating on connecting private users, and still others providing transit between users and the core. Figure 10 illustrates a possible configuration.

The core networks (called national service providers [NSP] in the United States) compete with each other to carry Internet traffic. They include internetMCI, SprintLink, PSINet, and UUNet Technologies. They have high-capacity links between their routers—capable of operating at gigabits per second and more. NSPs connect with each other in two ways:

- Through independent "network access points" (NAP). These are commercial operations and provide high bandwidth switching between networks. They are generally confined to a small geographical area (e.g.,

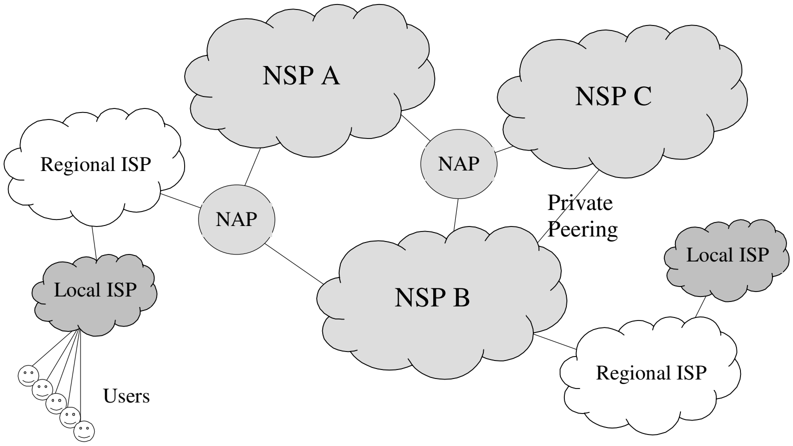

Figure 10: High-level Internet structure. The networks shown may have complex structure internally. Each is run by a separate administration and is an "autonomous system" in Internet terminology.

a single building) and consist of high-speed networks such as gigabit Ethernet that host routers belonging to the NSPs. NAPs are sometimes called metropolitan area exchanges (MAEs).

- Through private "peering" arrangements. These are direct connections between routers belonging to the NSPs.

Regional Internet service providers (ISPs) are next in the hierarchy. As the name suggests, they cover a smaller geographical area than an NSP. To provide a service, they must connect to an NSP. This may be either direct or through a NAP. Local ISPs connect end users to the Internet. This may be via dial-up (for many private users) or leased line (for corporate users).

Naturally all this must be paid for, and the ultimate source of revenue are the customers of the ISPs. It is not easy to discover precisely how money flows between the providers because such information is commercially sensitive. In principle anyone could construct a NSP or ISP and negotiate with existing operators to obtain interconnections. Existing operators may or may not welcome the newcomer—it is all a matter or commercial policy.

Peering arrangements vary. Two operators may simply agree to carry each other's traffic on a quid pro quo basis, or there may be payments in one direction or the other. Possibly an operator may agree to carry only certain traffic, based on source or destination for example. DIFFSERV (discussed in a subsequent section) will make all this more complex because it allows packets to be marked for special treatment. Operators will need to establish service-level agreements and accounting procedures to deal with this.

Continual improvements have been made in access technology that carries traffic between the customers' premises and the ISP. Much of this exploits the existing telecommunications infrastructure. The public switched telephone network (PSTN), in conjunction with MODEMs and ISDN, provide the ubiquitous dial-up service. This service provides ISPs with a convenient charging model based on "connect time" but takes no account of the volume of datagrams sent and received (and hence the real load imposed on the network). The point to point protocol (PPP; Simpson, 1994) is used over these connections; it provides access control and delimits datagrams on the wire. Faster access can be provided by asymmetric digital subscriber loop (ADSL) and cable modems that exploit telephone wiring and television cable, respectively. With these technologies, the full path from the customer's equipment to the ISP often involves other technologies such as Ethernet and ATM. Standards exist that specify how PPP may be used over these technologies, and this is evidently desirable because of PPP's access control and, not least, its familiarity (this does result in somewhat baroque architectures, however).

Variations on the Theme—Firewalls, Tunnels, Virtual Private Networks, Network Address Translation, and Proxies

Internet architecture developed in an environment in which maximum openness and wide connectivity were principal objectives. Furthermore, the network was small, and there seemed to be few architectural limits to expansion. The situation has now changed; wide connectivity is frequently seen as a security threat, and the recent vast expansion has seen the depletion of the IPv4 address space. In this section, I discuss some adaptations (some would say distortions) of the architecture in response to this changing situation.

It is common to deploy a firewall router, which selectively discards datagrams. Such routers are placed so as to control access between a site and the wider Internet, usually with the aim of improving security. Control can vary in complexity. A simple control is to specify which ports can and cannot be used. For example, allowing only destination port 80 on outgoing datagrams effectively restricts outgoing traffic to World Wide Web requests. Controls may also operate on IP addresses and protocols. Firewalls

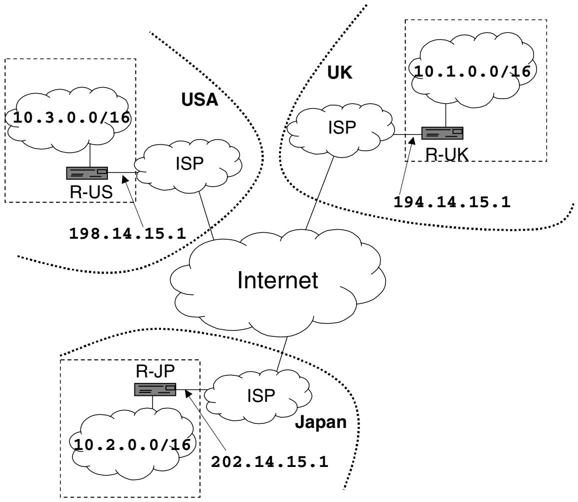

Figure 11: A virtual private network built on the Internet. An organization with three sites finds the Internet to be a cost-effective way of providing connectivity between them. The arrangement allows traffic to flow between the sites but excludes traffic to or from the wider Internet.

may be operated by ISPs as well as end users. The aim then is either to protect end users from attack or to promote the ISP's commercial interests by restricting the activities available to some classes of user.

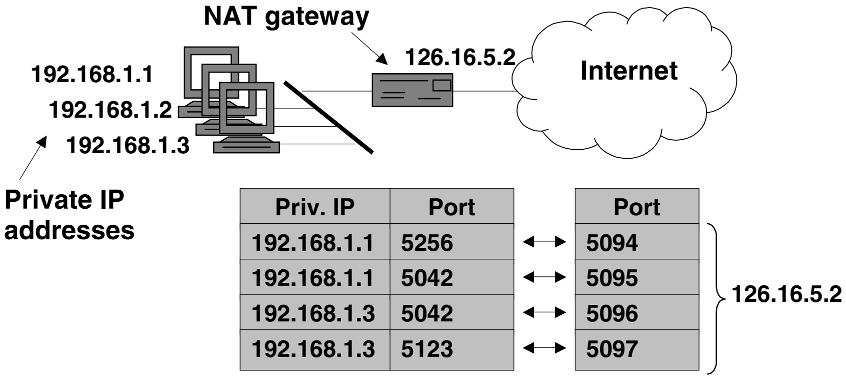
A way of exploiting the Internet while preserving independence from it is to build a virtual private network" (VPN) from IP-in-IP tunnels. Figure 11 shows such an arrangement in which an organization has three widely spaced sites each with its own network of computers and a connection via a router to a local ISP. Hosts on the organization's networks are allocated addresses from a network specifically designated to be private (such addresses should never appear on the "real" Internet). A datagram sent by a host on the U.S. site to one in the United Kingdom will be routed to the router *R-US*. This router, like the other two, has a real IP address allocated by the local ISP. Its routing table tells it that the datagram must be sent to the router *R-UK*. To achieve this the datagram, complete with its header, becomes the data part of a new datagram with destination address 194.14.15.1. When the datagram reaches *R-UK* it is "unwrapped," and the original datagram is forwarded on to the United Kingdom network. If desired, the three external routers can be configured to disallow all traffic to or from the rest of the Internet. A further refinement is to use "secure tunnels" by exploiting the IPSec standards (Atkinson & Kent, 1998; discussed later) and encrypting the tunneled datagrams.

The private address space can also help a site which has insufficient addresses for local hosts; for example, many consumer ISP contracts allocate just one IP address per customer even though the customer may have more than one host requiring an IP address. This problem can be solved in part by network address translation (NAT).

Figure 12 shows one way of using NAT as specified in RFC1631 (Egevang & Francis, 1994). It shows a single "real" IP address being shared by several hosts on a local network each of which has a "private" IP address. As packets leave the site, the NAT gateway changes their source addresses in the IP header to the real IP address that has been assigned. The reverse transformation must be applied to the destination addresses of incoming packets; the problem is to know which private IP address should be selected. This is achieved by including the transport protocol ports in the mapping. The mapping ensures that all source ports currently in use are distinct. These source ports will be the destination ports of incoming IP datagrams and can be used to select the correct mapping. Thus an incoming datagram with destination port 5095 will have its destination IP address and port set to 192.168.1.1 and 5042, respectively.

NAT is a rather ugly fix and breaks an architectural rule that IP addresses should identify the end points of a communication. Some applications, notably FTP, make use of this rule, and NAT gateways have to treat FTP specially as a consequence. The number of such special cases seems likely to increase in the future.

The NAT operation described is fine provided the applications act as clients; but suppose a user wanted to run a Web server on the machine with address 198.168.1.1. The NAT gateway would map this address so that the



Priv. IP	Port		Port
192.168.1.1	5256	↔	5094
192.168.1.1	5042	↔	5095
192.168.1.3	5042	↔	5096
192.168.1.3	5123	↔	5097

Figure 12: Network address translation. The private IP addresses and ports used locally are mapped to/from real IP addresses and ports as they pass through the NAT router.

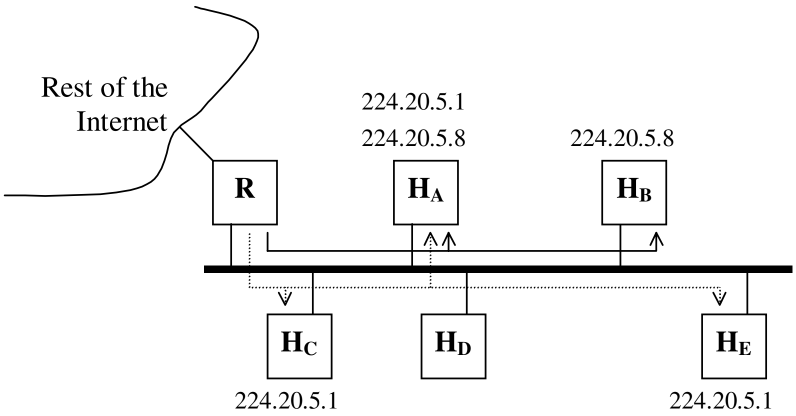


Figure 13: Multicast delivery to local area network hosts.

outside world sees the server running at address 126.16.5.2, which is fine. The user, however, would like the server to appear to listen on the "standard" WWW port, port 80. This means a permanent mapping in the NAT gateway is necessary so that 198.168.1.1 port 80 always maps to 126.16.5.2 port 80. This demonstrates that NAT gateways have a natural firewall capability; if the NAT gateway does not have a mapping for port 80, no incoming Web request can succeed.

It is in no one's interest to generate unnecessary Internet traffic. World Wide Web proxy servers situated on a customer or ISP network aim to confine a sizable portion of Web traffic to the local area. Proxy servers maintain a cache of popular, recently accessed Web pages. Browsers are configured so that Web requests are sent not to the true destination server but to the proxy. If the requested page has been cached, the proxy will respond; otherwise it will forward the request to the true destination. Mechanisms exist to ensure that any cached copy is adequately up-to-date, but problems still arise. A variation on this theme is the so-called transparent proxy. Here Web requests are intercepted and redirected to a proxy server even though the user has not requested it and the browser has not been configured to permit it. This unwarranted interference with traffic has been justified on grounds of efficiency but is a clear breach of the Internet end-to-end principle. Problems, when they arise are likely to be mysterious and intractable.

Multicast IP

Several modern applications require data to be delivered to multiple destinations, including multiway conferencing and video distribution. A network service that does this efficiently is called a multicast service. Many of the networks on the edges of the Internet are LANs, and these have inherent support for multicast. The aim of multicast IP is to route multicast datagrams across the Internet in a way which ensures they reach all the LANs where there are destination hosts. Efficient multicast should never send more than one copy of an IP datagram between two routers. It should be the job of routers to replicate an IP datagram and forward copies down multiple paths as necessary. The mechanisms for achieving this were developed mainly by Deering (1998). From a user's point of view, the model resembles that of a radio transmission where, in order to receive, one must "tune in" to a frequency. The Internet analog for a frequency is a multicast group address. Hosts wishing to receive multicasts to a particular multicast group address have to inform the network that they wish to do so. This "user to network signaling" is handled by the Internet group management protocol (IGMP; Fenner, 1997). Multicast addresses look like ordinary IP addresses, which means there is no problem with carrying them in the source and destination fields of IP datagrams. They are "class D" addresses with the following format:

Class D   1110XXXX   XXXXXXXX   XXXXXXXX   XXXXXXXX

If a router on a LAN receives an incoming datagram with a multicast address (e.g., 224.20.5.1), it has to decide whether to multicast the datagram on the LAN. If there is at least one member of the 224.20.5.1 group on the LAN, the datagram must be multicast; otherwise, it should be dropped. For example, Figure 13 shows hosts on a LAN belonging to two multicast groups (224.20.5.1 and 224.20.5.8). Any datagram to either of these addresses must be multicast on the LAN. The router discovers group memberships on the LAN through IGMP.

Multicast Address Resolution

For transmission on a LAN to take place, the IP multicast address must be resolved to a LAN multicast address. In the case of Ethernet, for example, an algorithmic procedure is used that forms a MAC address as

<00000001000000000010111100$_2$> + < low-order
23 bits of the IP multicast address>

This is not a one-to-one mapping, and it is possible to end up with two IP multicast groups on a LAN mapped to the same MAC multicast address. This is unfortunate but not disastrous. It means that a host that has joined the group with address 224.20.5.1 will also receive datagrams intended for (e.g.) 224.148.5.1 and will have to filter these out with software.

Multicast Routing

A routing mechanism is necessary to ensure that all transmissions to a multicast address reach the correct set of routers and hence the correct set of LANs. In common with the normal Internet strategy, this mechanism has to be robust in the face of network failures. This can be achieved by minimizing the state information retained by routers and allowing this information to be continually refreshed, which requires an efficient dynamic multicast routing protocol This turns out to be a difficult problem to crack and is still the subject of much research.

Several multicast routing protocols make use of information held by routers as a result of their normal unicast (host-to-host) operation. For example, a router employing a link-state routing protocol has enough information to be able to calculate a shortest path route from any source to any destination. By calculating shortest paths from a multicast source to all known destinations, a reasonably efficient multicast tree can be constructed. All routers involved should calculate the same tree so that no problems with loops result from inconsistencies. As it stands, this technique will deliver multicast datagrams to all destinations, including those that have no group members. This is solved by allowing routers to send "prune" messages saying, "do not forward datagrams for this address to me." The multicast extensions to open shortest path first protocol (MOSPF; Moy, 1994) is of this type. The distance vector multicast routing protocol (DVMRP; Waitzman, Partridge, & Deering, 1998) uses similar ideas but is based on a distance vector unicast routing protocol. Another protocol, protocol independent multicast, (PIM; (Estrin, 1997) uses similar techniques when many group members are concentrated in an area (dense mode) but a different technique when members are widely distributed (sparse mode).

IP Security

Many applications, especially in e-commerce, require security. In particular, they require strong authentication of the participants in a transaction and, possibly, traffic confidentiality. (It is worth noting that the source address in the IP datagram header is easily faked and should not be relied on for authentication purposes). Such security can be provided in the applications themselves. Providing security in the IP layer is attractive, however, because potentiality, it can satisfy the needs of most applications.

A series of standards collectively known as IPsec specify the rules for IP security. There is an initial handshaking phase between source and destination during which a security agreement (SA) is negotiated. This agreement includes details of the precise security mechanisms and options to be used.

IP datagrams carrying IPsec traffic have an extra header immediately following the IP header. Two types of header are possible:

1. An authentication header (AH) is used when just authentication is required. This header includes a digital signature for the source of the datagram.
2. An encryption security payload (ESP) header is used when authentication and confidentiality is required. It includes parameters relevant to the encryption algorithm. The header is followed by the encrypted payload and an authentication trailer that has a function similar to that of the AH.

Implementation of IPsec is fairly limited but growing. It finds particular application in conjunction with VPNs built from IP-in-IP tunnels as described earlier.

Mobile IP

There is a difference between "wireless" and "mobile." A host on a wireless LAN may move physically around a building, but, as long as it remains on the same LAN, it has not moved as far as the Internet is concerned—it can still be reached by the same route. For the Internet, mobility occurs when a host moves to a location served by a new router. When this happens, the mobile host's IP address is wrong because its network prefix remains that of its "home" IP network. Unless this is tackled, the host will not receive IP datagrams because these will be routed to the home network. The problem is solved by means of two agent processes (see Perkins, 1996). The newly arrived host registers itself with the "foreign agent" (FA). If it is willing to accept the newcomer, the FA contacts the "home agent" (HA), which resides on the home network. From this point forward, all incoming packets are intercepted by the HA and forwarded to the FA; this uses IP-in-IP tunneling similar to that used in a VPN. The resulting route—source ⇒ HA ⇒ FA ⇒ mobile host—may be inefficient. The scheme is effective, however, because it requires no changes to be made to fixed hosts and routers.

Management in the IP Layer

ICMP

ICMP is the Internet control message protocol (Postel, 1981c). ICMP messages are used mainly to convey information about errors or conditions that require attention. There are many message types including the following:

- Echo request and response, used to probe hosts and routers to check whether they are alive and responding. The "ping" program, available on most systems, employs these messages.
- Time exceeded, used to indicate that an IP datagram has been discarded by a router because its TTL field has reached zero.
- Destination unreachable and host unreachable, used by routers to indicate discard for a variety of reasons.

The weakness of the ICMP mechanism is that its messages suffer the same problems as do other IP datagrams, thus one can never be sure they will be delivered. They can be regarded as providing useful hints about the nature of problems but cannot be relied upon.

Host Configuration (DHCP)

To operate, an IP host needs several pieces of information, including its IP address, the address mask for the local network, the IP address of the local DNS server, and the IP address of at least one router. Configuring all this information by hand on a network with thousands of hosts

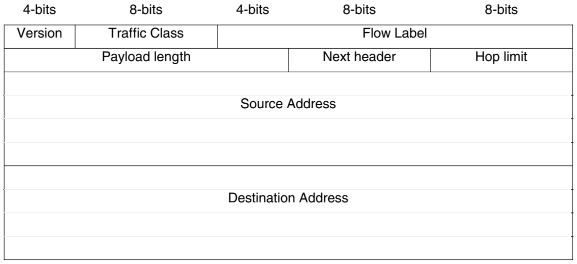

Figure 14: Internet Protocol version 6 header.

would be an administrative nightmare. The dynamic host configuration protocol (DHCP; Droms, 1997) provides a solution. When a host starts up, it broadcasts an IP datagram requesting a DHCP server. Assuming such a server is present on the local network, it will reply with the relevant information. In many cases, the IP address allocation will be dynamic. This allows a pool of IP addresses to be shared among a larger number of hosts. Only those currently connecting to the Internet need be allocated addresses, which goes some way to tackling the shortfall of addresses in IPv4.

The IP v6

A major motivation for a new version of IP was the shortage of IPv4 addresses. IPv6 (Deering & Hinden, 1998) addresses are four times as long, which should give enough addresses for the foreseeable future. (If one IPV6 address is allocated each microsecond, the addresses will last for 10^{25} years). Other major driving factors were mobility, which requires multiple address allocations as a host moves through the Internet; ease of configuration so that simple devices can be plugged and work without human intervention; security; and better support for different qualities of service.

The IPv6 header is shown in Figure 14. Despite the fourfold increase in address length, the header is just 40 bytes. This is something of an illusion, however, because some functions (e.g., security) require an additional "extension header."

The "traffic class" and "flow label" fields relate to QoS issues. Traffic class is used within the DIFFSERV scheme to indicate one of several predefined traffic classes. IPv6 routers should understand these classes and prioritize datagrams appropriately. The flow label relates to the finer grained INTSERV scheme. It is used by a host to mark a stream of related IP datagrams, which should be accorded a previously negotiated priority. These schemes are explained in the next section.

IPv6 wraps up several add-ons to IPv4 and makes these formally part of the protocol. These include ICMP, IGMP, DHCP, and IPsec. It has a much richer address structure that allows much greater scope for address aggregation; whereas IPv4 simply allows a collection of hosts to be aggregated into an IP network, IPv6 allows a hierarchy of aggregations. For example, one scheme has a "top-level" identifier followed by a "next level" identifier (probably denoting a particular site) a site identifier (like an IPv4 subnet) and an interface identifier (like an IPv4 host part).

The service provided by IPv6 is essentially unchanged, and the overall architecture remains as before; IPv6 provides simple datagram delivery, and the end-to-end layers (transport and application) build on this. To date IPv6 deployment has not been widespread. The two protocol versions can and do coexist, however, and pockets of IPv6 are beginning to emerge. It seems possible that the emergence of more powerful wireless devices such an "third-generation" mobile phones may see a ballooning of demand for IP addresses and a consequential rapid deployment of IPv6.

TRAFFIC MANAGEMENT IN THE INTERNET

For some time it has become clear that the basic "best efforts" IP service was not suitable for all applications. This is particularly so for applications with tight constraints on delay. These applications require some stronger guarantees on the maximum end-to-end delivery times for their IP datagrams (i.e. they require specialized QoS). This translates into a requirement for priority treatment by the routers through which their traffic passes. Several problems need to be addressed:

How can applications tell the routers their requirements? We need some form of "signaling" between applications and the routers.

How can routers identify which IP datagrams require which treatments?

Can we build routers that can give different priorities to different applications so that their QoS requirements are met?

INTSERV

The Integrated Services (INTSERV) initiative (Braden, 1994) was the first attempt to address these problems. It introduced the concept of a "flow"–a sequence of IP datagrams all headed to the same destination(s) and all requiring the same QoS. An application which requires special QoS for a flow engages in an explicit negotiation with the network routers it will use. The resource reservation protocol (RSVP) (Braden, Clark, & Shenkar, 1997) is employed for this signaling. The source sends an RSVP message describing the flow in terms of its peak and mean rates. The receiver then calculates the capacity that routers should reserve to meet the delay requirements. It then sends a reservation message asking all the routers along the path to reserve the required capacity. Of course the capacity might not be available, in which case an error message will be sent back to the receiver. In a CO network, this negotiation would be done only once, when the connection is set up. In the CL Internet, it must be repeated at intervals to cope with changing traffic patterns, changing routes, and so on.

During negotiation the source indicates how the flow is to be identified. This can be a combination of source and destination IP addresses, protocol identifiers and ports. This means that routers have to look at multiple header fields (and know something about transport protocols) to determine to which flow an IP datagram belongs, which will certainly slow things down. IPv6 includes a 20-bit "flow label" field into which a (hopefully) unique value can be placed. This may enable routers to classify incoming IP datagrams by examining only one field.

DIFFSERV

It is now recognized that the INTSERV approach, used alone, is appropriate only for small networks. The problem is that hundreds of thousands of flows are likely to pass through routers on core networks, and managing all these is impossible. What is needed is something much more coarse grained that allows routers to implement a few "behaviors" suited to broad classes of traffic. This is the approach used in the differentiated services (DIFFSERV; Blake et al, 1998) scheme. The "type of service" field in the IP header, now renamed the DIFFSERV field, is used to indicate the class to which an IP datagram belongs. A router has only to look at this field to know which behavior should be applied.

Effectively DIFFSERV allows the Internet to offer several classes of service to its users. The basic class offers the familiar "best efforts" service and would be relatively cheap. Traffic with tight delay constraints would use a class guaranteeing very high priority—and would pay accordingly. For this to work, ISPs must have mechanisms in place to count packets belonging to each class so that appropriate charges can be made. They must also negotiate service level agreements with neighboring networks to ensure there is an onward commitment to treat high-priority traffic appropriately. Furthermore, the guarantees offered with respect to a particular traffic class cannot be completely open ended; sources will have to agree to keep the rate at which traffic is generated within prenegotiated bounds. Traffic will have to be "policed" to ensure that these bounds are respected. Despite these complications, there now seems to be momentum behind DIFFSERV that should lead to wide deployment.

Although DIFFSERV was originally seen as an alternative and more scalable approach to INTSERV and RSVP, the two can be seen as complementary. For example, RSVP may be used to request reservation of resources for a DIFFSERV service class. RSVP also has a role in traffic engineering in conjunction with MPLS.

Performance Issues

Traffic volumes continue to increase as do the capacity of networks and links; new applications require tighter bounds on delay. This has a number of implications for the engineering of Internet components.

- Host operating systems need better real-time performance. Some popular operating systems are poor in this regard and contribute a major proportion of end-to-end delay.
- Routers, especially core routers, must handle increased traffic volumes. At the same time, they are expected to classify IP datagrams on the basis of the DIFFSERV field and process accordingly. Coping with this increased rate and volume of per-datagram processing is challenging for router manufacturers. One approach, multiprotocol label switching (MPLS; Rosen, Viswanathan, & Callon, 2001), attempts to exploit the fact that a whole stream of IP datagrams is likely to require the same processing. MPLS labels such streams through the use of an additional field. Once a stream has been labeled, routers have only to look at the label to determine the route, the priority, and so forth.
- Generally, transmission rates increase while end-to-end delays remain constant. Thus ARQ protocols such as TCP must operate in an environment in which many more segments may be sent before an acknowledgment can be expected. This can lead to inefficient operation some enhancements have been made to TCP to combat these.

CONCLUSION

The Internet is built through the implementation of a common service—the IP service—on its constituent networks. This is a minimalist service providing little more than basic connectivity. Keeping the IP service simple leaves maximum flexibility to the applications that may choose transport protocols suited to their needs. Many applications require reliable, sequenced delivery of data. These applications may employ the TCP protocol that satisfies these requirements and, additionally, assists with the management of congestion.

The IP service itself is based on the use of routers that relay traffic between networks. The routes followed are not normally predetermined and may vary with network load. IP addresses identify hosts and the IP networks to which these belong. Correct assignment of IP addresses is essential to Internet operation. Internet expansion has put pressure on the original addressing scheme. This has led to "work-arounds" such as NAT and, ultimately, to a much more flexible scheme within IPv6.

The management of congestion remains an issue and has an impact on newer, delay-sensitive applications. Initiatives such as DIFFSERV address the needs of such applications and are intended to lead to an Internet capable of carrying "multiservice" traffic having a variety of QoS requirements.

The early history of the Internet was characterized by the following philosophy: Keep the network simple, put the complexity in the hosts. More recently, commercial pressures have encouraged providers to add complexity to the network so as to offer "enhanced" services to their customers; firewalls, NAT gateways, tunnels, and proxies all reflect this strategy (and all bring awkward problems in their wake). At the same time, it is proving difficult to persuade providers and customers to support ostensibly more elegant enhancements such as IPv6, IP multicast, and IPSec. Thus we see a tension between Internet architects who wish to defend and build on the elegance of the original design and commercial interests who have customers to serve and need solutions that can be deployed straight away. One must hope that this tension will continue to be creative.

GLOSSARY

Autonomous system (AS) A collection of hosts, networks, and routers operated by a single administration. Routing within an AS is the sole responsibility of the AS administration. Routing between ASs uses a standardized Exterior Gateway Protocol such as BGP.

Border gateway protocol (BGP) A protocol used to exchange information between autonomous systems (AS). The information indicates which ASs are "reachable" from the sending AS.

Dynamic host configuration protocol (DHCP) A protocol that allows a host to obtain Internet configuration information from a server. DHCP is especially applicable when a host is first switched on.

DIFFSERV An initiative aimed at providing quality of service control on the Internet by classifying traffic into a few broad categories. Each category is then given appropriate treatment by routers.

Domain name (DN) A unique name that is used to name an object in the context of the Internet, for example, www.bluffco.com.

Domain name system (DNS) A system of servers that provides a directory service for the Internet. Each server manages part of the domain name space and communicates with other servers to look up names in "foreign" domains.

File transfer protocol (FTP) The standard protocol on the Internet for transferring files between hosts. Its role has, to some extent, been usurped by HTTP.

Gateway In the context of the Internet, a gateway is an alternative name for a router.

Host A computer attached to a network on which applications run.

Hypertext transfer protocol (HTTP) The protocol used by a Web browser to retrieve information from a Web server.

Internet control message protocol (ICMP) A protocol that provides simple management capabilities alongside the Internet Protocol. ICMP is used mainly for reporting problems and errors.

Internet group management protocol (IGMP) The protocol used by hosts to manage their membership of IP multicast groups.

INTSERV An initiative aimed at providing quality of service control on the Internet through explicit reservation of resources.

Internet protocol (IP) The protocol that governs basic data delivery on the Internet. It defines the format of the IP datagram complete with its source and destination addresses. IP will attempt to deliver the datagram to the intended destination but will not attempt to recover any errors that may occur.

IP datagram A packet formatted according to the rules of the Internet Protocol.

IPsec A protocol that can add confidentiality, integrity, and authentication to the Internet Protocol.

IPv6 Version 6 of the Internet protocol; a new standard that incorporates greatly expanded addressing and solutions to mobility, multicast, security, management, and configuration problems.

Network address translation (NAT) A scheme that allows several hosts to share a single "real" IP address.

Packet A combination of data plus control information that is treated as a unit by a data communication network.

Port A number that identifies a particular application or service available on a host.

Router A device that relays IP datagrams between networks. It determines where to send the datagram by referring its destination address to a routing table.

Resource reservation protocol (RSVP) A signaling protocol that allows hosts to reserve Internet resources to obtain a desired level of quality of service.

Transmission control protocol (TCP) A protocol that provides reliable, sequenced, flow-controlled data exchange between hosts. Common applications such as file transfer and the Web use TCP to provide the reliability they need.

User datagram protocol (UDP) A simple protocol that allows an IP datagram to be sent to a particular port on a particular host. UDP does not enhance the IP service in any way.

Internet Censorship

Julie Hersberger, *University of North Carolina at Greensboro*

INTRODUCTION

Internet censorship has become a major social issue in various countries as Internet access becomes more available to large numbers of users globally. Currently, there are more questions than answers in regards to essential Internet censorship issues. Censorship is dependent on the following critical points: Who controls Internet access, both legally and ethically, in not only the United States but also in the international arena determines Internet governance? Who then decides what content should or should not be accessible constitutes content control? Who owns Internet content and how ownership is determined are the realm of intellectual property? As Internet connectivity increases worldwide, legal and ethical discussions and arguments become increasingly complex. Others might perceive what some consider to be an ethical or legal denial of access to the Internet as censorship. Censorship is technically a legal action although the term is not always used as such in everyday usage. Even the attempt to define the term "censorship" in order to begin useful discussion proves difficult. In addition to the issues of governance, content discussions, and intellectual property questions, new advances in technology also affect Internet access and raise censorship concerns.

The definition of key terms involved in such a discussion need to be established first in order form an analytical framework to be established. Definitions of key terms are important but dilemmas arise as to whose definitions prevail. The United States is one of the countries at the forefront of Internet use and has thus been at the forefront of the Internet access controversy. Historically, there has been a long ongoing discussion of information access, censorship, obscenity, and pornography based on First Amendment rights of free speech and assembly in the United States. Freedom of speech, however, is not a legal absolute and does not always protect certain areas such as libel (defamation), incitement (including where hate speech overreaches and advocates violent acts), obscene materials and child pornography, or Internet spam. Issues of security, privacy (especially as this applies to the endangerment of children), and intellectual property are also Internet categories where censorship comes into play.

As the novelty of the Internet diminishes and as more and more users become more Internet savvy, the controversy over access and censorship of the Internet becomes more manifest. The Internet allows for the full range of speech media as compared to single-transmission media such as books, television, or movies. Confusion exists in determining legal governance of the Internet and in subsequent development and application of the definition of the term "censorship." In the strictest legal interpretation of a definition of censorship based on First Amendment rights, only the U.S. government can technically censor speech, represented as text or symbolic speech, which includes visual and aural media.

In lay terms and common usage, however, censorship is simply defined as an attempt by anyone to limit access to text or visual media, or the term is applied to a person or a group who attempts to act as a censor. This bifurcation of legal and lay perspectives becomes even more confounding due to the confusion over the legal standards for what constitutes obscene, indecent, or inappropriate material. Obscenity is a court-determined standard (*Miller v. California,* 1973) and establishes that a work is judged obscene if it fails a three-prong test. The three prongs consist of (a) whether the average person applying contemporary community standards would find the work, taken as a whole, appeals to prurient interests; (b) whether the work depicts or describes, in a patently offensive way, sexual conduct specifically defined by the applicable state law; and (c) whether the work taken as a whole lacks serious literary, artistic, political, or scientific value. "Obscene" is a designation that only applies to materials in terms of sexual content. Individuals often refer to hate speech or violent images as being obscene but they are not legally so. Indecent material includes the category of pornography and continues to be a very problematic and very subjective area, as is true also of the domain of inappropriate material. Indecent and inappropriate materials are still legally protected for dissemination to adults; however, courts have decreed that it is illegal to distribute pornography to minors under the age of 17 (*Ginsberg v. New York,* 1968). Child pornography is not legally accessible in the United States in any format. Persons accessing child pornography are open to legal prosecution regardless of the format accessed. Distinguishing what constitutes pornographic material from indecent or inappropriate works becomes very difficult due to the lack of useful definitions.

Such designations are of critical importance in terms of promulgating laws, policies, and procedures. The main ongoing discussion is how such laws are transferable to the Internet. Due to the emotional nature of the discussion of Internet censorship, confusion over governance issues, and a lack of understanding of the legal basis for what constitutes censorship, access to the Internet promises to remain a prominent legal and social concern for years to come. What is legal in the traditional sense of censorship and access may not be easily transposed to cyberspace. As these issues are examined, important decisions will define, refine, and clarify who will have access to what on the Internet locally, nationally, and internationally. Censorship needs to be considered on a legal level, but there are ethical implications. Text and images are legally protected under First Amendment measures or international equivalents, but this does not imply that all such material ought to be available. For an excellent analysis of ethics and Internet access see Spinello's *Cyberethics* (2003).

GOVERNANCE ISSUES

Internet governance is, in many ways, an oxymoron as the original purpose of connecting networks was to facilitate the transfer of information easily and without oversight. Censoring information exchange was not a concern during the early developmental phase of the current Internet architecture. The historical evolution of the Internet, beginning with the U.S. Department of Defense's ARPANET by the Advanced Research Projects Agency in the late 1960s, intentionally established a network whose main function was to facilitate rapid digital communication in times of national emergencies. An analogy would be similar to that of the interstate highway network that was established to facilitate rapid transportation efforts during national emergencies. Few people were part of this network composed mainly of computer scientists within the U.S. government and a few universities. Later, in the 1980s, the National Science Foundation network (NSFNET) was developed and ARPANET's role became greatly diminished. In addition to government networks, NSFNET included several university networks and thus the term Internet came to be. The primary purpose of the early Internet was, again, information sharing, so the network was developed to easily transmit all types of textual and graphic data. This attention to detail in promoting ease of transmission was to become a major governance issue later. Adding to the governance confusion is that even though the U.S. government supported the early Internet efforts, it was developed for government and academic use, not commercial use. In the 1990s, as the Internet became much more of an open network, with commercial enterprises flourishing and users outside of the government and academia gaining access, growth increased at a rapid rate. The Internet architecture, which was developed to facilitate sharing, made it extremely difficult to impose restrictions on information sharing. Commercial needs, though, often require restrictions due to intellectual property issues. As a result the governance of the Internet, and concomitantly who can legally censor access or content material is complex and confusing. Even if some form of national or international consensus could be reached regarding Internet governance it is unclear what actions could be taken to limit information exchange. Internet architecture still supports ease of file sharing, leading to difficulty with the ability for music exchange. Music piracy versus the legal exchange of music files has been addressed recently in courts. Free downloads of music files in some instances may boost music sales. Downloading entire music CDs rather than paying for the official product amounts to piracy. Copyright holders may legally limit access to music files, which does not constitute censorship in the traditional sense of intellectual property rights. Music fans view the law as an abridgment to their right of access to information and from their perspective, such limitation amounts to censorship. Case law will be used to clarify and refine legal governance issues.

Regulatory agencies attempting to govern Internet access and content may begin to investigate control at the architecture and infrastructure. New systems may utilize changes in code that would shift control from users to developers and providers. Such a change would not be popular with long-term Internet users who are used to the anarchic atmosphere of trading information at will. One of the most attractive qualities of the Internet is that decentralization aids in the speed and functionality of information transfer. Future governance issues concerning new architecture and infrastructure approaches will be decided in national and international courts. The evolution of e-commerce adds another layer of governance issues, especially in the global market. Censoring of commercial information again lands in the legal sector, but whose laws ought to restrict global commerce remains a critical question.

CENSORSHIP AND INTERNET CONTENT

Internet censorship affects individuals, groups, nations, etc. Two major issues must be addressed concerning governance of the Internet and censorship. Who controls access to the Internet is as critical a question as denying a right of access to the Internet. The second issue concerns Internet content, or what is actually available on the Internet. Both issues comprise legal and ethical elements. A teenager could level a charge of censorship against a parent who installs filtering or tracking software, but this cannot be considered legal censorship since the parents' action could be interpreted as ethical parenting. A further example of possible censorship with regards to denying a right of access is where public libraries or school libraries install filtering software to block predetermined categories of Web sites from use. Whether this is governmental censorship is still being addressed by the U.S. Supreme Court. Schools may also be able to argue that they can legally limit what content is actually published on their Web site. *Hazelwood v. Kuhlmeier* (1988) could be cited as a precedent in limiting student speech on the Internet. In *Hazelwood,* the courts ruled that schools could legally control the content of school newspapers and such a decision could be argued to transfer to the Internet. Whether many may interpret the outcome of the case as legal, or ethical, the decision remains very open to further discussion in terms of censoring access to and the content of the Internet.

Internet service providers (ISPs) also have the ability to impose restrictions on Web content without legally abridging First Amendment rights. Free markets allow for consumers to choose from a variety of Internet providers and any restrictions or limitations of accessing content and posting content should be clearly stated in any agreements arranged between consumer and provider. An example of this is the Prodigy case in the early 1990s (Stratton Oakmont, Inc. v. Prodigy Services Co, 1995) where an Internet service provider imposed restrictions on what could and could not be posted to its electronic bulletin board service. Prodigy claimed that they were not a common carrier and thus not bound to transmit all messages. Furthermore, they claimed other electronic outlets that allowed for free expression existed so that the content that they were prohibiting did not amount to a restriction of access to information. The inclusion of First Amendment rights, FCC regulations, and antitrust laws all within the Prodigy case show the impact of Internet censorship in the commercial arena but show that there are differing limitations from those of the government limiting free speech. In the global legal arena, efforts to determine Internet regulation regarding censorship are still in the process of governance clarification and discussion. Cultural norms vary greatly worldwide, and what is legally accessible in some countries may be illegal in others. Whose rights will then prevail in international legal cases is still being determined in courts worldwide.

LEGAL ISSUES AND INTERNET CONTENT

Laws, policies, rules, and regulations have all been enacted in order to limit both access to the Internet and content posted. Historically, as laws and rules are enacted, individuals and groups have a right to legally challenge such actions where they are perceived to abridge access rights. A robust body of case law exists in the United States relative to censorship topics including sexual content, pornography, obscenity, hate speech, libel, and unwanted speech. At issue currently is whether these historical rules and refinements that have been established to apply to past forms of communication media apply to the Internet. Current legal cases in the United States provide insight into the judicial, legislative, and presidential perspectives regarding Internet content control with such efforts aimed at the protection of children from inappropriate Internet content. The Communications Decency Act of 1996 (CDA) and the Child Pornography Prevention Act of 1996 (CPPA) were both congressional statues, signed into law by then President Bill Clinton. Even though the statutes embodied congressional and presidential support, legal challenges were filed to challenge the constitutionality of the measures. Subsequent congressional attempts to limit the access of minors to Internet materials include the Children's Online Protection Act (COPA) and the Child Internet Protection Act (CIPA). As these have all been government actions to restrict access to the Internet, the classic definition of censorship would apply. Examining the court challenges to the enactment and enforcement of the CDA, CPPA, COPA, and CIPA can identify critical issues.

Internationally, a growing body of statutes and challenge cases is beginning to clarify and refine Internet censorship issues in other countries. These new cases are beginning to challenge jurisdictional claims regarding content control on an international basis.

United States

Legally, the body of case law affecting Internet access and censorship has been growing since the mid-1980s. No attempt is made here to produce a comprehensive review of case law, but a review of selected important cases that affect access to content on the Internet provides insight into the critical issues concerning Internet censorship. Most cases address obscene or pornographic materials and their access by children. Other cases address interstate commerce and jurisdiction issues. The first Internet obscenity case (*U.S. v. Thomas,* 1994) also addressed the issue of geographical jurisdiction of cyberspace. In this case, a Tennessee court found a California couple guilty of transporting obscene materials across state lines via their computer over interstate phone lines to a Memphis postal inspector. The couple had established a private, adults-only electronic bulletin board system (BBS) where subscribers could order pornographic materials online in addition to chatting and exchanging files. The Miller test's (*Miller v. California,* 1973) reliance on community standards to dictate what is obscene is particularly difficult to adjudicate in a global medium. The Thomases requested a venue change from Tennessee to California where presumably community obscenity standards for indecent materials would be more liberal than those of Tennessee. Lawyers argued that the new technology required a rethinking of the traditional geographic location of cases. In obscenity cases, trials may be held in the district from where the materials were transmitted or in the district in which they were received. Another jurisdictional issue for Internet obscenity cases may also add where the material was published as another possible venue for prosecution of cases if it differs from the location where materials were transmitted or received. The court did not embrace the argument advanced by the Thomases, that they had no control over where their Internet subscribers are located geographically and that a chilling effect would occur if BBS owners had to screen who would receive their materials. According to the court decision, members had to submit applications with home addresses and phone numbers so the couple had the necessary information to screen accepting applications from users in states with stricter community standards than California. In effect, the court ruling requires BBS operators to become experts not only on community standards in the 50 U.S. states, but also become experts on international law. The critical issue of community standards in a global medium is also addressed in the Supreme Court's consideration of CDA and COPA.

The Communications Decency Act was overturned by the Supreme Court in *Reno v. ACLU* (1997). The CDA prohibited the transmission of obscene or indecent materials to minors using community standards. In its attempt to protect minors, the court found that the CDA overly restricted adult access to Internet information. Three main considerations led a court majority to overturn the CDA. First, no existing technology existed to effectively bar minors from gaining access and thus the act was considered to be overbroad by the court. Secondly, the act was deemed also overbroad for failing to define "indecent" or "patently offensive," and thirdly, the affirmative defenses offered were not narrowly tailored enough (*Reno v. ACLU,* 1997). Overall, the court found that the extension of the CDA's breadth was unprecedented and struck down the act.

In its next iteration, the CDA morphed into CDA II known also as the Children's Online Protection Act. Once the act was signed into law, the American Civil Liberties Union filed suit. In *Ashcroft v. ACLU* (2002) the Supreme Court heard the argument that COPA too was overbroad and overly dependent on community standards. COPA differed from the CDA in three important ways. First, where the CDA addressed the Internet as a whole, COPA focused on the World Wide Web (WWW) only. Second, COPA only addressed commercial speech, not all speech. Thirdly, whereas the CDA attacked "indecent" and "patently offensive" speech, COPA only restricted speech that was harmful to minors. The majority of the justices supported sending the case back to the Third Circuit court to address three key issues. Was COPA overbroad for reasons other than its use of community standards? Was the statute constitutionally vague? Finally, would the statute survive strict scrutiny analysis (*Ashcroft v. ACLU,* 2002)? Unlike the decision in *U.S. v. Thomas* (1995) where consumers applied for membership to a BBS by sending their home information, COPA regulates World Wide Web access and no technology currently exists to establish users' geographic addresses. In effect, a community that wishes to exist without access to certain materials not only rids itself of that material, but all Internet users would be prohibited from accessing that information. The court reenforced that implementation of COPA regulations is still enjoined until the lower court re-addresses these critical areas. Whether community standards are nationally or geographically bound will be clarified in future discussions of this and other legal challenges. Which community standards are used to determine access to or content on the Internet will continue to be debated and refined over time.

Another ruling by the U.S. Supreme Court (*Ashcroft v. Free Speech Coalition,* 2002) addressed the Child Pornography Prevention Act of 1996 and its prohibition of graphic depictions of explicit sex involving real or computer simulations of minors. The justices all agreed that pornography depicting real children in sexually explicit situations remains obscene and beyond First Amendment protections. The issue directly addressed simulations of child pornography using computer-generated images. In *New York v. Ferber* (1982) the court determined that the process of producing child pornography, in addition to the distribution and sale of such material, was harmful to actual minors and should be prohibited despite whether the resulting images could be adjudicated to be legally obscene. Justice Kennedy's opinion points out that the CPPA reaches beyond the standards for obscenity as established in either *Miller* or *Ferber.* The CPPA prohibited all formats of images including photographs, film, video, picture, and computer or computer-generated image or picture. The Court majority agreed that such a prohibition would apply to works of classical art, to films of *Romeo and Juliet,* and to the recent Academy Award-winning film, *American Beauty,* rendering these works vulnerable to censorship under the Act. The court majority also agreed that the Act was overbroad in attempting to prohibit depictions of minors in explicitly sexual situations using adult actors. Justice O' Connor agreed with the majority on this point, but disagreed that prohibiting computer-generated simulations was overbroad. The severe penalties levied CPPA offenders were also a concern of the court majority. A first-time offender could be sentenced to a maximum of 15 years in prison with a repeat offender receiving not less than 5 years or more than 30 years maximum sentencing. The court majority agreed that such a severe penalty threat would have a chilling affect on legitimate artistic efforts. Finally, the court majority did not agree with the CPPA that the fact that virtual child pornography might be used to seduce minor children and thus harmful to minors was reasonable. Nor did the argument that virtual pornography might increase a pedophile's appetite for real child pornography and encourage illegal acts persuade the justices to limit access to virtual child pornography. Other sections of the CPPA are still being discussed in the legal arena, and it is likely that subsequent statues will continue to attempt to legally block access to questionable Internet content concerning child pornography.

In addition to COPA and the CPPA, Congress also enacted the Children's Internet Protection Act of 2000. In the CIPA, Congress tied the receipt of e-rate (education rate) funding to the installation of blocking or filtering software in public schools and public libraries. The e-rate funding was established by Congress (Universal Service Fund for Schools and Library Program) as telecommunications discounts provided to libraries in low-income communities in order to support Internet access for educational purposes. Libraries also were required to enact a policy that addressed inappropriate Internet access, with what constitutes "inappropriate" materials being determined by a local school board or library. The policy also needed to prohibit unauthorized access by minors, protect personal information of minors, and to restrict minors access to materials harmful to adults. Libraries were required to hold a public hearing on the proposed Internet safety policy. The American Library Association (ALA) filed suit in the U.S. District Court, Eastern District of Pennsylvania. The suit is not contesting the provision that public schools were required to install blocking or filtering software on all public access computers; however, the suit contends that blocking or filtering access to public library Internet terminals is a First Amendment violation. The statute authors claim that tying the receipt of federal funding to acquiring and monitoring use of blocking or filtering software is not a First Amendment issue. The ALA suit notes several weaknesses to the statute, pointing out that public libraries were established to provide educational and recreational materials to a wide range of users. Libraries are not legally required to provide Internet access, but if they choose to do so, they are governed under the laws of traditional public fora where First Amendment rights apply. The ALA suit claims that the government witnesses overstated the efficacy of blocking and filtering software used in those public libraries. Further noted was that the government witnesses admitted that their blocking and filtering software standards applied equally to both adults and minors, thus reducing access for adults to the level of what is appropriate for minors only. A critical point is that the suit does not claim an absolute right to access speech, but that right exists for adult library patrons not to have to petition the government for the right to access disfavored speech to which they are legally entitled (*ALA v. U.S.,* 2002). The suit contends that the statute is overly dependent on the proposition that e-rate funding is restricted only to educational pursuits, a proposition that has never been legally established.

The Third District Circuit Court of Appeals issued a unanimous finding that the law did abridge the First Amendment concerns of prior restraint, vagueness, and overbreadth. In the effort to protect children from accessing indecent or inappropriate materials, copious amounts of legally protected speech would be prohibited for access by adults. The judges mainly based their opinion on the premise that Internet filtering is faulty, blocking text but not images, failing to prohibit much that is illegal while blocking a substantial amount of speech that is legally protected. The case is being appealed to the U.S. Supreme Court as of the writing of this chapter.

A pattern has emerged where Congress enacts legislation that attempts to limit adult access to the Internet in order to protect children and then consequently various free speech groups challenge these statues in court. So far, the Supreme Court has been reluctant to limit access to legally protected speech for adults at that level which does not cause harm to minors. It is expected, however, that this pattern will continue as the legislative and judicial branches of government attempt to establish any legal limits to Internet access.

International

Other countries are also addressing issues of Internet censorship in the legal arena. However, gaining access to government actions that constitute censorship internationally can be difficult. Many countries restrict access to government records and the media does not always publicize such government actions. Thus it can be difficult to gauge the extent of Internet censorship occurring internationally. A few cases are beginning to be made public and some countries are making public their legislative actions. Australia's government has introduced legislation making it a criminal act for users and ISPs to make materials unsuitable to minors available, even if these materials are limited to use only by adults. Singapore, another country whose government limits access to Internet speech, has done so by establishing posting laws regarding political campaign posting regulations. The European Union Council (EU) and the European Parliament have also addressed the issue of the production of, processing of, possession of, and distribution of child pornography. One final example is that of China where the government shut down cybercafés that did not block or filter access to pornographic sites. These are but a few examples of actions to limit access to the Internet in just a few countries worldwide.

A current legal case of interest concerns a Web developer's posting of information prohibited in another country and their being sued to block that information in order to conform to the laws of that other country. In the case of UEJF & LICRA v. Yahoo (2000) a French court found that Yahoo!, Inc. based in California had violated French penal code by offering Nazi and Third Reich memorabilia for sale on their auction site. Two nonprofit organizations sued to force Yahoo to block transmission to France. The International League against Racism (Licra) and the Union of French Jewish Students (UEJF) initiated the suit. The Paris court found that Yahoo had violated the plaintiffs' rights under French law. If Yahoo did not cease disseminating the auction information to France a fine of 100,000 francs per day (U.S.$13,000) would be levied. The fact that Yahoo's policy prohibits the offering of items connected to hate speech played an important role in the court's decision. Yahoo then counter-sued in a California district court in claiming that French court orders were neither recognizable nor enforceable in the United States. The California court upheld Yahoo's claim. In a very recent decision, the Ninth Circuit of Appeals in San Francisco overturned the lower court ruling (*Yahoo! v. Licra,* 2002). The judges ruled that Yahoo could not sue persons who had no presence in that country nor have committed a crime in that country. The court also noted that the defendants ought to be able to exercise their rights in their home forum. The Appellate Court stated that the lower court had been "caught up in the novelty of the case, the French disregard for the First Amendment, and Yahoo's need for an American forum to protect its rights." The court also strongly stated that U.S. courts ought not issue advisory opinions regarding foreign court decisions when no attempt has been made to enforce the orders or judgments in the United States. Finally, the court stated that U.S. district courts ought not provide the means for "forum-shopping plaintiffs" to circumvent legitimate foreign court decisions in order to create "dueling courts" as an exercise in public relations or for other purposes (*Yahoo! v. Licra,* 2002, pp. 46–47). Some legal scholars are worried that this decision could limit access internationally to that speech legally acceptable in the most restrictive of countries worldwide. Others argue that other countries have the right to determine what is lawful within their sovereign borders and that such legal cases are needed to sort out jurisdictional issues.

Efforts to censor access to information on the Internet will continue to be proposed in the government arenas both nationally and internationally. Hopefully, opposing groups will be able to question such legislation in the national and international courts to discuss important Internet access issues regarding Internet content.

CENSORSHIP AND INTELLECTUAL PROPERTY ON THE INTERNET

Ownership of Internet information is another area where charges of censorship versus legitimate access and content limitations must be considered. As is true with content-based censorship questions, there is a long history of intellectual property (IP) legal challenges in both the United States and in other countries worldwide regarding traditional communication media such as print, radio, and television. Whether these traditional laws and decisions are transferable to Internet IP issues continues to be challenged, tested, reviewed, and refined. Interpretations of the legal status of property and the subcategory of intellectual property vary widely in the global market. Intellectual property laws attempt to balance the rights of product creators, owners, and users through copyright, patent and trademark statutes, and case law decisions.

Alleged copyright and trademark violations are the two areas where Internet censorship accusations are most frequently leveled. The Copyright Act of 1976 was amended in 1980 to include the protection of software development at a level similar to that of traditional protected works. The ease of accessing and sharing Internet information raises many copyright infringement accusations. The "fair use" section of the Copyright Act has been interpreted and reinterpreted in courts in the United States. Tensions arise when claims of fair use come into conflict with claims of ownership and denial of right of access. Usually, the decision is not that users do not have the right to access information, but that they do not have the right to copy and reuse the material traditionally granted under the doctrines of fair use and the right of first sale.

The Digital Millennium Copyright Act (DMCA) was enacted by Congress in 1998. The DMCA bans the use of technological devices that provide the means to circumvent protection systems and other access measures in an attempt to limit file sharing. The DMCA is aimed at protecting the rights of copyright creators and holders while striving to make certain file sharing illegal when software is developed to circumvent antipiracy encryptions coded into software for commercial sale or to develop software that enables the illegal copying of software. Critics of the DMCA argue that the act overly favors creators and rights holders and results in censorship when it abridges individual rights of traditional copyright law such as first-sale rights, fair use, and thus the right of free speech.

A case of interest is that of Jan Johansen, who is being criminally prosecuted in his home country of Norway for developing DeCSS software that allows DVDs to potentially be copied or played on unlicensed equipment. Johansen is only a teenager but managed to develop code that circumvents DVD protection systems. Johansen then shared the code via his Web site for international access. The Motion Picture Association of America (MPAA) filed suit against the use of DeCSS under the terms of the DMCA that supports the rights of copyright holders of creative works to limit access. Encyrption codes are not protected as First Amendment speech according to the U.S. courts, which upheld the ban of sharing DeCSS on the Internet (Electronic Frontier Foundation, 2002; Spinello, 2003). The courts determined that the code that instructed the computer to decrypt the software protection system was not considered speech under First Amendment protections (*MGM v. Grokster,* 2002) Other court cases are addressing other instances where protection systems have been circumvented under the rubrics of right of first sale and fair use. The decisions of these cases will add to the body of case law clarifying what constitutes legal access while interested parties attempt to limit censorship through limiting or prohibiting copying and sharing of materials on the Internet.

A substantial section of the DMCA addresses the implementation of treaties established by the World Intellectual Property Organization (WIPO). These treaties address the issues of copyright protection systems and copyright management information and the evaluation of the impact of copyright law and amendments on electronic commerce and technological development. The WIPO focuses on two major intellectual property fields. The first pertains to industrial property questions concerning inventions (patents), trademarks, industrial designs, and geographic indications of source. The second field concerns copyright and concomitant rights related to copyright and the collective management of copyright. The WIPO has been in existence in some form since the late 1800s. Currently, membership countries number 179, which is over 90% of the countries worldwide. One of the main purposes of WIPO is to broker international treaties that affect creators and owners while encouraging dissemination and use of IP. Recent treaties, such as the 1996 WIPO Copyright Treaty and the 2000 Patent Law Treaty, affect access to Internet materials. The WIPO Arbitration and Mediation Center maintains a list of professionals worldwide who are trained to deal with domain disputes. In 2000, the Center handled 1,850 cases (WIPO, 2002). Domain name arguments traditionally take the form of "twins," where multiple parties lay claim to the same name. Anyone with the name "McDonald" could run into problems when trying to claim a domain name where the major U.S. corporation of the same name might dispute ownership. "Parasites" are those who register a domain name that sounds very similar to a famous company name with the intent to enhance sales of their own products. "Cybersquatting" is when individuals or groups register the same or similar domain names of famous entities with the intent resell them back to the well-known people or companies (Spinello, 2003).

Software development falls under both the patent and copyright areas. Ideas cannot be patented or copyrighted, but representations of ideas can be. Patents often are classified under the "first to file" rule and ownership may not be registered with the originator of the product. As a result, who controls access to certain software code becomes controversial. Some software developers and owners believe in open source code sharing that others do not.

Universal consensus does not exist as to whether a right to ownership of information exists on the Internet in the same way it does in traditional formats. The WIPO is affiliated with the World Trade Organization (WTO) and there are those worldwide that disagree with the efforts of both organizations. The Against Intellectual Property Homepage (2002) claims that information as property and information ownership are not beneficial to society as a whole. Whether copyright is even ethical is addressed by Warwick (2001), who argues that traditional U.S. copyright laws have valued the benefit of created works to society as a right over the value and rights of creators. The Electronic Frontier Foundation (EFF, 2002) Web site frequently addresses the issue of IP and information access and content control.

Deep-linking is the practice of bypassing a Web site's homepage and linking to a lower level page within the site (*Deep Linking,* 2002). Legal cases in Germany, Denmark, and the United States illustrate how this issue can be construed as censorship when governments become involved in determining copyright infringements. In the case in Germany, copyright law awards exclusive dissemination and reproduction rights to the maker of an online database. A German publishing group, Verlasgruppe Holtzbrinck, sued NewClub.de that produces a search engine for news stories by aggregating headlines, claiming that the search results and linkages directly to articles violated and abridged their property rights. According to the publishing group, their news headlines constitute a database and thus these links violate their right to control dissemination and reproduction. The German courts are working to clarify "temporary copying acts" and allowing search engines to link to subordinate Web pages. A similar case in Denmark also involved search engines that link to newspaper articles directly, bypassing the main homepages of the news providers. The Danish Newspaper Publishers Association claims that bypassing their homepage diminishes revenues to advertisers when readers are diverted to lower level pages. In an earlier case in the United States, Tickets.com won the right to link to a subordinate page on Ticketmaster's site without linking to the main homepage. The court's decision compared the unique Internet linking system more to a library card catalog than a violation of copyright law. As long as the search engine results make it clear who is responsible for posting the Web content, no copying violation has occurred. Other legal cases will further clarify the relationship between search engines, advertising, linking, and copying both nationally and internationally.

National and international legal cases, in addition to national and international discourse, aided greatly by Internet sharing, will further the clarification of competing rights of information access between users and creators. Whether the prohibition of access to Internet information meets the level of censorship claims abridging fair use or the right of first sale, or whether intellectual property rights being upheld will continue to be debated in courts of law and on the Internet itself remains to be seen.

CENSORSHIP, TECHNOLOGY, AND INTERNET PRIVACY

Internet privacy and security issues are peripheral censorship issues but ought to be included in discussions on rights of information access and content control. Conflict arises between advocates of information being made available in its freest forms versus claims of right to privacy or security concerns. In the United States the Constitution does not designate a particular right to privacy, but over time case law and statutes have carved out more and more privacy rights pertaining to personal information of individuals. The Fourth Amendment protects the rights of individuals to be secure in their homes, papers, and effects against unreasonable search and seizure without probable cause issued by a court of law. Computer records would presumable fall under the category of "papers and effects" as being constitutionally protected. However, with the passage of the Patriot Act in 2001, what merits governmental right of access to personal information has broadened greatly, giving sweeping powers to international intelligence agencies in addition to domestic agencies. Expanded government surveillance with a very low level of evidence to substantiate probable cause has been established. Software, called "spyware" has been developed for the sole purpose of surveillance and logging Internet activities and allows not only the government but other individuals to monitor computer use. Internet service providers may voluntarily furnish user information, not including content information, without a court order or subpoena. The Patriot Act also allows the government to investigate computer trespassing without requiring a court order. Such expanded government surveillance of computer use might result in a chilling effect on Internet users who might self-censor what information they seek and which Web sites they view.

In a case that combines several aspects of Internet censorship, the Nuremberg Files case involves Internet content, privacy, hate speech, and access. The Web sites are the work of Neal Horsely, who maintains the sites (Nuremberg Files, Christian Gallery, 2002) through Pathway Communications. The sites are provided in order to collect information on those associated with abortion clinics for future court actions, according to the Web sites. Past sites had posted "wanted posters" containing personal information including names, home addresses, home phone numbers, and photographs mainly of physicians who performed abortions and clinic staff and owners. As persons on this list were killed or wounded, an X would be drawn through their photo. Also a line would be drawn through the deceased person's name. Those wounded were noted in gray type. In 1999 a Planned Parenthood organization along with an abortion clinic and four doctors filed suit in Oregon under the government's Freedom of Access to Clinics Entrances Act, which prohibits threats of violence to deny access to clinics. An Oregon federal jury found for the plaintiffs and awarded $109 million dollars in damages to Planned Parenthood, the clinic, and the doctors (*Planned Parenthood v. American Coalition of Life Activists,* 2002). A three-judge appellate court overturned the ruling in 2001, stating that the Web site speech was protected by the First Amendment. The court further ruled that even though the speech could be considered highly offensive, that the language could not be construed as representing a true threat as the site was conceptualized to provide public advocacy and was not seen as a call to action. In 2002 the Ninth U.S. Circuit Court of Appeals overruled the previous court decision, determining that "violence is not a protected value" (*American Coalition of Life Activists v. Planned Parenthood,* 2002). Court justices in the majority stated that the site demonstrated intent to inflict bodily harm existed and that there was a pattern of violence in the way the content was portrayed. The court did not uphold the monetary award of $109 million and the lower court is currently reconsidering that issue. The case is expected to be appealed to the U.S. Supreme Court. This case includes the issue of content by including wanted posters of abortion clinic affiliates on the site. Privacy rights are called into question by including personal information on where people live and their phone numbers and includes information about family members and friends. Access issues are also part of the case as the site content provider, Neal Horsely, has had difficulties in finding Internet service providers who will allow the site to be offered.

Again, questions over who owns information and whether this information can be shared easily over the Internet are called in to question where personal information is concerned. Traditionally, medical information is owned by the doctor or hospital providing service to an individual who had no control over the transfer of this information. Recently however, patients have been accorded more rights over what information health care providers may share without their permission. Individuals do not own their addresses or phone numbers so the U.S. Post Office and phone companies can sell this information to others without the permission of individuals. Banks and credit report companies often share personal financial information of individuals. Personal consumer habits and behaviors are tracked and sold without the knowledge of the individual. The Internet facilitates sharing information, which is of value to others and much of this sharing is beyond the control of the individual. In some cases, companies offer individuals to "opt in" or "opt out" of information sharing. Identity fraud is on the increase with so much personal information available via Internet sources. The government is examining many of these areas, especially in the medical and financial sectors, to balance competing rights of ownership versus access. Whether the attempt to limit the sharing of personal information is censorship is still under discussion in many arenas on many levels. Courts will need to balance information ownership issues against the rights of owners to share or sell information against the security needs of individuals. For a more in-depth discussion of privacy and security as censorship concerns, see Spinello (2003) on regulating Internet privacy.

CONCLUSION

The Internet is a complex connection of numerous computer networks originally developed to facilitate the ease of sharing information. As the number of users has grown exponentially worldwide, censorship issues have also grown almost at the same exponential rates. The amount of information available has also grown at a tremendous pace. Technology, mainly in the form of software, continues to proliferate rapidly in an intricate point–counterpoint trend where access to information is expanded, followed by software that then limits access. Who should have access to what material is the critical question being asked over and over again in evolving iterations. Many Internet users view the denial of access to information as censorship. In the United States, censorship questions have been traditionally answered legally in courts of law and based on constitutionally protected First Amendment rights of free speech. Internationally, rights of free expression vary widely by geographic area and cultural norms. Global jurisdictional questions are still being debated and will probably continue to be discussed for a long time to come, which is not inherently a negative pursuit. A long-term debate concerning whose laws take precedence or whether new international laws need to be promulgated are needed. We hope the discussions will include a wide range of stakeholders that should result in better legal and ethical decisions regarding Internet access and content control.

GLOSSARY

Censor Legally, a person who acts in an official capacity to preview or inspect works including books and other publications, films, etc., in order to purge inappropriate material; commonly, anyone attempting to prohibit access to information, books, films, etc.

Censorship Legally, the abridgement of the freedom of speech or freedom of the press by government action; commonly, the prohibition of access to information, books, films, etc.

Child Internet Protection Act (CIPA) Successor to both COPA and CDA and signed into law in 2000; restricted the disbursement of e-rate (see e-rate) subsidies to public schools and public libraries to only those agencies that have installed computer filtering software; overturned at circuit court level in 2002 mainly due to concerns over faulty technology only in terms of public libraries. Schools are still required to implement the law as written. Currently under appeal in the U.S. Supreme Court.

Child Pornography Materials in which minors under the age of 18 are depicted participating in sexual acts. Not protected under the First Amendment in the United States as such materials are considered obscene even if they do not technically meet the legally established obscenity standards.

Child Pornography Protection Act (CPPA) Signed into law in 1996; expanded child pornography statutes to include graphic depictions of computer-simulated images of minors engaged in sex acts or the use of adults who appear to be underage. In 2002 the Supreme Court overturned the law for being overbroad, as it would, in part, prohibit legal portrayals of teenage sexual behavior in art and literature. Considers that the creation of an image that does not involve actual children is not child abuse.

Children's Online Protection Act (COPA) Successor to Communications Decency Act and signed into law in 1998; aimed at commercial Web vendors and required some form of proof of adult status and identification be collected prior to disseminating pornography. The law was challenged on the basis that it impairs access by making adults provide identification to access legally protected speech. In 2002 the Supreme Court reviewed the case and subsequently remanded it back to the lower court to review whether the act is constitutional or overbroad under the community standards principle.

Communications Decency Act (CDA) Signed into law in 1996 in an attempt to regulate the distribution of pornography on the Internet with special concern regarding access by children. Ruled unconstitutional by the U.S. Supreme Court for being vague and overbroad in scope concerning indecent speech and for potentially limiting Internet content for adults to only that which is appropriate for minors.

Copyright A right granted that allows the creator of a work, the work-for-hire of a creator, or one who has purchased the right from a creator to control the dissemination of the work.

Cryptology The practice of encryption and decryption or decoding (see "encryption").

Deep-linking The practice of bypassing a Web site's homepage to connect to a subordinate page.

Digital Millennium Copyright Act (DMCA) Passed by the U.S. Congress in 1998; addresses issues of copyright privileges and rights in the digital arena. Key areas focus on prohibiting the development of technological tools to unlock digital protections placed on electronic materials to deter copying and sharing.

Encryption The practice of coding information in such a way that renders others unable to decrypt without the use of a secret key or password.

E-rate Telecommunications discounts offered by the U.S. Government to public schools and public libraries.

Fair use Establishes provisions for copyright law under which materials may be copied and distributed for educational purposes. In the digital arena the issue of "fair use" is being reconsidered.

First sale Establishes provisions under copyright law where the consumer is granted the right to subsequently loan, sell, or give that copy to someone else. Also under review in terms of the digital arena.

Inappropriate materials Books, movies, images, etc. that are deemed not proper or suitable. Most often used to distinguish "age" appropriate materials for children.

Indecent materials Books, films, images, etc. that offend public norms and mores.

Intellectual property Property rights granted to creators or rights holders of copyright, patents, trademarks, trade secrets, and fair competition.

Obscene A legal designation of materials that fall outside the bounds of community standards of decency. Usually such materials appeal to lewdness and lasciviousness.

Open source code Software where the programming code is published openly so that a wide range of people can access the code and add to it; opposite of where code is considered proprietary and thus considered a trade secret.

Patent A federally granted right to control the dissemination of something that someone has invented, improved, or produced.

Patriot Act Passed by Congress in 2001 and affords the U.S. government extended powers in gathering information regarding possible terrorist threats by lessening individual civil liberties concerning privacy and search and seizure.

Pornography Materials depicting sexual or erotic acts or behaviors with the sole intent to arouse or excite in a sexual manner.

Trademark A distinctive label, either a motto, name, symbol, etc., that an organization uses to identify or advertise its products. The Patent and Trademark Office in the United States is in charge of issuing patents and trademarks in addition to overseeing and monitoring conflict.

Internet Etiquette (Netiquette)

Joseph M. Kayany, *Western Michigan University*

INTRODUCTION

Netiquette (net + etiquette) can be defined as the informal guidelines developed by the users of the Internet for acceptable online behavior. These are developed over time in a variety of virtual environments and Internet applications. This chapter reviews the generally accepted standards of appropriate behavior for popular applications such as e-mail, newsgroups, chat, FTP, and the World Wide Web.

Defining Netiquette

Netiquette is a blend of common sense, common courtesy, and dictates of the computer technology and culture established by Internet users (Miller, 2001). The norms of behavior are adaptations of real-life etiquette to the unique features of the online technology and environment. Although many of these guidelines have evolved into formal rules that system administrators and owners of proprietary systems enforce, netiquette, in the broader arena of the Internet, is still based on an informal honor system. Etiquette comes from the French word for "ticket" (Shea, 1994), suggesting that compliance with socially defined behavioral norms is the ticket for entry to a network or society. Violators may be ignored and ostracized by the members of the group. Moreover, it is a dynamic social practice that is being continuously interpreted and redefined within the cultural milieu of a collectivity. These norms are rarely universal but specific to each social group or culture, both real and virtual.

Significance of Netiquette

Rules and norms are part of the unique identity of any social collective. Respecting group norms demonstrates fundamental respect to the group itself (when in Rome, do as the Romans do) and is essential to building a community. The Internet as a social collective is, however, very different from other groups. First, it is not grounded on affinities of culture, race, or physical proximity. Secondly, it is growing faster than any other community in history. Traditions and cultural norms are useful in dealing with such rapid pace of change.

As a communication medium, the Internet possesses certain unique features. On the one hand, it is unable, as of now, to convey the full range of nonverbal communication cues, and on the other, it gives users greater control over both the temporal and spatial coordinates of communication. That is, it sustains both synchronous and asynchronous interaction with individuals both far and near. On the one hand, its users can disguise their identities, but on the other, the messages exchanged on the Internet are guaranteed to be neither private nor secure. These unique features do influence the process and outcome of communication that occur through the Internet. The conventions that develop over time around a communication technology are often the by-products of the collective experience of those who have explored its strengths and constraints in diverse communication contexts. Therefore, knowledge of these conventions and practices is essential to anyone who proposes to use these technologies effectively.

Origins of Netiquette

Although early computer networks were primarily developed to enable researchers and academics to exchange research data and documents, those with access to the network often used it for social interaction, as a convenient, informal, and quick substitute to mailed letters or phone tag. In addition to one-on-one communication, store-and-forward applications such as electronic bulletin boards and Usenet newsgroups that allowed the simulation of a group discussion also became popular. Network users could access virtual locations where messages classified by topic were stored in chronological order. Geographically dispersed users were drawn to these shared spaces because of shared interests. Their posts and responses were experienced as group communication activities that led to group bonding, affinity, and identity. Such spatially dispersed collectivities were termed "virtual communities" in opposition to geographically bound real-life communities.

Unregulated Environment in Virtual Communities

Unfortunately, life in these virtual communities was often not as tranquil and congenial as expected. Rebukes, insults, name-calling, and even profanity became frequent on the Net, a phenomenon that came to be known as "flaming." The uncharacteristically unruly behavior on the Net had several explanations. Some argued that the type of people who inhabited the Net in the early days of computer-mediated communication were responsible (Lea, O'Shea, Fung, & Spears, 1992). Early Net users were almost exclusively young computer professionals and hackers, who not only considered themselves at the cutting edge of technology but also of social transformation. The Internet allowed them to break free of the traditional spatial boundaries of communication channels and enabled them to interact outside their cultural boundaries. Flaming was seen as a by-product of this new adolescent hacker culture that defied traditional definitions of appropriate behavior. Flaming was also thought of as a consequence of the nature of the medium itself. The Internet is a text-based communication channel that is low in "social presence"—a measure of the extent to which a person experiences the other person's presence during the communication process. Since the chance of a face-to-face encounter between users is limited, it's easy to feel insulated and anonymous. People are more willing to engage in socially inappropriate behavior when they perceive the other person to be distant—often on another part of the globe (Kiesler, Siegel, & McGuire, 1984).

It was not rare to find such virtual communities becoming war zones where civility and community building gave way to acrimony and hostility. In this context it became clear to many Internet users that civility and mutual respect were vital to maintain the Internet as an acceptable form of social communication. Groups agreed on standard practice and communicated it in publicly accessible files called FAQs (Frequently Asked Questions). Newcomers were expected to read these and comply with the suggested standards. Ironically, many flames were initiated by "old timers" trying to chastise "newcomers" for violating the published norms of online behavior.

Flaming

Sending an impolite and insensitive message that is perceived as an insult or violation of group norms is known as "flaming." A flame can initiate a series of flames or a flame war. Flaming is often an emotional reaction to a post deemed inappropriate by a member of the group. It could be because a new member is perceived to have violated the accepted norms of a group, or because a member is deemed to have wasted everyone's bandwidth by long posts, repetitive questions, indiscriminate cross-posting, or commercial spamming. Sometimes, people respond in anger to any violation of another's privacy when someone divulges personal information or when someone violates standard practices of quoting correct sources (McLaughlin, Osborne, & Smith, 1995).

Flaming is very often sparked by a misunderstanding of the tone of the message. A joke, which would be recognized as such in a face-to-face situation, could be interpreted as offensive by any one of the hundreds of users and it could lead to a flame war. The inability to convey emotions and mood has been a major drawback of the medium.

Emoticons or "Smilies"

One of the ways the online community addressed the lack of nonverbal cues was by developing keyboard-generated symbols that represent various emotions. These nonverbal surrogates are popularly known as "smilies" or "emoticons." For instance, a smiling face created with a colon, hyphen, and right parenthesis on the keyboard :-) looks like a smiling face when you bend your head to the side. A winking smile can be created with a semicolon, hyphen, and right parenthesis ;-) that says "I am only joking" or "I am being ironic." When this combination of keystrokes is added after a text, it tells the reader that the text that precedes it is being written in a jovial mood and ought to be taken in that spirit. Table 1 shows some of the most popular smilies.

Netiquette and the Real World

The early expectations of online media were based on a unique cosmopolitan cyber-culture governed by the value system of a sophisticated educated minority who wished to congregate, communicate, and relate to others like themselves. However, in the 1990s, there was a radical shift in the direction of the Internet's growth. The introduction of the World Wide Web's user-friendly interface was one of the primary reasons for its enormous popularity among the public. The original metaphor of

Table 1 Common Smilies or Emoticons

:-) or :)	Happy; jovial
;-) or ;)	Wink, light sarcasm: "I am only joking," "I am being ironic"
:-(	Sad, disappointed
:-|	Indifference
:-D or :-o	Surprise
:-@	Scream
:-O	Yell
:-*	Drunk
;-}	Leer
:-||	Angry

virtual community gave way to a new way of thinking about the Internet—as an information superhighway and a vehicle for e-commerce. As more people flooded to the Internet for its "informational and commercial" potential, the public's attention was diverted from its potential for companionship and community. The Internet increasingly became another source of information like the radio, TV, newspaper, or the library and another channel of communication like the telephone or conventional mail (often referred to as "snail-mail" because of its physical limitations). Online communication became routine at the workplace, schools, and home. People used e-mail to interact not only with strangers around the globe, but more frequently to keep in touch with their colleagues, neighbors, and friends. As a result, the perception of online media as the lifeline to a unique cyberspace existence and of netiquette as the universal norms of behavior in the virtual world gave way to real-life norms of behavior adapted to the multitude of social contexts. As a result, it is increasingly difficult to talk about a unique set of netiquette guidelines that apply to a homogenous online environment. Instead, netiquette is increasingly a reflection of the physical world, with highly contextualized norms of behavior specific to a group, corporation, society, or community. These norms are extensions of the existing culture applied to the practice of online communication.

Despite the trend toward context-specific norms, an understanding of the traditional practices is useful because they are based on a clear grasp of the strengths and weaknesses of the technology and founded on the core principle of all etiquette—respect for the other. The remaining sections of this chapter are devoted to a discussion of the norms that have found broad acceptance among the users of Internet applications such as e-mail, bulletin boards, chat rooms, FTP, and the World Wide Web. Perhaps the best use of these guidelines would be as benchmarks while individuals and groups discern appropriate behavior in particular communication contexts.

E-MAIL NETIQUETTE

E-mail netiquette guidelines revolve around the central theme—respect. While trying to effectively present the message and ourselves, we should take care to respect the receiver, his or her convenience, bandwidth, and privacy as well as the e-mail conventions and symbolisms developed over time. It is worth reiterating, however, that these norms are neither universally applicable nor appropriate to all communication situations. Interaction history is a key factor that governs decisions regarding appropriate behavior in person-to-person e-mail, whereas in e-mail to groups, factors such as the purpose, size, and geographical dispersion may contribute to the dynamic of discerning what is appropriate in a specific context.

Respect the Other

Salutations

It is safe to use the same salutation that you would use in other forms of communication such as a written letter, telephone, or face to face. For instance, if the correspondent signs his/her first name in the e-mail to you, you can use the first name salutation while replying, although conventions regarding the use of first name ought to be carefully examined while e-mailing to a woman from a different cultural background.

Aim at Consistency

You may check and respond to your e-mail once a day or once a week, but what is important is that you be consistent. People develop expectations on how soon they can expect a reply from you. Inform others if you not available to maintain the routine. Use the auto-responder function of e-mail programs to inform those expecting a reply from you that you are unavailable. However, avoid using the auto-responder option if you are subscribed to discussion groups and listservs.

Be Kind to New Users

Ignore the netiquette violations of others, especially of newcomers. If you must point out errors, do it with compassion, always through a message sent directly to the e-mail address of the offender and not to the entire group.

Redirect Missed Deliveries

If you receive in error a message intended for another, forward it to the appropriate person with a note. If you do not know the e-mail address of the intended recipient, notify the sender.

Signature File

Make sure that pertinent sender information is appended to the end of each message. It is common practice is to use a "signature file" that gets automatically appended to each message. It contains all the necessary information about the sender—name, title, organizational affiliation, mailing address, e-mail address, and phone and fax numbers. Limit the size of signature files to four lines. Avoid long quotes or images built out of keyboard characters that will often appear as gibberish if the default font setting of the receiver is different from the sender's.

Resist the Urge to Respond to Flame

If you are the victim of a flame, do not respond while you are still emotional. It is safe to leave the reply in your outbox for a day before sending it. If a flame was sent to a list of people and you feel compelled to respond to the flame, do not send the reply to the whole group; instead, e-mail your response to the person directly.

Protect Privacy of E-mail Messages

Any personal e-mail you receive is intended for "your eyes only." It is not appropriate to forward such e-mail without the sender's permission.

Protect Privacy of E-mail Addresses

While e-mailing a list of recipients, if you put the e-mail addresses in the "To:" or "CC:" (carbon copy) fields, the e-mail addresses of all the recipients will be displayed to each recipient at the top of the message. When you are sending a common e-mail to a group of people who may not be known to each other, you risk disclosing the e-mail addresses of those who may not want it to be published. This can compromise the privacy of the recipients. No one has the right to give out another person's e-mail address. You can address this problem by putting the e-mail addresses of all the recipients in the "BCC:" (blind carbon copy) field. The list of e-mail addresses will then not be displayed to all recipients.

When members of the group are known to each other, displaying the e-mail addresses of all recipients may have value. For example, in arranging a meeting of a small working group, it may help members to know who has been invited or copied. Nevertheless, it is annoying when one must scroll through a long list of addresses to get to the message.

Respect Copyright

Do not forward anything, articles, graphics, music, or multimedia files that are copyrighted. Remember that personal e-mail is also copyrighted. If you are not sure about the copyright, verify. If the author grants permission to distribute the materials, include the copyright notification.

Respect Another's Convenience

Be Brief

A general netiquette principle is that one's communications should not waste other people's time. There are people who receive hundreds of e-mails daily. Many people pay for Internet connection by the hour. Hence, keep the messages brief and to the point.

Include Meaningful Subject Headings

Use detailed subject headings. Instead of the generic "Greetings" or "Hello" or "Question for you," the subject line should contain a clear summary of your message that allows the receiver to know what the message is about without having to open it. It allows the receiver to prioritize the hundreds of messages he/she receives each day. Many people look for clear subject lines to evaluate the legitimacy of the message because there have been many instances of e-mails with viruses in attachments that arrive in people's mailboxes with innocuous-looking generic subject lines.

Use One Topic per E-mail

Make sure that each e-mail addresses only one topic. Multiple subjects in the same e-mail are harder for the receiver to file and retrieve. Further, if an e-mail with multiple topics must be forwarded to different people for appropriate action, the receiver will have to divide it into separate topics.

Increase Scannability

Increase the ability of recipients to scan the message by writing short paragraphs and by including subheadings if the message is more than a screen-full long.

Use Plain Text

It is tempting to use the formatting capabilities of the new e-mail programs and create a message in HTML with fancy fonts, colors, and images. In addition to clogging the network and increasing the download time, many e-mail programs are unable to display formatting. Often such HTML formatting appears as gibberish making the message unreadable. However, if all the recipients are capable of receiving HTML formatted messages, you may use such formatting. You can avoid the hassle of having to keep track of each person's computer capabilities by sending messages as plain text only.

Table 2 Common Acronyms on the Net

BTW	By the way
IMHO	In my humble opinion
FYI	For your information
LOL	Laughing out loud
ROTFL	Rolling on the floor, laughing
TTYL	Talk to you later
TTFN	Ta Ta for now
Gr8	Great
Ty or 10q	Thank you
OMG	Oh my God
WB	Welcome back
BBL	Be back later
HB	Hurry back
NP	No problem
kotc	Kiss on the cheek

Use Acronyms and Slang with Care

Acronyms and slang should be used only when you are sure that the other person knows the meaning. It is easy to assume that the receiver is familiar with them. Acronyms save keystrokes for the sender but they might make comprehension of the message more difficult for the receiver. Slang may hold different meanings and lead to misunderstandings especially in international settings. Table 2 shows some of the popular acronyms on the Internet.

Refer to the Message in the Reply

When replying to a message, include portions of the original message so that the receiver will immediately know the reference of your response. However, include only those portions of the message relevant to the response.

Respecting Another's Bandwidth

Think of Those with Slow Connections

A majority of Internet users rely on slow modem connections to access the Net. Many people pay for the Internet connection by the hour. Hence, it is important that your e-mails do not result in loss of time or money for the recipients.

Avoid Empty Shells

Do not include the whole text of a long message if you have nothing of substance to say than "OK," "yes," or "me too." In this respect, it is important to respect the customs of the group. If the group values such brief notes of support, encouragement, and congratulations as a way to build group cohesion, they may be perfectly appropriate.

Ask Permission for Attachments

When sending attachments, ask the recipients if they are interested in receiving the file. Always send the file in a format compatible with their system and software.

Verify That Attachments Are Virus-Free

There are now viruses that propagate via people's address books so you may appear to be receiving an attachment from a friend when it is actually a self-generated automated virus. Thus, when sending an attachment to someone it is important to explain what the attachment is and that you certify it is virus-free.

Be Stingy with Copies

Limit distribution of copies of e-mails based on the need to know. Send copies only to those who really need to get a copy.

Be Judicious with the Forward Option

Many a netiquette violation occurs because of the ease of forwarding e-mails. It is so effortless to forward a joke, an inspirational slide show, chain letters, inspirational stories, or virus warnings. Refrain from forwarding anything that you would not spend first class postage if you were to mail it out. As for virus warnings do not forward them unless you have verified them.

Respect E-mail Conventions and Symbolisms

Avoid All-Caps

Use mixed case to type the message. Don't type the messages in all caps. Not only is all-caps text harder to read, but it is also considered the cyberspace equivalent of shouting. This is one of the conventions accepted from the early years of Internet. However, caps may be effectively used to emphasize a word, or at most a sentence.

Avoid All Lowercase

Avoid all lowercase as well because the receiver may interpret it as a sign of sloppiness. All lowercase may sometimes be deliberately chosen to convey that the message should not be construed as formal. Acronyms, informal grammar, and all lowercase are the online equivalent of a scribbled note as opposed to a carefully crafted e-mail that conveys the formality of a typed letter.

Incorporate Emotions

Always be aware that e-mail is a text medium. In the absence of facial expression or voice, the tone of the message can easily be misinterpreted. Smilies may help convey some of the emotions but they should be used sparingly. Use only the most common smilies; it is possible that some of your recipients may not understand the meaning of a smilie (Table 1). Therefore, a verbal indication of the emotion being expressed in brackets can be used instead of smilies to make sure that the receivers are clear about the tone of your message. (Example: {smile}. Some people have begun using pseudo-HTML tags around text to indicate these emotions. Example: <smile> This text is silly </smile.) Do not, however, use smilies in communication environments where formal communication is expected.

Use Humor with Extreme Caution

Body language cues are essential to the interpretation of humor and sarcasm. In the absence of such cues, exercise *extreme* caution while using humor in Internet communication.

Pay Attention to the Language

It is rude to make mistakes in grammar, spelling, sentence structure, and punctuation. Re-read the messages before clicking the send button. However, it is also considered rude to criticize spelling mistakes, typos, and mistakes that suggest the sender is not a native speaker of English.

Respect the Network

Do Not Forward Executable Files

Never forward any executable files. Many viruses are transmitted as attachments whose names end with the suffix ".exe."

Keep Your System Virus Free

One of the dangers of computers being connected to each other is the possibility of a virus-infected computer infecting others. Hence, one of the important netiquette duties of every computer user is to keep his/her system healthy with regular virus checks. However, if you notice that your system has been infected, send a warning to all your e-mail contacts about a possible virus infection that may have reached them through you.

Break the Circle of Hoaxes, Urban Legends, and Chain Letters

These are messages that originate from some evil genius and get recirculated by the newbies and the naïve. Old hoaxes never die; they just get a new life cycle. Some hoaxes have been reborn so many times that they are often considered "urban legends." For instance there is a proprietary cookie recipe that the sender is apparently circulating to get even with the owners of the recipe. Then there is a story of a kid who wanted to get a postcard from as many people as possible before he died. There are plenty of phony messages and pranks on the Net especially as we get closer to April 1 each year. The best thing to do is never forward them or respond to them.

Check the Validity of Virus Hoaxes

The most popular of such practical jokes is a virus hoax that asks the recipients to forward it to as many people as they know. Don't forward it before you check with virus system administrators to ascertain the veracity of a virus warning. This will help you protect your own system as well as those of the others.

Reject Chain Letters

A typical chain letter asks recipients to forward it in exchange for some spiritual or material reward, often with a threat of harm if you don't forward it. Don't forward such messages to anyone unless you know the message is true, or you can authenticate the message and the identity of the sender. In all likelihood, it will be impossible to reach the originator because most pranks and hoaxes have forged headers and signatures.

Respect and Commercial E-mail

Early e-mail users zealously protected the medium as a noncommercial forum so that any attempt to use e-mail for advertising or sale of products and services was considered the most serious violation of netiquette. However, the success of direct mail as a very effective advertising method has encouraged people to blatantly disregard this principle. Advertisers have taken on e-mail because of the ease of distribution and low cost. Despite all protests by those who resent such commercial use of e-mail (known as spamming) as a violation of their privacy and an encroachment on their bandwidth, spamming is not going to go away because it does hit the few interested people. However, every sales person recognizes that respecting the customers and dealing with them honestly generates customer good will. It is the sneaky spammer that people resent the most.

Use Honest Subject Lines

State clearly the commercial purpose of the e-mail. Some advertisers prefix the subject line with "Adv:," which lets the receiver know that the message is an advertisement.

Use One-Line Solicitation

Instead of mailing out a detailed description of the product or service, mail a one-line solicitation asking those interested to e-mail for details. Even those not interested in what you are selling would appreciate your respect for their bandwidth.

Suppress E-mail Addresses

Always use e-mail software that suppresses the e-mail addresses of the other recipients.

Customize Lists

Use customized databases of recipients. Direct your e-mails to those most likely to be interested in your product or idea. It is also appropriate to conduct initial research on how commercial messages are likely to be received and to spare those forums that have clearly stated that commercial mail is unwelcome.

Provide a Remove Option That Works

Give a legitimate option for people to remove their name from your mailing lists. Often when people use the "remove" button to request removal of their e-mail address, they start getting more spam because the remove button was a trap. By requesting removal they have verified that theirs is indeed a "live" e-mail address. This is unethical.

Know the Law

There may be regulations prohibiting commercial e-mail in some countries, in organizations, or in electronic forums. Be aware of these laws before spamming. Even when no laws exist prohibiting such activity, remember that excesses by spammers might result in eventual legislation that will make it difficult to use this technology as a cost-effective marketing tool.

Safeguard Your Own Interest and Image

E-mail Is Not Ephemeral

Do not e-mail anything that you would not say face to face to a person. E-mails can be saved and circulated. Hence do not e-mail anything that can cause you embarrassment if your boss, spouse, friends, or children read it, now or years later. Don't e-mail anything that you don't want to see in print, posted on a bulletin board, in a newsletter, or in front of a jury. Always be aware of the privacy policies of your Internet service provider (ISP) or the corporation that provides you Internet access.

Seek Clarity

Very often e-mail communication occurs with people we do not know in real life. Our impressions of each other are based exclusively on the way text is presented in e-mail. Hence composition is an important factor in the appropriate presentation of the message and of us.

GROUP NETIQUETTE

In this application of computer networks, simulation of group interaction is achieved through store-and-forward computer servers that accept messages from participants. There are three major types of group communication platforms (Table 3), which differ in terms of how they regulate access and deliver messages. Listservs and newsgroups store the messages in the host computer. Newsgroups have an open access policy that allows anyone to access the messages. Listservs restrict access to subscribers only. Access to messages on mail servers is also limited to subscribers but they differ from listservs in how they deliver messages. Listservs store the messages in the host computer that subscribers can access, whereas mail servers forward copies of the messages to the e-mail inboxes of subscribers.

The e-mail netiquette guidelines discussed in the previous section E-mail Etiquette apply to group discussion settings because group posts are essentially e-mails directed at a group. In groups, it is rare that we know every participant. We have no way of knowing who the participants are. Therefore we ought to pay greater attention to netiquette so that we do not cause discomfort to any one

Table 3 Types of Group Communication Platforms

	Access to group	Message delivery
Newsgroups	Public access	Stored in the host computer
Listservs	Access through subscription	Stored in the host computer
Mail servers	Access through subscription	Copies e-mailed to subscribers

of the members. We must be as cautious of our behavior as if we were among strangers in a country with a different culture and language.

Respect the Group

Read FAQs and Lurk

Do not jump right into the discussion. Read the FAQs and the group archives. Introduce yourself if new members are expected to introduce themselves. Then lurk around and listen to the conversation to get a sense of who the group members are, what interests them, and what is acceptable.

Pay Attention to Procedure

Read the instructions on the procedure for subscribing and unsubscribing. Pay special attention to the two separate e-mail addresses commonly used by mailing lists and listservs. The first is for sending "subscribe" and "unsubscribe" requests. The second is for posting messages to the group. Avoid the common mistake of e-mailing to the group a "subscribe" or "unsubscribe" command.

Avoid Empty Messages

If your post does not add value to the discussion and is not of interest to the whole group, don't send it. Avoid messages that contain "test," "hello," or "me too." You can post test messages in test groups. If you want to congratulate or thank a group member, use individual e-mail.

Freeloaders

Do your own homework and try to find the answer before posting a question in a group. Posting a request for help should not be the lazy way out of searching the Internet or going to the library or e-mailing an expert directly.

Auto-responders

Turn off the auto-responder function of the e-mail addresses used to subscribe to a mailing list. Otherwise, to every message forwarded to the e-mail address by the mail server, a receipt response will be send back to the server, which in turn will be distributed to every member, thus creating a large volume of unwanted e-mail in the group.

Cross-Posting

Generally, it is not considered appropriate to send the same post to more than one group. When a message is cross-posted to several related groups to assure that it reaches all those potentially interested in it, people subscribed to several related groups end up getting multiple copies. If you decide to cross-post, you can minimize the annoyance of those who receive multiple copies by making the message brief and providing a link to more detailed information.

Be Generous

Offer answers and help if you are in a position to do so. The usefulness of a group depends on what group members are willing to contribute. Share your expertise and give it generously.

E-mail Responses

If you post a question, don't ask for the answer to be e-mailed to you. Other people may have similar questions and might benefit from the answers posted in the group. Moreover, members might point out a wrong answer if it is posted to the group. Requests that information be e-mailed to you because you don't normally read the group are considered rude.

Summarize

If you've asked a question and received several responses, summarize them and make the summary available so that others might learn.

No Personal Messages

Do not post personal e-mails intended for an individual in the discussion group. Such messages waste the bandwidth of the rest of the group. Messages not of interest to the group should not be posted to the group.

Be Patient with Newcomers

Be tolerant of common netiquette violations of newcomers to the group. If you are compelled to send an emotional response to a member that could spark a flame war, e-mail the message directly to the member and not to the group.

Avoid Commercial Uses

Most group participants resent any effort to use the forum for commercial purposes. Hence, avoid any form of sale, advertisement, or promotion. On the other hand, you may use your expertise in an area of interest to the group and help group members. This in turn can create good will among group members who might eventually become clients or customers.

Respect Copyright and Privacy

Do Not Post Copyrighted Material without Permission

Don't post copyrighted material to the group without explicit permission to do so. Remember, personal e-mail is copyrighted. Never ever post a personal e-mail from another person to the group without permission.

Protect Privacy

Don't disclose personal information—including passwords, credit card numbers, home addresses, or phone numbers to anyone online. Do not post other people's personal information anywhere online.

Public Nature of Groups

Remember that discussion forums are public forums and that messages are archived. Hence, do not post a message that may cause you embarrassment if retrieved and published years later.

CHAT AND INSTANT MESSAGING NETIQUETTE

Chat and instant messaging are Internet applications that allow users to interact with each other in real time. With these applications, simultaneous or synchronous interaction is made possible either in a public forum or in a private space between two or more individuals. Chat and instant messaging are used primarily in an informal, entertainment-oriented social interaction setting, although instant messaging may also be used as a way to manage time and get a quick turnaround on something in a work environment.

Many of the e-mail and group netiquette guidelines discussed already apply to these synchronous communication situations. Those guidelines specific to chat context or instant messaging are those norms based on the unique features of the real-time environment.

Be Brief

Instant messaging is not meant for long messages. Some chat systems limit length of messages. If you have to post long messages, break it up into multiple messages with each ending with a "MORE. . . ."

Choose Appropriate Handles and Nicknames

Some chat programs require you to choose a "handle" or "nickname" in order for users to chat without revealing their true identity. Choose a name that reflects well on you. Do not select names for their shock value. Do not use this facility to impersonate someone else. It is also not considered appropriate to keep on changing one's handle frequently during the same session.

Lurk after Introductions

If you are new to the group, lurk for a while to familiarize yourself with the topic being discussed, the tone of conversation, and above all the culture of the group. Unlike in bulletin boards, however, one cannot lurk anonymously in a chat room. Others are aware that you have entered the room. Hence, if you plan to lurk rather than participate in discussion, it is appropriate for you to introduce yourself and state your reasons for lurking.

Greeting the Group

When you enter a room, greeting the group is appropriate. The form of greeting will depend on familiarity with the group participants. With friends, a *kotc* or a *hugs* is common. (Please see Table 2 for common acronyms.) After the greeting, it is appropriate to wait to be acknowledged by the group members before jumping into discussion.

Label Personal Messages

If a post is directed at one of the members, address them by name so that the group knows that it is meant for one of them.

Respect Private Rooms

Creating a "private" room to communicate with specific individuals in the chat room is a legitimate use of chat rooms. Hence, do not "barge" into "private" rooms where your presence is unwelcome or where you are not invited.

Don't Flood

In a chat environment, flooding is a form of disruptive behavior. Flooding is the sending of a large amount of text to a channel in a short amount of time. One can cause flooding by hitting the return key repeatedly or by inputting large images. This causes the chat room screen to "scroll" so fast that it becomes difficult for other members to read the screen.

In voice chat-rooms, any behavior that would make it difficult to participate in the chat is considered a netiquette violation. For example, leaving the microphone open and playing loud music makes chat difficult for others.

Unsolicited Advertising

Do not post or transmit any unsolicited advertising, promotional materials, or any other forms of solicitation in chat rooms, except in those areas (e.g., shopping rooms) designated for such a purpose.

Know That Chat Can Be Logged

Although a chat environment simulates a face-to-face interaction where the words spoken are ephemeral, chat room conversations and instant messages can be logged and circulated. Hence, judiciousness appropriate to e-mail is applicable to chat messages as well. Sloppy writing and spontaneous flames may come back to haunt you years later.

Say Your Goodbyes

When ready to leave the room, say you are about to leave. Wait a while before you quit so that you will have chance to respond to any messages that were already in transit when you announced your intention to leave. Your last message should clearly state that it is your last post.

Use Alerts

Most chat programs allow the user to indicate his or her status and availability. Use these alerts consistently, so that those wishing to contact you can check on your availability.

Respect Another's Convenience

Technically, instant messaging and chat enable real-time interaction but remember that it is contingent upon the availability and convenience of both parties. Your need to chat or instant message should not disrespect the other party's need or desire not to engage in it at that time.

FTP NETIQUETTE

File transfer protocol (FTP) is an application that allows Internet users to move documents, programs, graphics, etc. to and from a network server. Authorization is required to access most network computers; however, documents and programs for public distribution are saved in a section of these computers that can be accessed without username or password. The following netiquette guidelines pertain to the downloading of documents and programs from this public space through a process known as "anonymous FTP."

Sign on with E-mail Address

While logging in as "anonymous," it is customary to respond to the "password" prompt with your e-mail address, although it is not necessary to gain access to the server.

This allows the system administrators to track the level of FTP usage, if they choose to do so.

Download Large Files during Off-peak Hours

When possible limit downloads, especially large downloads (1+ MB), for off-peak hours.

Minimize Connection time

Keep FTP connection times minimal. Don't leave an FTP connection open and unattended if you're not using it. You will be tying up a line for another user trying to access the site. You should respect the time restrictions of the sites you visit, in order to enable other users who want to use the site.

Pay Copyright and Shareware Fees

Check for copyright or licensing agreements before downloading programs. If there is a registration or shareware fee associated with the program, pay the fee if you decide to keep the program after the prescribed free trial period. Sometimes copyrighted software may have been illegally uploaded into FTP archives. Hence, check the copyright. If there is any doubt regarding the copyright of a program, don't download it.

Upload with Permission

Do not upload or download registered or copyrighted software to FTP sites. Don't upload files without the permission from the system administrator of the FTP site.

Check for Viruses

Do not upload virus-infected programs to FTP sites, and conversely, be sure to virus-check all programs you download from FTP sites.

WEB COMMUNICATION NETIQUETTE

Web development has gone through various stages of evolution. In the early HTML days of the Web, when it was a text-based system designed to create an interlinked knowledge pool, content was at the heart of Web development. Later, when it evolved into a broadcast tool to disseminate information, design and presentation became central. Many of the designers took to the Web as a form of creative self-expression than as a medium to communicate information. In recent years, however, there has been greater attention on the usability of Web sites as well as the responsiveness of organizations via their Web sites. The emphasis seems to have shifted from publication of information to effective communication. When the emphasis is on communication, netiquette becomes a key factor. From the point of view of the designers, it involves respect for the users and their information needs.

Design with the User in Mind

Usability pertains to designing and maintaining a Web site such that visitors will be able to meet their information needs in an efficient and user-friendly environment. It involves minimizing download time, increasing scannability of pages, and providing valuable up-to-date information. A good site is logically organized so that visitors can get to the information in three clicks or less.

Make Each Page on the Site Freestanding

Most Web users arrive at a site via search engines. This means that they do not often enter a site through the front page or the splash page. Hence, it is important that every page on the site has the information regarding the organization affiliation of the Web site, the physical location/address of the organization, the date the page was last updated, an e-mail link to contact the webmaster or the owner, and a link to the splash page of the site.

Inform Those Listed as External Links

Many Web sites increase value to their sites by providing external links. In the early years, it was recommended that you request permission for linking be sought. Doing so may not be practical any longer because some of the popular sites may get flooded with requests for permission. However, it is a good etiquette from your perspective to inform those you have linked to your site. The owners of these sites may choose to ignore you or they may reciprocate by linking to your site.

Permission for Borrowed Content

Anything on the Web—graphics, text, audio, video, and the design—is copyrighted. Although legal action can be pursued only if the Web site is registered, it is certainly against all netiquette guidelines to steal from others' Web sites without permission.

Direct Link to Graphics on Another Site

A worse offense is to provide a direct link to a graphic on your Web site. This means that every time a user clicks to your page, the user's browser goes to the linked site to download the graphic. With every hit to your site, the other Web site's bandwidth is being used without any sort of remuneration.

Warning Users of Controversial/Age-Appropriate Content

If the Web site contains material inappropriate for young people, in addition to providing a splash page that warns visitors of the nature of the content, designers should make it easier for people to block Web sites if they consider that the content on your site is inappropriate for themselves or their children. Appropriate key words and description should be included in the metatags to facilitate such filtering.

Consider Bandwidth Limitations

Despite the hype about the broadband Internet solutions, most people access the Internet using modem connections. High-resolution graphics, audio files, and video increase download time. Ten seconds is considered the threshold of frustration. Designers should make an effort to design pages low on graphic content so that their pages will load under 10 s. Thumbnails of larger images should be used so that users can decide whether they want to open the large picture.

Design for Cross-Browser Compatibility

Colors, graphics, and text are displayed differently on different browsers and monitors. Designers should seek to achieve cross-browser compatibility by including only those features available on all browsers. Web-safe colors and generic fonts should be used as far as possible. Do not design for the latest versions of browsers, plug-ins, or monitors. If tables are used to design pages, make sure that the table width is not greater than 600 pixels. Be wary of using design features such as frames that older versions of browsers do not support. If a page requires a plug-in or program to correctly open it, provide the link to the site where the program can be downloaded.

Make the Site Accessible

When providing audio and visual content, provide alternate text content that conveys essentially the same function or purpose as auditory or visual content. Add ALT tags to every nontext element on the site to make the site accessible to the vision-impaired, those using text browsers, those using nongraphic channels such as pagers and mobile phones, or those who have turned off the graphic display capability of their browsers. When using color, make sure that text and graphics are understandable even without color. If you use tables for layout, provide a nontable version to allow technologies such as screen readers to access the content.

Privacy Issues

Web designers have developed ways of tracking the users by implanting cookies in the user's computer. Cookies can make life easier for the users by remembering previous settings, passwords, etc. However, companies often use them to gather valuable data on the Web-browsing habits of users. When done surreptitiously, it is not only a violation of netiquette but unethical as well.

Increase Responsiveness

It is common practice among Web designers to include an e-mail address to contact the owner of the Web site. In addition to the convenience associated with it, publishing the e-mail address is also symbolic—that you welcome communication from the users. As a result, users expect a reply. A timely response is good netiquette. Many organizations have not yet recognized the significance of being responsive to e-mails that originate from their Web sites. It is probably more important in creating a good impression of the company than an expensive and sophisticated Web site.

Copyright Issues for Web Users

The area where Web users violate netiquette most frequently involves copyright. Browsers have made it easy for people to download documents, graphics, audio files, and video. It is easy to assume that when there is no clear copyright statement, it is not copyrighted. You may not use graphics, text, audio, or video from other Web sites on your own site unless the owners clearly indicate that the material is not copyrighted.

INTERNATIONAL CONSIDERATIONS

Because Internet technology and technical standards were developed in North America, it is no surprise that English became its lingua franca and norms of behavior were developed in the context of the cultural and ethical standards of the West. As the Internet becomes a global medium of social communication, it is likely that netiquette guidelines will become increasingly situational and culture-specific. This will make it harder for Net users to be sure that they do not give offense. In the case of e-mail it is not so hard to be sensitive to the cultural and social context of the recipient because we know who the recipient is. However, it becomes more difficult in discussion groups and Web sites where the recipients are not known. In these contexts, consider the following steps to avoid any misunderstanding among international audiences.

Use Generic Language

Remember that the majority of people who read and understand English are not native-born English speakers. Hence, as far as possible, use simple language. Avoid slang, acronyms, and contextual innuendo. It is rare that people in one part of the world will understand local slang or be aware of an acronym in another part of the world.

Use Universal Time and Measurements

Use the date and time format that will be understood by all when e-mailing to someone in another country or to a group, which is accessed by people from different parts of the world. Use September 11 instead of 9/11, which may be confused for 11th September or 9th November. Time is best written as 2:30 p.m. GMT or 14:30 GMT. When indicating measurements, use both metric and English systems (kilometers and miles, pounds and kilograms).

Use Humor with Extreme Caution

Even the funniest stories can offend someone in some place. Hence, use humor with extreme caution when an international audience has access to the post.

Deciding on an Appropriate Level of Formality

Outside North America, people in positions of authority and those who are older expect certain deference from those younger. Hence, you must consider age and rank while deciding the tone of the e-mail. In some parts of the world, all forms of written communication are considered formal. As long as you are not sure how formal you are expected to be, start the initial e-mails in a formal tone. Eventually, you will know the extent to which you can become informal.

ENFORCING NETIQUETTE

Increasingly, netiquette norms are becoming formal rules that require compliance from users. Group moderators and ISPs have set them up as conditions for access. Courts have upheld the right of the ISPs to suspend services to those who violate these norms of behavior. The decentralized nature of the Internet prohibits centralized enforcement mechanisms or netiquette-enforcement agencies that supervise online behavior. On the other hand, informal enforcement of netiquette has been fairly successful.

However, this system of peer enforcement requires active engagement by the Internet community. Instead of leaving enforcement to a handful of netiquette vigilantes who flame, pursue, and track down violators, each Net user is encouraged to educate and enforce appropriate Net behavior.

Help Educate/Inform the Newbie

Most netiquette violations are committed by newbies who do not have the patience to read the FAQs. Politely inform them of violations through direct e-mail. Do not post a flame to the group.

Ignore the Flamer and the Evangelist

It is wiser to provide silent treatment to those flooding the Internet forums with a constant flow of propaganda. Today's e-mail and bulletin board programs allow us to filter out messages from e-mail addresses and domains with whom we do not want to have interaction. Known traditionally as the "kill file," this feature can be used to effectively ban people from your network.

Report Violators

Despite having strict rules, most ISPs do not have a mechanism to identify violators. Hence, they want members to report violators. Most ISPs have an e-mail address for reporting violations. Usually, it is abuse@hostname.domain. For instance, AOL's abuse report address is abuse@aol.com. Whenever someone consistently violates rules regarding flaming and spamming, take time to report them to the appropriate address.

CONCLUSION

Because of the asynchroneity of the medium, the Internet is perhaps the most polite and considerate form of communication. E-mail messages don't interrupt recipients during dinner (Miller, 2001). Respect for the other is ingrained in the very nature of e-mail.

Despite the speed of delivery and apparent informality, the Internet can also be a tool for deliberate communication. It helps us avoid spontaneous, thoughtless blurting out of words that we may later regret. The Internet allows us to compose a message with thought and consideration for the other person. The absence of nonverbal cues is often cited as a weakness of computer-mediated communication. The lack of social presence helps us avoid unpleasant situations. We can walk away from a confrontational situation by ignoring an insult or avoid people with whom we do not want to interact without being obvious about it.

As the Internet becomes a popular medium of communication, it will take its rightful place among the channels of communication as one of the options available to us. Thus, choosing a medium respectful of the communication situation and the people involved in it will itself become the ultimate netiquette guideline.

GLOSSARY

Bandwidth The information-carrying capacity of the network connection. The greater the bandwidth of the connection, the shorter the download time.

Blind carbon copy (BCC) A feature that hides the e-mail addresses to which the message is sent.

Bulletin board A location in the computer network where people post their messages so that others who access the site can read them.

Cross-post Posting the same message across several bulletin boards and newsgroups.

E-mail lists Grouping of e-mail addresses under one title in order to distribute the same e-mail automatically to this group of addresses.

Frequently asked questions (FAQ) A document available in most discussion groups/chat rooms that describes the purpose of the group, the rules, and procedures for membership and participation; may also be found at a Web site, providing basic information about the site, its services, products, and terms and conditions.

Flame An emotionally charged message posted in a discussion group or sent via e-mail that insults or rebukes others.

Flame war A sequence of flames.

Flame-bait A provocative post intended to upset readers in order to elicit an emotional response.

Flood Sending a large amount of text to a channel in a short amount of time; considered rude in a chat environment.

Frames A style of Web design that creates on the same browser screen multiple windows to display different pages simultaneously.

Hypertext markup language (HTML) The coding scheme, developed by Tim Berners-Lee, used to format Web pages.

Kill file The list of e-mail addresses or domain names that a person has assigned to be excluded from his/her communication network.

Listserv A small program used to automatically redistribute e-mail to names on a mailing list, commonly used to sustain a discussion group on the network.

Lurking Observation of the proceedings in discussion groups and chat rooms; that is, reading the discussion and chat threads without contributing to the conversation.

Metatags The information in the ;<HEAD> section of an HTML document that contains data about the HTML document that is not displayed by the browser. Metatag key words and description are useful to search engines to classify and describe Web sites.

Newbie Newcomer to the Internet in general or to an Internet application.

Newsgroup Name of a discussion group on Usenet.

Spamming Unsolicited distribution of the same message to many e-mail addresses to promote an idea, product, or service; also used maliciously to disrupt communication.

Splash page The opening page of a Web site that uses an animated design and serves as the title page of the site.

Store and forward Communication network systems that store the messages for a time before transmitting them to the ultimate recipients.

Usenet A world-wide system of discussion groups that predates the Internet.

Virtual communities An online collectivity of geographically dispersed users who are drawn to the group because of shared interests.

Internet Literacy

Hossein Bidgoli, *California State University, Bakersfield*

INTRODUCTION

This chapter provides a basic literacy of the Internet and Web technologies. It provides a brief history of the Internet and then explains domain name systems, navigational tools, and search engines. The chapter defines intranets and extranets and compares and contrasts them with the Internet. The chapter concludes with a brief survey of popular applications of the Internet including tourism and travel, publishing, higher education, real estate, employment, banking and brokerage firms, software distribution, healthcare, and politics. Other chapters throughout the *Encyclopedia* will further explain most of the topics presented here.

THE INFORMATION SUPERHIGHWAY AND THE WORLD WIDE WEB

The backbone of the information superhighway and electronic commerce (e-commerce) is the Internet. The Internet is a collection of millions of computers and network systems of all sizes. Simply put, the Internet is the "network of networks." The information superhighway is also known as the Internet. No one actually owns or runs the Internet. Each network is locally administered and funded, in some cases by volunteers. It is estimated that, in 2003, more than 200 countries are directly or indirectly connected to the Internet. This number is increasing on a daily basis and makes global e-commerce a reality.

The Internet started in 1969 as a Defense Department Advanced Research Projects Agency project called ARPANET. It served from 1969 through 1990 as the basis for early networking research, and as a central backbone network during development of the Internet. Since the Internet began in 1987, it has grown rapidly in size.

ARPANET evolved into the NSFNET (National Science Foundation Network) in 1987. NSFNET is considered the initial Internet backbone. The term Internet was derived from the term "internetworking," which signified the networking of networks. NSFNET initially connected four supercomputers located at San Diego, Cornell, Pittsburgh, and Illinois to form the backbone. Other universities and government labs were subsequently added to the network. These backbones linked all existing networks in a three-level structure:

Backbones;
Regional networks; and
Local area networks (LANs).

Backbones provide connectivity to other international backbones. The NAPs (network access points) are a key component of the Internet backbones. A NAP is a public network exchange facility where Internet service providers (ISPs) can connect with one another. The connection within NAPs determines how traffic is routed over the Internet and they are also the focus of Internet congestion. Local area networks (LANs) provide the standard user interface for computers to access the Internet. Phone lines (twisted pair), coaxial cables; microwaves, satellites, and other communications media are used to connect local area networks to the regional networks. TCP/IP (transmission control protocol/Internet protocol) is the common language of the Internet that allows the network systems to understand each other. TCP/IP divides network traffic into individually addressed packets that are routed over different paths. Protocols are conventions and rules that govern a data communications system. They cover error detection, message length, and speed of transmission. Protocols provide compatibility among different manufacturers' devices.

The NSF and state governments have subsidized regional networks. NSFNET's acceptable use policy initially restricted the Internet to research and educational institutions; commercial use was not allowed. Due to increasing demand, additional backbones were allowed to connect to NSFNET and commercial applications began.

The World Wide Web (WWW or the Web) changed the Internet by introducing a true graphical environment. It has been around since 1989, proposed by Tim Berners-Lee at CERN. WWW is an Internet service that organizes information using hypermedia. Each document can include embedded reference to audio, images, full motion video, or other documents. The WWW consists of a large portion of the Internet that contains hypermedia documents. Hypermedia is an extension of hypertext. Hypertext allows a user to follow a desired path by clicking on highlighted text to follow a particular "thread" or topic. This involves accessing files, applications, and computers in a nonsequential fashion. It allows for combinations of text, images, sounds, and full-motion video in the same document. It allows information retrieval with the click of a button. Hypertext is an approach to data management in which data are stored in a network of nodes connected by links. The nodes are designed to be accessed through an interactive browsing system. A hypertext document includes document links and supporting indexes for a particular topic. A hypertext document may include data, audio, and images. This type of document is called hypermedia. In hypertext documents the physical and logical layouts are usually different. This is not the case in a paper document. In a paper document the author of the paper establishes the order and readers are instructed to follow the predetermined path.

A hypertext system provides users with nonsequential paths to access information. This means that information does not have to be accessed sequentially as in a book. A hypertext system allows the user to make any request that the author or designer of the hypertext provides through links. These links choices are similar to lists of indexes, and can lead the reader on a "custom path."

Any computer that stores hypermedia documents and makes them available to other computers on the Internet is called a server or a Web server. The computers that request these documents are called clients. A client can be a personal computer at home or a node in a local area network at a University or at an organization. The most exciting feature about the Internet and the WWW is that these hypermedia documents can be stored anywhere in the world. A user can as easily jump from a site in the United States as to a site in Paris, France, all in a few milliseconds.

DOMAIN NAME SYSTEMS

Before a user can begin to navigate the Internet and use it for personal use or e-commerce applications, an understanding of domain name systems (DNS) (also called domain name servers) is essential. Domain names are unique identifiers of computer or network addresses on the Internet. The following are examples of domain names:

Netscape.com

Microsoft.com

UN.org

Whitehouse.gov

They come in two forms: English-like names and numeric or IP (Internet protocol) addresses.

Table 1 Organizational Domains (Generic Top-Level Domains) (gTLD)

.com	Commercial organizations (e.g., Microsoft)
.edu	Education and academic organizations (e.g., California State University)
.int	International organizations (e.g., United Nations)
.mil	U.S. military organizations (e.g., U.S. Army)
.gov	U.S. government organizations (e.g., Internal Revenue Service)
.net	Backbone, regional, and commercial networks (e.g., The National Science Foundation's Internet Network Information Center)
.org	Other organizations such as research and nonprofit (e.g., The Internet Town Hall)

The Internet Corporation for Assigned Names and Numbers (ICANN) is the nonprofit corporation that assigns and keeps track of these addresses. This was previously performed under U.S. Government contract by IANA (the Internet Assigned Numbers Authority) and other entities.

IP addresses are less convenient because numbers are more difficult to remember. The English-like names are electronically converted to IP addresses for routing (transferring information from one network to another network). Domain names are used in URLs (uniform resource locator or universal resource locator) to identify a particular Web page. A URL is basically the address of a file or a site on the Internet. For example, in the URL http://www.csub.edu/~hbidgoli, the domain name is csub.edu. Every domain name has a suffix that indicates which top-level domain (TLD) it belongs to. In the above example the suffix is edu, for educational institutions. Combinations of the letters of the alphabet as well as the numbers 0 through 9 can be used in domain names. The hyphen is the only other character utilized; spaces are not allowed.

The top-level domain is the field on the far most right. It denotes the type of organization or country the address specifies. TLDs are divided into organizational (generic) and geographic (country code) domains. (See Tables 1 through 3.)

This system makes it easy to identify the type or location of the organization by looking at the last section of the domain name. Organization, which is the second field from the right, refers to the name of the organization. A name for a small company is as easy as a company name. The two left-most fields of the domain name refer to the computer. This is relevant for large organizations with several levels of subdomains. An example of a relatively complete Internet address is the address of a document in the Virtual Tourist Web site: http://www.vtourist.com/vt/usa.htm. A brief explanation from left to right follows:

Table 2 Some of the Proposed New Domain Names

.aero	For aviation industry
.arts	For entities emphasizing cultural and entertainment activities
.biz	For businesses
.coop	For cooperative or cooperative service organization
.firm	For businesses or firms
.inc	Corporations
.info	For entities providing information services
.law	For those in the legal profession
.museum	For a museum or professionally affiliated personnel
.name	For a noncommercial site associated with a private individual
.nom	For individuals or family names
.news	For news-related sites
.pro	For a site associated with a certified professional or professional organization
.rec	For entities emphasizing recreation and entertainment activities
.shop	For businesses offering goods and commodities
.store	For electronic storefronts
.web	For entities emphasizing activities related to WWW (World Wide Web)
.xxx	For adult content

http—Means of access, hypertext transfer protocol. This is how the majority of Web documents are transferred.

www.vtourist.com—This is the address of a Web site. It is uniquely defined and differentiated from any other Web sites. WWW is an Internet service that organizes information using hypermedia.

vt—This is a path or directory. A server may be divided into a series of directories for a better organization.

usa.htm—This is the document itself. The htm extension indicates that this is an html (hypertext markup language) document. It is the authoring language used to create documents on the Web. HTML defines the structure and layout of a Web document by using a variety of tags and attributes. A separate chapter in the *Encyclopedia* discusses HTML. Most hypermedia documents are written in HTML format. Servers that do not support long extensions display htm, while other servers display html.

Table 3 Sample Geographic Domains (Country Code Top-Level Domains) (ccTLD)

.au	Australia
.br	Brazil
.ca	Canada
.fr	France
.de	Germany
.hk	Hong Kong
.il	Israel
.jp	Japan
.kr	Korea (Republic)
.ru	Russia
.es	Spain
.uk	United Kingdom
.us	United States
.va	Vatican City State
.zw	Zimbabwe

NAVIGATIONAL TOOLS, SEARCH ENGINES, AND DIRECTORIES

Navigational tools allow the user to surf the Internet and search engines provide access to various resources available on the Internet such as library searches for writing a term paper or making a reservation for an airline ticket. Directories use indexes of information based on key words in the document. As will be discussed later in the chapter, Yahoo! is the most popular directory on the Internet.

The original command language of the Internet was based on computer commands and was difficult to learn by most users. Character-based languages were used for tasks such as downloading files or sending e-mails. These languages are UNIX-based, meaning the user was required to know the specific syntax of many commands. Everything was communicated in plain text, and graphics, sound, and animation data were not available. The introduction of graphical browsers such as *Netscape Navigator* changed all of this. *Microsoft Internet Explorer* and Netscape Navigator are the best-known graphical browsers available for navigating the Internet. Each of these browsers combine powerful graphics and audio and visual capabilities. Each Web server has a "homepage" or a "Web site" that publishes information about the location. Using character-based browsers such as Lynx, a user will find this information in text form, while graphical browsers such as Microsoft Internet Explorer support images and sound clips as well.

Navigational Tools

Microsoft Internet Explorer and Netscape Navigator are among the most popular navigational tools. Microsoft Internet Explorer is the most popular graphical browser in the Internet world. With strong marketing support from Microsoft and improvement in its features, Internet Explorer has gained the leadership in the browser market. Netscape Navigator is another graphical browser available for all major platforms. Netscape, similar to Internet Explorer, provides a true graphical environment that allows the user to surf the Internet using a mouse and the point-and-click technique. Similar to other Windows applications, Netscape Navigator features a standard menu bar and toolbar buttons for frequently used commands.

Directories and Search Engines

There are several search engines and directories in use. Yahoo! is the most popular directory and Google, Excite, and Infoseek are three of the popular search engines. These programs allow a user to scan the Internet and find information. A search could be research for a term paper or finding an exotic antique for a personal collection or anything in between. The following paragraphs briefly describe Yahoo!, Google, and Excite (Bidgoli, 2002).

Jerry Yang and Dave Filo founded Yahoo! in April 1994. Yahoo! is one of the best-known directories on the Internet. A directory is a search service that classifies Web sites into a hierarchical subject-based structure. For example, Yahoo! includes categories such as art, business, and entertainment. These categories are organized by topic. The user can go to a category and then navigate for specific information. Yahoo! also includes an internal search engine that can expedite the search process. Yahoo! soon expanded to offer other services and became a portal on the Internet. A portal or gateway for the WWW is a new application that serves as an information search organizer. Portals provide a single-point integration and navigation through the system. Portals create an information community that can be customized for an individual or a corporation. Portals serve as a major starting site for individuals who are connecting to the Internet. Some of the services offered by Yahoo! include Yahoo! Travel, Yahoo! Classifieds, Yahoo! Pager, and Yahoo! Autos.

Larry Page and Sergey Brin, two Stanford Ph.D. candidates, founded Google in 1998. Google helps its users find the information they are looking for with high levels of ease, accuracy, and relevancy. The company delivers its services to individuals and corporations through its own public site, http://www.google.com, and through cobranding its Web search services. To reach the Google Web site, user simply types "www.google.com" (its URL) into the location box of his/her Web browser and presses the Enter key. At the initial Google screen the user enters the desired search item(s), for example "e-commerce," and then again presses the Enter key or clicks on the "Google Search" button. In a few seconds the items that closely match the search items will be displayed. As the Web site's default language is English, the user can choose a different language by clicking the down arrow to the right.

Excite, Inc. was founded in June 1994. Its basic mission is to provide a gateway to the Internet and organize, aggregate, and deliver information to meet users' needs. The Excite Network, including the Excite and WebCrawler brands, contain a suite of specialized information services that combine proprietary search technology, editorial Web reviews, aggregated content from third parties, and bulletin boards. The Excite Network serves as a central place for consumers to gather and interact during each Web experience. Excite PAL is an instant paging service. By entering the names and e-mail addresses of friends, family, and colleagues into Excite PAL, a user can find them online.

As of March 2002, there were an estimated 114 million Internet users online in the United States at work or at home, 80% of whom are estimated to have made some type of search request during that month.

INTERNET SERVICES THAT SUPPORT ELECTRONIC COMMERCE

Electronic mail (e-mail), news and discussion groups, Internet relay chat (IRC), instant messenger, and the Internet phone are among the services offered by the Internet that could enhance a successful e-commerce program. Other chapters in the *Encyclopedia* will provide a more in-depth discussion of these services. In this chapter a brief overview of these services is presented (Bidgoli, 2002).

Electronic mail or **e-mail** is one of the most popular services available on the Internet. Using e-mail a user can create a letter electronically and send it over the communications media. New products and services can be announced to the customers using e-mail. Confirmations can be sent using e-mail and also many business communications can be effectively performed using e-mail. When a user sends an e-mail, the message usually stays in the recipient's computer until he/she reads it. In many e-mail systems, the receiver is able to store the e-mail message in an electronic folder for future reference. E-mail is fast and will get to the recipient's computer in a matter of seconds or minutes. All is needed in order to send an e-mail message is the e-mail address of a recipient on the Internet. A user can also send a single e-mail message to a group of people at the same time. A user can apply all the word processing tasks such as spell checking and grammar correction before sending the e-mail message. Document files and/or multimedia files can be attached to an e-mail message and a user could ask for delivery notification. With e-mail a user can usually establish various folders with different contents and send a particular e-mail to a specific group. Using e-mail enables a user to establish an effective message distribution system for advertising products and services.

The Internet brings together people with diverse backgrounds and interests. **Discussion groups** that share opinions and ideas facilitate this. Each person in a discussion group can post messages or articles that can be accessed and read by others in the group. **Newsgroups** can be established for any topic or hobby and allow people to get together for fun and entertainment or for business purposes. For example, a user may join a newsgroup interested in ancient civilization, or a user may join a newsgroup that can help in writing and debugging a computer program in a specific programming language. Newsgroups can serve as an effective advertising medium in e-commerce environment.

Internet relay chat enables a user to interactively communicate in a written form with other users from all over the world. It is similar to a coffee shop where people sit around a table and start chatting. The two major differences between this electronic coffee shop and a real coffee shop are that there is no coffee and the user does not see the people that he/she is chatting with. However, a user is able to participate in many different discussions with people anywhere in the world who have the same interest.

Instant messenger is a communication service that enables a user to create a private chat room with another user. Different instant messengers offer different capabilities. They typically alert a user whenever somebody on his/her private list is online, then a user may initiate a chat session with that particular individual.

Internet telephony is the use of the Internet rather than the traditional telephone company infrastructure and rate structure to exchange spoken or other telephone information. Because access to the Internet is available at local phone connection rates, an international or other long-distance call will be much less expensive than through the traditional calling arrangement. This could be a major cost saving for an e-commerce site offering hotline services, help desk, and so forth.

Three new services are now or will soon be available on the Internet:

1. The ability to make a normal voice phone call (despite whether the person called is immediately available; that is, the phone will ring at the location of the person called). In most of the technologies currently available, a "phone-meeting" must be arranged in advance, and then both parties log onto the Internet at the same time to conduct the conversation.
2. The ability to send fax transmissions at very low cost (at local call prices) through a gateway point on the Internet in major cities.
3. The ability to leave voice mail at a called number.

WHAT IS AN INTRANET?

The excitement created by the Internet has been transferred to another growing application called intranets. In simple terms, whatever that a user can do with the Internet he/she should be able to do with an organization's private network, or an intranet.

An intranet provides users with easy-to-use access that can operate on any computer regardless of the operating systems in use. Intranet technology helps companies disseminate information faster and more easily to both vendors and customers and can be of benefit to the internal operations of the organization. Although intranets are fairly new, they have attracted a lot of attention in a very short time (Bidgoli, 1999, 2002).

The intranet uses Internet and Web technologies to solve organizational problems traditionally solved by proprietary databases, Groupware, scheduling, and workflow applications. One should understand that an intranet is different from a local area network (LAN) or wide area network (WAN), although it uses the same physical connections. An intranet is an application or service (or set of applications or services) using the computer networks (the LANs and WANs) of an organization and that is why it is different from LANs and WANs. The intranet is only logically internal to the organization. Intranets can physically span the globe, as long as access is specifically defined and limited to the specific organization's community of users behind a firewall or a series of firewalls.

In a typical intranet configuration, all users in the organization could access all the Web servers. The system administrator must define the degree of access for each user. They can constantly communicate with one another and post information on their departmental Web servers. However, usually a firewall (or several firewalls) separates these internal networks from the Internet (the worldwide network).

Within these departmental Web servers, individual employees can have their own Web pages broken down by department and a series of Web pages. For example the following departments each may include several Web pages as parts of the organization's intranet program:

Finance;
Human resources;
Information services;
Manufacturing;
Marketing; and
Sales.

So what is an intranet? In simple terms, an intranet is a network within the organization that uses Web technologies (TCP/IP, HTTP, FTP, SMPT, HTML, and XML) for collecting, storing, and disseminating useful information throughout the organization. This information supports e-commerce activities such as sales, customer service, and marketing.

Employees can find internal information and they can bookmark important sites within the intranet. Furthermore, individual departments can create their own Web sites to educate or inform other employees about their departments by implementing intranet technology. For example, marketing can present the latest product information, while manufacturing can post shipping schedules and new product designs. The human resources department can post new jobs, benefit information, new promotions, and 401K plan information. The finance and accounting departments can post cost information and other financial reports on their sites. The president's office might post the next company picnic on its site. This information collectively supports a successful e-commerce program.

THE INTERNET VERSUS INTRANETS

The Internet is a public network. Any user can access the Internet assuming the user has an account with an ISP. The Internet is a worldwide network, whereas intranets are private and are not necessarily connected to the Web. Intranets are connected to a specific company's network and usually the users are the company's employees. An intranet is separated from the Internet through a firewall (or several firewalls). Intranets usually have higher throughput and performance than the Internet and are usually more secure than the Internet.

Apart from the above-mentioned dissimilarities, the two have a lot in common. They both use the same network technology, TCP/IP, and they both use browsers for accessing information. They both use documents in HTML and XML formats and both are capable of carrying documents with multimedia formats. Also, they both use the Java programming (or its derivatives) language for developing applications.

Intranets may or may not use any of the technologies beyond HTML, i.e., Java programming, JavaScript or VBScript, Active X, Dynamic HTML, or XML. One of the

Table 4 The Internet versus Intranet

Key Feature	Internet	Intranet
User	Anybody	Employees only
Geographical scope	Unlimited	Limited to unlimited
Speed	Lower than that of an intranet	Higher than that of the Internet
Security	Lower than that of an intranet	Higher than that of the Internet
Technology used	TCP/IP	TCP/IP
Document format	HTML	HTML
Multimedia capability	Could be lower than that of an intranet	Could be higher than that of the Internet

advantages of an intranet is that since the organization can control the browser used, it can specify a browser that will support the technologies in use. Beyond Web documents, the organization can also specify the use of the Internet phone, e-mail, video conferencing, and other Web technologies supported by the chosen browser. Table 4 summarizes the similarities and dissimilarities of these two technologies.

SELECTED APPLICATIONS OF AN INTRANET

A properly designed intranet can make the type of information listed in Table 5 available to the entire organization in a timely manner. This information directly or indirectly can improve the efficiency and effectiveness of an organization (Bidgoli, 1999, 2002).

Many internal applications in use today can be easily converted to an intranet or can be supported using an intranet. Human resources applications, such as job information, name and phone number lists, and medical benefits, can be displayed on a human resources Web site. The finance Web site might present information on time cards, expense reports, or credit authorization. Employees can easily access the latest information on a server. With e-mail, e-mail distribution lists, and chat lines, employees can retrieve meeting minutes.

The intranet also allows organizations to evolve from a "calendar" or "schedule"-based publishing strategy, to an "event-driven" or "needs-based" publishing strategy. In the past, companies published an employee handbook once a year. Traditionally, the handbooks would not be updated until the following year even though they may have been outdated as soon as they arrived on the users' desks. Some of these organizations sent a few loose pages as an update every so often. The employee is supposed to add these additional pages to the binder. After a while these materials become difficult to go through to retrieve specific information.

With an intranet publishing strategy, information can be updated instantly. If the organization adds a new

Table 5 Possible Information Provided by an Intranet

New product offerings
Product catalog
Project information
Distribution of technical drawings

Accounting and Finance
Budget planning
Credit authorization
Expense report

mutual fund to the 401K programs, content on the benefits page can be updated immediately to reflect that change, and the company internal homepage can include a brief announcement about the change. Then the employees have the new information at their desktops as soon as they look up the 401K programs.

Intranets dramatically reduce the costs and time of content development, duplication, distribution, and utilization. The traditional publication model includes a multistep process including

Creation of content;
Production of the draft;
Revision of the draft;
Final draft preparation;
Migration of the content to the desktop publishing environment;
Duplication; and
Distribution.

However, intranet technology reduces the number of steps to only two (it eliminates the duplication and distribution steps):

Creation of content; and
Migration of content to the intranet environment.

However, content still needs review and approval regardless of the medium used for delivery.

WHAT IS AN EXTRANET?

Interorganizational systems (IOSs) facilitate information exchange among business partners. Some of these systems such as electronic funds transfer (EFT) and e-mail have been used in traditional businesses as well as in the e-commerce environment. Among the most popular IOSs are electronic data interchange (EDI). Both EDI and extranets provide a secure connection among business partners. Their roles in a business-to-business e-commerce are on the rise. These systems create a seamless environment that expedites the transfer of information in a timely matter.

Some organizations allow customers and business partners to access their intranets for specific business purposes. For example, a supplier may want to check the inventory status or a customer may want to check his/her account balances. These networks are referred to as extranets. It should be noted that an organization usually makes only a portion of its intranet accessible to these external parties. Also, comprehensive security measures must ensure that access is given only to authorized users and trusted business partners.

An extranet is defined as a secure network that uses Internet and Web technology to connect two or more intranets of business partners, enabling business-to-business, business-to-consumer, and consumer-to-business communications. Extranets are a network service that allows trusted business partners to secure access to useful information on another organization's intranet. Table 6 provides a comparison of the Internet, intranet, and extranet (Bidgoli, 2002; Fletcher, 1997).

There are numerous applications of extranets in the e-commerce world. One such example is Toshiba America Inc. Toshiba has designed an extranet for timely order entry processing. Using this extranet more than 300 dealers can place orders for parts until 5 p.m. for next day delivery. Dealers can also check account receivable balances and pricing arrangements, read press releases, and much more. This secure system has resulted in significant cost saving and has improved customer service (Jones, 1998).

Another example of an extranet is the Federal Express Tracking System (http://www.fedex.com). Federal Express uses its extranet to collect information and make it available to its customers over the Internet. The FedEx Web site is one of the earliest and best-known examples of an extranet—an intranet that is opened to external users. The customer can access FedEx's public site, and enter his/her tracking number and locate any package still in the system. Using this system a customer can enter all the information needed to prepare a shipping form, obtain a tracking number, print the form, and schedule a pick-up.

Extranets provide highly secure, temporary connections over public and private networks between an organization and a diverse group of business partners outside of the organization. These groups may include

Customers;
Vendors;
Suppliers;
Consultants;
Distributors;
Resellers; and
Outsourcers, such as claim processors, or those with whom the company is doing collaborative R&D or other collaborative work, such as product design.

Extranets not only allow companies to reduce internetworking costs; they also provide companies with

Table 6 Comparison of the Internet, Intranet, and Extranet

	The Internet	Intranet	Extranet
Access	Public	Private	Private
Information	Fragmented	Proprietary	Proprietary
Users	Everybody	Members of an organization	Groups of closely related companies

a competitive advantage, which leads to increased profit. A successful extranet program requires a comprehensive security system and management control. The security system should provide comprehensive access control; user-based authentication, encryption capability, and comprehensive auditing and reporting capabilities.

An extranet offers an organization the same benefits that an intranet offers while also delivering the benefits from being linked to the outside world. Some of the specific advantages of an extranet include (Bidgoli, 2002) the following:

Coordination—An extranet allows for improved coordination among participating partners. This usually includes suppliers, distributors, and customers. Critical information from one partner can be made available so that another partner can make a decision without delay. For example, it is possible for a manufacturer to coordinate its production by checking the inventory status of a customer.

Feedback—An extranet enables an organization to receive instant feedback from its customers and other business partners. It gives the consumers an opportunity to express their views about products or services before those products or services are even introduced to the market.

Customer satisfaction—An extranet links the customer to an organization. This provides the customer with more information about products and services and the organization in general. This also makes ordering products or services as easy as a click of the mouse. Expediting business-to-business e-commerce is definitely one of the greatest benefits of an extranet.

Cost reduction—An extranet can reduce the inventory costs by providing timely information to the participants of a supply network program. Mobil Corporation, based in Fairfax, VA, designed an extranet application that allows distributors throughout the world to submit purchase orders. By doing this, the company significantly increases the efficiency of the operation. It also expedites the delivery of goods and services (Maloff, 1997).

Expedite communication—Extranets increase the efficiency and effectiveness of communication among business partners by linking intranets for immediate access to critical information. A traveling salesperson can receive the latest product information from his/her hotel room before going to a sales meeting. A car dealer can provide the latest information to a customer on a new model without making several phone calls and going through different brochures and sales manuals.

SELECTED INTERNET APPLICATIONS

Several segments of service industries have significantly benefited from the Internet and its supporting technologies. The Internet has enabled these businesses to offer their services and products to a broad range of customers with more competitive prices and convenience. The Internet offers numerous tools and advantages to these businesses to sell their products and services all over the world. Table 7 lists popular Internet applications.

Table 7 Popular Internet Applications

Marketing and advertising
Distance learning
Electronic conferencing
Electronic mail (e-mail)
Electronic posting
Healthcare management
Home shopping
Interactive games
Inventory management
News groups and discussions
News on demand
Online banking
Online employment
Online software distribution
Online training
Online politics (voting, participating in political forums, chat groups, and using the Internet for political fund raising)
Remote log-in
Sale of products and services
Telecommuting
Transferring files with file transfer protocol (FTP)
Video on demand
Videophones
Online demo of products and services throughout the world
Virtual reality games
Online request for proposal (RFP), request for quotes (RFQ), and request for information (RFI)

In the following pages some of the major beneficiaries of the Internet and e-commerce will be reviewed.

Tourism and Travel

Tourism and travel industries have significantly benefited from various Internet and e-commerce applications. As an example, the Tropical Island Vacation (http://www.tropicalislandvacation.com) homepage directs prospective vacationers to an appropriate online brochure after responding to a few brief questions about the type of vacation they would like to take. Customers simply must point and click on appealing photographs or phrases to explore further. Another example is Zeus Tours (http://zeustours.com), which has been very effective at offering unique and exciting tours, cruises, and other travel packages online. Many Web sites allow customers to reserve tickets for planes, trains, buses, cruises, hotels, and resorts. Sites such as biztravel.com (http://biztravel.com) allow its business customers to plan a trip, book a vacation, gather information on many cities, gather weather information, and much more. Expedia.com, Travel.com, Travelocity.com, Priceline.com, hotels.com and Yahoo! Travel are other examples of sites that offer all types of travel and tourism services.

Publishing

Many major textbook publishers in the United States and Europe have homepages. An interested individual can read the major features of forthcoming books or books in print before ordering them. The Web sites of some publishers include a sample chapter from specific books, or entire books that can be read online for free for 90 days, while others allow online customers to purchase portions of rather than the entire book. The Web site of John Wiley & Sons (http://wiley.com), publisher of *The Internet Encyclopedia*, allows a prospective buyer to search the online catalog based on the author's name, the title of the book, and so forth. When the desired book is found, it can be ordered online.

Higher Education

Major universities also have homepages. An interested individual can go on a tour of the university and read about different departments and programs, faculty, and academic resources. Many universities throughout the world are creating virtual divisions that offer entire degree programs on the Internet. Many professional certificate programs are also offered through the Internet. These programs and courses provide a real opportunity and convenience for individuals in remote areas and individuals who cannot attend regular classes to enroll in these courses. They also provide a source of revenue for many colleges and universities that are facing enrollment decline in their service areas. They also allow renowned experts to teach a course to a broad geographic audience.

Real Estate

Numerous real estate Web sites provide millions of up-to-date listings of existing and new homes for sale throughout the world. These sites are devoted entirely to buying and selling real estate. The buyer or seller can review neighborhoods, schools, and local real estate prices. These sites allow the customer to find a realtor, find brokerage firms, and learn many home-buying tips. Some of these sites offer or will soon offer "virtual tours." These virtual tours will enable a buyer to view a prospective property from distance. This is achieved by using virtual reality technologies. Some of the services offered by a typical real estate site are listed below:

Appraisal services;
Buying;
Checking neighborhood profiles;
Checking schools profiles;
Financing;

Table 8 lists examples of major real estate sites.

Table 8 Examples of Online Real Estate Sites

Prudential California (http://www.prudential.com) provides wireless listing services and property data for agents.
ERA (http://www.era.com) is an Internet-based application with listing information for agents.
Century 21(http://www.century21.com) is an electronic system for tracking agent referrals worldwide.
Re/Max (http://www.remax.com) is a contact management tool for agents that interface with Palm Pilot.
Homestore.com (http://www.homestore.com) provides a listing of more than million properties throughout the United Sates.
Mortgage Expo.com (http://www.mortgageexpo.com) provides a listing of more than 800 home lenders throughout the United Sates.

Employment

Employment service providers have established a Web presence. Table 9 provides a listing of some of the popular sites to use for finding or recruiting for a job, especially if it involves information technology.

Banking and Brokerage Firms

Online banking is here. Many U.S. and Canadian banks and credit unions offer online banking services. Although online banking has not been fully accepted by the customers, many banking-related resources are being utilized. For example, many banks use e-mail to communicate with their corporate customers. E-mail is a less expensive alternative to a telephone call, especially for long distances. Financial reports for banks can be easily distributed via e-mail to mutual-fund investors or customers.

The banking industry's ultimate goal is to carry out many of their transactions through the Internet. Consumer acceptance is the major factor that has kept this business from exploding. It is generally believed that a secure nationwide electronic banking system is almost in place. Soon people will be able to use their PCs and the Internet to do all types of banking activities.

As will be discussed in one of the chapters in the *Encyclopedia*, digital signatures are a key technology for the

24/7 customer service by e-mail
Accessing the old transactions
Categorizing transactions and producing reports
Exporting banking data to popular money management software
Obtaining online funding for checking accounts
Obtaining online mortgage and CD applications
Obtaining written guarantee against frauds and late payments
Obtaining instant approval for personal loans
Obtaining interactive guides to aid selection of a proper banking product or service
Obtaining interactive tools for designing a savings plan, choosing a mortgage, and/or obtaining online insurance quotes all tied to applications
Obtaining online application for both checking and savings accounts
Obtaining online forms for ordering checks, and issuing a stop payment
Obtaining free checks, and free foreign ATM use
Obtaining IRA and brokerage account information
Obtaining loan status and credit card account information online
Paying bills
Paying credit card accounts
Transferring funds
Viewing digital copies of checks

banking and brokerage industry since they provide an electronic means of guaranteeing the authenticity of the sending party and assurance that encrypted documents have not been changed during transmission. The current mergers and acquisitions taking place and the frequent downsizing within the financial industry strongly support Internet banking. Table 10 lists some of the services available via the Internet for banking activities (Carter, 1999).

Many brokerage firms offer stock and other security transactions online. They provide quotations for stocks, bonds, and other securities. To encourage more customers to use these services, they offer discounts.

Software Distribution

Several major software vendors offer software on the Internet. Customers can view listings of software available, and order and designate an installation time. Microsoft and several other software companies already offer free software via the Internet. Routine downloading of the Netscape Navigator and Microsoft Internet Explorer browser applications are two good examples. Both are relatively small programs. In contrast is the Microsoft Office Suite, which would take significantly longer to download through an online application service provider. Given today's communications throughput and bandwidth limitations, program size will definitely pose a challenge to online software distribution.

A successful application in this area is the distribution of anti-virus programs over the Internet. Several of the vendors of this software application are already using the Internet to sell their software to prospective buyers. A major advantage of this method is the frequent and the automatic updates that the vendors provide for their customers. The Internet makes this process a cost-effective venture for both the vendors and the customers.

The development of online copyright protection schemes continues to be a challenging problem. If users need an encryption code to "unlock" software, backups may not be possible. However, the odds are in favor of online software distribution as it provides an inexpensive, convenient, and speedy method of purchase and implementation (Cross, 1994; Hayes, 1995).

Healthcare

Electronic patient records on the Internet could provide complete medical information and allow physicians to order lab tests, admit patients to hospitals, refer patients to other physicians or specialists, and order prescriptions. Test and consultation results would be directed automatically to electronic patient records. The advantages of this approach include the fact that all patient information would be accessible from one central location. Another positive side of this application is that it would allow easy access to critical health information. Imagine a person who is far away from home and runs into a serious health problem due to injury or other causes. Any physician in any location will be able to download the complete medical history of this patient and prescribe a suitable treatment in a short period. However, these systems may offer disadvantages such as information privacy, accuracy, and currency.

Telemedicine (http://telemedtoday.com) may provide the medical profession with the ability to conduct remote consultation, diagnosis, and conferencing. This could result in major annual savings in travel costs and overhead for medical care professionals. As part of the information superhighway, a personal health information system (PHIS) could conceivably provide interactive medical tools to the public. Public kiosks located in shopping malls would be equipped with user-friendly computer equipment for Internet access. Patients would be prompted through the diagnosis procedure by a series of questions. Premature onset of disease could be minimized with this aggressive and proactive approach (Anonymous, 1994).

Virtual medicine on the Internet may allow specialists at major hospitals to operate on patients remotely. Telepresence surgery, as this is called, would allow surgeons to operate all over the world without physically traveling anywhere. A robot would perform the surgery based on the digitized information sent by the specialist over the Internet. Robots would have stereoscopic cameras to create three-dimensional images for the surgeon's virtual reality goggles. Physicians would operate in a virtual operating room. Tactile sensors on the robot would provide position information to the surgeon so that he/she can feel what the robot feels. Already prescription drugs are sold online and there are several Web sites that offer medical services (Bazzolo, 2000).

Politics

In the United States, in recent years the Internet has become a major promotional tool for all major political contenders in races for the White House, the House of Representatives and Senate, and other races. Political candidates use the Internet to announce the platforms that they are running on, their major differences with their opponents, their leadership styles, forth-coming debates, political events, and so forth. They even use the Internet for fund-raising.

The Internet may facilitate empowering voters and revitalizing democracy. Twenty-first century citizens may vote using a computer connected to the Internet, resulting in increased participation. Part-time legislators may have remote access to Washington and they may be able to remain geographically close to their constituents. Of course, an identification system will have to be in place, which could very likely use voice identification, face scan, finger image, or some other biometric verification technology. If such a system becomes available, then security of voting application, security of voting results, and counting accuracy must be carefully analyzed. Currently, the U.S. House of Representatives is attempting to put all pending legislation online. Presidential documents can be found on the Internet. Full-text versions of speeches, proclamations, executive orders, press briefings, daily schedules, the proposed federal budget, healthcare reform documents, and the Economic Report of the President are available. There are a number of repositories of this information that can be found using search engines.

GLOSSARY

ARPANET (Advanced Research Projects Agency Network) Started in 1969 and served through 1990 as the basis for early networking research, and as a central backbone network during development of the Internet.

Directories Use an index of information based on key words in a document. Yahoo! is the most popular directory on the Internet.

Domain name systems (or domain name servers, DNS) Unique identifiers of computer or network addresses on the Internet. Whitehouse.gov or csub.edu are two examples. The first one uniquely identifies the White House and the second identifies California State University in Bakersfield.

Extranet A secure network that uses the Internet and Web technology to connect two or more intranets of trusted business partners, enabling business-to-business, business-to-consumer, and consumer-to-business communications.

Hypermedia Allows links for combinations of text, images, sounds, and full-motion video in the same document. It allows information retrieval with a click of a button.

Hypertext Provides users with nonsequential paths to access information whereby information does not have to be accessed sequentially as in a book.

Internet A collection of millions of computers and network systems of all sizes. Simply put, the Internet is the "network of networks."

Intranet A network within the organization that uses Web technologies (TCP/IP, HTTP, FTP, SMPT, HTML, XML, and its variations) for collecting, storing, and disseminating useful information throughout the organization.

Navigational tools Allow the user to surf the Internet, Microsoft Internet Explorer and Netscape Navigator being two prime examples.

Search engines Provide access to various resources available on the Internet such as library searches for writing a term paper or making a reservation for an airline ticket. Google.com is an example.

URL (uniform/universal resource locator) The address of a file or a site on the Internet used to identify a particular Web page.

Internet Navigation (Basics, Services, and Portals)

Pratap Reddy, *Raritan Valley Community College*

INTRODUCTION

The Internet is a system of computer networks designed to send and receive data. This chapter introduces the basic concepts of Internet navigation. It explains what the Internet is, the infrastructure (both hardware and software) needed to access it, and the services and facilities available. Internet navigation includes the use of communication services such as electronic mail (e-mail), listserv/mailing lists, news groups, Internet relay chat, downloading services such as file transfer protocol (FTP), and search services like the World Wide Web and the ubiquitous Web portals.

What Is the Internet?

The Internet may be defined as a web of computer networks spanning the globe to send and receive data in a seamless fashion. The Internet is a form of organized anarchy; it's in flux all the time, and it's decentralized because no company, organization, or government runs it.

The Origin of the Internet

The Internet sprouted from the Advanced Research Project Agency's ARPANET, an undertaking of the U.S. Department of Defense in 1969. It was conceived to test the idea of a communication link that could withstand a nuclear attack. An in-depth discussion about the history of the Internet may be found in a separate chapter within the encyclopedia.

How Does It Work?

The Internet is based on TCP/IP protocol and the packet-switching technology. Transmission control protocol (TCP) is responsible for breaking up messages into sequences of packets, each approximately 1500 bytes. It makes and breaks the connection between computers on the Internet, whereas the Internet protocol (IP) takes care of routing the data packets on the Internet. At the destination, the TCP software reassembles these packets into complete messages.

As shown in Figure 1, messages are sent from the sender to the router. Then they are sent to the Internet. The router is a special purpose computer that connects different computer networks on the Internet (Andrews, 2001, p. 72).

How Can Users Access the Internet?

There are three ways of connecting to the Internet (Figure 2 depicts the three types of connections):

1. Using the Internet from a school or a college or university. Most likely, the computers at educational institutions have network cards and are connected to the institution's local area network (LAN), or they use cable modems.
2. Using the point-to-point protocol (PPP) to dial up an Internet service provider (ISP) to get connected to the Internet.
3. Using a cable or digital subscriber line (DSL) or similar service that connects to the Internet.

How Do Users Select an ISP?

Selecting an ISP is not difficult. According to Ackermann and Hartman (2002), the basic criteria that one needs to take into account before selecting an ISP are access (including dial-up cost), reliability, service, speed, fees, and features (see http://ispfinder.com for additional information about ISPs).

What Is the Internet Infrastructure?

The infrastructure of the Internet is made up of technologies that enable connections through various modalities; for example regular modem, DSL, cable modem, fiber-optic cable, wireless, and satellite.

Regular Modem

A regular modem and a dial-up number connect to the Internet at speeds of 56 kilobits per second (Kbps), in practice around 49 Kbps (the telephone network limitation).

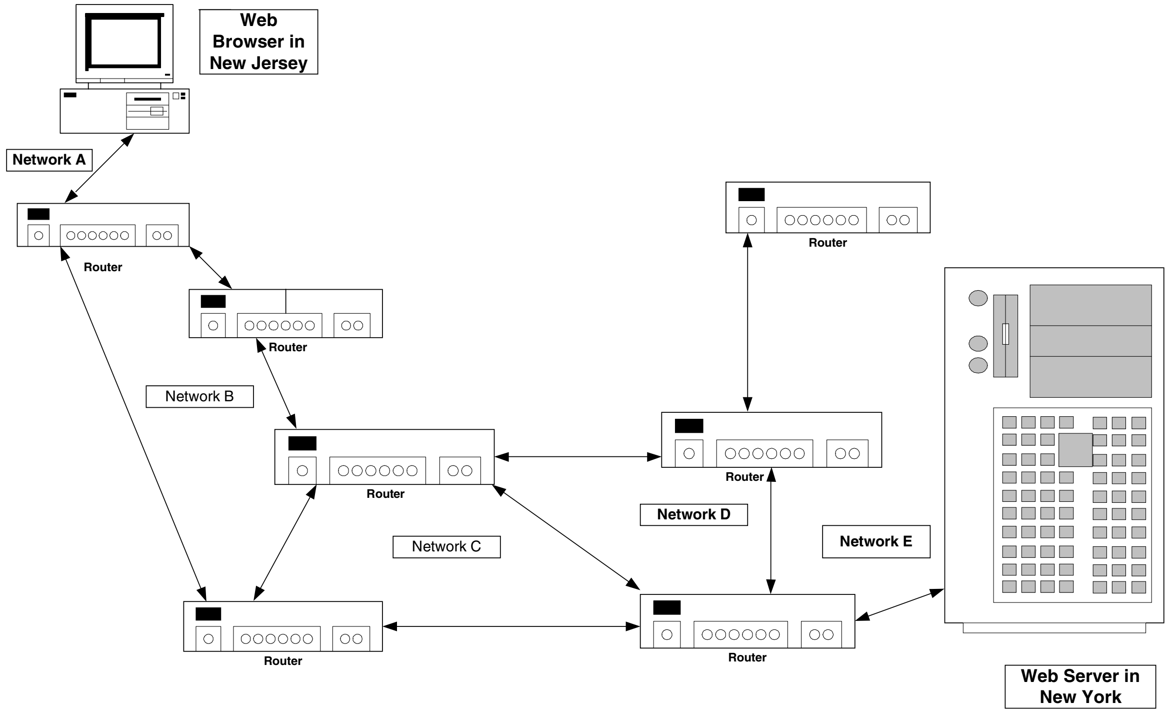

Figure 1: The Internet.

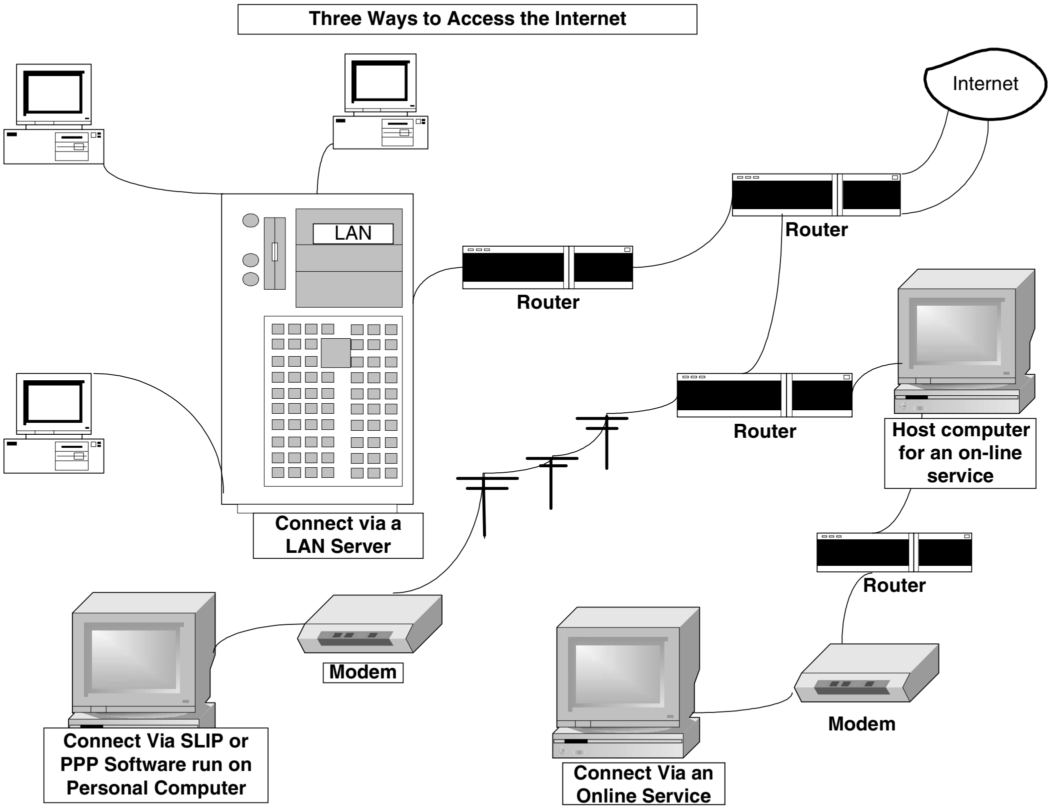

Three Ways to Access the Internet

Connect Via SLIP or PPP Software run on Personal Computer
Connect Via an Online Service

Figure 2: Three ways to access the Internet.

Cable Modem

The cable TV network provides speeds of 500 to 2,000 Kbps for downloading data. The upload speeds are similar to a telephone modem—48 Kbps at best. In a cable network, typically 500 to 2,000 homes are serviced by the same signal with a bandwidth of 27 to 39 mega (million) bits per second (Mbps). In the worst case scenario, if all of these users try to access the Internet at the same time, they each will get a share of the bandwidth but only 13.5 Kbps of it—worst than a dial-up modem. However, in practice, it's unlikely that all users will be on the Internet at the same time.

Types of Cable Modem Connections

One-Way. As the name implies, in this type of connection, data can only move downstream. If the user has data to be uploaded, it must go over the regular dial-up connection and thus requires dependence on the plain old telephone system (POTS).

Two-Way. Using this type of technology, the user can send and receive data. Because many customers share a cable, data collision during uploading is likely. A proper timing sequence for data transmission may prevent collisions, however. In the case of downloading, collision is not possible, because the head end or the central office (CO) can schedule downloading for each subscriber as it sees fit to avoid collision (Smith, 2002).

The major players in the cable modem business can be found at the following Web sites: Earthlink (http://www.earthlink.net), Range Broadband (http://www.the-bridge.net), RCN (http://www.rcn.com), and HSA (http://www.hsacorp.net).

Digital Subscriber Line (DSL)

DSL involves using regular telephone lines at a very high-speed connection. There are various types of DSL connections:

Very High Bit DSL (VDSL). The connection speeds for this type may approach 52 Mbps. Telecommunication companies such as QWEST offer this service in certain parts of the United States. This type of connection is effective over short distances.

Asymmetric DSL (ADSL). With this type of connection, the available frequencies of a line are divided up, based on the assumption that most Internet users either look at or download much more data than they send or upload. Connection speeds for downloads are 3 to 4 times faster than speeds for uploading. ADSL is dependent on the subscriber's distance from the provider's central office. The limit is 18,000 feet (5,460 m). Therefore, as the distance of the connection increases, the strength of the signal gets weaker, and the speed of the connection decreases. Although ADSL could theoretically provide an 8-Mbps connection speed at a distance of 6,000 feet (1,820 m), in practice the speed rarely surpasses 1.5 Mbps for downloads and 64 to 640 Kbps for uploads.

There are two subtypes of ADSL: carrier-less amplitude phase (CAP) and discrete multiple tone (DMT). ISPs increasingly use more DMTs than CAPs. Because each ISP uses a different modem, it is important to be aware of this before switching to a new service (http://www.howstuffworks.com/dsl.htm).

Symmetric DSL (SDSL): This type of connection does not allow simultaneous phone and Internet use. As the word *symmetric* implies, the upload and download speeds are the same.

Rate Adaptive DSL (RADSL): This is a variation of ADSL. In this type of connection, the modem can adjust to the speed of the connection depending on the length and quality of the line.

High-Bit-Rate DSL: This technology has long been used in T1 connections. It requires a two-line pair (four wires) as opposed to one-line pair, which is common to most DSL. In a newer type of connection, HDSL-2, a one-line pair is used but it covers shorter distances.

Integrated Services Digital Network DSL (ISDN DSL): This is ISDN-based DSL technology, which cannot be used for voice calls. It provides speeds of 144 Kbps in both directions (Smith, 2002). The following is a list of major DSL service providers in the United States (additional information about DSL service can be found at Broadband Report.com http://www.dslreports.com): AT&T (http://www.att.com), Qwest (http://www.qwest.com), Sprint (http://www.sprint.com), and Verizon (http://www.verizon.com).

The Internet Connection Through Satellites

Even today, many developing nations and some remote parts of industrialized countries lack an efficient wired infrastructure technology such as telephone, DSL, and cable to deliver high-speed Internet access. Satellite Internet is an alternative to address this issue. In such a system, the content provider beams a signal to a satellite that then bounces the signal back to Earth, where it can be received by millions of subscribers.

Although satellites could be employed for Internet communication, little research is being conducted in this area. This may be due to factors such as problems of latency and the cost. Smith (2002) observed that whereas the latency is a mere 10 to 100 ms in the case of DSL and cable modem, it is 239 ms for one-way and 478 ms for two-way satellite communication. This is because it takes 239 ms for the light to reach geosynchronous satellites at a speed of 186,000 miles per second. Two companies in particular that are doing business in satellite Internet connection are Hughes Electronics Corporation (http://www.hughes.com) and Starband Communications (http://www.starband.com/).

Internet Connection Through Wireless Technology

The evolution of wireless technology can be classified as follows: First-generation cell phones use analog technology, second-generation cell phones use digital technology (such as personal services communication [PCS]), and third-generation (3G) cell phones use the 1.9-GHz range, which is also the technology used for laptop computers. The major players in the wireless Internet

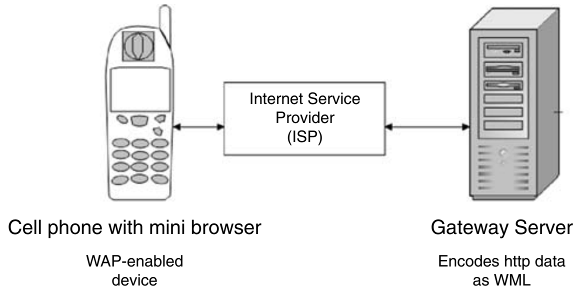

Figure 3: Wireless Internet.

field are CAI Wireless (http://www.caiwireless.com) and Winstar (http://www.winstar.com).

As depicted in Figure 3, accessing a Web site using the Internet-enabled cell phone involves the following steps: (a) The user turns on the cell phone and opens its mini browser; (b) the cell phone sends out a radio signal, searching for service; (c) a connection is made with the ISP; (d) the user selects a Web site to view; (e) a request is sent to the gateway server using wireless application protocol (WAP); (f) the gateway server retrieves the Web site information using hypertext transfer protocol (HTTP); (g) the gateway server encodes the HTTP data as wireless markup language (WML); (h) the WML-enabled data is sent to user's WAP-enabled device (cell phone or other handheld device); (i) the user sees the wireless Internet version of the Web page selected. For an in-depth discussion of wireless Internet, please see the chapter dedicated to that topic in this encyclopedia.

Internet Connection Through Fiber-Optic Cable

Consumers can get an Internet connection through fiber-optic cable via one of the following modalities:

Fiber to the Curb (FTTC)

In this method, fiber-optic cable is run from the central office of the service provider to the curbside of the consumer's office building or apartment complex. From there, an optical network unit (ONU) converts the optical signal to an electrical signal, and then the message is carried into the consumer's apartment or building.

Fiber to the Home (FTTH)

In this case, the ONU device is in the apartment complex or the building. Up to 32 subscribers can access the signal at 622 Mbps speeds for downloading and 155 Mbps for uploading.

The major player in the fiber-optic arena is Surewest Broadband (http://www.surewestbroadband.com/wf/). In a newer FTTH technology, using a dedicated fiber cable between subscriber and the central office, one could achieve 155-Mbps asymmetric speeds (Smith, 2002).

INTERNET SERVICES

There is a vast array of services, programs, and applications available on the Internet—from the ubiquitous e-mail to the arcane gopher and many in between. Some of these programs and applications used to navigate the Internet are the following:

- E-mail,
- Listservs and mailing lists,
- Usenet and news groups,
- Internet relay chat (IRC),
- Telnet,
- FTP,
- World Wide Web, and
- Portals.

This section includes a detailed discussion of Telnet, listservs and mailing lists, Usenet and discussion groups, the World Wide Web, and portals. An in-depth discussion of some of the remaining services can be found in separate chapters in this encyclopedia.

It is important to understand the domain name systems and the data types on the Internet before any discussion of e-mail. The domain name system (DNS) will take care of the translation of a domain name into an IP address or vice versa. For example, if a user were to type the URL http://www.raritanval.edu, the DNS would translate it into an equivalent IP address of 192.231.207.100. We could also type the URL http://192.231.207.100 for a quicker response, but this is not recommended because it is not easy to understand as the regular URL. The *nslookup* can be used to find an IP address of a domain name or vice versa. Users can access this from http://www.dns411.com or http://www.lasaltech.com/cgi-bin/nslookup.

How Does the DNS Work?

When a computer in the United States wants the IP address of a computer in India, it first looks at the local DNS server to find this information. If that does not work, then the U.S. server contacts the DNS server in India to get the information it needs and then provides it to the computer in United States.

Domain Names

In the URL http://www.raritanval.edu, *www* is the computer name, *raritanval* is the organization name, and the *edu* is the organization suffix or main or primary domain. A domain name could be divided further into what is called a subdomain name as follows: http://webct.raritanval.edu, where *raritanval.edu* is the domain name and *webct* is the subdomain name.

International Domain Names

Domain names outside the United States are, for example, as follows: Australia = au, India = in, Japan = jp, China = cn, United Kingdom = uk, South Africa = za. A domain for a university in Japan could be ftp.meiji.ac.jp, for example, where the domain *ac* stands for academic (college or university), analogous to *edu* in the United States, to denote colleges and universities. See the URL http://www.iana.org/cctld/cctld-whois.htm for a list of international domain names.

The following are the top-level domain names that have been in use for some time and the new ones that were approved recently:

Top-Level Domains

.com (commercial)
.edu (higher education)
.net (networking companies)
.org (nonprofit organizations)
.gov (U.S. federal government)
.mil (U.S. military)
.int (international treaties)

New Top-Level Domains

.aero (air-transport industry)
.biz (Business)
.coop (cooperatives)
.info
.museum
.name (for registration by individuals)
.pro (accountants, lawyers, physicians, and other professionals)

Communication

Electronic mail (E-mail)

Asynchronous Communication. In asynchronous communication, the sender and receiver are not necessarily online at the same time. E-mail, Usenet, and listserv are some examples of such communication. E-mail is the most widely used service on the Internet. More than a billion messages are sent on the Internet each day. A detailed discussion of e-mail can be found in a separate chapter of this encyclopedia.

Listserv

A listserv is a system that makes it possible to create, manage and control electronic "mailing lists" on a corporate network or on the Internet. Listservs have been continually improved and expanded to become the predominant mailing list system in use today (Lsoft, 2002).

A subscriber to a listserv automatically receives via e-mail all the messages that are sent to the listserv. Listservs are used on the Internet to send and receive messages on a variety of topics. Because the discussions are asynchronous (i.e., not taking place in real time), users have time to think and respond to the e-mail at their leisure.

There are two types of listservs: moderated and unmoderated. In a moderated listserv, editors screen messages for appropriateness; in an unmoderated listserv, everybody on the list receives every message posted to the list. This may result in hundreds of e-mail messages per day.

How to Send a Message to a Listserv. To subscribe to a Web Designers Listserv, send a blank e-mail message to join@alistapart.com. Do not write anything in the body; leave the CC and BCC blank.

The EDUCAUSE listserv online is a weekly e-mail notification system that summarizes news and information found on the EDUCAUSE Web site.

To subscribe, send a message to LISTSERV@ LISTSERV.EDUCAUSE.EDU. Leave the subject area blank, and in the body of the message write SUBSCRIBE EDUCAUSE-ONLINE YOUR NAME

Example: subscribe educause-online Pratap Reddy

Netiquette. When one is navigating the Internet, basic netiquette, network etiquette, is expected. It includes avoiding spamming and flaming. For additional information on netiquette, see http://www.albion.com/netiquette/index.html. Additional resources of listservs include the following:

- http://www.javascript.com/newsletters/
- http://paml.org (publicly accessible mailing Lists)
- http://www.lsoft.com/lists/listref.html (catalog of Listserv lists)

What Is Telnet?

Telnet is a program that connects a computer to a remote computer. A telnet program can be invoked from Windows 95 or higher (start–run telnet), from UNIX prompt, or from a Web browser. Telnet is used to navigate the Internet for the following purposes:

- To connect to remote servers, such as college and university computer systems, using a valid login address and password. This enables the user to access system resources that are made available to them.
- To connect to libraries and similar organizations, which allow users to login without a password.

Telnet connections do not provide for a graphical user interface (GUI); one would simply see text information. The information retrieval would be faster, however, because it does not contain any graphics. If a user simply wishes to do a library search, for example, then a telnet search would be better than a WWW search, which may involve graphics.

How to Access Telnet From a Web Browser. Type the telnet host address in the Web browser. For example, telnet://nyplgate.nypl.org. The system prompts the user to enter a login name and password. If the telnet host is a library or similar type, then one may not need a password but only a log-in name. This log-in name is usually listed on the telnet session for convenience. In the case of New York Public Library, for example, the log-in name is nypl.

After typing a log-in name and password, if required, the user will be connected to the remote host computer and is then ready to access the resources provided on the host computer.

The following telnet servers can be accessed from a user's Web browser. Log-in information could be found during the telnet session.

- telnet://hp.falcon.edu
- telnet://fedworld.gov
- telnet://freenet.victoria.bc.ca

Another resource for telnet can be found at http://www.udel.edu/interlit/chapter10.html.

USENET and News Groups

User networks also known as Usenet or news groups are asynchronous discussion forums about many topics such as computers, social issues, music, and recreation by people from all over the world. News is obtained from a NNTP (network news transfer protocol) server. For example, Raritan Valley Community College in New Jersey, gets its news from a server called *news.bellatlantic.net*. In turn, this server may get a feed from some other machine. One could subscribe to the Usenet or news groups from a Web browser by connecting to a USENET server. Discussion articles are read with the help of a newsreader. We could also use the Web browsers such as Netscape, Microsoft Explorer, or Lynx to read news. Individual contributions and articles to these news groups are known as *postings*. News groups differ from listservs and Internet relay chat. In a listserv, the messages are directly e-mailed to the subscriber's e-mail box, whereas in a news group, the messages are posted on a news server. To read them, the user has to log in to the news server. When posting messages, however, the user has the option of directly e-mailing the discussion participants. Participants of discussion groups are expected to follow *netiquette* or network etiquette.

Names for News Categories

- Alt (alternative news groups on many topics)
- Comp (computers)
- Rec (recreation)
- Soc (social)

For example, *soc.culture.indian.telugu* is a news group of Telugu speaking people of Indian origin; *alt.rec.humor* is a discussion group devoted to humor; and *comp.lang.javascript* group is for JavaScript programmers, which is under *lang* subgroup, and this subgroup is under the main group *comp* (i.e., computers).

Users can subscribe to these news groups either from an ISP, college, university, or directly through a Web browser from the URL http://groups.google.com.

To access a master list of news groups, go to http://www.magma.ca/~leisen/mlnh/mlnhtables.html.

Internet Relay Chat (IRC)

Internet relay chat is *real-time* communication. Both sender and receiver are online at the same time. An in-depth discussion about Internet relay chat can be found in a separate chapter in this encyclopedia.

Downloading: File Transfer Protocol (FTP)

The file transfer protocol is designed to upload (send) and download (receive) files. To perform FTP activities, one needs a computer or a similar device and a software client or program. Users can access anonymous FTP servers from a Web browser by simply typing ftp://sunsite.unc.edu, for example. A detailed discussion of FTP and other downloading software can be found in a separate chapter in this encyclopedia.

Searching: The World Wide Web

The World Wide Web (WWW) is a collection of hypertext and media information that is accessible through the Internet. Tim Berners-Lee, a European scientist, was instrumental in pioneering the idea of the World Wide Web. The W3C (consortium) has been formulating the guidelines for the expansion of the WWW.

To access documents from the Web server, one usually uses a Web browser, such as Netscape, Microsoft Explorer, and Lynx. The HTTP is used to make the connection between a Web client (browser) and a Web server.

Web Client Software

This is the program used to read documents on the Web. There are two types of Web browsers: graphical and nongraphical.

Nongraphical User Interface (Non-GUI) Web Browser

Lynx is a nongraphical, text-only browser that can be invoked from a UNIX server. Because it does not display audio or video, the download is faster. To learn more about Lynx refer to the following URL: http://lynx.browser.org.

Graphical User Interface (GUI) Browsers

The three most common Internet browsers are

- Netscape (version 4–6, 7),
- Internet Explorer (version 4–6), and
- Opera (version 6.03).

All of these Web browsers have features such as searching and retrieving data, performing basic e-mail functions, and facilitating synchronous (IRC) and asynchronous communication (news groups).

Web Browser Protocols

Web browsers are capable of interpreting the following Internet protocols:

- ftp://wuarchive.wustl.edu,
- http://www.raritanval.edu,
- telnet://nyplgate.nypl.org,
- gopher://gopher.ptloma.edu, and
- news:soc.culture.indian.

A Web browser displays the documents written HTML, extensible markup language (XML), and scripting languages such as JavaScript.

HTML Versus XML

The primary purpose of the HTML is markup and linking of text documents. It tells the browser how to format or style the content. In other words, it says, "make this bold, make that italic."

Unlike HTML, XML focuses on communicating content. It draws relationships between content and leaves the formatting to style sheets such as cascading style sheets (CSS) and extensible style sheet language (XSL).

Web Browser Icons

Back and Forward: If the user clicks on these icons, the previous and following document respectively will be displayed in the Web browser.

Reload or Refresh: These icons will reload or refresh a Web page from the server.

Favorites or Bookmarks: By highlighting the URL in the address or location area of the browser, the user can save the URL as "Favorites" or "Bookmarks" for future use. In Netscape, the user can edit these URLs and save them in the Personal Bar and click on them to visit them. It's a good idea to store the most frequently visited URLs on the Personal Bar.

File: This icon is used to open, save, print, and send via e-mail a document.

Edit: In Internet Explorer, this icon is used to copy, cut, paste, select all, and find something on the page. In Netscape, in addition to these functions, using the preferences option the user can configure the browser to send and receive e-mail, read and post news, and store the home page address.

View: This icon is used to increase or decrease the font size and view the Web page's HTML source code.

Mail: This icon is used to read mail and news. The user needs to set up the Web browser so it knows where to get the mail.

Home: To load a home page, click on home. The user can configure the homepage URL either from tools or Internet options of the Explorer browser or the edit and preferences option of Netscape. The next time the browser loads, it will start with this page, the home page.

History: This icon is used to display navigation activities in the recent past on the Web browser.

Enhancing Web Browser Functionality

Web browsers, particularly, the GUI types, use additional software known as plug-ins, and helper applications to extend their functionality. A plug-in is an application that extends the browser functionality. It runs within the browser. Examples are programs such as Real Audio, Shockwave, and QuickTime. A helper application is when the Web browser encounters a file type such as a sound, image, or video, and it hands off the data to other programs, called helper applications, to run or display the file. Most helper applications are shareware or freeware that can be found on the World Wide Web. One can configure these in the helper application dialogue box found under *preferences* in the options menu of Netscape Web browser. A helper application, unlike a plug-in, runs independently outside the Web browser. Examples include Microsoft Excel.

Ports

In a Web server address, users sometimes use a suffix that ends with a number. These numbers are used to address software or services running on a computer. Using port numbers, a host computer can run several software applications or processes including ftp, telnet, http, and pop all on the same machine, but each on a different port number. The typical port number assignment schema is as follows:

- ftp: 20
- telnet: 23
- smtp: 25
- http: 80
- pop3: 110

To find more about Web browsers, check the URL http://www.upsdell.com/browsernews.

Search Engines

An in-depth discussion of search engines can be found in a separate article within the encyclopedia.

Zipping and Unzipping Files

To save storage space on the medium (floppy or hard disk), one can use an algorithm and substitute a simple code for the repeated words of the text. For a simplistic illustration, let's say we have the text "when it rains, in the Amazon, it rarely rains, but pours." Here, a simple letter can substitute for all the repeated words or numbers and thus save the storage space. Obviously, when one is transmitting this file on the Internet, it takes less time because it is smaller in size. At the receiving end, however, the data has to be restored by filling in the appropriate words in place of the codes used before. Programs such as WinZip or PK Zip accomplish this process of stripping the words and inserting the words before and after.

Users may download this shareware from http://www.winzip.com.

What Is a Cookie?

When a user visits a Web server and performs a transaction, for example, buying an item online, the Web server leaves an identification number on the user's Web client (the Web browser). This information is stored in a place called a *cookie* and stored on the user's computer on the hard drive. The next time the user makes a visit to this server, the browser will send the cookie information to the server so it can recognize the user and his or her past activities. Then, for example, it might greet the user by name and show the pages that were last visited. The user has the option of accepting or rejecting the cookie information by configuring the Web browser appropriately.

Security Risks on the Internet

Users of the Internet should be knowledgeable about the security risks associated with it. These can originate from servers, Trojans, and viruses. A hacker or cracker, a computer miscreant, targets a list of known servers and gains unauthorized access to others' computers or causes computer resources to become unavailable resulting in what is known as *denial-of-service* (DOS) attack.

A *Trojan horse* or *Trojan* is a computer program used by hackers/crackers to gain entry to other computers. The cracker uploads such a program to a popular download site. When a user downloads this program, it gets installed on the user's computer and can delete files on the computer or can function as an unauthorized server whereby the cracker can telnet to this server and access it illegally.

Internet users can take the following measures to reduce security risks: (a) Use antivirus software to detect and warn the user of the presence of Trojan horse; (b) restrict downloads from only trusted sites; (c) configure firewalls to block certain classes of outgoing traffic, for instance, traffic directed to ports associated with protocols that one does not use. A firewall is a dedicated router or computer that protects a network from outside attack and prevents insiders from attacking outside systems. A more detailed discussion of Internet security, firewalls, and viruses can be found in other chapters of this encyclopedia.

Web Portals

What Is a Portal?

Winston Dictionary defines a portal as “a gate, door, or entrance; especially one that is stately and imposing, as of a cathedral.”

Jenny Rickard (2000, p. 3) noted that “portal technology provides the capability to aggregate content from multiple sources, integrate [Enterprise Resource Planning] backbone systems into a role-based self-service transactions . . . access role-based analytic information and, if desired, facilitate commercial transactions.”

The Evolution of Portals

The word portal derives from the meaning of the word *port*, which denotes an entrance. The concept of a Web portal has evolved from the domain of the intranet, which leads to the Internet. Discussing the distinction between an intranet and a portal, Paul Krill (2001) observed that the portals lead the user to a structure on data and a navigation scheme around massive quantities of information. The intranet on the, other hand, operates as a data silo, providing unstructured information and a conglomeration of services. They work together. Whereas the intranet holds the data repository, portals provide the seamless infrastructure to access the information from the intranet.

So a portal is a Web site that offers a broad array of resources and services such as e-mail, search engines, online shopping and auctions, chat, instant messaging, personalized calendars, and more. This definition includes the popular community portals such Yahoo, MSN, Excite, and Lycos. The definition of a corporate portal is a bit more elaborate.

Although search engines and portals have similarities, they are different. A key distinction between a search engine such as AltaVista and a portal such as Yahoo is that whereas a portal provides a structure of categorized links to topics such as business, finance, leisure, news, sports, and travel, a search engine provides search results containing the key words that you have entered for the search. See Figures 4–6 for a listing of Yahoo (http://my.yahoo.com) and Google (http:/news.google.com) portals and AltaVista (http://www.altavista.com) search engine results.

Portal Architecture

Whereas a client–server employs a problematic two-tiered architecture, portals employ three-tiered architecture. The weaknesses of two-tiered architecture are many (3- and n-Tier Architectures, http://www.d-tec.ch/e/3tier.html):

- The client or the personal computer processes and presents information that leads to monolithic

applications that are expensive to maintain which is why these systems are referred to as "fat clients."

- Because most of the work is being done on the personal computer, there would be an increased load on the network to transport data back and forth from the server to the computer.
- Computers are less trustworthy in terms of security because they can be easily cracked.

What Is Three-Tiered Architecture?

Three-tier architecture, as shown in Figure 7, includes a client tier, an application tier, and a data storage tier. In

this paradigm, the client tier is responsible for the presentation of data, receiving user events, and controlling the user events. This makes it a "thin-client." The application tier hosts the business logic, whereas the data storage tier is responsible for data storage. The benefits of three-tier architecture include the following:

- Development time is quicker because of the reuse prebuilt business logic components.
- Servers are trusted systems; they have fewer security threats compared with clients.
- The business logic and the data storage are closer. The client only receives the processed data, so that network traffic is reduced.

Types of Portals

Based on their features, portals are divided into horizontal and vertical categories. Horizontal portals are also called community or mega portals. They are public Web sites. Examples include Yahoo and Excite. An enterprise portal that caters to a particular market segment is known as a vertical portal (or vortal). In other words, a vortal offers a gateway to information related to a specific industry such as automotive, banking, health care, insurance, law, and others. Examples include esteel.com, a site for buying and selling steel products. A vertical portal used by a university, for example, can deliver the information specific to the college, and in addition it should also function like a public Web portal. Unlike a horizontal portal, it requires authentication information when one tries to login (Katz, 2002). For a detailed list of vertical portals see the link at http://www.verticalportal.com.

The list of portal categories includes animals, arts, beauty, business, computers, entertainment, education, food, home and garden, government, health, living and society, money and investing, news, real estate, reference, shopping, sports, people and family, travel, and vehicles. Each category includes many portals.

Community Portals

The dominant players in the community portal arena include Yahoo, Excite, MSN, Lycos, and Google. In a 1999 report, *The Power of Portals: Who Is Using Them and How,* the International Data Corporation (IDC) and Relevant Knowledge reported that Yahoo and Excite are the two community portals in the *visitor loyalty* and the *duration of visitor stay;* 161 minutes for Yahoo and 160 minutes for Excite. Yahoo is one of the speediest portals on the Web. Its competitors—excite, geocities, and tripod—do a much better job of allowing the user to set up a Web page with built-in message boards and chat. Yahoo's message boards and the chat are the most populated on the Web. "Simplicity and familiarity breed loyalty in the Web-portal market place," observes Glen McDonald (1999), in his article *Portal Profiles: Why Yahoo Is #1.* Community portals make money by selling ads, e-commerce transactions, and sponsorships. For example, the portal http://GoTo.com offers top placement on its search site to the company willing to pay the most (McDonald, 1999).

My.Yahoo. My.yahoo has an excellent directory that will guide the user to other sites if the user decides to leave Yahoo. Notable services include online photo albums and an experts channel (for quick answers to questions on a host of topics). The my.yahoo site is probably the most highly customizable of all the portals. For example, when one configures an http://my.yahoo.com portal, it adds information about movies playing in that locality.

MSN. Microsoft Network, or MSN, is highly configurable, including the layout and colors, even letting the user choose which components to show. One can also add local weather and favorite links and gain quick access to a hotmail account. It can be accessed from http://www.msn.com.

My Netscape. Mynetscape is also highly configurable, including any favorite features (mail, stocks, bookmarks) in one place. It is accessible from http://www.mynetscape.com.

Excite.com. This portal (http://www.excite.com) also has many useful features, as well as the flexibility to customize it to the user's taste.

Google. The news portal (http://news.google.com) recently launched by google.com uses complex mathematical algorithms to cull news from all over the world and display these hundreds of news stories with automatic updates every 15 minutes.

GeoPortals. This portal (http://www.GeoPortals.com) includes groups of sites and search engines organized by subject and subcategories.

Corporate Portals

Sagemaker (n.d.) in its white paper *The Benefits of an Enterprise Information Portal* presents a generally accepted view of the corporate portal as a browser-based environment that

- securely integrates and personalizes internal and external content and applications into a scalable user interface for communities of e-business users across the enterprise,
- provides scalable infrastructure to seamlessly integrate disparate data sources and applications, presenting a unified view across a fully configurable user interface, and

- enables an individual member of staff to manage the flow of information in order to make informed business decisions, to implement these decisions and to be able to communicate with others in making similar decisions (http://www.itpapers.com).

Wayne Eckerson (1999), a senior consultant with the Patricia Seybold Group, characterizes the ideal characteristics of an enterprise portal in this way:

- The enterprise portal must connect to multiple, heterogeneous data stores, including relational databases, multidimensional databases, document-management systems, e-mail systems, Web servers, news feeds, and various file systems and servers.
- An enterprise portal needs to provide a full range of query, report, and analysis capabilities in a highly integrated fashion.
- The enterprise portal must support network-level security, encryption, session-management, and authentication services to safeguard sensitive corporate information and prevent unauthorized access.
- Developers and administrators should be able to customize the portal to create a distinct corporate look and feel, including graphics, banners, and channels.
- You want the professionals in your organization to have easy, quick, intelligent access to all the information they need in order to make good business decisions.

Examples of Corporate Portals

Before they adopted corporate portals, administrators at the Ames Department Store, with 479 store locations and 32,000 sales associates in 19 states, had to make 479 phone calls to communicate an urgent massage like a product recall. Similarly, they had to mail 32,000 mailers to its sales associate to inform them of new benefits. Likewise, Colliers, a Boston-based commercial real estate company, with offices in 52 countries and more than 250 offices, used to disseminate news, training, and research information to employees via push technologies such as fax and e-mail. Even a high-tech company like Hewlett Packard (HP) with more than 10,000 personnel used to rely on 4,700 intranet URLs, many containing duplicate and out-of-date information.

The solution to the problems experienced at Ames, Colliers, and HP was to use enterprise information or corporate portals (EIP), software developed by companies such as Plumtree and Hummingbird. Such software transforms the intranets and the paper-based information systems into the equivalent of a personalized start page. As observed by Sarah Roberts-Witt in her article *Digital Doorways* (2001), corporate portals are a doorway to all the information a company needs to function. A simple Web browser is used to access the knowledge management, collaboration tools, and other applications that the company makes available to the appropriate people to make intelligent business decisions.

Richard Dragan (2001) noted, in his article *Corporate Portals: More Than Just a Pretty Face*, that the major players in the corporate portal software design are Lotus (K-Station), Microsoft (Share Point Portal), Plumtree (Corporate Portal), Viador (E-Portal), Hummingbird, Epicentric (Foundation Sever), Oracle (9/As 2 portal), Sybase (Sybase Enterprise portal 2.5), IBM (WebSphere portal), CA (Clever Path), Sun (Sun One portal), and Yahoo (Portal Builder 4.0).

Obstacles

One of the major hurdles in the implementation of corporate portals is the problem associated with the integration of numerous data sources and applications. Using software connectors, gadgets, and portlets (small applications), however, one could include the popular software applications like outlook e-mail or other company applications.

Studies reveal that the portal development and implementation process can be expensive, ranging from $300,000 to $1 million. The benefits are worth every bit, however. These include increased productivity and low costs over time. It was revealed in a study that Johnson Controls, a $17-billion component manufacturer with 22,000 employees who use the portal, saved as much as an hour a day on information searches. This translates to significant cost savings. Corporations should encourage the use of their portals, however, because the benefits are not automatic. Furthermore, end users should be asked their opinion as to what they would like to see in the portal design. With this “buy in” should be more widespread.

For someone on a limited budget, hosted portals may be an option. For example, http://www.onepage.com is a software company that offers both hosted and licensed versions of the portal software for under $100,000. There are other less expensive options, such as PHP-Nuke, an open source software that can be used to develop a small business or personal portal. This software and other information can be obtained free of cost, from http://phpnuke.org and http://www.postnuke.org

Financial Portals

Writing in *ABA Banking Online*, Bill Orr (2000) predicted that, in the near future, the portal business will be restructured from the present general-purpose sites to a small number of generic portals such as shopping, financial services, sports, and entertainment. The banking industry plans to offer aggregated accounts to its customers. For example, consumers might prefer to shift their accounts to one primary service provider from two banks, say, a brokerage and a mutual fund firm.

Healthcare Portals

CGI Group (2001), in its white paper report titled *Corporate Portals for Healthcare Providers—A Strategic Solution to HIPPA Compliance*, writes that to comply with the Health Insurance Portability and Accountability Act of 1996 (HIPPA), many health care providers are integrating their patient accounting systems with multiple clinical systems and the user community, resulting in portal-based platform systems.

Voice Portals

NMS Communications (2002; http://www.nmss.com), in its white paper *Voice Portals: The Heat of the Voice Web* mentions that the confluence of the Internet and the telephone has resulted in a new technology named voice portal. Voice portals provide Internet content and electronic commerce services—from any phone, anywhere—using spoken commands. Voice portals allow callers to access e-mail, traffic information, local, national, international news, latest sports scores, stock prices, weather reports, and much more.

Advances in speech technology and the popularity of the mobile phones have helped the growth of voice portals tremendously. The Kesley Group predicts that by the year 2005, there will be more than 128 million voice portal users and revenues will reach $12.3 billion. The key players in the voice portal business include Tellme (http://www.Tellme.com), Bevocal (http://Bevocal.com), and Yahoo (http://phone.yahoo.com). Speech software vendors include Nuance (http://www.nuance.com) and SpeechWorks (http://www.speechworks.com).

Education Portals

Writing in the *Chronicle of Higher Education,* Florence Olsen stated that at many colleges and universities, particularly the larger ones, it is not uncommon to have hundreds of thousands of Web pages and other applications scattered on scores of Web servers. If all this information could be consolidated into a Web portal, then the organization, storage, and retrieval of information would be more efficient. For example, instead of sending an e-mail message to every college member about the college closing due to an inclement weather, the institution could just publish this information on the Web portal. Educational portals have many capabilities. For example, a student can log in to one place to do a variety of things—enroll for a class, send e-mail to instructors, look at grades, pay tuition—all in one place. In the preportal days, the student was required to log in to many servers.

Some of the education portals in use today allow users to access information on financial aid, student loans, transcripts, paying bills, and billing statements. In the world of higher education, Campus Pipeline, Blackboard, and PeopleSoft have been in use for the last 5 years or so. Some colleges are building their own portal software. Campus Pipeline, Plum Tree, and Epicentric are the major players in the development of education portals. Software tools from these companies integrate the information from various databases, file servers, and the Web pages that the colleges already have in place.

In addition to the commercial activities listed here, the open source approach is also in play for the development of education portals. Campus Pipeline, in collaboration with 10 universities, has designed new software called *luminis,* by starting out with open source software called uportal (http://www.uportal.com), developed by several hundred universities.

CONCLUSION

As discussed in the aforementioned pages, the Internet has many services—from simple e-mail to the powerful Portal—that can be harnessed to make our lives more productive. As Smith (1994, p. 2) observed, "Change in technology exerts a greater influence on societies and their processes than any other factor." The principle behind this school of thought, known as technological determinism is certainly true in the case of the Internet. It has changed the way of life in many in the industrialized countries. In the best circumstances, we will continue to seize the opportunities that the Internet can provide to enhance the quality of life for people around the world.

GLOSSARY

Bandwidth The range of frequencies that move along a communication link, such as a telephone line or cable television wire. The higher the bandwidth, the more the information—whether voice, video, or data—that can travel to a computer.

Bookmark A system used to keep track of uniform resource locator (URL) locations on the Web.

Browser A software program used to navigate the World Wide Web. Netscape Communicator, Microsoft Internet Explorer, Opera, and Lynx are examples of browsers.

Client–server A program with two components: software that runs on a personal computer (the client) and software that runs on a host computer (the server). A client software is Netscape Communicator; a server software is either Netscape Enterprise Web Server, Apache, or the Internet information server (IIS).

Domain name system (DNS) server A computer that identifies host computers on the Internet.

File transfer protocol (FTP) An Internet protocol for transferring files from one computer to another.

Helper application On the Web, a program that provides a function that a browser cannot perform; such as processing pictures, video, or other types of data or initiating a telnet session.

Hypertext markup language (HTML) A set of formatting commands or tags placed around text or pictures to create a Web page.

Hyperlink A button or highlighted text that activates a jump to another Web page.

Internet A network of computer networks that allows computers to exchange data, messages, and files with other computers.

Internet service provider (ISP) A business that offers Internet accounts that connect directly to the Internet. AOL is an example of an ISP.

Local area network (LAN) A network of computers set up in a limited geographic area such a building or a college campus.

Listserv A program that maintains lists of e-mail addresses. A listserv can be used as a bulletin board; messages mailed to it are sent to all subscribers.

Modem A device used to convert digital data into analog and vice versa.

Netiquette Rules to maintain civility in online discussions as well as special guidelines unique to the electronic nature of forum messages on the Internet.

Plug-in Software that extends the functionality of a Web browser. Examples include Real Audio, and Shockwave.

Portal A portal is a Web site that provides the entrance and access to structured information.

Protocol A set of rules used for computer communication. Examples include TCP/IP, FTP, and Telnet.

Router A device that connects any number of LANs.

Spamming Electronic junk mail or junk newsgroup postings. Some people define spam even more generally as any unsolicited messages.

Transmission control protocol (TCP) A part of the TCP/IP set of rules for sending data over a network.

Telnet A protocol that allows a user to connect one computer with another remote computer.

Uniform resource locator (URL) A host address on the Internet, for example, http://www.raritanval.edu

USENET The term that applies to a group of computers that exchange network news.

Wide area network (WAN) A computer network covering a wider geographic area than a LAN. For example, a corporate network covers many locations across the country.

WinZip A Windows-based program to zip (compress) and unzip (uncompress) files.

World Wide Web (WWW) A collection of HTML documents on the Web.

Internet Relay Chat (IRC)

Paul L. Witt, *University of Texas at Arlington*

ONLINE COMMUNICATION USING INTERNET RELAY CHAT

Internet relay chat (IRC) is a worldwide system of real-time, text-based conferencing on the Internet. IRC was the first online chat system to achieve widespread adoption, and despite the increasing popularity of Web-based chat rooms and instant messaging systems, it continues to be the synchronous medium of choice for many thousands of Internet users. Numerous sites on the World Wide Web contain IRC tutorials, network information, and software downloads. Because IRC is based on a client-server networking model, users simply install client software on their local computer and access the Internet to create a new channel (chat group) or join an existing channel. Using established network protocols, messages travel from an individual's computer to an IRC server, then are relayed through other servers if necessary before being delivered to the designated recipient(s). IRC supports private, one-on-one conversations (analogous to real-time e-mail) as well as the simultaneous distribution of messages to all users in the channel (analogous to a real-time listserv or newsgroup). Interactions on IRC channels involve users from all over the world, take place in many different languages, and focus on a wide range of topics. Most interactions on IRC are casual and "chatty" in nature, but sometimes they involve specific personal, academic, or organizational communication objectives. At any given moment, tens of thousands of IRC users are conversing about sports, science, technology, academics, news, recreation, and entertainment, as well as engaging in spontaneous personal and social interaction.

Historical Development

Following the earliest experiments in real-time chat systems in the 1960s and 1970s, IRC was created in 1988 by Jarkko Oikarinen, an engineering student at the University of Oulu, Finland. By extending the features of an early Unix-based function called Talk, Oikarinen's innovative technology allowed multiple users at different geographical locations to enter designated channels and engage in synchronous online discussion. By 1990, the system had expanded to include 38 IRC servers located at universities in Scandinavia and the United States (Hamman, 1999). IRC gained notoriety as a strategic global communication system in 1991, when real-time messages were received from IRC users inside Kuwait during Iraqi occupation. In 1993, IRC enabled computer users in Moscow to communicate with outsiders during the uprising against President Yeltsin. Following the terrorist attacks in New York and Washington in September 2001, IRC networks became extremely active, initially to support communication with survivors and rescue workers, and later to allow users from around the globe to vent their feelings, rally support for victims, and engage in political and ideological debate. When other communication systems failed or became congested during these international crises, computer users with access to the Internet used IRC for up-to-the-minute interaction with external parties.

In recent years, rapid growth in the number of individuals with Internet access has contributed to rapid growth in the use of IRC. At the beginning of the 21st century, hundreds of thousands of users were communicating via IRC networks. Charalabidis (2000) reported that the total number of IRC users was increasing as much as 30% annually, and that the largest IRC networks had tens of thousands of channels and sometimes experienced more than 50,000 simultaneous connections. Although many Web users gravitate to popular, easy-to-use messaging systems, such as ICQ ("I Seek You") and Instant Messenger, IRC continues to appeal to the more technology-oriented specialist. In fact, "newbies" (newcomers) may find the IRC communication climate to be unfriendly or hard to understand at first. IRC commands and interfaces are not especially complicated, but casual Web users are often more accustomed to the very simple interfaces of browser-based Web chat systems. Furthermore, experienced users on some networks adopt an exclusivist attitude by refusing to communicate with newbies, or by using vague or highly specialized jargon that is unintelligible to outsiders. On these networks, newcomers are more likely to obtain advice and direction from channels devoted to IRC help.

STRUCTURE AND OPERATION

Servers, Networks, and Channels

As IRC works on the client-server networking model, the IRC server is the central point of communication through which all messages pass en route to individual client computers. In the simplest IRC network structure, the computer of each user runs a client program to connect to a common server. The server runs an application called an IRC daemon (ircd), which allows connections from individual users and relays messages from one client to another by passing them through the server. Some IRC chat systems consist of a simple network in which a single server manages connections and communications among all its clients. However, most IRC servers are connected to other IRC servers, thus opening the IRC system to potential communication among all users with connections to all the servers on the network. Originally, there was only one IRC network consisting of a few servers, but as IRC grew in popularity and complexity, it splintered into multiple networks. Today there are hundreds of IRC networks that are constantly evolving through expansion and redefinition. They range in size from very small, family-oriented chat networks, to such global networks as EFnet or the expansive IRCnet, which links well over 100 servers and supports thousands of chat groups, or channels (see Table 1). Channel names are fairly stable, but channel topics change regularly, and the announced topic frequently bears no relation to the conversation actually occurring on the channel.

To engage in Internet relay chat, users select an IRC network and connect to one of the available servers, using a nickname (e.g., SuperTig) rather than their real name. Using the /list command, users can consult a list of public channels currently available on that server. The channels listed as *#channelname* are global and can be accessed through any server on the network; channels listed as *&channelname* are available through that server alone. Some channels are designated "secret" and are not open to others. By entering the command /join #channelname, users join a channel and usually receive the MOTD (message of the day), containing some basic information from the server's database about the channel's current activity (topic, nicknames of current users, etc.). The new user is then ready to communicate with others by sending a message that will appear more-or-less synchronously on the screens of all channel participants (see Figure 1). Newbies can usually find help on the channel *#irchelp*, and other help channels may be listed in the MOTD. The command /leave or /part will terminate the connection to the channel, and the command /quit will terminate the connection to the network. In reality, connecting to an IRC server is not always simple, especially for newcomers. Connection may be prevented if the user enters an incorrect server name, chooses an unacceptable nickname, or has been *K-lined* (specifically banned from the server for some reason). Users who connect to the Internet through large, popular ISPs (Internet service providers) may find some channels closed to them, based on the stereotype that such subscribers are probably newbies and therefore unwelcome on certain channels.

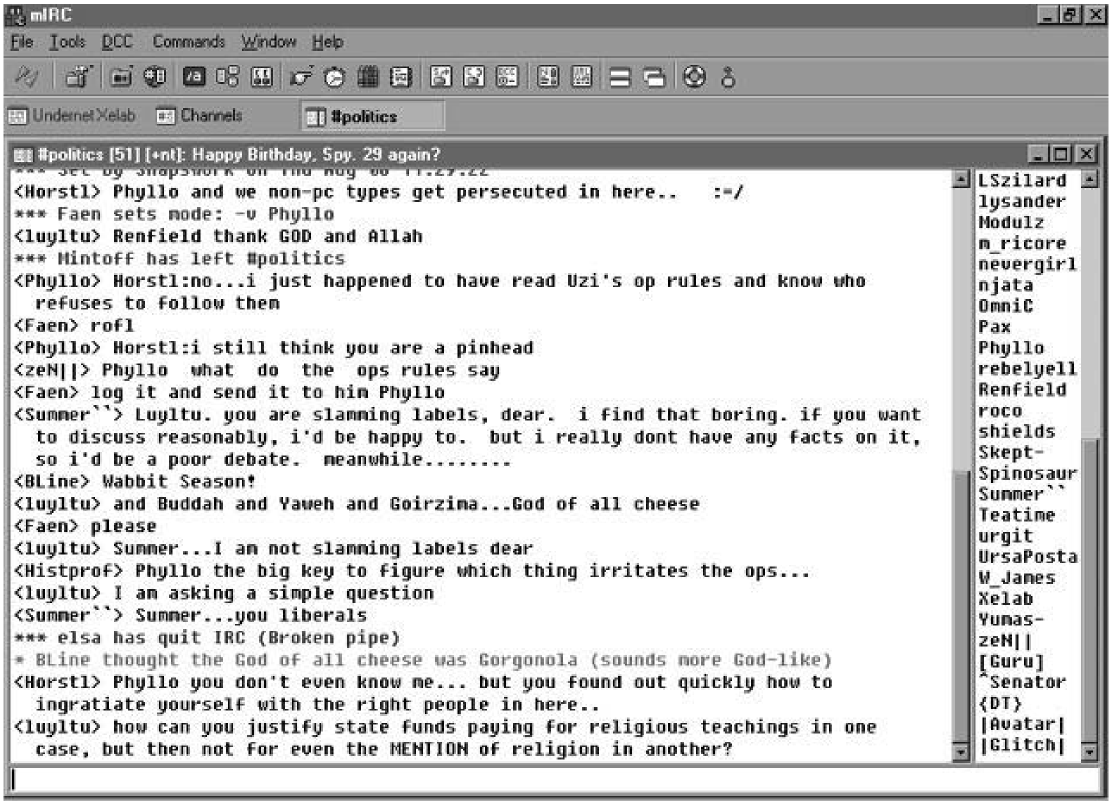
Table 1 Some of the Largest IRC Networks

Network	Number of Servers	Help Site and Server List
Efnet	40	http://efnet.org
IRCnet	>120	http://www.ircnet.com
DALnet	30	http://www.dal.net
Undernet	40	http://www.undernet.org
GalaxyNet	30	http://www.galaxynet.org
WebNet	15	http://www.webchat.org
NewNet	15	http://www.newnet.net
ChatNet	15	http://www.chatnet.com

With text-based IRC client software, such as ircII, commands are entered manually by the user in typical command-line format familiar to Unix users. With graphical interface client software, such as mIRC and Ircle, a click of the mouse on an icon generates the same result. Because the original IRC source code was not copyrighted, some networks have developed proprietary functions and features unique to their IRC system. The result is that all commands are not standardized across all IRC networks. Most of the basic commands are recognized by all IRC servers, however, and users who frequent a network typically learn specialized commands quickly through observation and by inquiring on a channel devoted to IRC help.

Although most users connect through IRC servers, the major IRC client programs also allow a direct client connection (DCC). Two clients who are connected to the same IRC network can initiate a direct connection between themselves. IP (Internet protocol) addresses are typically used to establish the DCC connection, and messages or shared files pass directly from one client to the other without being relayed by the IRC server. Many of the more experienced users prefer to use DCC for their one-on-one interactions and file transfers, because DCC frequently results in faster message exchange, a higher degree of privacy, and avoidance of network problems such as lags and netsplits.

IRC networks are not immune to problems of congestion or breakdown. Like all other packet-switching Internet communication systems, users sometimes experience delays in the transmission of electronic messages. This delay (known to IRC users as "lag") is irritating to all Internet users, but it is especially problematic in synchronous communication systems characterized by real-time interaction. A 10-s lag can dramatically change the timing and effectiveness of some types of online interaction, as threads of conversation become entangled and users appear to be "talking over" one another. Increased lag may be caused by heavy traffic on the Internet or IRC network, a malfunctioning server, flooding, or a denial-of-service attack (see below). Lag is sometimes related to a netsplit, which occurs when one or more IRC servers lose their connection to the network. Netsplits fracture the network and effectively create separate network fragments



#politics [51] [+nt]: Happy Birthday, Spy. 29 again?

Figure 1: Screenshot of online interaction using mIRC.

that may or may not continue to operate separately. Netsplits often result in a buildup of packets queued for delivery to servers that are no longer available. After a netsplit, servers sometimes reconnect to the network and are able to update the server with activity that occurred during the netsplit. Sometimes a netsplit results when an IRC operator revises the network's connection to other servers in order to achieve a more efficient or more desirable network configuration.

IRC Client Software

In order to engage in online communication using IRC, users need access to the Internet through an Internet service provider (ISP) or direct network connection. They must also install a communications software program, called an IRC client. The client software serves as the interface between the individual computer (the client) and the IRC server (serving the needs of multiple clients). The IRC client processes the commands that are typed or clicked by the user and then employs network protocols, such as TCP/IP (transfer control protocol/Internet protocol) to transmit them to the server.

IRC supports communication across different operating platforms, enabling the flow of messages between PC and Macintosh computers, as well as UNIX-based computing systems. IRC clients for these and other operating systems are readily available, and free downloads or demonstration copies can be found on most of the major FTP (file transfer protocol) sites on the Internet. Some IRC clients are available as shareware, meaning that after a free trial period, if users wish to continue using it, they are asked to purchase the software or pay a modest registration fee. Generally, the cost of IRC client software is quite reasonable.

Text-Based IRC Clients

Early IRC users were almost exclusively Unix based, and the majority of today's IRC servers are Unix servers. Individual computer users who use a terminal emulation program to establish a dial-in connection to an organization for Internet access effectively turn their computer into a terminal, making use of a shell account on the Unix system. The most common IRC client for Unix and related systems (such as shell accounts and Linux) is ircII. This full-featured, text-based client was the first widely used IRC client and still serves as a reference standard for essential commands and functions. More advanced users sometimes use ircII's scripting language to create scripts that streamline complex processes, generate customized output, or perform certain functions automatically when prescribed conditions occur.

Graphical Interface IRC Clients

The majority of online communicators connect to the Internet through Windows-based PCs or Macintosh computers. IRC clients have been developed for both platforms, offering the point-and-click ease of use characteristic of graphical user interfaces (GUIs). The major GUI clients receive ongoing attention from their developers, and excellent support is available for learners. The client of choice for many PC users employing Windows operating systems is mIRC, a powerful, intuitive, and reliable application. Because PC users outnumber those on Unix and Macintosh platforms, mIRC is probably the most widely used IRC client on the Internet today. Easy-to-use menus and buttons, customizable functions, and extensive user support contribute to the popularity of mIRC (see Figure 1). The most widely used IRC client for Macintosh computers is Ircle. A stable, full-featured IRC client, Ircle provides buttons, menus, and icons to facilitate common IRC functions. Ircle users may also employ AppleScript to modify the client to their custom specifications. Good user support and innovative features place IRC interactions within easy reach, even for beginning Ircle users.

IRCops, Chanops, and Users

The IRC system hierarchy of networks, servers, channels, and clients is reflected in an administrative hierarchy of people who oversee each level of the system. End users who direct their IRC client to connect to a network should be aware of the scope of authority and control exerted by IRC operators and channel operators. Newbies sometimes embarrass themselves and irritate others by inappropriately posing questions or filing complaints with the person they perceive to be in charge of a channel or server.

IRCops

IRC operators generally oversee the operation of an IRC server, maintain routing functions in relation to other servers on the network, modify server settings, and monitor general activity on the server. Sometimes the original server administrator fulfills the role of IRCop, and sometimes the administrator selects one or more experienced and qualified users to serve as IRCop. Servers typically have more than one operator, in order to ensure constant observation of activity on the server. In the event of a server failure or network fault, IRCops work to restore network connections. They also enforce the policies and procedures of the server they oversee. If a user violates policy or misbehaves in some way, the IRCop usually issues a warning. Users who are reprimanded by an IRCop are sometimes unaware of the power the operator has to control activity on the server. For example, an IRCop can issue a /kill command that effectively bans the offending user from further access to the server and, in some cases, the entire network. Determining the identity of a server's IRCops is not always easy. When they are listed in the MOTD (message of the day) or active user lists, their "user mask" (nickname plus host name) is usually marked with an asterisk (*Stinkbug!skb220@rhl.net). The command /stats o may be used to identify active operators, and some IRC clients support the command /who -oper. Many IRC users never have direct communication with an IRC operator unless their activity on the server violates accepted practice and attracts the operator's attention. IRC operators do not exert control over channel activities; they leave those functions to the channel operators.

Chanops

Each IRC channel (chat group) is initiated or overseen by a channel operator, or chanop. Channel operators exert management and control over the channel's topic, mode, and settings, and they regulate how many users and specifically which users are allowed to interact on the channel. If users misbehave, become obnoxious, or irritate the channel operator, most chanops do not hesitate to ban them from the channel. Any user may become a chanop by creating a new channel or by being given operator status by a chanop on an existing channel. This status is valid only for the duration of the current IRC session, and when chanops leave the channel, they ordinarily lose their operator status. However, if operators are registered as super-ops with an IRC channel service, they can effectively maintain control over a channel even during their absence. Many IRC channels have several operators active at any given time, but occasionally a channel may function without an operator at all. Channel operators are usually identified with an @ sign before their nickname (@SuperTig). Most IRC clients support the command /who -chops as a means of identifying channel operators.

Chanops can remove users from a channel and ban them from future access. On password-protected channels, they can invite users to join and can issue them the key to enter. On moderated channels, chanops can give selected users a voice that allows them to post messages to the channel while other users can only receive messages. Channel operators can grant chanop status to other users, and they can remove chanop status from other operators. Any IRC user who creates a new channel with the /join #channelname command automatically becomes the operator for that channel. When a new channel is created, some basic channel modes and settings should immediately be set to establish guidelines for the activity allowed by users and operators on the channel.

Common User Commands

Table 2 contains a sampling of user commands commonly employed across different IRC clients and servers. Users of text-based clients enter these commands manually, whereas users of GUI clients usually click on icons or drop-down menus to engage the function, and the client automatically generates the command. Some commands contain specific parameters or are qualified by "flags" that set the limits of the command output. Table 3 contains the most common commands used by channel operators.

SOCIAL FACTORS

IRC and Online Community

As with all online communication systems, IRC is more than a network of computers relaying electronic files among themselves. Fundamentally, IRC systems are composed of humans who utilize the computer network to exchange information or conversation with others. The people who employ IRC for human communication reflect the demographic diversity of general Internet users, with a few notable exceptions. As a somewhat specialized online community, IRC has drawn those who are more technically proficient, whose computer skills enable them

Table 2 Basic User Commands

Command	What Command Does
/join #channelname	Joins the user to a global channel on the network, unless the user is banned or the channel is restricted (invite-only, secret, etc.)
/join#channel1,#channel2	Allows the user to simultaneously participate in both of the channels listed
/mode MyNickname +i	Sets the mode of the user "MyNickname" to invisible, enhancing privacy and security
/list	Produces a list of channels on the server; often used with various flags and parameters
/set hold_mode on	Prevents a long list from scrolling beyond the monitor's limits
/names	Shows a list of nicknames of users currently on the network (potentially a huge listing, so always use parameters)
/names #channelname	Shows a list of nicknames of users currently on the channel (also very large on some channels, so use parameters)
/who #channelname	Lists nicknames, usermasks, and other information about current users on a channel
/whois NewName	Produces basic information from the server's database about the user "NewName"
/msg NewName	Sends a private message to the user NewName; messages to all users are entered without the/msg command
/dcc chat NewName	Requests Direct Client Connection with the user "NewName;" if NewName accepts, a direct private chat will bypass the IRC server (may be more private, less lag)
/nick othername	Changes a user's nickname to the one specified
/ignore badguy	Blocks or ignores messages from user called "badguy"
/part or/leave	Signs a user off of a channel; may be followed by a parting comment
/quit	Terminates connection to the network; may include a brief comment

to easily perform such tasks as the following: downloading and installing software from an FTP site; learning intuitively the features and functions of new software applications; using line commands, scripting, or hand coding to accomplish tasks; adapting to the specific styles and conventions of online communication forums; and maintaining sufficient safeguards to protect his or her personal privacy and system security.

Many individuals "meet" regularly on IRC channels, where they develop close relationships and a true sense of community. On some channels, the basis for commonality is the agreed-upon topic (such as advanced applications of certain software), and participants willingly share techniques and resources in mutual support of one another. Other channels are predominantly social in nature, marked by spontaneous casual conversation. In both types of IRC communities, significant one-on-one relationships often develop. There are many reports of IRC users who decided to move their relationships offline and meet face to face, and not a few have become business partners or marriage partners (e.g., Hoff & Hoff, n.d.). Of course, the majority of IRC relationships are restricted to the online context, but they constitute legitimate relationships that fill meaningful social roles for many users. Friends made on IRC are not only "virtual" friends but also "real" friends.

Table 3 Basic Channel Operator Commands

Command	What Command Does
/join #NewChannel	Creates a new channel with the specified name
/mode #NewChannel +o|l|m|v|t	Sets the channel modes to Operator (chanop status can be assigned or removed), Limit (limits the number of users allowed at one time), Moderated (all users receive, but only some can post messages), Voice (grants selected users the ability to post messages), and Topic (set by operators only); several other modes are available
/mode #NewChannel	Reveals all the current mode settings for the channel
/mode #NewChannel +o mybuddy	Gives the user "mybuddy" operator status
/mode #NewChannel -o mybuddy	Removes chanop status from the user "mybuddy"
/mode #NewChannel +l 20	Limits the number of users on NewChannel to 20
/mode #NewChannel -l	Removes the limit on number of users
/mode #NewChannel +v angelbaby	Allows the user "angelbaby" to post messages to NewChannel
/topic #NewChannel IRC clients	Changes channel topic to "IRC clients"
/kick #NewChannel satanson	Kicks the user "satanson" off the channel
/invite mybuddy #NewChannel	Invites the user ″mybuddy" to join NewChannel

Communication researchers study the social, relational, and communicative dynamics of online communication forums such as IRC. Overall, these studies indicate that computer-mediated communication systems do support the development of meaningful relationships, effective decision-making groups, and a legitimate sense of community (Finholt, Sproull, & Kiesler, 1990; Walther, 1996, 1997). Nevertheless, research has also identified some important differences between face-to-face and online communication. For example, in face-to-face interactions, people normally communicate interpersonal liking through such nonverbal cues as eye contact, smiles, proximity, touch, open body positioning, and vocal expressiveness (Richmond & McCroskey, 1999). Because the usual nonverbal behaviors are absent in the online context, a greater responsibility is placed on verbal messages for feedback, affect, and nuance of meaning. Some IRC users attempt to replace nonverbal messages by inserting affect cues <grin>, demonstrative punctuation (no!!!!!!!!!), or emoticons, such as the smiley face :-) and its many variant forms. The absence of nonverbal communication cues led some early researchers to judge online communication as incapable of conveying subtle relational messages and therefore an unsatisfactory medium for meaningful interpersonal exchange (Daft & Lengel, 1984). However, in the intervening years, online skills have improved and online communication norms have evolved, with the result that 21st-century communicators routinely use IRC to engage in effective and meaningful interaction of all types.

IRC and Relationship Development

As IRC users employ new communication strategies, they sometimes find relationship opportunities in the online community that do not exist for them face to face. For example, research has shown that the decision to initiate face-to-face interaction with someone may be directly or indirectly affected by the other person's physical appearance, nonverbal behaviors, vocal attributes, age, gender, or ethnicity (Berscheid & Walster, 1978). It may seem unkind or unfair, but people often choose whether or not to interact with others on the basis of these traits. When people go online to engage in conversation on IRC, however, these physical characteristics are obviously not visible. Many users choose a nickname that is not gender specific, and many avoid asking or revealing details of personal identity. Even when personal characteristics are discussed online, they are virtually impossible to verify and seemingly have little or no impact on IRC interactions anyway. The result is that on IRC, unattractive people can relate as equals with the beautiful and handsome; those with vocal or speech problems can engage in fluent expression; those who painfully experience bias or discrimination in face-to-face encounters may confidently enter chat groups as social equals, perhaps for the first time in their lives.

Therefore, this new communication environment may actually enhance the potential for long-term relationship development by expanding the ways interpersonal relationships develop. An example is seen in the widely researched "matching hypothesis," which theorizes that people usually date and marry someone with approximately the same physical attributes as themselves (e.g., both are attractive or both are plain in appearance). By contrast, couples who first meet on IRC may vary considerably in physical attractiveness. Online relationships can deepen over time through self-disclosure, empathic "listening," and progressively more intimate communication. When the relationships are moved offline for face-to-face meetings, differences in physical appearance seem relatively unimportant in comparison to the many points of commonality already discovered. In such cases, IRC may provide a more just and balanced communication context than traditional meeting places.

Anonymity and Virtual Identity

The relative anonymity that enhances relationship development on IRC might also introduce an element of deception. Obviously, users may project a virtual identity very different from their true identity. Their intent in doing so might be harmless and recreational, or it might be deceptive and dangerous. IRC, as do all online communication systems, occasionally draws users who are malicious, misleading, or mentally unstable. For example, pedophiles frequently pose as youngsters in forums frequented by children, hoping that the child will trust them with information or engage in conversation with them. According to accounts in the popular press, some long-term relationships that seemed healthy and secure online turned out to be dangerous when the couple met face to face, because one of the parties had been projecting a virtual identity to conceal unwholesome motives.

SECURITY AND LEGAL ISSUES

Hate and Harassment on IRC

The anonymous nature of online communication systems such as IRC may contribute to the use of aggressive or inflammatory verbal abuse in the form of harassment or hate speech. Most IRC interactions involve the use of nicknames only, and users rarely reveal their true identities. This anonymity may contribute to a perception of low accountability, with the result that some IRC users may verbally lash out against individuals or groups in ways that are offensive and illegal. For American citizens, First Amendment (free speech) privileges extend to IRC interactions, but so do criminal laws preventing hate speech, inciting violence, and stalking. Cyber-stalking, which is expressly forbidden by U.S. federal law, occurs when a user annoys, abuses, threatens, or repeatedly initiates unwanted communication with another. Responsible channel operators seek to eliminate such activity on IRC by banning the offending user and, if necessary, reporting them to legal authorities. Of course, many IRC participants are not U.S. citizens and not constrained by American laws, pointing up the ethical and legal complexities of global communication networks.

Children and IRC

Although a significant percentage of overall Internet users are under the age of 18, a relatively small percentage of IRC users are minors. In truth, IRC is not especially suited to the needs and concerns of children. The more widely known Web-based chat systems maintain terms of service that restrict certain activities and topics of discussion. Offenders in these chat rooms can be quickly and effectively removed by administrators. IRC channels, on the other hand, are generally not restricted, and people may talk about anything they choose. It is not infrequent to encounter adult conversations and offensive language on IRC that would be unsuitable for children. On moderated channels, chanops can always remove a user's "voice" and disable the offender's ability to contribute to further discourse, but such censorial functions are not characteristic of most IRC channels. IRC is perceived by many to be spontaneous, freewheeling, unrestricted, and unpredictable—a kind of "wild west" communication context.

In carefully controlled and appropriate IRC channels, children may benefit from online conversation with other children from around the world, with teachers and classmates, and with extended family members or parents who are traveling. Unsupervised, however, children on IRC may encounter such risks as cyber-stalking, possibly leading to physical stalking, if the child reveals personal information; offensive and harmful conversations with unwholesome characters such as pedophiles; and exposure to sexual content, viruses, or other harmful material, if the child accepts a file transfer from an unknown IRC user. Numerous laws and regulations exist to protect minors on the Internet, and responsible IRC users should immediately report any suspicious activity involving a minor on IRC.

Scripts and Viruses

Informed IRC users are aware of the many risks involved with file transfers, through both hard media and the Internet. When users install new software, download Web pages, or receive files such as disks or CDs from external sources through networking or hard media, some degree of security risk is introduced. It is a rare occurrence, but even respected commercial software has been distributed with inadvertent flaws that damage systems. More common is the intentional or unintentional passing of a virus or harmful script from user to user through various Internet connections, including IRC. Responsible users minimize these risks by maintaining awareness of current security threats, practicing discretion when networking, and using updated virus detection software.

Most viruses are in .exe or .ini files, but they can also be concealed in zipped files or embedded in completely unrelated file types, such as .jpg or .gif files. When launched by an unsuspecting user, viruses can cause irreparable harm to individual computers and potentially spread throughout entire systems. Some viruses are not destructive but merely irritating, such as those with pop-up messages of a humorous or salacious nature. Others may disable or destroy hard drives, data files, operating systems, and peripheral components or create havoc throughout entire networks.

People who share word processing files, script files, graphics, or other file types on IRC may potentially be spreading viruses, trojans, or worms. Trojans (or Trojan horses) are spread by users who transfer seemingly benign files containing harmful concealed code. Worms are viruses that propagate themselves and migrate from one application to another within a computer, and from one computer to another within a network. Fortunately, virus protection software is inexpensive and readily available on all operating platforms. IRC users should load virus protection software, keep it current through frequent data updates as new viruses appear, and carefully scan every file that is received or shared by IRC transfer.

Scripts represent another source of external control and increased security risk. Scripts are files containing macros (or miniprograms) that enable an application to combine or automate various functions. IRC users have created scripts for such tasks as completing nicknames from typed initials, automatically performing ping operations, generating automated "away" responses, and customizing the output of IRC interactions. Some early IRC users enhanced the function of their IRC clients by writing scripts that have subsequently been incorporated into more recent versions of the software. Within the IRC community, techniques of script writing constitute a frequent topic of conversation, and the sharing of scripts among users is relatively common. A number of Web sites or FTP download sites serve as archives or clearing houses for the open sharing of scripts and script paks (sets of coordinated scripts) for various IRC clients. When an IRC user downloads a script file from an archive or another user, however, there is always risk that the file may contain concealed or deceptive code that may launch unexpected or harmful functions in the receiver's system.

Most IRC clients include options to limit or disable the automatic or unintentional running of scripts, just as the major Web browsers include settings to control scripting functions encountered on the World Wide Web. Because harmful functions can be inserted into otherwise legitimate scripts, cautious IRC users run scripts only after proofreading every line of the code. Safe practice also calls for the careful screening of IRC users before accepting from them any files of any type. Common practice states that files should never be accepted from an unknown person, and file transfers from known parties should always be scanned for viruses before being opened.

Mischief and Sabotage on IRC

Many people use IRC safely and never experience viruses, takeovers, or threats to their security. It is not uncommon, however, to encounter less-serious offenses allegedly launched by mischievous youngsters known as "script kiddies." Anyone who has been on IRC very long has probably observed attempts by an aggressive user to take charge of a channel or disrupt the flow of messages on a channel or network. "Channel taking" may be accomplished if a user is granted chanop status or deceptively uses an operator's nickname, then "de-ops" the other operators and indiscriminately bans users, kicks them off the channel, or silences their voices by turning the channel into a moderated one. Sometimes malicious users simultaneously send multiple files to another user, known as "flooding." If practiced on a large scale, flooding can significantly increase lag on a channel or entire network. Most IRC clients include optional settings that limit flooding to that client.

A more serious form of sabotage exists in denial of service (DoS) attacks, harmful data packets that sneak through loopholes in an operating system's security and launch erroneous messages from or to the client. DoS attacks, sometimes called "nukes," are against the law and can cause the host to disconnect from the Internet, freeze, or crash entirely. IRC can be exploited to facilitate a DoS attack by sending scripts called "bots" to unsuspecting users. Bots use vulnerabilities in the operating system to initiate the attack simultaneously from multiple computers.

Because internal security is especially critical to certain types of organizations, some companies or institutions have restricted the use of IRC and other Internet functions through the use of firewalls, prohibiting any computer in their network from connecting to an IRC server. For any IRC user, whether institutional or private, the best defense against mischief and sabotage is to refuse to accept file transfers or DCC chat requests from unknown persons, to carefully peruse every line of script code before launching it, and to maintain updated security files for operating systems, IRC clients, and virus protection software.

THE FUTURE OF IRC

To date, many people view real-time online communication systems such as Internet relay chat as little more than a novelty. In fact, use of the word "chat" in serious organizational contexts may cause some institutional leaders or educators to grimace and assume that the medium only promotes idle chitchat. As a generic communication medium, however, IRC and other chat systems possess great potential to assist modern communicators in reaching important organizational and personal communication goals. Future developments in IRC software and the Internet infrastructure may enable everyday use of video and voice chat, for example, that could dramatically alter the nature of the IRC communication medium.

Organizational Applications

Businesses, institutions, and organizations of all kinds place a high value on frequent communication among employees, suppliers, clients, customers, and/or members. IRC can be employed within an organization to support real-time collaboration among employees at different geographic locations, increasing productivity while keeping down long-distance communication costs. Customer service systems that now offer e-mail support can be expanded to include real-time exchanges via IRC. Employee teams, whether large or small, can use IRC for group planning, brainstorming, or coordinating joint projects. The ability to use IRC for file transfers can support the sharing of internal documents, or the distribution of such external information as product brochures, technical specifications, and press releases. As mentioned above, however, a growing number of organizations have responded to concerns about security or privacy issues by installing firewalls that prevent the use of IRC and other external file-sharing applications on their networks. Some universities, for example, have discontinued the use of IRC or created tighter accessibility restrictions to protect their systems from outside interference. Of course, an organization could choose to maintain an internal IRC server with no connections to outside networks, or to use moderated or secret channels on existing networks.

Educational Applications

The same collaborative benefits available to organizations apply to the use of IRC in educational settings. With the rise of distance learning, distributed education, Web-based training, and e-learning, teachers and students are enthusiastically embracing new communication technologies to support interaction across distances. Furthermore, teachers and trainers who provide classroom courses are finding that chat systems can serve to link the course participants in dialog outside of class. Some college professors, for example, require students to engage in a certain number of exchanges on the class listserv, or to participate in a certain amount of time in class chat groups, as a means of increasing student dialog or gaining facility in the use of new technologies. As the number of World Wide Web users continues to grow, so also does the demand for visual communication in online contexts. The introduction of new Java-based IRC clients will presumably open the way for IRC networks to develop multimedia or highly interactive capabilities, which may very well signal a new era for IRC.

International Applications

A specific educational and practical application that is enhanced by IRC is the learning of different languages. As a global communications medium, IRC has drawn users from virtually every country of the world. By connecting to an IRC channel in a second language, learners can observe native speakers using everyday language, a valuable learning tool. Because IRC easily supports private, one-on-one conversations, communicators from two different language groups can agree to engage in basic conversation, adjusting the topic and/or linguistic level to match the abilities of the learner as they would in face-to-face conversation. A great advantage to the learner is the near-synchronous nature of IRC—the ability to pause and reflect, or even quickly look up an unknown word in a dictionary—before responding. IRC has great potential to enable multilingual and multicultural interaction between individuals or groups of individuals who wish to engage in global communication. For example, children in two classrooms in two different countries can interact as individuals or groups on an IRC channel created for a joint class project. Anyone who values global communication as a means of enhancing tolerance and understanding can embrace IRC as a convenient and readily available global communication system. For those who travel, study abroad, or live far from their home country, IRC provides a reliable and inexpensive means of keeping in touch with home or office.

Emergency Applications

In times of local, national, or international crisis, public communication systems are often overloaded or out of service. In September 2001, for example, in the hours following the terrorist attacks on New York and Washington, telephone switching systems became clogged as tens of thousands of people tried to connect with friends and family in the area. In such times of crisis, computer users with an Internet connection can use IRC to provide real-time contact when other communication systems are unavailable.

In the years ahead, new communication technologies will emerge to support increasing demands for interpersonal and mass communication. Tomorrow's global society will depend to an increasing degree on terrestrial wireless, satellite, and fiberoptic communication systems. Internet relay chat, as a reliable means of real-time online conferencing, will continue to evolve into a medium capable of serving the communication needs of the 21st century.

GLOSSARY

Ban Status of a user forbidden by a chanop to enter a channel.

Channel A virtual chat group in which users interact, discussing specific topics or engaging in general conversation.

Chanops Channel operators; they monitor and maintain a channel by setting the parameters and inviting or expelling users.

Client Software run by the local computer of an IRC participant, converting the user's actions into commands recognized by an IRC server.

Daemon (IRC daemon, or ircd) Software run by a server connected to the Internet, accepting connection requests from clients and relaying messages among users.

Direct client connection (DCC) Connection established between two users that allows them to bypass the network for increased privacy and faster connection.

Flooding Simultaneously sending many messages to a single user, thus "flooding" a channel or an entire network with unwanted messages, probably increasing lag.

Internet Relay Chat (IRC) Real-time, text-based communication medium that employs a network of servers to connect geographically separated users.

IRCops IRC operators who monitor and maintain IRC servers; they generally have very little to do with the operation of channels.

Lag A delay in the transmission of messages between users or between a user and a server.

MOTD (Message of the day) An automated confirmation message containing certain information and practices relating to a channel, its activities, and its current participants.

Netsplit Disruption in the connection between servers that results in the fracturing of the network into subdivided parts and in the disconnection of some users.

Newbie A newcomer to IRC.

Nickname An invented name that uniquely identifies the user on the network.

Scripts Files containing code that enables an application to combine or automate various functions.

Internet Security Standards

Raymond R. Panko, *University of Hawaii at Manoa*

INTRODUCTION

When the Internet was created, security was left out of its Transmission Control Protocol/Internet Protocol (TCP/IP) standards. At the time, the crude state of security knowledge may have made this omission necessary. Today, however, security expertise is more mature. In addition, the broad presence of security threats on the Internet means that security must be addressed deliberately and aggressively in Internet standards. This chapter describes three ways to add standards-based security to the Internet. The first is for users to add standards-based security to specific dialogues, that is, to two-way conversations between pairs of communicating processes. Today this can be done largely through the use of virtual private networks (VPNs) using Point-to-Point Tunneling Protocol, IPsec (Internet Protocol security), secure socket layer, and other "add-on" security protocols. This "security overlay" approach is not as desirable as good general Internet security standards, but it solves some specific current needs of users. The second approach is to add more security to central Internet standards. In addition to the "core four" standards (IP, TCP, User Datagram Protocol, and Internet Control Message Protocol), these central Internet standards include supervisory standards (such as the Domain Name System, Dynamic Host Communication Protocol, Simple Network Management Protocol, Lightweight Directory Access Protocol, and routing protocols), and application standards (such as Simple Mail Transfer Protocol, Hypertext Transfer Protocol, and File Transfer Protocol). As this chapter describes, a strong effort to retrofitting existing Internet standards to add security is underway at the Internet Engineering Task Force (IETF) but is far from complete. The third way to add security is to take a comprehensive look at the Internet to decide how security *should* work on the Internet. This could lead to anything from the creation of *multiple Internets* with different classes of security for different types of users to the creation of international policies to make forensics more effective when there are attacks.

This chapter looks at these three broad approaches in the order just presented. It does not include a discussion of security for single network standards, such as Ethernet, Asynchronous Transfer Mode (ATM), Frame Relay, and wireless local area networks. Rather, it focuses on internet standards, which link together multiple networks. The chapter focuses more specifically on TCP/IP internetworking, which is used on the Internet, rather than on IPX/SPX and other forms of internetworking. More formally, it focuses on security in TCP/IP standards at the Internet, transport, and application layers.

SECURITY THREATS AND DEFENSES

Before looking at security in Internet standards, it is necessary to have an understanding of the major security attacks and defenses.

Penetration Attacks

One set of threats against which networks must guard is attackers attempting to hack systems (access them intentionally without authorization or in excess of authorization) or attempting to conduct denial-of-service attacks against them by crashing or slowing them to the point of being useless to their legitimate users.

Attacks on Dialogues

Second, when two parties communicate, they normally engage in a dialogue in which multiple messages are sent in each direction. These dialogues must be secure against attackers who may wish to read, delete, alter, add, or replay messages. In general, dialogue security has been the main focus of IETF efforts to add security to Internet (TCP/IP) standards. Hacking and denial-of-service are sometimes addressed, but this is comparatively uncommon. Consequently, I focus on dialogue security here.

Confidentiality

Confidentiality means that eavesdroppers who intercept messages en route over the Internet cannot read them. Encryption is the chief tool against unauthorized reading en route.

Authentication and Integrity

Authentication means that the receiver of messages can verify the identity of the sender to ensure that the sender is not an impostor. There are two forms of authentication. In *initial authentication*, one side proves its identity to the other side at or near the beginning of a dialogue. In *message-by-message authentication*, the sender continues to identify itself with every message, much as parties exchanging letters sign each letter. Message-by-message authentication is crucial to good security.

Integrity means that if a message has been captured and changed en route, then the receiver will be able to detect that a change has occurred. All forms of message-by-message authentication provide message integrity as a by-product. If a message is changed during transmission, either deliberately or through transmission errors, authentication will fail, and the receiver will discard the message.

Message-by-Message Authentication

Impersonation is a serious problem because many Internet standards are supervisory standards that govern how devices on the Internet function. If an attacker can trick a network management program system or other supervisory system into accepting false information, the resultant damage can be widespread. There are two common message-by-message authentication methods: HMACs and digital signatures. Both are described in more detail in the chapter Digital Signatures and Electronic Signatures.

Digital Signatures

In digital signatures, the sender hashes the message to be sent. This creates a message digest. The message digest is then signed (encrypted) with the sender's private key, which only the sender should know. This produces the digital signature, which the sender appends to the message before transmission.

The receiver recomputes the message digest in two ways. First, as the sender did, the receiver first hashes the message to produce the message digest. Second, it decrypts the digital signature with the true party's public key. This should also produce the message digest—if the sender is the true party. Otherwise, the message digests will not match, and the message will be rejected. In addition, digital signatures produce message integrity; if an attacker changes the message en route, the message digests will not match and the message will be rejected.

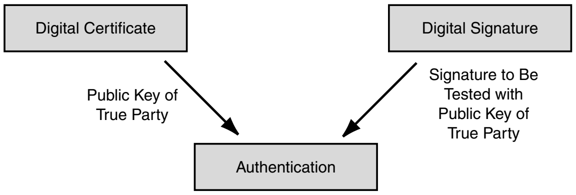

Figure 1: The need for digital certificates with digital signatures.

Digital Certificates

Note that digital signatures require the digital signature to be tested with the *true party's* public key—not the public key of the sender (who may be an impostor). The definitive way to get public keys of a true party is to get a digital certificate from a trusted certificate authority (CA). This digital certificate has the name of the true party and the true party's public key. It also has a digital signature signed by the CA's private key so that the certificate cannot be changed without this change being detected.

One problem with digital certificates is that certificate authorities are not regulated in most countries, leading to questions about their trustworthiness. Although European countries are planning to create regulated CAs, the United States and most other countries are trusting market forces to handle certificate authorities.

Another problem with digital certificates is that a CAs must create complex public key infrastructures to create public key–private key pairs, distribute private keys and digital certificates, and allow users to download certificate revocation lists (CRLs), which are lists of ID numbers for certificates that were revoked before their valid period ends.

Is it possible to distribute public keys without using certificate authorities? Pretty Good Privacy (PGP) offers one way to do so. Each user has a "key ring" of trusted public key–name pairs. If User A trusts User B, User A can trust User B's key ring, which may, of course, contain keys received through further distributed trust. This approach works, but if an impostor can dupe even one user, trust in the impostor can spread widely. This is not a good way to manage large public systems of routers, Domain Name System (DNS) hosts, and other sensitive devices.

It is also possible to distribute public keys manually. This works well in small systems, but it does not scale well to very large systems because of the labor involved.

HMACs

Another tool for message-by-message authentication is the key-hashed message authentication code (HMAC). For HMAC authentication, two parties share a secret key. To send a message, one of the parties appends the key to the message, hashes the combination, and adds this hash (the HMAC) to the outgoing message. To test an arriving message, the receiver also adds the key to the message and hashes the combination. This creates the HMAC. If the received and computed HMACs are the same, the sender knows the secret key, which only the other party should use.

HMAC processing requires little processing power because it only involves hashing, which is a fast process. In contrast, public key encryption and decryption, which are used in digital signatures, are extremely processing intensive.

A secret key needs to be created and distributed for each pair of communicating parties, however. In large systems of routers and hosts, this is highly problematic. One approach to reduce this problem is to use public key authentication for initial authentication, then use Diffie–Hellman key agreement or public key distribution to send the secret keys between pairs of communicating parties. This still requires a public key infrastructure.

Another solution is to use community keys, which are shared by all communicating parties in a community. The problem here, of course, is that if a single member of the community is compromised, attackers reading its community key will be able to authenticate themselves to all other members of the community.

Adding Security to Individual Dialogues

The first approach to creating standards-based security is for users to add security to individual existing dialogues. Effectively, this overlays security on the Internet for limited purposes without requiring the creation of completely new Internet standards.

Cryptographic Systems

Secure dialogues require that confidentiality, authentication, and integrity be protected. This is a somewhat complex process involving several phases.

Cryptographic System Phases

Establishing a secure dialogue typically involves four sequential phases (although the specific operations and the order of operations can vary among cryptographic systems). Figure 2 illustrates these phases. The first three are handshaking stages at the beginning of the dialogue. After the secure dialogue is established, the two parties engage in ongoing secure conversation.

First, the two parties must select standards options within the range offered by a particular cryptographic system. For instance, in encryption for confidentiality, the system may offer the choice of a half dozen encryption methods. The communicating parties must select one to use in their subsequent exchanges. The chosen methodology may offer several options; these, too, must be negotiated.

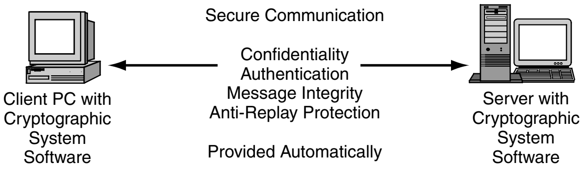

Figure 2: Cryptographic system.

Second, the two parties must authenticate themselves to each other. Although this might seem like it should be the first step instead of the second, the two parties need the first phase to negotiate which authentication method they will use to authenticate themselves.

Third, the two parties must exchange one or more secret keys securely. These keys will be used in the ongoing dialogue that will take place after the "handshaking" steps are finished.

Fourth, the security of the communication is now established. The two parties now engage in ongoing dialogue. Typically, nearly all communication takes place during this ongoing dialogue.

The User's Role

Few users have the training to select security options intelligently, much less handle authentication and other tasks. Consequently, cryptographic systems work automatically. The user selects a communication partner, and the systems of the two partners work through the four phases automatically.

At most, users may have to authenticate themselves to their own systems by typing a password, using an identification card, using biometrics, or by using some other approach. This user authentication phase tends to be the weak link in cryptographic systems because of poor security practices on the part of users, such as using weak passwords.

The Policy Role

Different security options have different implications for the strength of a dialogue's security. Users rarely are capable of selecting intelligently among options. Consequently, companies must be able to set policies for which methods and options will be acceptable, and they must be able to enforce these policies by promulgating them and enforcing their use.

Figure 3 shows how policy guides security in IPsec, which is discussed later in the chapter. In IPsec, security often is handled by IPsec gateways. When two IPsec gateways begin to communicate, they establish security associations, which are contracts for how security will be done. A policy server can tell the IPsec gateways what security association parameters they may or not select. This ensures that the IPsec gateways do not select security associations that are too weak for the traffic they will carry.

This approach works with host computers as well as with IPsec gateways.

Adding Security at the Data Link Layer

Dial-Up Security and PPP

Early computer systems used dial-up security. As Figure 4 shows, the user dialed into a server, generally using the Point-to-Point Protocol (PPP) at the data link layer. Later, companies added security to this approach by creating remote access servers (RAS) for sites. The user dialed into the RAS, authenticated himself or herself (usually with a password), and then received access to all servers at a site or to selected servers.

If a company had several remote access servers, normally a RADIUS (Remote Authentication Dial-In User Service) server or some other authentication server is used to store authentication information remotely, as Figure 5 shows. This way, all RASs use the same authentication data. Otherwise, if a firm has several RASs, their authentication data may be inconsistent. Adversaries might try different RASs until they find one that is configured incorrectly.

PPP can be used without security, but PPP offers moderately good encryption and several options for authentication ranging from nothing to strong security options. Again, the dialogue partners must select the security options they wish to employ.

Tunneling

Although PPP is secure, it is limited to a single data link because it operates at the data link layer, as Figure 5 illustrates. When a connection is made over the Internet, however, each connection between a host and a router or between two routers is a separate data link. PPP cannot function over the Internet.

Consequently, Internet-based data link layer security approaches must use tunneling. In tunneling, a data link layer frame is placed within the data field of a packet (the opposite of the usual situation). The packet is sent from user computer to the RAS, across multiple links. The RAS reads the tunneled (encapsulated) frame. Although this effect seems needlessly complex, it allows us to use traditional PPP user-RAS security over the Internet.

Point-to-Point Tunneling Protocol (PPTP)

The first tunneling protocol was the Point-to-Point Tunneling Protocol (PPTP). As its name suggests, PPTP is a way to tunnel PPP frames over the Internet. PPTP uses PPP encryption and authentication mechanisms, using them over an entire Internet connection instead of over a single dial-up data link. PPTP has a number of moderate security weaknesses, but it is good for low-threat environments. It offers medium security for moderate threat environments.

Verifier (Server)

Figure 5: Point-to-Point Tunneling Protocol.

Layer 2 Tunneling Protocol (L2TP)

Although PPTP works and is attractive, it is limited to transmission over an IP network such as the Internet. The L2TP can work over a number of transmission mechanisms, including IP, frame relay, and ATM, to name just three. L2TP does not offer security by itself, however. It requires users to rely on the IPsec protocol, discussed in the next section, to provide security at the Internet layer during transit. L2TP is a pure tunneling protocol, not a security protocol.

Adding Security at the Internet Layer

The Internet layer (or network layer) is the core layer in TCP/IP internetworking. The Internet Protocol (IP) is the main packet standard at this layer. IP comes in two versions—IP Version 4 (IPv4) and IP Version 6 (IPv6). IPv4 is the dominant version in use on the Internet today, but IPv6 is beginning to grow, especially in Asia, where relatively few IPv4 addresses were allocated when the Internet was first created.

IPsec

The IETF has been working to retrofit IP to be more secure. Their effort has crystallized around a group of standards collectively called IPsec (IP security). Although IPsec was initially planned for IPv6, the IETF has developed it to work with IPv4 as well.

Encryption and Authentication

The dominant way of using IPsec is to employ the encapsulated security protocol (ESP) option, which offers both encryption and authentication. Here I focus on ESP rather than on the authentication header (AH) option, which only provides authentication. AH is useful primarily when encryption is illegal, which is a rare situation.

Tunnel Mode

As Figure 6 shows, IPsec can operate in two modes: tunnel mode and transport mode. In tunnel mode, IPsec is handled by IPsec gateways at the two sites of the communicating parties, not by the computers of the communicating parties themselves. The packet to be delivered securely is tunneled by encapsulating it in another packet, encrypting the packet to be delivered securely, adding authentication, and sending the encapsulating packet from one IPsec gateway to the other. Although attackers can read the IP header of the encapsulating packet, they cannot read the secured packet, nor can they change the secured packet without the change being obvious.

Tunnel mode is attractive because it does not require the individual users to have IPsec software on their computers or to know how to use the software. In fact, the users may not even be aware that IPsec is protecting their packets over the Internet. Windows, which dominates client operating systems today, did not get native

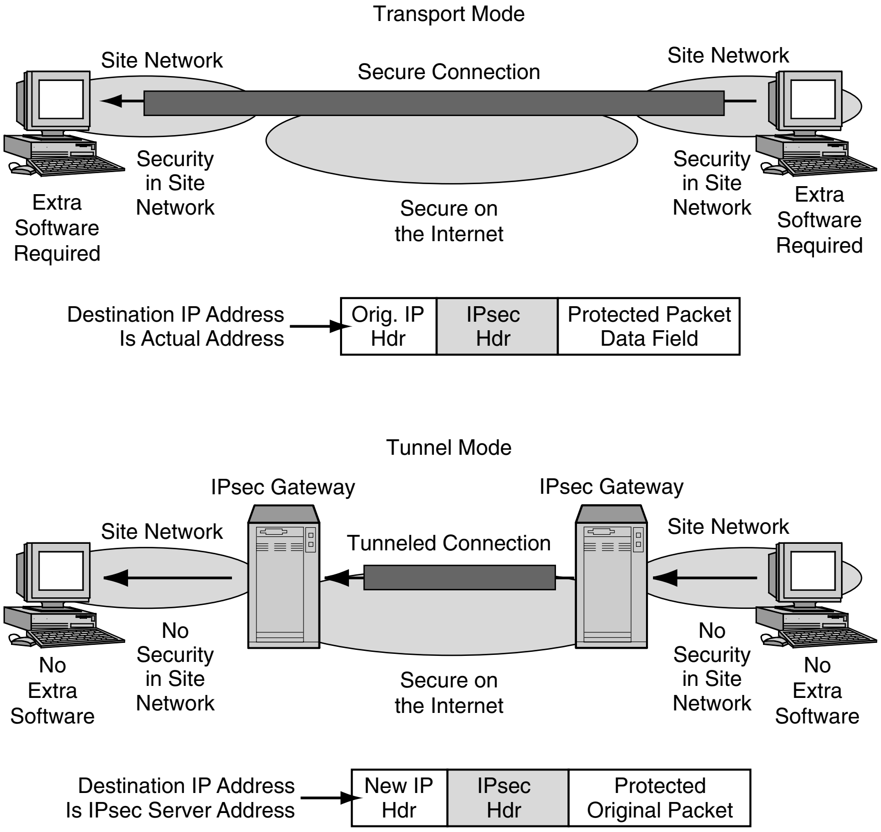

Figure 6: IPsec in tunnel mode and transport mode.

IPsec support until Windows 2000. Implementing IPsec software on the many older personal computers (PCs) in the firm would require a massive investment in large companies.

The disadvantage of tunnel mode is that it does not provide any protection for the packet as it travels within the two sites. The focus is entirely on security during Internet transmission.

Transport Mode

In contrast, as Figure 6 also shows, transport mode offers *end-to-end* encryption and authentication between the two computers. This approach provides security not only while packets travel through the Internet but also when the packets are passing through local site networks on their way to and from the Internet. Although the Internet exposes traffic to many attackers, there also are dangers within corporate networks. In fact, some of the worst attacks are made by corporate insiders working within corporate networks.

Although this end-to-end security is attractive, it comes at a price. Larger firms have thousands or even tens of thousands of PCs. Transport mode requires the presence of IPsec software on every PC to be protected. As noted previously, Windows only began shipping with native IPsec software with Windows 2000, and retrofitting older computers would be extremely expensive.

A more modest problem is that transport mode packets must have the IP address of the receiving computer in the destination address field of the packet header. If sniffers can be placed along the route of these packets, attackers will be able to learn the IP addresses of many corporate hosts. This is a first step in most types of Internet-based attacks. In contrast, tunnel mode packets only have the IP addresses of the receiving IPsec gateway in their destination address fields. This only tells attackers about the IP address of a single machine that usually is well hardened against attacks.

Combining Tunnel Mode and Transfer Mode

One solution to the relative weaknesses of the two modes is to use both. The user can employ transport mode end-to-end but also to use IPsec in tunnel mode between sites as a second layer of protection. This will provide end-to-end encryption while still hiding the IP address of communicating hosts. Of course, implementing IPsec protection twice adds to cost.

Adding Security at the Transport Layer: TLS

IPsec is a complex security mechanism, but it has the advantage of transparency. IPsec protects *all* higher layer traffic at the transport and application layers automatically, without requiring higher-layer protocols to do any work or even be aware of this protection.

In some applications, dialogues are limited to World Wide Web or at most the Web and e-mail. Under these conditions, the costly burden of implementing IPsec is not justified, and many firms turn to a simpler protocol, Transport Layer Security (TLS), which was originally created by Netscape as Secure Sockets Layer (SSL) and was then renamed by the IETF when it took over the standard's development. If your URL begins with "https," then you are using TLS.

Although IPsec provides a blanket of protection at the internet layer, TLS creates a secure connection at the transport layer. This secure connection potentially can protect all application layer traffic. Unfortunately, TLS requires that applications be *TLS-compliant* to benefit from this protection. Although all browsers and Web servers can use TLS, only some e-mail systems can use TLS, and few other applications can benefit from TLS protection at the transport layer.

TLS was created for electronic commerce, in which a residential client PC communicates with a merchant server. TLS requires the merchant to authenticate itself to the client using digital certificates and digital signatures. Few residential client PC owners have digital certificates. So although TLS allows client authentication, it makes it optional. This lack of mandatory client authentication is a major security vulnerability that is intolerable in many situations.

In corporate settings, however, the organization can require clients as well as servers to use digital certificates. This eliminates the main security limitation of TLS, although TLS in general offers only moderate security.

Adding Security at the Application Layer

For the application layer, IETF is adding security to a number of application layer standards (described in further detail later). In addition, many vendors are adding proprietary security to their applications, such as database applications.

Multilayer Security

As Table 1 shows, security can be applied at several standards layers. A major principle of security is defense in depth. Almost all security protections break down from time to time. Until they are fixed, the attacker has free access—unless the attacker must break through two or more lines of defense, the company still will be protected while it repairs a broken security countermeasure. Consequently, companies would be better protected if they added dialogue security at more than one layer, for example, by implementing both IPsec and application security. This is an expensive undertaking, however, so it is uncommon.

Table 1 Multilayer Security

LAYER	CRYPTOGRAPHIC SYSTEM
Application	Kerberos
Transport	Secure Sockets Layer/Transport Layer Security
Internet	IPsec (Internet Protocol security)
Data link	Point-to-Point Tunneling Protocol, Layer 2 Tunneling Protocol
Physical	Not applicable; no messages are sent at this layer, only individual bits

Added Dialogue Security and Firewalls

Although adding security to dialogues passing through the Internet is attractive, it creates problems for firewalls. Firewalls are designed to examine all packets coming into or leaving a firm. When firewalls find attack packets created by hackers, they drop them. Almost all cryptographic system packets are encrypted, however. Unless they are decrypted before passing through the firewall, the firewalls cannot scan their packets for attack signatures. Consequently, companies that buy added security by implementing cryptographic systems tend to lose some scanning security. This places a heavier burden on end stations to do scanning, and many end stations are client computers, the owners of which lack the willingness, much less the knowledge, to do packet scanning.

Adding Security to Individual Internet Standards

Although adding dialogue security to individual dialogues works, it would be better for Internet standards themselves to offer high security. When the Internet was first created, none of its standards offered any security. Today several TCP/IP standards offer security. Unfortunately, the more closely one examines their security features, the less adequate many appear. Fortunately, the IETF has a broad program to add security to a broad range of existing Internet standards individually.

A Broad IETF Commitment: The Danvers Doctrine

In 1995, a meeting of the IETF in Danvers, Massachusetts, reached a consensus that the IETF should develop strong security for all of its protocols, Request for Comments (RFC) 3365. Originally, the consensus was limited to a decision to use strong rather than weak encryption keys that met existing export restrictions. Soon, however, this Danvers Doctrine expanded into a consensus to develop strong security for all TCP/IP protocols. As a first step, all RFCs are now required to include a section on security considerations. Considerable progress has also been made in adding security to individual TCP/IP standards, as the following sections detail.

User Choice

Although all TCP/IP standards are to be given strong security, the IETF decided that it should be the option of individual organizations whether to implement security in individual protocols. In part, this decision reflects a desire not to force security on anyone. In part, it also reflects the fact that some networks are in protected environments that do not require security.

An important consequence of the decision to leave security up to organizations is that organizations must decide which security options to use. There are five broad layers of functionality in networking—physical, data link, internet, transport, and applications. Implementing security at all layers would be horrendously expensive and generally unnecessary.

Consequently, many organizations wish to implement security at only one layer. Although this provides security, individual security technologies often are found to have vulnerabilities. To maintain protection during these periods of vulnerability, organizations probably will wish to implement security in the protocols at two layers at least. While one layer's security is being repaired, the other or others will continue to provide protection.

SECURITY AND VULNERABILITIES

In discussing the security of Internet protocols, there are two issues. One is whether security has been built into the protocol at all and to what degree it has been placed in the protocol. This is the aspect of Internet protocol security I focus on in this chapter.

Another aspect of Internet protocol security is whether the protocol or its implementation has vulnerabilities that attackers can exploit. In some cases, the protocols themselves are exploitable because of design oversights. In more cases, vendor implementations cause problems. For instance the BIND program, which is dominant for Domain Name System servers, and the Sendmail program, which is dominant on UNIX Simple Mail Transfer Protocol (SMTP) servers, have both had long and troubled histories of security vulnerabilities.

In some cases, such as BIND and Sendmail, a single code base is used by most or all vendor implementations. In other cases, the same flaw is discovered in multiple vendor code bases. (For example, in February 2001, two major vulnerabilities were found in the Simple Network Management Protocol version 1 programs of multiple vendors.) In both of these situations, the discovery of a vulnerability can suddenly put a significant fraction of the Internet's servers or routers at risk until organizations can download patches.

In addition, many firms fail to install patches quickly or at all. This makes some vulnerabilities exploitable for weeks, months, or even years after they are discovered. All too often, firms only patch vulnerabilities in earnest when a virus or hackers create widespread damage.

Although vulnerabilities are important, they are situation-specific. This chapter must focus on security within Internet standards themselves.

The Core Four

There are four core standards at the heart of the Internet. These are IP, TCP, and UDP, and ICMP.

Internet Protocol (IP)

The main job of the Internet Protocol (IP) is to move packets from the source host to the destination host across the Internet, which consists of thousands of networks connected by routers. IP is a hop-by-hop protocol designed to govern how each router handles each IP packet it receives.

A packet may travel over one to two dozen routers as it passes from the source host to the destination host. Many core routers in the Internet backbone handle so much traffic that they can barely keep up with demand. To reduce the work done on each router, IP was designed as a simple, unreliable, and connectionless protocol. Although packet losses on the Internet are modest, IP is a "best effort" protocol that offers no guarantee that packets will arrive at all, much less arrive in order. Given this minimalist vision for IP, it is hardly surprising that security was completely left out of IP's core design. Given continuing router overload, it would be difficult to make IP secure throughout the Internet.

IPsec was created to add security to the Internet Protocol, making IPsec more than a security overlay method. IPsec cannot achieve its promise without a truly worldwide system of certificate authorities, however.

Transmission Control Protocol (TCP)

To compensate for IP's unreliability at the internet layer, TCP/IP was given a reliable sibling protocol, TCP at the transport layer. When TCP was created in the early 1980s, however, security technology was far too immature to be implemented. Today there are no plans to add security to TCP given the IETF's focus on IPsec and IPsec's ability to provide security for higher layer protocols.

User Datagram Protocol (UDP)

When transport layer error correction is not required or is not practical, applications specify the UDP at the transport layer. Like TCP, UDP was created without security and is also is unlikely to receive security extensions because of the IETF's reliance on IPsec.

Internet Control Message Protocol (ICMP)

IP merely delivers packets. It does not define any Internet layer supervisory messages. To compensate for this, the IETF created the ICMP to carry supervisory information. ICMP messages are carried in the data fields of IP packets. ICMP messages allow hosts to determine if other hosts are active (by "pinging" them). It also allows hosts to send error messages to other hosts and to tell other hosts or routers to act differently from how they have been acting. ICMP is a powerful tool for network managers. Unfortunately, this power also makes ICMP a popular tool for hackers. Making ICMP less useful to hackers would also tend to make it less useful to network administrators, so the IETF has done nothing to implement ICMP security. For this reason, most corporate firewalls block all ICMP traffic except for outgoing pings and returning pongs.

If ICMP were given good authentication, corporations might be more willing to allow it through firewalls. In addition, authenticated ICMP would protect against attacks generated within the firewalls at individual sites. There are no current IETF activities to add authentication and other security to ICMP, however. The reason may be that ICMP messages are carried in the data fields of IP packets, which can be protected by IPsec, including the authentication of the sending ICMP process.

Administrative Standards

The "core four" Internet standards do most of the work of the Internet, but several other administrative protocols are needed to keep the Internet functioning. The following sections discuss security in the most important of these standards.

Domain Name System (DNS)

The DNS allows a source host to find the IP addresses of a destination host if the source host only knows the destination host's host name. In a sense, DNS is like a telephone directory for the Internet.

Most client users only know the host names of the servers they use. Consequently, if the DNS were to fail for some period of time, clients could no longer reach servers. On the positive side, DNS is hierarchical and highly distributed, so that if one DNS server goes down, service continues. The top level of the DNS server hierarchy only has 13 root DNS hosts, however, and one of them periodically feeds changes to the others. Although these root DNS hosts are geographically distributed, most use the same software, leaving them open to common mode attacks if vulnerabilities are found. Also, geographical distribution is not much protection when there are only 13 targets to attack. In later 2002, a brief denial-of-service attack degraded the service given by 9 of the 13 root DNS hosts. Had this attack been more intense, and had it continued over many hours, service disruption across the Internet would result.

The threat of such concentrated resources (rare on the Internet) is real, but the root DNS servers are well protected with both technical and human protections. Below the root servers are a larger number of DNS servers for the various generic and national top-level domains, and there are many corporate DNS servers. At each level, there are more DNS servers to give less concentration, but the loss of nonroot DNS servers near the top could still be widely damaging to the resources within the domain they serve.

To address problems with DNS security, the IETF DNSSEC Working Group is developing an authentication approach based on public key encryption with digital signatures. There are a (relatively) limited number of high-level DNS servers, so giving each a public key and a private key is not too daunting a challenge. As long as DNS servers do not get taken over so that their private keys can be stolen, authentication should be good. The DNSSEC effort is just getting underway, however, so widespread DNS protection will not be realized for some time to come. Nonetheless, methods for the critical issue of authentication have already been created (RFC 3118).

Simple Network Management Protocol (SNMP)

The goal of the Simple Network Management Protocol (SNMP) is to allow a central administrative computer (the manager) to manage many individual managed devices. Figure 7 shows that the manager talks to an agent on each device. The manager does this by sending the managed devices Get messages (which ask for information on the device's status) or Set messages (which tell the managed device's configuration).

Obviously, SNMP is a powerful management tool. Unfortunately, it is also a golden opportunity for attackers. It potentially allows them to learn a great deal of information about a network through Get commands. It also allows them to do an endless amount of damage through malicious use of the Set command to create misconfigurations on large numbers of devices. These misconfigurations can make the devices unusable or can even make them interfere with the operation of other devices.

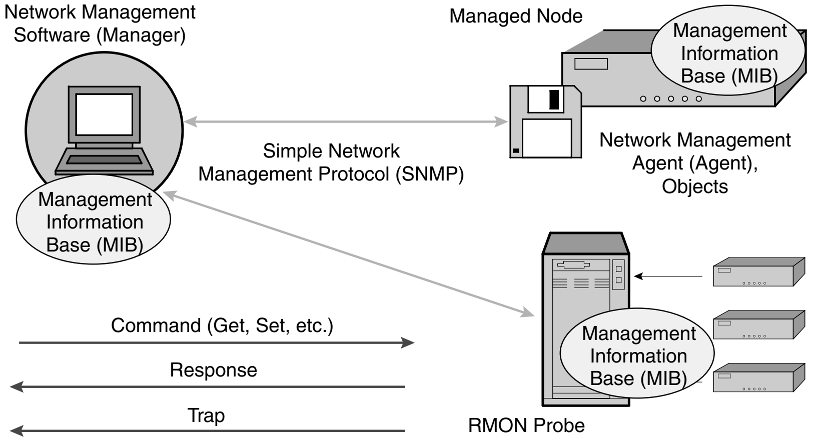

Figure 7: Simple Network Management Protocol (SNMP).

SNMP version 1 had no security at all, making the protocol extremely dangerous, given its power. SNMP Version 2 was supposed to add security, but an inability to settle differences within the IETF prevented full security from being built into it.

Version 2 did receive one authentication advance. To send SNMP messages to a version 2 SNMP agent, a manager would have to know the agent's "community string," which is like a password. In practice, many firms have all of their agents use the same community string. In fact, many do not change the vendor's default community string, which often is "public." Furthermore, community strings are sent in messages without encryption, so attackers with sniffers can quickly learn community strings.

Only in version 3 did security get built into SNMP extensively. Version 3 offered confidentiality (optional), authentication, message integrity, and time stamps to guard against replay attacks.

Unfortunately, SNMP version 3 security is based on HMAC authentication and integrity, which requires the network administrator to have a secret bit string and for each managed device to know that secret bit string. This means that any attacker learning the string will be able to impersonate that manager. As noted earlier, widely shared secrets tend to be easy for attackers to learn, and when many devices must know the shared secret, the company is not likely to change the shared secret frequently.

This severe problem could be solved if the standard specified the use of digital certificates for managers. Authentication and integrity only require that managed devices know the manager's public key, and there is no problem with shared public keys. In addition, public key encryption allows the secure exchange of symmetric keys for bulk encryption for confidentiality. Nonetheless, the large number of devices involved and the desire to keep processing loads on managed devices low has made public key authentication and integrity unattractive to standards makers.

In addition, SNMP is connectionless, and it uses connectionless UDP at the transport layer. Connectionless operation reduces the network load created by SNMP. It is difficult to add security to connectionless applications because, as noted earlier, security typically begins with handshaking phases that are difficult (although possible) to implement in a connectionless protocol.

Lightweight Directory Access Protocol (LDAP)

Increasingly, companies store security information and other critical corporate information in central repositories called directory servers. To query data in a directory server, devices commonly use the Lightweight Directory Access Protocol (LDAP), which governs search request and responses.

The IETF has long understood the importance of creating good security for LDAP in light of the extreme importance of information contained in the directory. The core security focus of LDAP must be authentication because successful impostors could learn large amounts of damaging information about a firm if they could get wide access to this data by claiming to be a party with broad authorization to retrieve data.

The first version of the standard, LDAP version 1, had no security and generally was rudimentary. LDAP version 2 provided authentication options for the first time. It permitted initial anonymous, simple, and Kerberos 4 authentication.

Anonymous authentication means that no authentication is needed for some users. These users would be given access to certain information on the server, much as anonymous File Transfer Protocol (FTP) users are allowed to download information from selected parts of an FTP server. Generally speaking, anonymous authentication should be turned off on directory servers with sensitive information.

Simple authentication requires the user to transmit a user name and password. This information is sent in the clear, without encryption. Anyone who reads the user name and password will be able to authenticate themselves later as the party.

Kerberos 4 authentication uses a central authentication server separate from the directory server. Unfortunately, Kerberos 4 had known weaknesses. Most notably, Kerberos 4 uses a long-term shared secret key to communicate with each device. If enough traffic uses this key, a cryptanalyst can determine the key and then impersonate the device. (Kerberos version 5 only uses the long-term key for initial authentication and then uses a session key for remaining communication during a time-limited session.)

The latest version of LDAP, version 3, also supports anonymous and simple authentication. Again, anonymous authentication should not be turned on for sensitive servers. In addition, sites that use simple authentication should protect application-level LDAP traffic with lower layer protection, most commonly TLS at the transport layer. This ensures that eavesdroppers will not be able to read the user name and password.

LDAP version 3 also supports the simple authentication security layer (SASL). This method allows the searcher and the directory server to authenticate each other in several ways, including Kerberos 5, HMACs, and "external authentication." External authentication means that the parties can perform authentication any way they wish, essentially taking authentication outside the LDAP process. For instance, if the searcher and directory server create a TLS connection at the transport layer, the authentication that takes place at that layer may be sufficient. SASL is extremely flexible, but companies that use it must ensure that sufficiently strong authentication is selected.

Although LDAP version 3 offers good authentication, it does not support public key authentication using digital signatures except through SASL or if the organization using it uses TLS and digital certificates for both parties to secure LDAP traffic.

LDAP version 3 makes encryption for confidentiality optional. This may seem odd, but many firms use TLS at the transport layer to protect LDAP traffic. TLS does encryption, and many firms feel that doing encrypting LDAP traffic at the application layer as well would be needlessly expensive.

Address Resolution Protocol (ARP)

When a router receives a packet, it looks at the packet's destination IP address. Based on this information, the router sends the packet back out another port, to the destination host or to a next-hop router that will handle the packet next. In this chapter, I use the term "target" for the destination host or next-hop router.

The destination IP address in the packet gives the target's IP address. To deliver the packet, however, the router must encapsulate the packet in a data link layer frame and deliver the frame to the target. This requires the router to know the data link layer address of the target, for instance, the target's Ethernet message authentication code address.

If the router does not know the target's data link layer address, the router must use the Address Resolution Protocol (ARP). The router first broadcasts an ARP request message to all hosts on the subnet connected to the port out which the packet is to be sent. If the subnet is an Ethernet network, the broadcast data link destination address is 48 ones. Switches will deliver frames with this address to all hosts on the subnet.

Within a broadcast frame, the router sends an ARP request message. The ARP request message contains the IP address of the target. All hosts except the target ignore this message. The target, recognizing its IP address and sends an ARP reply message back to the router. This message tells the router the target's data link layer address.

Now that the router knows the target's data link layer address, the router takes the IP packet it has been holding and places it in a frame with the target's data link layer address in the destination address field. The router sends this frame to the target.

The router also places the target's IP address and data link layer address in the router's ARP cache. When the next packet addressed to this IP address arrives, the router will not have to use ARP. It will simply look up the data link layer address in the ARP cache.

ARP assumes that all hosts are trustworthy, and thus an attacker host on the same subnet as the target can use this trust to make an attack. Most simply, the attacker host can flood the router with ARP reply messages associating its data link layer address with every IP address on the subnet. If the router accepts some of these messages, it will suffer ARP cache poisoning.

The next time a packet arrives at the router, the router may rely on the poisoned cache to send the packet to the attacker rather than to the correct target. This allows the target to read the contents of the packet. The attacker can then simply drop the packet, creating a denial-of-service attack against hosts on the subnet.

Alternatively, the attacker can listen to real ARP response messages to learn the true data link layer addresses of subnet hosts and send the packet on to the correct target. This attacker-in-the-middle attack permits the attacker to continue reading packets without alerting the victim hosts to this fact. This approach may also allow the attacker to hijack the communication session between the source and destination hosts, inserting its own packets into the dialogue. Currently, there are only preliminary efforts within the IETF to add authentication to ARP.

Dynamic Host Communication Protocol (DHCP)

It is possible to configure a client PC manually, typing in its IP address and other configuration parameters needed to communicate over the Internet or a corporate internet. Servers typically are configured manually. Client PCs, however, are configured automatically by getting these configuration parameters from a Dynamic Host Configuration Protocol (DHCP) host.

When a client PC boots up, it realizes that it has no IP address. It broadcasts a DHCPDISCOVER message to learn what DHCP servers are reachable. Each DHCP server that receives the request sends back a DHCPOFFER message that gives an offer specifying what IP address it will provide, a lease time (how long the client may keep the IP address), and other configuration information.

The client PC selects one offer and sends a DHCPREQUEST to that server accepting the offer. The DHCP server sends back a DHCPACK message acknowledging the acceptance. The client PC is now configured.

DHCP was note designed to authenticate the client or the DHCP server, and this allows several possible attacks. For an example, an attacker posing as a client PC can repeatedly request DHCP service, each time accepting an

IP address. Within a few seconds, the DHCP server will be drained of available IP addresses. If a legitimate client then requests configuration service, it will not be able to get an IP address and so will not be able to use the Internet or an internal corporate internet.

The attacker also can impersonate a DHCP server. The attacker will then respond to all DHCPDISCOVER messages with an attractive offer (long lease duration, and so forth). If a client accepts this configuration information, this information may cause the client to send packets that cannot be delivered or to act in other ways that harms itself or other hosts.

The IETF is now working on DHCP authentication. RFC 3118 (Authentication for DHCP Messages) defines two authentication options for DHCP. The first involves a key that is shared by the client PC and by the DHCP server. This key is transmitted in the clear. This option is only useful for protecting the client against a host that accidentally installed a DHCP server.

The second option requires each client to share a secret key with each DHCP server. The client and server use this shared secret to add an HMAC to each message. If vendors adopt this option, companies can have fairly strong authentication, although the authentication will not be as strong as it would be if digital signatures and digital certificates were used.

Application Layer Standards

To users, the Internet is attractive because of its application standards for the World Wide Web, e-mail, and other popular services. Although decent security is present for some application standards, many continue to have only weak security, if they have any at all.

Hypertext Transfer Protocol (HTTP)

To communicate with a Web server, a browser uses the Hypertext Transfer Protocol (HTTP), a simple protocol that offers no security by itself. All browser and Web server programs support TLS security, however. Although TLS has some theoretical weaknesses, it offers sufficiently strong Web server authentication and confidentiality for consumer e-commerce transactions. For high-volume business-to-business e-commerce, however, TLS security is marginal.

E-mail Security

Security for e-mail is perhaps the great scandal in IETF history. Competing cliques within the IETF have consistently refused to cooperate in selecting security standards for e-mail. Consequently, companies that wish to implement e-mail security have to use a nonstandard method to do so.

Not surprisingly, sending application layer e-mail traffic over a secure TLS transport connection is the most popular way to secure e-mail in organizations today. TLS is well understood, offers consumer-grade security, and has been widely used for HTTP security for several years. Fewer organizations use another approach, S/MIME (Secure Multipurpose Internet Mail Extensions).

A third approach, "Pretty Good Privacy" (PGP), is used primarily by individuals. Organizations have tended to stay away from PGP because it uses user-based transitive trust (if User A trusts User B, and if User B trusts User C, User A may trust User C). As noted earlier, this is not a good security policy. If a single user mistakenly trusts an impostor, others may unwittingly trust the impostor as well. Also, PGP has had a troubled development history.

Remote Access

The first ARPANET application was Telnet, which allows a user to log in to a remote computer and execute commands on it as if the user were local. This allows ordinary users to access remote services. It also allows system administrators to manage servers and routers remotely. This use of remote administration is attractive, but it must be done carefully or hackers will end up "managing" corporate servers and routers.

Unfortunately, Telnet has poor security. For example, Telnet does not encrypt host user names and passwords. Hackers can intercept user names and passwords and then log in as these users with all of their privileges.

Telnet should never be used for remote administration because hackers intercepting root passwords would be able to execute any commands on the supervised machine. Telnet is not alone in this respect. In the UNIX world, rlogin and rsh do not even require passwords to gain access to a computer, although other conditions must apply.

For remote administration, some organizations turn to the Secure Shell (SSH) protocol, which offers good authentication, integrity, and authentication. Unfortunately, SSH version 1 had security flaws, and although these have been fixed in SSH version 2, many version 2 implementations will also allow version 1 connections, thus leaving the system open to attack.

File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP)

Another early ARPANET service that continues to be popular on the Internet is the File Transfer Protocol (FTP), which allows users to download files from a remote computer to their local computers and sometimes to upload files from their local computers to the remote computer. Unfortunately, FTP also sends user names and passwords in the clear, making it dangerous. In addition, although the use of Telnet has declined to the point where quite a few companies simply stop all Telnet traffic at their firewalls, FTP is still widely used. The FTPEXT Working Group is considering security for FTP.

FTP has a simpler sibling, the Trivial File Transfer Protocol (TFTP). TFTP does not require user names or passwords, making it a darling of hackers who often use this protocol after taking over a computer to download their rootkits (collections of hacker programs) to automate their exploitation of the computer they now "own."

Other Applications

There are many other Internet applications, and their standards vary widely in their degree of security. In addition, database applications and many other applications are not standards based. Unfortunately, many operating system installations automatically turn on applications without the systems administrator's or user's knowledge. For example, when SNMP vulnerabilities were found in 2002, it was discovered that many machines should not have been running SNMP at all. An important rule in hardening clients and servers against attack is to turn off all applications that are not absolutely needed to run the computer.

One important area for the future is security for Web services. Although some progress has been made, existing security is so embryonic that it would be premature to discuss.

MAKING THE INTERNET FORENSIC

Forensics is the application of science to criminal prosecution. One of the biggest problems in Internet security today is simply that there is almost no way to stop attackers. Victims must operate almost entirely on the defensive while under constant attack. As any military scientist will attest, this is a poor basis for security.

The Problem of Prosecution

Few attackers are ever prosecuted. In some cases, the laws of a country are insufficient. In the case of two of the worst viruses—CIH and Love Bug—governments gave up on prosecution because they could not prosecute under their countries' statutes. Although the legal situation has become clearer, prosecutors are reluctant to prosecute security incidents. In many cases, the perpetrator is a minor, and only slap-on-the wrist penalties are possible. In other cases, prosecutors feel that even for adult perpetrators, prosecution is too expensive for the minor penalties that the courts have tended to apply. Post-September 11 laws have toughened penalties somewhat, but prosecutors in general still feel that prosecution for hacking and other attack activities is a low priority. Unless losses are in the tens of thousands of dollars, law enforcement officials probably will not prosecute.

Administrative Sanctions

A more promising approach is to sanction perpetrators by cutting off their Internet access and making it difficult or impossible for them to restore Internet access. To take the onus off the ISP, a court could make the decision based on ISP data, and the legal system could even impose ticket-based fines for modest infractions (such as sending probing messages), as is done for automobile misbehavior.

Attacker Identification

In many cases, attackers do little or nothing to hide their identities. For instance, hackers often send out many probing messages against companies they plan to attack. These messages must have the attacker's IP address in the packet so that the attacker can see replies.

In other cases, attackers hide their identities by working through a string of computers, as shown in Figure 8. The last computer in the string can be identified fairly quickly, but tracing several attack computers in sequence tends to take so long that the attacker can hide his or her identity before defenders can trace the attack.

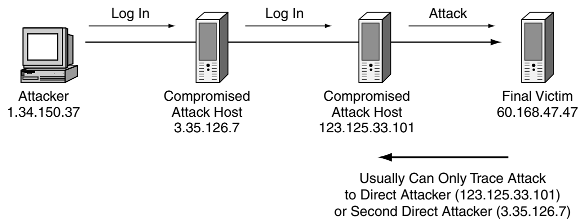

Figure 8: Using a sequence of computers to generate an attack.

To make attackers easier to identify, ISPs could keep connection information far longer than they do today. (Today IP source address information is only stored for a brief period of time for billing purposes if it is stored at all.) Because of the costs involved, ISPs have been unwilling to store connection information for long periods of time. However, several countries are now considering laws to require the long-term storage of connection information plus the ability of law enforcement personnel to get at such information quickly for traceback.

The IETF is now working on a new standard to make traceback easier. This is a new ICMP message type, traceback. Each router will randomly but rarely transmit ICMP traceback messages to the destination host. These traceback messages will list routers along the way.

Even if an IP source address is spoofed, occasional ICMP traceback messages that the victim received in a denial-of-service attack or any other type of sustained attack will still be able to determine the route of the attack. Routers may also send occasional traceback messages back to their sources to aid in the analysis of certain types of reflection attacks. It will take some time for the IETF to ratify the new message type and for many of the Internet core routers to implement the standard, if they implement it at all. (It would cost money for them to do so and would reveal the ISP's internal router architecture, leaving ISPs vulnerable to certain attacks.)

Proactive ISP Efforts to Stop Attacks

More proactively, ISPs could use intrusion detection systems to watch packets coming from their own customers. If many attack packets began to appear, the ISP could inform the attacker and threaten to cut off Internet access. If the attacker failed to desist, the ISP could cut off their service. Generally, ISPs do not wish to do this (although a few already do). First, they do not want to lose customers. Second, intrusion detection and analysis would be expensive. ISPs, in other words, would have little to gain and much to lose. Stopping hackers at their source connection is so attractive, however, that governments should force ISPs to do intrusion detection and to cut off attackers. There is now sufficient danger to the entire Internet system to make such a requirement reasonable. ISPs that fail to do filtering might even be "black holed" by other ISPs, much as some ISPs that fail to stop their users from spamming have been black-holed.

Of course, there would have to be procedural safeguards to protect users who are not really attackers but whose computers have been compromised by attackers.

(At the same time, it is reasonable to require users of compromised computers to clean out their computer if they wish to continue service.)

An Internet Network Operations Center?

One way to increase security on the Internet is to create a network operations center (NOC) for the Internet. Data on the status of the Internet would be delivered to the NOC from multiple sensors distributed throughout the Internet. This would include performance data to spot congestion on the Internet. It would also include attack data.

Centralizing attack data and adding trend detection software might allow the early detection of massive attacks so that actions to stop the attack could be undertaken before massive attacks spread too far. Early detection might also improve the probability of finding the sources of attacks.

Unfortunately, this type of NOC could also allow snooping on legitimate traffic for political purposes. Given diverse opinions on hacktivism (hacking for political purposes), separating legitimate from illegitimate traffic might be controversial.

Creating Multiple Internets?

Another possibility is to create multiple Internets with different levels of security. During the 1970s, the U.S. military attempted to do this by creating milnet (which became the Defense Communication Network). What we may see in the future is the emergence of a business-class Internet and a consumer Internet (probably today's Internet). The business-class Internet would have high security throughout, and the consumer Internet would either have today's casual security or the type of expanded security we have seen in this chapter.

Interconnecting Internets with different security levels would be difficult. Although firewalls between high-security and low-security Internets would lessen the danger, air gaps between them would be needed for high security. Even then, users might surreptitiously interconnect multiple Internets by connecting servers or clients to two or more Internets simultaneously.

THE STATE OF INTERNET SECURITY STANDARDS

Today if two communication partners wish to communicate securely, they can do so by adding dialogue security on top of nonsecure Internet transmission. For lightweight needs, they can turn to PPTP or TLS. For industrial-strength security, they can use IPsec.

General Insecurity

More generally, however, the standards that the Internet needs for message delivery (IP, TCP, UDP, and ICMP), Internet supervisory standards (DNS, SNMP, LDAP, etc.), and Internet application standards (the Web, e-mail, etc.) vary widely in security from none to semiadequate. Consequently, the Internet today is rather fragile and open to seriously damaging attacks. Given the pace of security implementation in individual standards, the fragility of the Internet is not likely to change radically in the immediate future. Even after more secure standards are developed, it will take several years for them to be widely adopted.

The Broad IETF Program

At the same time, there is extremely broad concern with security across the IETF. Although some standards have better security than others, standards working groups appear to be playing leapfrog in their efforts to improve security across a broad spectrum of Internet standards.

The Authentication Problem

The most difficult problem in Internet security standards is authentication. Quite simply, unless authentication uses public key authentication (such as digital signatures) coupled with digital certificates managed by a reliable and well-regulated network of certificate authorities, authentication strength will only be moderate. Creating large public key infrastructures will take years, however, and although European countries are moving to manage and regulate certificate authorities, the United States is has adopted the let-the-market-do-it philosophy that has worked so well recently in the energy industry and in corporate financial reporting.

The Primary Authentication Problem

One broad and deep problem in authentication is the primary authentication problem—proving the identity of a person or organization in the first place, say, to give them a digital certificate or accept them as an employee. Identity theft has long allowed impostors to obtain fraudulent drivers' licenses and other authentication instruments. Even within closed systems, such as corporate networks, the prime authentication problem can be daunting. For consumer authentication and other large communities, the technical and operational problems for credible initial authentication are extremely daunting.

Protection From Denial-of-Service Attacks

One security threat that has barely been faced so far is the prospect of denial-of-service attacks. Although a few standards have taken some steps to reduce these attack risks, this is an area of little general development within the IETF.

The Need for a More Forensics-Friendly Internet

Although technical security is important, tremendous strides in security could be made if ISPs were required to cut off service to attackers and if ISPs and corporations were required to keep audit data for at least a month instead of for a few hours or days. In general, we need laws to make the Internet a more forensics-friendly environment.

Corporate Responsibility and Operational Security

We also need to make the Internet more of a responsible community. In many attacks, adversaries use "innocent" computers as attack tools. This is possible because so many irresponsible users and companies fail to protect and harden their computers. Many attacks, especially denial-of-service attacks, can only be stopped at the source, and many attacks, including virus attacks, can only be reduced substantially by reducing the number of gullible e-mail users. At the corporate level, firms should harden their computers against being taken over and also should do egress filtering on their firewalls to prevent their computers from attacking others if they are taken over. Standards may help, but "operational security" is still the key to security on the Internet.

GLOSSARY

Community key A secret key shared by multiple devices within a network.

Cryptographic system A standards-based system for automatically providing multiple protections in a dialogue between two parties.

Denial-of-service attacks Attacks that attempt to render a computer or network useless; this type of attack is not addressed in most Internet security efforts.

Dialog security Security applied to a dialogue between two parties; often added on top of nonsecure Internet transmission.

Digital signature A message-by-message authentication system based on public key encryption. To work well, the parties should have digital certificates from trusted certificate authorities.

Forensics The application of science to prosecution.

Internet Engineering Task Force (IETF) The body that creates TCP/IP standards for the Internet. The IETF is now engaged in a broad effort to add security to Internet standards.

IPsec The family of standards for adding security to both version 4 and version 6 of Internet Protocol transmission.

Kerberos server An Authentication system in which a central server gives out authentication information.

Key-hashed message authentication code (HMAC) A message-by-message authentication system based on a secret key shared by the two parties.

Multilayer security Providing security at multiple layers to provide defense in depth.

Password authentication Authentication in which the two sides know a password. Sometimes the password is sent in the clear (without encryption).

Policy server In a security system, a server that tells devices how they must implement security.

PPP tunneling (PPTP) Delivering a point-to-point (PPP) frame across the Internet by encapsulating it in an IP packet.

Remote access Accessing a computer remotely for management; includes Telnet (nonsecure) and secure shell protocol (secure in version 2).

Transport Layer Security (TLS) A general standard for adding security at the transport layer; formerly called Secure Sockets Layer (SSL) and also called HTTPS because URLs beginning with "https" are requesting SSL/TLS security.

Virtual private network (VPN) Family of standards for adding security to a dialogue. Includes PPTP, IPsec, and TLS.

INTRODUCTION TO INTERNET2

Context

The Internet2 project was established to support a variety of academic innovations requiring advanced networking capabilities. The mission of Internet2 is to improve scholarship and to serve the needs of academics in universities, colleges, and schools who require cutting-edge data processing solutions. This “invitation only” initiative is hosted by a consortium of academic, corporate, and government entities known as the University Corporation for Advanced Internet Development (UCAID). Over 200 U.S. educational institutions, recognizing the potential of technologically enhanced teaching, learning, and research tools, have partnered with corporate and government agencies to establish this “next-generation Internet.” UCAID’s vision is to facilitate and coordinate the development, deployment, operation, and technology transfer of advanced, network-based applications and network services to further U.S. leadership in research and higher education and accelerate the availability of new services and applications on the Internet (Houweling, 1999). This next-generation Internet promises to do what academics and researchers hoped the first-generation Internet would do: allow scholars to collaborate with colleagues and students around the world.

Need

The present-day Internet, originally fostered by a partnership of academia, industry, and government, was not designed to handle the volume of personal and commercial use that it is currently expected to support. Originally developed to exchange data through file transfer protocol (FTP) and share resources by remotely logging in through Telnet connections, the Internet’s popularity grew with the advent of the graphical user interface (GUI), which stimulated the use of electronic mail, the Internet’s most-used feature. According to Computer Industry Almanac, Inc. (2002), Internet usage has exploded, growing from 4 million users in 1991 to over 530 million users in 2001. By the end of 2005, it is projected to host over one billion users. At the same time the general population’s use of this medium has increased, the academic institutions that pioneered the Internet have been developing online educational programs that require far more speed and bandwidth than the current networks provide. Some of these programs involve revolutionary collaborative models, to be used by teachers, scientists, and researchers, that are expected to run on networks 1,000 times faster than today’s fastest networks.

The need to expand educational opportunities through the use of virtual learning laboratories and other distance learning opportunities prompted a number of educators to develop interactive multimedia applications, precipitating the need for a powerful and speedy network with capabilities far outreaching the original Internet. Out of this grew a collaborative effort by a number of universities and research centers to research and develop networking technologies that would support their needs. They expressed the need for a reliable and high-capacity technological infrastructure that would allow a collaborative exchange of research materials and an open atmosphere for the exchange of software development tools. Thus, in 1996, 30 universities collaborated on plans to build a communications network that was to be more powerful than the current network system. This new network system, Internet2, would assist these academics in returning to their original vision of a vehicle primarily used to promote education and research.

SHORT HISTORY OF THE INTERNET

Origins

Rooted in the military culture of the cold war, the Internet's original ancestor was established at the Advanced Research Projects Agency (ARPA) of the U.S. Department of Defense. It was called ARPANET and was created out of the need for a robust, redundant system capable of carrying critical military data throughout a relatively small network of then-powerful computers. Serving as a critical element of military preparedness and civil defense, ARPANET was designed to function regardless of any kind of network disruption, no matter how cataclysmic. The original ARPANET has been replaced by a succession of bigger, faster, more powerful networked systems, leading to today's Internet. Sensing the potential of distributed computing for science discovery and application, the National Science Foundation created a network dedicated to academic research and development based on the ARPA's Internet protocol. Operating from a system of regional computing systems interwoven by an Internet "backbone," the Internet offered researchers immediate access to colleagues and files throughout the world.

The Internet has grown into a loose amalgam of individual networks and computer systems, all operating according to agreed-upon network protocols, allowing the worldwide transfer of information between systems built on a variety of operating platforms. Unlike many of the well-known commercial online network service providers (e.g., America Online, AT&T Broadband), no individual, company, agency, or institution owns the Internet. It is a "distributed" system of interconnected computers and networks. This means that no single "hypercomputer" or "supernetwork" drives it. Rather, it is an enormous, electronic global "neighborhood." Some "houses" are bigger and more luxurious than others, but each one arranges its own furniture and landscaping.

The Internet's origin may be traced back to an American sense of shock and fear caused by the 1957 launch of Russia's first-ever space orbiting satellite, Sputnik. The earliest Internet-type operation was launched in 1969. At the time, this network comprised four hosts (the University of California, Los Angeles; Stanford University; the University of California, San Bernardino; and the University of Utah). At its midlife (1982), the Internet had grown to more than 200 hosts. By 1995, there were almost 6 million hosts, and at the start of 2002, the number of hosts had grown to approximately 147 million.

Nearly 200 countries are now connected to the Internet (post-Taliban Afghanistan has recently become connected). When we add other networks capable of interfacing with the Internet in some manner or other, the number of nations involved increases still further. By 1995, the number of Web home pages had surpassed 20,000. As of March 2002, Zakon (2002) placed the number of Web servers at more than 38 million. Because most servers host multiple Web sites, the number of sites should be in the hundreds of millions.

Some noteworthy Internet benchmarks are illustrated in Table 1.

With such growth has come a change in purpose and tone. In its earliest incarnation, the primary Internet purpose was military. As the Internet moved beyond military use, its function shifted to research and scholarship. At the dawn of the 1990s, the Web had neither entered the national lay consciousness nor become viable for commercial transaction. The 1990s changed all that. In the industrially developed world, the Internet became an indispensable tool for all kinds of business, serving vendors and consumers alike. As a result, the charitable camaraderie that characterized a relatively small number of Web users in the early 1990s has now become primarily a commercial marketplace, where transactions for information, misinformation, financial services, transportation, products, education, romance, entertainment, culture, hate, and pornography are routinely carried out. From an earlier culture of open information sharing, a more defensive posture, to protect commercial and personal interests, has emerged. By the year 2000, the old neighborhood had changed for good.

With this change has appeared an ever-growing danger of mischief, intellectual property theft, and malicious destruction. Ever more devastating computer viruses and worms spring up faster than updated virus protection software can thwart them. Major institutional networks have been disabled for days at a time and sometimes longer by such viruses as *Melissa* (1999), *Love Letter* (2000), *Nimda* (2001), and *Code Red* (2001). Network hackers have broken into the presumably secure private networks of major corporations (e.g., Microsoft), transportation services (e.g., British Rail), and the governments of several nations (e.g., the U.S. Senate). Predators have harmed children. Meanwhile, a passionate debate rages between those who advocate legal restraints on putatively harmful Internet exploitation and those who value intellectual freedom above everything.

Globalization

Although a worldwide affiliation of groups vocally opposes economic and cultural globalization, Internet-based e-commerce has not only made common business transactions more accessible to global markets, it has also created exponentially richer international choices in education, entertainment, and culture. For example, classical music buffs may choose from nearly 100 radio stations

Table 1 Internet Time Line

Year	Event
1957	First orbiting space satellite, Sputnik, launched by the former USSR
1963	First dial-up modem developed
1969	Four-node ARPANET established with network speed of 50 kpbs
1972	First e-mail message sent using the @ sign; first computer chat undertaken
1976	First Internet routers developed; Queen Elizabeth II sends e-mail
1977	First transport control protocol (TCP) developed
1979	Emoticons ";-)" first appear in e-mail messages as antidote to dry text
1980	Accidental virus brings ARPANET temporarily to a halt
1982	TCP/IP protocol established as technical standard to drive Internet traffic
Mid-80s	Loose coalition of networks in ARPANET becomes known as Internet
1988	"Worm" infects 10% of all Internet hosts
1989	Creation of interconnected regional academic networks
1990	ARPANET decommissioned, leaving a loose network of networks, the Internet
1991	World Wide Web and Gopher are launched
1992	First Internet audio and video transmissions
1993	MOSAIC, the first GUI Web browser released; White House comes online
1994	First banner ads appear on the Web; first pizza ordered online
1995	Real-time audio streaming technology launched; Radio Hong Kong hits the Internet
1996	Internet becomes truly global; U.S. Communications Decency Act (CDA) passed
1997	CDA ruled unconstitutional; Microsoft challenges Netscape with Internet Explorer browser
1998	U.S. Postal Service sells stamps for downloading and printing from the Web
1999	Securities fraud on Web raises a small company's stock price by 31% in one day
2000	Catastrophic "denial of service" attacks launched against Amazon, eBay, and Yahoo
2001	Napster forced to suspend free service; resumes shakily as a subscription service
2002	Internet boasts more than 147,000,000 hosts (727,000 in 1992; 235 in 1982)

(2002), "Hobbes' Internet Timeline," available at http://www.zakon.org/robert/internet/timeline; Verizon Corporation (2001), "Who We Are: BBN Timeline," available at http://www.bbn.com/timeline.

worldwide, many of them uninterrupted by annoying commercials. Such a shift in the network zeitgeist has created many employment opportunities and threatened others (e.g., travel agents). The Internet domain-naming system, only recently limited to six categories (.com, .edu, .gov, .mil, .net, and .org), has added several new categories to accommodate growth (e.g., .biz, .info, .aero, .name, .pro, .coop, .us, and .museum). Partly because of the inchoate spawning of commercial traffic, Internet2 represents an effort to regain the prominent place research and education formerly held on the original Internet.

INTERNET DEEMED INADEQUATE

Traffic

Although the present-day Internet grew out of the national defense need for uninterrupted communications, it soon became a popular medium for researchers and academics who wished to share research and data. Once considered the domain of researchers, with the introduction of the graphical user interface browser, the Internet quickly became usable for a wider audience. The introduction of Mosaic, which was quickly followed by Netscape and then Microsoft Internet Explorer, forever changed the face of the Internet. Rather than a medium used only by those who understood how to navigate a text-only protocol, the Internet became accessible to anyone who could operate a mouse and a keyboard. This increased usage quickly became a problem for a network system that was not originally developed to handle this increased amount of traffic.

One solution to the Internet traffic problem has been to increase bandwidth as well as the speed with which the data is sent. A number of universities have added T1 and T3 lines, and a new Internet protocol is being tested. The current Internet protocol, TCP/IP, uses a packet-switching protocol that Vinton Cerf (1995) likens to "sending a novel on many postcards." Although this may be appropriate for e-mail transmission, it is inadequate for the smooth transmission of audio and video files (Lan & Gemmill, 2000). The need to speed up the delivery of information has led to the creation of IPv6, which is currently being promoted and coordinated by the Internet2 IPv6 Working Group. This new protocol, Internet protocol version 6, allows files to be transported as one packet to many locations. More important, this same protocol promotes the collaborative participation envisioned by the original designers of the Internet. For instance, the technology behind multicasting enables a number of medical experts from remote locations to collaborate during time-sensitive diagnostic medical procedures. The Internet2 backbone networks, Abilene and VBNS+, use IPv6 as their Internet protocols.

The Needs of the Educational Community

The Internet has impacted the teaching and learning community in a very important way. Interaction between students and faculty through such online communication tools as e-mail, instant messaging, synchronous chat, and asynchronous forums has allowed the learning experience to move outside the walls of the classroom. Internet tools have given faculty members the opportunity to post online quizzes, handouts, lectures, and digital materials for easy access by students. The Internet has also provided the availability of online library materials that can be accessed by students and faculty any time of the night or day from their homes or offices. Even though these advances are significant, Internet2 visionaries suggest that a new generation of network-based applications necessitates the capacity to build a unique environment that "will engender new possibilities for the synthesis of ideas that can ultimately lead to the creation of important new knowledge" (Wasley, 1996). The current generation Internet cannot accommodate these needs.

Quality of Service

The Internet does not distinguish between low-priority e-mail messages and medical collaborative broadcasts where a delay in transmission could be critical. Additional congestion is caused by sending live video streams because the broadcast must be sent from point of origination to each separate requestor. Distance learning opportunities are hindered by both lack of speed and bandwidth. Internet2 researchers are working on these quality-of-service issues by considering issues of priority and multicasting, and by increasing the number of possible Internet addresses.

WHAT INTERNET2 IS

Vision

The essence of this new generation of network-based applications revolves around collaboration among individuals with access to data and resource materials. Internet2 member institutions have developed a number of new initiatives, including digital video for video conferencing and remote control instrumentation, multicast streaming designed to deliver video efficiently, media-rich collaborative and interactive learning environments in such areas as medical education, interactive and simulation-based teaching initiatives, tele-immersion programs designed for educational virtual reality systems, remote auditioning opportunities, and transmission of live, high-quality, uncompressed audio.

Infrastructure

Currently, two major networks support the research and advanced networking technologies envisioned by this consortium, by offering high-capacity connections. Abilene, known as the network backbone of Internet2, and vBNS+ networks connect universities to gigaPoPs (gigabit points of presence), which serve as network hubs independently sponsored by regional networking communities. Capable of reaching speeds approximately 200 times faster than DSL (digital subscriber line) and cable connections of today, the next generation network is connected through a series of robust regional aggregation points using the most advanced protocol for transmission of data.

Commercialization

The University Corporation for Advanced Internet Development (UCAID) is a nonprofit organization that supports Internet2 specifically for educational and research institutions. According to one of UCAID's six founding principles, member organizations wishing to provide Internet2 services to commercial organizations must offer these services separately. That is, Internet 2 network hubs, referred to as gigaPoPs, and other commercial network hubs must "remain appropriately distinct." The commercial organizations currently involved in the Internet2 project are those that have offered their services in the development of the project. Cisco Systems, 3Com, Advanced Network & Services, AT&T, IBM Corporation, Intel Corporation, ITC DeltaCom, Juniper Networks, Lucent Technologies, Microsoft Research, Nortel Networks, Qwest Communication, SBC Technology Resources, Spirent Communications, Sun Microsystems, WorldCom, and Yotta Yotta are currently listed as corporate partners of the Internet2 consortium. Such partnerships have contributed to the development of security measures against potentially harmful network infiltration, have connected with educational institutions to support technologically advanced communications, have granted access to information, and have provided strong funding opportunities.

Security

Security on the traditional Internet has continued to defy surefire solutions. To address this issue, Internet2 member organizations are involved in a number of working groups. Some of these groups are working on middleware, which is described on the Internet2 Web site as the "glue (or the) layer of software between the network and the applications" (UCAID, 2002i). Participants in such working groups as VidMid (Internet2 Video Middleware Group) are focusing on common middleware solutions to security challenges. VidMid's February 2002 draft, *A Framework of Requirements, Threat Models, and Security Services for Videoconferencing over Internet2*, outlines its plans for security initiatives related to video conferencing tools and applications. Among the considerations outlined in this draft are issues related to theft of service, impersonation of servers, authentication of users, firewall issues, and encryption.

THE INSTITUTIONAL STAKES OF MEMBERSHIP

Once an institution becomes a member of Internet2, the stakes of membership are high. Representative groups within the research, academic, and corporate communities may need to take on various scholarly, ethical, financial, and instructional responsibilities within the Internet2 consortium.

The Stakeholders

Internet2 is an organization driven by its membership, which includes for-profit and not-for-profit organizations (UCAID, 2002h), including those in the research and corporate communities.

The Research Community

Individual stakeholders within the research community may include pure researchers, professors, information technology (IT) professionals, and research and education administrators. It is these groups who will facilitate and lead the Internet2 research and educational initiatives emanating primarily from universities. Available new technologies in research, teaching, and learning are forcing the creation of cutting-edge network capabilities (UCAID, 2002e). As a result of these advanced networking capabilities, researchers are developing new sets of teaching and learning applications (Lan & Gemmill, 2000).

To assist institutions in meeting these research and educational goals, the National Science Foundation, through its High Performance Network Connections (HPNC) program, has committed millions of dollars in grant funding for American higher education and other institutions with significant research and education missions "to establish high performance Internet connections (at or above 45mbits per second) to support cutting edge science and engineering research" (NSF, 2002).

Members of the research community who wish to keep abreast of Internet2 priorities and initiatives can look to the UCAID Applications Strategy Council (ASC) and the Network Research Liaison Council (NRLC) for current information. The ASC helps identify priorities for research and education. NRLC helps identify priorities related to adapting computer systems to fit the Internet2 infrastructure, including research, access, and prototype deployment (UCAID, 2002a).

The Corporate World

Corporate stakes in Internet2 can be more or less substantial depending on the type of membership. Corporations may agree to contribute goods, equipment, services, cash, grants, human resources, and capital ranging from $100,000 to $1,000,000 for their participation in the Internet2 project (UCAID, 2002c; O'Beay, 2002). Annual fees for corporations range from $10,000 to $25,000, depending on their total annual revenue.

Fortune 500 companies, such as IBM, Quest Communications, Lucent Technologies, and AT&T, have formed the foundation of Internet2 corporate memberships. However, the three levels of corporate membership (partner, sponsor, and member) have allowed content providers and research organizations, such as CREN and EDUCAUSE, to become Internet2 members. Members of the corporate community who wish to keep abreast of Internet2 priorities and initiatives can look to the UCAID Industry Strategy Council (ISC). The ISC provides a strategic vision related to advanced networking and applications development and helps focus technology transfer aspects of UCAID initiatives (UCAID, 2002a).

Higher Education

When a college or university commits to Internet2 membership, it pledges to provide a significant financial investment to the project. Institutions pay an annual $25,000 fee to be a regular member of Internet2. Everything considered, existing members typically estimate they will spend a minimum of $500,000 per year for their participation in Internet2 (UCAID, 2002k). This annual expense varies, depending on the current network infrastructure of the institution (UCAID, 2002k). At this level of financial support, applicants and members must be aware that in order to conduct cutting-edge research, they must make a substantial and continuing commitment to experimentation with, and to the evolution and use of, advanced networking technologies and applications (UCAID, 2002k). To help institutions with planning and decision making, the UCAID Network Planning and Policy Advisory Council (NPPAC) advises on matters related to the planning, development, financing, and management of advanced networks for research and education (UCAID, 2002a).

Although there are many grants available through federal sources, the Experimental Program to Stimulate Competitive Research (EPSCoR) is one program that some states may find particularly helpful (EPSCoR, 2002a). EPSCoR supports partnerships between the National Science Foundation and many states. Its goal is to leverage the potential of the states' science and technology funds to develop research infrastructure and to advance economic growth (EPSCoR, 2002b).

NUTSHELL SKETCHES ON WHO IS USING INTERNET2

The Academic Community and High-Definition Television

Since early 1999, the University of Washington, one of the original founders of the Internet2 initiative, has been working on the transmission of high-quality and high-speed video transmission using high-definition television (HDTV). At its fall 1999 Internet2 membership meeting, the University successfully demonstrated the transmission of a high-definition television stream from Stanford University to the University of Washington at 270 Mbits per second; approximately 5000 times faster than the speed of a 56K modem. Since that time, the researchers involved in this project have successfully sent multiple HDTV streams simultaneously. The University of Washington researchers credit the success of these experiments to the unique collaborative efforts of individual experts in the networking, computing, and video fields. The researchers believe that their reliance on industry standards has positive implications for future use by a number of interested parties, including those in the broadcast television industry.

The Academic Community and Video Conferencing

The University of Oklahoma has launched a program for teaching music through advanced network video conferencing. The increased bandwidth offered by the Internet2 backbone allows for a quality of sound and video transfer that was not available on the first-generation Internet. Rather than offering an alternative method to face-to-face teaching, music educators envision bringing world-class musicians to their courses, expanding their own teaching to new constituencies, increasing collaborative and research opportunities for faculty, and increasing outreach programs throughout the state of Oklahoma.

The Scientific Community and Distributed Computing

The Gemini Observatory's Internet2 connection offers astronomers the opportunity to use twin 8.1-m telescopes located in Hawaii and Chile to observe both the northern and the southern hemisphere skies from remote networked locations. An international partnership managed by the Association of Universities for Research in Astronomy, Gemini has a cooperative agreement with the National Science Foundation.

The Scientific Community and Tele-immersion

The Electronic Visualization Laboratory (EVL) (2002) at the University of Illinois at Chicago defines tele-immersion as

> collaborative virtual reality over networks, an extension of the "human/computer interaction" paradigm to "human/computer/human collaboration," with the computer providing real-time data in shared, collaborative environments, to enable computational science and engineering researchers to interact with each other (the "teleconferencing" paradigm) as well as their computational models, over distance.

Tele-immersions allow virtual excursions through the human body, machines, and buildings, as well as virtual visits to historical sites and to "environments that explore truths about irony, humor, music, and levels of consciousness" (Lemley, 2002), in which one can participate in such virtual physical experiences as jumping off a set of stairs. EVL's goal is to move their laboratory from the desktop to the next-generation Internet so that they can share their expertise with remote users and form a collaborative to encourage cooperative problem solving and development.

ADVANTAGES AND DISADVANTAGES OF INTERNET2

Access to Information

For Internet2 members, the potential for accessing large amounts of data and information is enormous. Through partnerships and collaboration, Internet2 applications, middleware, and engineering initiatives are all focused on increasing access to information for teaching, learning, research, and clinical missions of member institutions. Although this is certainly an opportunity for Internet2 members, those who are not Internet2 members do not have the same access to such information. This, in a sense, is creating a gulf between those who can only access the original Internet and those who can access Internet2—an academic digital divide of sorts. There are opportunities to bridge this gap, which include becoming a sponsored participant or a sponsored educational group participant (SEGP). A member university may sponsor organizations that are not eligible for Internet2 membership. Such organizations may include "educational institutions (including both not-for-profit and for-profit K-20, technical, and trade schools), museums, art galleries, libraries, hospitals, as well as other non-educational, not-for-profit or for-profit organizations" (UCAID, 2002f). The opportunity to become a sponsored participant or a SEGP allows the sponsored organizations to use Internet2 to collaborate with primary members or other sponsored members.

Although the potential for accessing information via Internet2 is great, in some disciplines there remain challenges to accessing the needed information efficiently. The health sciences and particle physics disciplines have unique challenges in that the computational research and subsequent data output create huge data sets. For faculty, such as those at Tufts University School of Medicine, Internet2 is helping to address access to information not previously available via traditional networks in health sciences, such as high-resolution magnetic resonance imaging and confocal microscopy.

On the other hand, in areas such as particle physics, some researchers believe that Internet2 will not be quite fast enough to meet their needs, and they await the creation of Internet3, which may be able to handle the amount of data generated by the computational outputs of particle physics research. At this time, these scholars continue to focus on creating simulations because there is still not a fast enough network to handle the petabytes (2^{50} bytes) of particle physics data.

Research Communication

The Internet2 philosophy is based on Metcalf's law, which states that the "value" or "power" of a network increases in proportion to the square of the number of nodes on the network (Robertson, 2002). Thus, the added value of Internet2 rests in the degree of collaboration among its members. Although Internet2 represents many disciplines, such as math, humanities, science, and engineering, some disciplines, such as social sciences, are not as well represented.

In the health sciences, Internet2 has allowed advanced research in instructional content and visualization (e.g., visible human project), simulations (e.g., virtual labs projects), and distance learning (e.g., virtual grand rounds and video conferencing); however, one overarching challenge in the health science area is the issue of network security and patient confidentiality. Policies and guidelines to these challenges are being identified by various health sciences Internet2 working groups.

Infrastructure Speed and Robustness

A particularly promising opportunity for Internet2 members is the speed at which they can now collaborate with colleagues and students around the world. In a recent Internet2 intercontinental land-speed record, "6.7 gigabytes of data was transferred across 6,800 miles (10,978 km) of network in less than one minute." The speed of this transfer was "923 megabits per second, or more than 3,500 times faster than a typical home broadband connection" (Wood, 2003).

A challenge that arises when we look at infrastructure speed and robustness is the issue of storage capacity.

Faster networks generate massive increases in data transmission, requiring comparable hardware improvements to store these data so they can be accessed and analyzed in an efficient manner.

Potential for Distance and Distributed Learning

One significant advantage of Internet2 is that it is changing the way professors teach and students learn. Faculty are enhancing their traditional face-to-face classrooms with real-time collaboration tools, simulations, and H.323 video conferencing. H.323 is an International Telecommunication Union (ITU) standard that allows transmission of Internet video conferencing over IP-based networks. Human sciences and arts have found tremendous opportunities in Internet2 that they do not have with the conventional Internet. For example, Internet2 facilitates access to full-motion video and high-fidelity audio. Without traveling, theatre directors can conduct remote auditioning using real-time video conferencing. Master musicians around the world can be present via video conferencing to conduct live master classes and teaching sessions with young musicians. These video conferencing opportunities have been made possible by Internet2 because the challenges of sample rates, frequency, and latency have been overcome to allow effective music education over the Internet.

As faculty members begin to expand their teaching techniques and adopt instructional materials that require advanced networks, comprehensive faculty development programs and corresponding support resources need to be in place. At individual institutions, adequate staff and resources are necessary to support such robust undertakings in teaching and learning. Faculty development and outreach initiatives can include training grants, online discussion forums, focus groups, desktop computer conferencing, structured workspace sharing, and consulting (online and face to face), typically in combinations rather than in single strategies.

Costs of Access and Infrastructure

Because the role of Internet2 is to promote networked teaching and bring scholarly research and development to fruition, the question of costly access to resources begs for attention. The capacity of some institutions to join the Internet2 community provides an opportunity that will allow these institutions to be at the forefront of advanced networking initiatives. To address this challenge of cost, institutions are now exploring various funding and cost-sharing models that may assist in defraying some of the initial and ongoing costs associated with being an Internet2 member. If the cost of membership is still prohibitive for smaller organizations, there are grant monies available to help offset the costs of membership and subsequent infrastructure upgrades. There are also other opportunities for Internet2 sponsorship agreements.

One advantage of being an Internet2 member is that members can obtain loaner equipment from the Internet2 applications working group. Members can request loaner equipment, such as portable access grid nodes, various types of video conferencing equipment, and preinstalled hardware with visual, immersive, and digital library applications.

HOW EXPERIENCE IS SHAPING INTERNET2

As it pioneers the meta-network of the future, as new research unfolds, Internet2 is taking precautions to develop appropriate policies and guidelines. Based on the experience of member institutions, as new information and knowledge is disseminated, current user policies governing Internet2 are reviewed and updated. To generate cutting-edge experience, Internet2 has announced a call for participation to its members. The call for participation asks members to propose "compelling, exemplary advanced content applications that will be valuable to the mission of member universities" (UCAID, 2002b). As a result of participation in such projects, Internet2 hopes to identify best practices for developers and applications management and monitoring and ways in which these experiences can support the teaching and research missions of member institutions.

Essential Partnerships

Thanks to close collaborations between academia and industry, Internet2 research and development initiatives have been made possible. At the core of these Internet2 collaborations are the partnerships formed to create Abilene, the network backbone of Internet2. In February 1999, Cisco Systems, Nortel Networks, Quest Communications, and Indiana University launched the Abilene project in the United States. In April 2002, Juniper Networks partnered with Abilene. A fall 2002 upgrade equips the U.S. Abilene network to use a routing product produced by Juniper Networks that can quadruple the speed of Internet2.

Other essential connections are those between member institutions and the Abilene backbone or gigaPoPs. Through their connections to regional and national networks, member research and development efforts are being joined. For example, the mid-Atlantic crossroads (MAX) is a gigaPoP in the Washington, D.C., area that connects to the Abilene network and to other national and international networks. Many universities, federal research laboratories, and commercial and nonprofit institutions in Washington, D.C, Maryland, and Virginia connect to this regional gigaPoP.

One example of a project utilizing MAX is that of the University of Maryland Space and Plasma Physics Group. This group uses MAX to compute large simulations at the Pittsburgh (PA) Supercomputing Center and the National Center for Supercomputing Applications at the University of Illinois at Urbana—Champaign. The computational results and graphical outputs of such massive data processing are shared collaboratively through MAX and the Abilene network with researchers at Dartmouth College and NASA. For institutions to join the MAX network and to benefit from its supercomputing capacities, an annual subscription fee of $12,000 is levied, with additional annual costs ranging from $45,000 to $180,000, depending on the institution's choice of connectivity and bandwidth.

Essential partnerships and research and development initiatives revolve around five technical areas of Internet2: applications, middleware, engineering, end-to-end performance, and backbone network infrastructure. Table 2 depicts research interests, working groups, and advisory councils within each of the five technical areas. These five technical areas rest on the foundation of a high-performance network where ideas and products can be evaluated and tested. Development initiatives and activities within each of the five technical areas are conducted in committees known as working groups (UCAID, 2002g). Each technical area has a director who oversees the activities of all related working groups and reports working group developments and highlights to the president of UCAID. In addition to these working groups, members can also participate in Internet2 activities through Sponsored Interest Groups (SIGs) and Birds of a Feather (BoF). UCAID also receives strategic and advisory guidance from the UCAID advisory councils on various matters related to advanced networking in higher education (UCAID, 2002b). The UCAID board of trustees elects council members, and each council is limited to 14 individuals; however, member institutions and other interested parties can keep abreast of council activities and council meeting minutes on the UCAID Web site.

Life-Long Learning

The Internet of today has made education available to students in new ways. Distance education, as it is called, allows students of all ages the convenience and flexibility of learning from their homes or offices. With such advanced applications as tele-immersion, digital libraries, and virtual laboratories, the possibilities for life-long learning are limitless. AccessGrid, for example, is a project of the Argonne National Laboratory Futures Lab and the Office of Computational and Technology Research of the U.S. Department of Energy. Through the use of new collaborative technologies, such as virtual reality environments, tele-immersion, and advanced two-way audio and video technology, AccessGrid supports collaborative teamwork sessions, seminars, lectures, tutorials, and training.

Sharing Intellectual Resources

Sharing intellectual resources is a cornerstone of Internet2 activity. Just as Internet2 is creating new applications, researchers are also inventing new middleware that will facilitate an unprecedented sharing of intellectual resources. At the core of the middleware initiative is the creation of directories that are known as the "operational linchpin" of Internet2 information resource sharing (UCAID, 2002d). Creation of these directories will enable a network security layer, allowing access to resources, people, and data within the Internet2 collaborative.

The goal in creating such directories is to "deploy a common middleware infrastructure to support the academic and administrative needs of the research and education community" (UCAID, 2002j). Directory projects that are currently under development include EduPerson and a Directory of Directories for Higher Education (DoDHE). These directories promote standardization in how applications and data are shared between institutions, with the aim of developing core middleware services allowing Internet2 members to communicate easily and quickly. These directories are the "first step in building an environment that opens new dimensions for sharing information across organizations" (EDUCAUSE, 2001).

With significant collaboration and information sharing across networks and between various academic, government, and corporate organizations, Internet2 and UCAID have recently approved an intellectual property framework. This framework addresses intellectual property, including hardware and software design, text, applications, documents, and innovations developed in connection with Internet2 activity.

CASE STUDIES

Case One: Internet2 and Sign Language Transmission

Gallaudet University, well known for its mission to educate a community of hard of hearing, deaf, and hearing students, has been a member of Internet2 since 1998. Cynthia King, Executive Director of Academic Technology, explains that Gallaudet has "long recognized the importance of a high-performance network—especially for sign language applications" (personal communication, May 25, 2002). Grants from IBM in 1998 and the National Science Foundation in 2001 have been used to explore and test video conferencing capabilities related to sign language transmission.

The traditional Internet has proved inadequate for the smooth flow of sign language streaming. Since April 2002, Gallaudet and the University of Tennessee—Knoxville have been conducting video conferencing experiments over Internet2. As King explains, "we are using the Delco Box, which is a Motion-JPEG system capable of 16-meg per second. This is about 20 times the typical best performance of H.323 video conferencing" (personal communication, May 25, 2002). Patrick Harris, Media Technical Designer at Galluadet, suggests that this advanced networking capability will "result in clearer high frame rate sign communication" (White, 2002).

As part of a Preparing Tomorrow's Teachers to Use Technology grant, education faculty have used the Internet2 connection to collaborate with other educators around the country. Thus far, the involvement of students has been limited; however, Dr. King explains that there are plans to involve students and faculty in the 2002–2003 academic year with the opening of a "new technology-rich" student academic center, which will commence the "official kick-off of the project where the Internet2 connection will be used more exclusively" (personal communication, May 25, 2002). A number of projects have been planned with a focus on science and education. Among these projects are the following: (a) some delivery of courses to schools in Pennsylvania that teach children in prekindergarten through 12th grade; (b) remote interpreting work with Gallaudet students who attend area universities for selected courses; (c) work with Gallaudet's regional centers to deliver instruction over the network; and (d) the continued Web casting of various Gallaudet events but with greater quality provided by the Internet2

Table 2 Research Interests, Working Groups, and Advisory Councils for Internet2 Technical Areas

Technical Area	Areas of Research	Working Group (WG), Sponsored Interest Groups (SIGs), Birds of a Feather (BoF) and Initiatives	Advisory Groups (AG) & Councils

connection. Dr. King further explains that there will be a continuation of faculty participation in curriculum and video-enhanced learning projects, with assistance from the academic technology staff, who will be instrumental in producing the digital media once the faculty have identified their curricular and video needs. "These related efforts will continue and be expanded in light of the new technologies we have available with Internet2" (personal communication, May 25, 2002).

A number of challenges remain. The biggest challenge, however, relates to the quality of video for sign language. Even with the advanced capabilities available through Internet2 networks, quality of service (QoS) issues need to be addressed. "We are interested in QoS issues, but understand that solutions won't be occurring in that space for some time" (personal communication, May 25, 2002).

Case Two: Crime & Punishment

In 1996, Kent Portney, Professor of Political Science at Tufts University, wished to provide his students with a better understanding of variability in criminal sentencing. He wanted his students to complete his undergraduate course on judicial politics and know how to isolate factors to explain variability in judicial sentencing. With the help of a FIPSE grant, he created a computer-based simulation entitled *Crime & Punishment,* in which the students act as judges. After being presented with real-life information about cases, the students sentence the defendants before them.

One of the challenges that presents itself when teaching variability of criminal sentencing in the classroom is that students have preconceived ideas about what causes variations in judicial sentencing. The goal of the *Crime & Punishment* simulation is to change those preconceived notions and help students to understand why judges sentence the way they do and to help students examine their own prejudices (Rosenberg, 1997).

Now in its third generation, the project has come a long way. Having Internet2 on the Tufts University campus allows quick access to the video in the simulation without loss of performance in displaying the video. Making this project available to students over Internet2 also accommodates several users simultaneously, without loss of speed or performance of the video. The current generation of this project allows all user inputs and case information to be stored in a database, which provides Portney access to his students' selections and sentencing decisions. This is critical when reporting information back to the students. Portney can manipulate the data received in the database and create graphs that represent students' choices and variability decisions based on the characteristics of the defendant.

Future generations and enhancements of this simulation are planned that will make full use of the collaborative nature of Internet2. Enhancements will make it accessible to other faculty members and allow all faculty to access the database of student decisions and compare their courses to other courses in this and other institutions. A longer term enhancement will allow other faculty to modify the simulation by adding their own video or cases, which would then become part of a large digital library for all users of the *Crime & Punishment* simulation.

Another significant achievement of this project is shown by the results of the learning assessments. Substantial learning effects have been shown as a result of students' interaction with this computer-based simulation. Students' misconceptions have been corrected because of their experience. The result is that students begin to look for more substantial and theoretical reasons for variation, focusing on theories of punishment and sentencing. As a result of using this simulation, Portney reports that student response to this simulation is "very well received and it is the highlight of his class" (personal communication, May 20, 2002).

As with any new-technology-based project, technical challenges are part of the territory. This project is no exception. The developers of *Crime & Punishment* struggled in the early stages to develop a model for capturing the real-life subjects in a video format. They have since developed a model that is efficient and that meets their needs. To optimize achievement of their enhancement goals, working with current Internet browsers and media players (such as RealPlayer), presents the challenge of maintaining control over what the end user experiences.

Although many years of research and development have gone into this successful project, Portney cautions that supplemental funding (such as this project's FIPSE grant) needs to be lined up before undertaking such an initiative and that it would be unacceptably frustrating to develop such highly interactive procedures if the appropriate resources were not in place.

CONCLUSION: PLAUSIBLE FUTURES FOR INTERNET2

Ted Hanss, Director of Applications Development for Internet2, suggests that "Internet2 networks are like a time machine, anticipating what may be possible in the future when everyone has access to high-speed broadband connections at home, school, and work" (Hanss, 2001). Such cutting-edge networks are also being planned by academic, government, business, and research communities worldwide. Canada, Europe, and Australia are developing advanced networks, such as CA*net3, Geant, and AARNet, making it possible to connect researchers from remote universities to resources ranging from real-time medical consultation to robust data sets. Such networks also have the potential to expand the capabilities of distributed computing by sharing work, space, and processing power to complete computations that are too sophisticated for even the current complement of supercomputers to handle.

In parallel with the Next Generation Internet (NGI) project sponsored by the U.S. government, Internet2 is focused on developing networking capabilities that will expand well beyond the capacity of the current Internet. NGI has significantly affected the Internet2 projects by directly funding connections between a number of academic institutions and the advanced networks of Abilene and vBNS+. These powerful connections have the potential to bring education to higher levels as institutions work together to develop new learning tools, collectively seek solutions to security issues, and strategically plan for future initiatives.

GLOSSARY

AARNet The Australian academic and research network; operates AARNet2 network, which provides Internet service to all 37 of Australia's universities.

Abilene An advanced backbone network that connects regional aggregation points (gigaPoPs) and supports the work of Internet2 universities.

CA*net3 The advanced Canadian research and education network developed by CANARIE.

Geant The pan-European academic and research network, reaching over 3,000 research and education communities in over 30 countries.

Gigabit Point of Presence (gigaPoP) A regional internetworking aggregation point used for accessing the Internet2 network.

H.323 An International Telecommunication Union (ITU) standard that allows transmission of Internet video conferencing over IP-based networks.

Internet Protocol version 6 (IPv6) Called the next version of the Internet protocol replacing Internet Protocol version 4, which is currently used by the current Internet.

Middleware The layer of software between the application and the Internet2 network, which provides services such as identification, authentication, and security.

University Corporation for Advanced Internet Development (UCAID) A nonprofit consortium of university members working in conjunction with corporations and others to provide leadership for advanced networking development.

vBNS+ (Backbone Network Service Plus) A very-high-performance, Internet2 backbone network.

Intranets

William T. Schiano, *Bentley College*

INTRODUCTION

An intranet is defined by the use of Internet technologies (HTTP, TCP/IP, FTP, SMTP) within an organization. By contrast, the Internet is a global network of networks connecting myriad organizations. The line becomes blurred when the internal system is opened to remote access and parts of the system are made available to customers and suppliers. This extension of an intranet to selected outsiders is often called an extranet. As networks continue to develop, distinctions among types of systems will become increasingly artificial and contrived, just as the once clear distinctions among hardware such as personal computers, servers, and minicomputers have lost meaning. When reading this chapter, concentrate on how the issues described may affect Internet technology-based systems within your organizations, rather than on the specific definition of any one system.

Because they are based on open Internet standards, intranets are easy to implement technologically. This can be a blessing and a curse. Although they can offer robust functionality with little investment, they are often rolled out with little forethought and therefore fail to make a significant contribution to the organization. This chapter outlines what intranets are; how they are used; the technologies for constructing and running them; how to implement, secure, and maintain them; and how to make them more efficient.

Much of the research and background information applicable to intranets is now being published in other areas. The technological issues overlap with the broader Internet, and many of the internal applications offered on intranets are now encompassed by enterprise applications and knowledge management. Some authors even refer to business-to-employee (B2E) applications (Hansen & Deimler, 2001), emphasizing the importance of focusing on the access to systems by those within the organization. This chapter draws on these and other literatures to offer a broad perspective on intranets and their application.

FEATURES OF AN INTRANET

Few organizations question the value of having an intranet in some form. Indeed, over 90% of major U.S. corporations have intranets (Baker, 2000). The benefits can range from a reduction of paper and headcount, always having the current version of any data or document available, to a central interface, or portal, and repository for all corporate systems and data. Intranets may encompass many different types of content and features. Other benefits include the use of Internet-standard network protocols that facilitate connections to the broader Internet.

Portal

> A door or gate; hence, a way of entrance or exit, especially one that is grand and imposing. (*Webster's Revised Unabridged Dictionary*, 1913)

Intranets are often designed to be "portals," serving as the central point of access to all information resources within an organization. The implication of grandiosity is deliberate and helpful, as good design can be a crucial determining factor in the success of an intranet. A portal also needs to be available regularly to a wide community, with access to multiple sources of data, both internal and external, with a useful search mechanism. The term portal often evokes third-party commercial portals such as Excite.com (http://www.excite.com) and vertical portals, also called vortals, such as aluminium.com (http://www.aluminium.com). These portals have struggled to establish successful business models, especially given the collapse of Internet advertising rates. Portals inside organizations, in contrast, have thrived, often with the support of the information systems (IS) department and the business users.

One of the greatest frustrations for information technology users inside organizations is the necessity of multiple systems with varied interfaces, including command-line based interfaces. With a portal, users have the ability to go to a single location, use a common, intuitive, and well-established graphical interface, and find their information. Types of the information and services found on intranets are outlined below.

Human Resource Materials

Human resource materials are an obvious and common type of content for intranets. Benefits management is a significant cost for organizations; tax withholding, health care election choices in the United States, and retirement and pension accounting all involve substantial processing costs. These processing costs include printing, distributing, completing, collecting, and entering data from paper forms, providing support to fill out the forms, and managing subsequent changes. With a well-designed intranet, employees can process their own benefits, saving substantial overhead and time. The forms tend to be highly structured, with well-defined fields, and the application can be scaled to all employees, reducing the cost of development per employee. These forms can also change regularly. Changing the online versions is much less expensive, and eliminates the possibility of employees filling out the wrong version of a form.

Human resources is also an excellent choice for intranet applications, particularly early in an intranet rollout, because every employee uses its services. Beginning with a common set of applications with which all or most employees interact may lead users to become familiar with other services located on the intranet as well. Self-service benefits also allow the human resource department to train less computer literate employees on an application that human resources knows intimately and that all employees must use (Meuse, 1999). This makes it an excellent introduction to the intranet. Unfortunately, most users only need to visit the employee benefits site once or twice a year, so the human resource function cannot be counted on to drive traffic throughout the year. However, newsletters can be published on the intranet, with notifications sent out via e-mail that may bring some traffic regularly.

Purchasing

For many organizations, especially larger ones, purchasing is a major cost that can be difficult to control. Managing the purchasing function and its information requirements is an inconvenience, and much of the cost is incurred in the overhead of processing purchases. The story of Ford's and Mazda's accounts payable departments has been retold many times and is famously cited by Hammer as an example of reengineering. Ford, with 500 people working in accounts payable, decided to compare itself to Mazda as a benchmark for its efficiency. Ford found that Mazda had only five people working in a similar department (Hammer & Champy, 1993). Although Mazda's efforts predated the Web, information processing was a crucial part of their efforts. This underscores the complexity and overhead often involved in purchasing. Intranets can greatly reduce purchasing overhead by simplifying the process and centralizing the collection of order data. Approval processes can be automated or at least facilitated, reducing paperwork and related clerical work.

Many office and maintenance, repair, and operations suppliers offer customizable versions of their product catalogs to be put onto client company intranets. This customization, which automates the process of billing and shipping, allows employees to order products directly without intervention from corporate purchasing departments. The order data are captured once, at the point of origin, stored in the appropriate database, and reused as needed without reentry, reducing mistakes and clerical staffing needs.

Operations

The intranet can be at the center of all operations for the company, serving in essence as an interface to all enterprise systems. This can include logistics, inventory, project management, and operational systems. With the increasing focus on customer responsiveness, time to market, and value chain integration, such operational transparency is becoming increasingly valued.

Directories

One simple, useful application is an electronic directory of employees. The directory can easily be kept current, and is regularly used by most employees, particularly if paper directories are no longer published.

Menus

Something as simple as cafeteria menus and catering information can be a useful tool to drive traffic to the site.

Calendar Systems

Centralized calendar systems are an excellent intranet application for many reasons. First, it is an extremely valuable service to all users who schedule meetings or other appointments. It is also something most people are likely to use on a daily basis. Benefits include the reduction of time spent in arranging meetings or other events, the elimination of "double booking," and the increased efficiency of all involved staff.

The system may be used to schedule meetings and conference rooms and to coordinate individual schedules. Such technologies can also synchronize personal digital assistants (PDAs), allowing employees to keep their calendars with them and also have them stored centrally.

Organizations may also enable the PDAs to access the intranet remotely via wireless technologies including WiFi and Bluetooth. Convergence of standards, advances in security, and decreasing hardware cost make such wireless access relatively inexpensive and viable.

Intranets may also include time clocks. As organizations move closer to activity-based costing, they require additional data on employee productivity. In particular, as more employees become knowledge workers, time tracking becomes an increasingly valuable tool and intranet applications make the input and analysis of these data easier, with widely accessible, familiar, intuitive graphical interfaces.

Group Collaboration

An increasing amount of work in organizations is being done by multiple people working collaboratively in disparate geographic locations, often at different times. Many intranet- and Internet-based applications are available to support such work. These systems include those for group authoring, document management, change control, moderated and threaded message boards, shared whiteboards, and workflow management software. Benefits of these applications can be realized by employees working on-site and remotely, making the intranet a necessary component of any organization's attempts to expand remote work arrangements such as telecommuting, hoteling, and accommodating those employees who are frequently on the road.

Hewlett–Packard found that such traditional group collaboration tools were not sufficient because they lacked the "causal proximity" necessary for productive group work. They implemented passive cameras to indicate whether someone was at or near their desk, and included an intercom-enabled telephone system and instant messaging, to foster regular, brief conversations (Sieloff, 1999). Such richer media helped emulate the benefits of working in the same physical location.

Syndicated Data

Many organizations make regular use of purchased external data feeds for strategic and operational work. Stock prices, weather, and news streams may all be purchased and made available through the intranet, customized for users based on their needs. Coordinating these streams requires careful management to balance easy access to current data with security.

Knowledge Management

Knowledge management has received a great deal of attention in the business and popular press. As organizations move away from manufacturing toward services, more knowledge is in the minds of workers than embedded in physical systems, or even documentation. This increases the cost of employee turnover and can impede growth.

Part of the challenge of knowledge management is uncovering, storing, and retrieving tacit knowledge. While many organizations struggle with simply managing explicit knowledge that can be readily articulated and documented, the greatest benefits often come from capturing tacit knowledge. The regular use of an intranet may encourage employees to routinely store information and knowledge and make explicit previously tacit knowledge.

Given the volume of information created in organizations, not only is indexing and retrieval important, but forgetting is also crucial. Archiving functions can move information out of the main databases to improve the relevancy of searches.

Implementing an intranet can fundamentally change the nature of the organization by reorganizing its business processes. By doing so, intranets can be a powerful lever of control (Simons, 1995), serving as a catalyst for change. General Motors credits its intranet, which links GM's 14 engineering centers with computer-aided design software and 3-D simulators, with an increase in creativity and even now recruits from the motion picture industry rather than just fine arts and automotive design programs (Rifkin, 2002) to take advantage of the Web-based skills. Such intranet-driven changes are so common that Pitt et al. have developed I-CAT, an instrument to measure the effectiveness of an intranet as a catalyst for change (Pitt, Murgolog-Poore, & Dix, 2001).

Technology

The technology for intranets is straightforward and similar to any other Web-based system. If the corporate network is TCP/IP, as most are, then starting an intranet site is as simple as placing a machine on the network, or finding one already connected, and installing or enabling a Web server. Current versions of Microsoft Windows desktop and server software come with Web servers installed and can be easily configured by anyone comfortable with personal computers. Once the server is up and running, the server may operate in background on an employee's ordinary PC workstation. Other employees may access the server by entering the IP address of the machine. Obviously, most users would prefer to type in a text domain name rather than a series of numbers. Such a text name would require either registration on the company's domain name server, which maps IP addresses to text names, or the use of Windows Internet Name Service (WINS), which serves the same purpose as DNS, but on Windows networks.

Content may be added to the Intranet in the form of HTML pages, which may be coded by hand, saved as HTML from word processors such as Microsoft Word, or written in HTML editors such as FrontPage and DreamWeaver. Simple programs may also be written to generate content in response to requests on the intranet through scripting in such languages as Cold Fusion, UltraDev, JSP, ASP, and Perl. HTML editors can generate simple scripts automatically for novice users. Such dynamic Web pages allow greater flexibility in the design of intranet Web pages.

Establishing the corporate portal/intranet as the access point for all information services is an appealing architecture for the IS department. Assuming the workstations are Windows-based, then all that needs to be installed on each machine is Microsoft Office with the Internet Explorer Web browser. This simplicity greatly reduces the support necessary for personal computers on the network because every employee in the company receives an identically configured computer with only standard Microsoft applications. This simplicity is one overarching benefit of an intranet over legacy network systems, since the need for individual computing support is significantly reduced by the common hardware and software, and user access is enabled through graphical, largely intuitive, interfaces.

All major software vendors have addressed the intranet market. Microsoft is working aggressively to integrate its desktop productivity software in Office with Web-based intranet tools, including video, Exchange server, and Microsoft Project (Microsoft, 2002). Microsoft even ships wizards for the creation of intranets, such as the 60 Minute Intranet Kit. Server software vendors such as Sun, IBM, and open-source Apache all offer intranet configuration suggestions and options for network and systems administrators familiar with those companies' products.

Enterprise system vendors have also focused heavily on Web-based access in the past several years. In that time, SAP, PeopleSoft, Baan, Oracle, and JD Edwards have all launched enterprise portal products to integrate their systems with a Web interface and other corporate intranet applications. Customer relationship management products such as Applix and Siebel have also launched portal interfaces in response to demands from the corporate market. The intranet/Web browser has become a common and accepted interface for corporate applications.

Extensible markup language (XML) is rapidly gaining support as a standard for Web documents. This is good news for intranets for several reasons. First, XML, with its focus on metadata, supports the complex, structured documents that populate most intranets. Second, as XML becomes a standard format for word processors, saving files to the intranet will become even easier. This approach has gained attention since Microsoft announced it intends to base its Office applications on XML. Finally, XML documents can be readily stored in databases and searched and retrieved quickly and easily, improving performance for large intranets.

Dot-coms were a major market for many of the software vendors who also compete in the intranet software market. With the collapse of the dot-coms, prices for Internet, and therefore intranet, software have dropped considerably. In addition, open-source software is becoming more robust, offering much less expensive alternatives to the major software vendors. Many companies use the open-source Apache suite to develop and manage their corporate intranets, and most major software vendors have started to support interface with Apache and other common open-source products.

As intranets grow, and increasing amounts of data are available, there must be a way to find information effectively. Information anxiety (Wurtman, 1989) is an inevitable challenge for intranets, given the volume of data likely to proliferate. Hewlett–Packard, for instance, found that within two years of launching its intranet, there were over two million documents stored on thousands of servers throughout the organization, and fewer than 5% of them were traditional official communications (Sieloff, 1999). Such volumes make information architecture (Rosenfeld & Morville, 2002) essential. Information architecture is a crucial component of successful intranets, and the hierarchical structure and navigation themes must be well thought out and implemented. An efficient and effective search engine available for the entire intranet is also required. Many organizations license third-party search engines to reduce the problems inherent in searching the wide variety and amount of information stored in an intranet.

Unless entries are key worded with metadata, users' searches are reduced to full-text searches, which are likely to return massive numbers of hits even with the best search engines. Proper metadata coding requires an appropriate taxonomy. Such a taxonomy may be available within the industry, or extant in the organization. If not, a thorough metadata taxonomy must be developed and implemented. Without a pre-hoc taxonomy, it is unlikely the metadata will be very useful. One survey found that only 31% of companies with enterprise portals had implemented a taxonomy (Answerthink, 2002), emphasizing the need for corporate information metadata management.

Establishing a taxonomy is only the first step; it must be used correctly and consistently to be effective. This requires all of those entrusted with entering data to use the taxonomy properly. This can be accomplished by simplifying the taxonomy so that there is no ambiguity in the interpretation, and there must be documentation and/or training to ensure consistency of the taxonomy's application at all data entry points. It is also likely that the taxonomy will need to evolve over time, requiring a plan for maintenance and continued training.

It may be possible to post much of the content on the Intranet with limited metadata coding because most users would find the content via browsing, or the search engine would likely find it and rate it as highly relevant.

Personalization

For users, having the most applicable material readily accessible can be extremely powerful and empowering. Customization strategies for intranet access can be individualized or group based. For example, a different interface can be developed for selective categories of employees, offering some customization at low cost, or personalization software can be installed to generate pages based on an individual's expressed or inferred preferences or behaviors. Most Web servers, including Microsoft IIS, iPlanet, and Apache, now come with basic personalization functionality.

However, Web developers have found that personalization is not a silver bullet. Indeed, Yahoo!, one of the largest personalizable sites on the Web, learned that most users, if given the choice, do not customize their interfaces (Manber, 2000). This makes designing the default pages and customizations more important than extensive customization options. Yahoo! also discovered that any customizations applied in one section of the site should apply to all areas, or users will become frustrated because they expect to need to set up customization only once. Yahoo! did find that a cadre of power users customized their interfaces beyond all expectations of the developers. Lessons learned from these power users can be applied to other users through redesign of the default or group-customized pages, underscoring the power of an information architecture steering group with input from all user groups.

Content Management

The Yankee Group outlines a three-stage content delivery cycle: creation, management, and presentation (Perry, 2001). Content management systems such as Vignette and Interwoven's TeamSite manage all three of these stages by storing all Web site data in a database. They facilitate content management by accepting external and internal automated data streams through syndicated, operational, and financial data, and receive input from publishers throughout the organization in word processing, spreadsheet, presentation, XML or HTML formats. These systems manage the data with change control, security, and workflow tools. Content management systems handle presentation by working with application servers such as BEA's WebLogic and IBM's WebSphere, to create pages based on templates created by designers.

For large intranets, content management can be a worthwhile solution. Much of the data on the intranet changes regularly, and updating a database is more efficient than making changes to all Web pages that contain it. Content management systems facilitate the distribution of intranet content over multiple channels, including multiple Web sites, possibly including externally accessible sites, high- and low-bandwidth versions, wireless/mobile, syndication, and even hard copy. Document management systems such as Documentum and Hummingbird and even document imaging software serve a similar purpose. In general, all of these products are evolving toward enterprise content management.

Ease of Use

The importance of usability is well established for all Web sites. In addition, usability has been linked to effective knowledge management (Begbie & Chudry, 2002). For intranets to be effective, they need a wide array of users across the organization. Providing extensive training and technical support to all users is not likely to be possible for reasons of cost and logistics. As employee turnover rises, reducing the learning curve for using the intranet becomes more important. Therefore the intranet must be well designed and simple to use.

IS DEPARTMENT INTRANET CHALLENGES

While intranets may be developed easily within departments with little support from IS, if the intranet is to scale and to function well, there are several areas the IS department must address. Indeed, intranets are likely to fundamentally change the nature of systems analysis and design, as users become more intimately involved in the process (Perry, 1998).

Standards vs Flexibility

The question of how much to constrain users in the interest of promoting standards for efficiency has plagued information systems professionals for decades. With intranets, the implications are substantially greater, as many people in the organization become, essentially, systems developers.

Controlling the use of spreadsheets and other personal productivity software was hard enough, but at least those systems were only accessed by one user, or perhaps disseminated over a sneaker net. With intranet data, potentially the entire organization has access to what is developed, and the developers have no formal training in systems analysis or design. Substantial duplication may arise, adding to costs and confusion. Poorly designed applications or content may lead to user rejection of the intranet, despite realizing other benefits.

The power of such distributed systems lies in the empowerment of employees with access to the data, and the ability to enter and manipulate it online. This empowerment is consistent with the principles of reengineering, "just in time," customer relationship management, supply chain management, and other management trends of the past several decades: enter data only once, at the source.

Intranet standards can be set for data storage, color schemes, templates, navigation, file naming, graphics formats, file formats, file sizes, and narrative voice. Content management systems can automate much of this standardization, and also establish approval processes for implementation.

Intranets have the benefit of limited or no access by those outside the organization, and this insulation offers many a false sense of security about the lack of need to protect the brand image. It is likely that much of the data on the intranet will make its way to suppliers and customers, whether indirectly or directly, because a successful intranet will be the primary source of information throughout the organization.

Availability

Once an intranet site is established, IS will be held responsible for ensuring that the site is available whenever needed. This may mean 24/7 in some instances. For a traditional system, with a limited number of professional developers operating in a staged development environment with source control on systems running in a data center, this is a well-solved problem, depending on resource constraints. However, for systems often hosted within departments outside IS control, and developed by untrained personnel, keeping the systems running can be a challenge. One poorly constructed script can bring a system to its knees and make diagnosis difficult. These systems are often not backed up, and nearly all lack any form of source control. However, such carelessness is not inevitable, and traditional IS methodologies may be applied to ensure the reliability of intranets.

Training and Support

As applications and services are moved onto the intranet, and traditional physical channels are closed down, there will be a significant need for training and support. Often the systems are brought live by departments without thought of the need for training personnel, but the support demands are made to the IS department. A training program can obviate many of the support calls, but requires a coordinated effort and a willingness on the part of departments to support in principle, if not financially, such training programs. Given the expense of lost productivity, such programs are often politically unpopular, but necessary for a successful implementation of any internal system.

Support for the systems is also a challenge because these applications may change frequently and the IS department may not have been involved in their construction. It is unrealistic, however, to believe that the call center, or its equivalent in smaller companies, will not be the main source of intranet support, whether de facto or de jure. Successful, sustainable intranets involve the IS department, especially for support.

Access

For the intranet to achieve its potential, it must displace other channels such as paper, phone, in person, and even e-mail. As these other channels are shut down, many employees who did not previously need access to a computer now need it to manage their benefits, enter a request for a repair with physical plant, look up a phone number, etc. This means providing access to all employees, many of whom have never needed computers before. Custodial staff, warehouse employees, and others may not need individual workstations, but do need convenient access to a computer connected to the intranet. This may mean extending the network to areas of buildings previously left unwired. While modern construction and wireless technologies make this less of an issue than previously, there may still be significant expense and effort to ensure intranet access to all. Access must also be established to legacy software systems that may not be Web-enabled.

Networks

Intranets may be more secure and reliable than the external Internet because companies have control over the network and servers on which they run. Intranet access may substantially increase the need for bandwidth on the network. Bandwidth demands can easily grow exponentially when an intranet is introduced, especially as the cost of multimedia hardware continues to drop. Although the cost of bandwidth is also dropping, the complexity of network management increases substantially as more bandwidth is used. Also, as demand for the services increases, the need for network reliability also rises. Good networks are more than bandwidth. As more work is intranet-based and dependent on the corporate network, availability, reliability, service, support, and scalability of the network all become crucial.

Security

> If a Sun employee attaches a modem inside our network without going through the firewall, he's fired. —Sun Microsystems chief network officer Geoffrey Baebr (*Information Week*, 1997)

Intranets may contain a great deal of sensitive personal and organizational data. These clearly need to be protected. The fact that intranets are for internal use only offers some a false sense of security. This laxity can lead to greater risks if there is any exposure to external access.

Intranet security is similar to security for any Web-based system, but potentially more complex because of the larger number of people with authorized access. When the Navy began implementing its Navy/Marine Corps Intranet (NMCI), it quickly found that the U.S. Department of Defense Information Technology Security Certification and Accreditation Process (DITSCAP) was difficult to apply. The Department of Defense needed to adapt the process to fit the needs of intranet development (Gerstmar, 2002).

Given that most security lapses are from authorized users within the organization, intranets create numerous potential breaches. Access controls for data and process may be set at the operating system, directory, application server, and Web server levels. Authorization can be done through passwords, or even biometrics, depending on the value of the information. Firewalls can be established not only at the border with the Internet to keep those outside the organization out, but also inside the organization to limit access to authorized employees.

Implementation

> Get the chairman in early, but get him out quick.
> —Alan Boehme, DHL Director of Business Planning (*InformationWeek*, 1997b)

It is well established that top management support is a crucial factor in the success of all information systems implementations. However, it is not always sufficient. Many intranets are small, bootstrapped applications implemented with little fanfare. For an intranet to be successful, the goals for the initiative must be articulated. This involves determining the audiences for the system, the services to be offered, and the extent to which they are to be used. Once the goals are known, then metrics can be established for measuring success. With metrics in place, a plan can be created for implementing the system. This is another reason to have a corporate information systems architecture that covers the development, implementation and maintenance of all intranets.

Run a Pilot Study

Because intranet systems are Web-based, prototypes are easy and generally inexpensive to build. This makes pilot testing an effective tool for determining the relevance of this technology in relation to a company's needs. However, it is important to keep in mind the goal of the pilot study. Many people incorrectly view pilot studies as always determining definitively whether a given system will work within the target community. Rather, most initial pilot studies should be tests for proof of concept, and should be repeated several times in different areas of the organization to ensure the generalizability of the concept test.

If the pilot is testing for proof of concept, then the population chosen for the test should be the one likely to adopt it. The initial pilot will be closely watched by many in the organization, and a failure could set the project back significantly. Participation in the pilot study is also an opportunity for potential users of the production system to invest psychologically in it. Potential users may be coopted into adopting the technology by being brought into the development process as well as testing. IS research has shown that involvement in the design process makes people more likely to support and use the intranet system when implemented, and with intranet technologies, these people can be involved not only in the abstract design but in the actual construction, increasing their actual and perceived investment in the system, and therefore the likelihood of their support.

Successful intranets require momentum to achieve critical mass. Gladwell (2000) refers to a tipping point, where phenomena, including technology adoptions, either succeed or fail. Gladwell notes three factors that determine the tipping point of a technology: the law of the few, stickiness, and context.

The law of the few reflects the fact that not all users or decision makers are equally influential. Gladwell identifies three types of people that are particularly influential: connectors, who know and interact with a large number of people; mavens, who are considered experts in a given area; and salespeople, who will advocate for a position in which they believe. When implementing an intranet, identifying and engaging people from each of these groups is crucial to the project's success.

Stickiness reflects the extent to which something is memorable. The term stickiness is often used in reference to Web pages to describe how long visitors stay. Time spent by visitors is an easily gathered measure of user interest in a page or site.

Finally, context refers to the way in which information about the innovation or technology is disseminated. For instance, something advocated by members of the business units is likely to be more successful than something promoted by an e-mail from the IS department.

When the concept has been firmly established as viable, and there is support within the organization, then a representative group that will be more likely to predict success in the organization as a whole may be chosen.

Once the system is implemented, it is essential to eliminate other sources of the same information or service. This can be done drastically or gradually. For instance, calls to the help desk or human resources could ask whether the employee has gone through the Web site. If she/he has not accessed the intranet before calling for support, IS or HR staff could offer to guide the caller through the site for resolution before providing an answer directly.

Maintenance and Management

A major component of a successful intranet is a plan for its control. The first obvious question is who should control it. Four common configurations have emerged: IS, corporate, human resources, and distributed. Any one of the models may work, depending on the goals of the intranet and the structure of the organization.

With the IS department in control of the intranet, the technology is likely to be well aligned with the existing systems and architecture, making it more reliable. However, in terms of prioritization, the IS department is likely to be the worst choice for deciding what needs to be updated first. At a minimum, putting IS in charge adds an additional layer of control beyond the creators of the content. Technologies such as content management can make it more viable for business units to control the system.

In a corporate structure, there is a decision maker within the organization who oversees the business units involved in the intranet. This person makes strategic decisions about the intranet. Tactical decisions may be delegated farther down the organization. The systems themselves may be built by the business units or the IS department.

Although human resources applications are among the most common and heavily used functions of intranets, as more operational information is added, most human resource departments are ill equipped to manage the systems.

The distributed model is appealing because the subject matter experts can be put in control of the data. With content management systems supported by the IS department, this model can be viable as the business users are relieved of responsibility for design, but retain control of content.

A plan for maintenance of the system is crucial. At a minimum, such a plan should address how often the information should be updated, who is responsible for removing out-of-date information, how information will be archived, and how often the design should be revisited. Redesigns should have a formal structure and budget process (Fichter, 2001). There should also be a disaster recovery plan commensurate with the importance of the intranet. Depending on the organizational value of the intranet, the plan for business continuity in the event of a disaster may range from periodic backups with a restoration plan, to off-site mirrored servers.

An acceptable use policy is an integral part of any intranet plan. Such a plan makes clear what is appropriate for the intranet, and may also include guidelines for Internet access as well. Although filters can be helpful in reducing inappropriate content, they are not a substitute for a well-articulated policy. For guidelines on creating an acceptable use policy, see Lichtenstein and Swatman (1997).

Cost/Benefit Calculations

Calculating the value of information technology has been the subject of extensive research over the past decade. The term productivity paradox is often used to describe the argument that despite rapid increases in spending on information technology, there is not a concurrent increase in productivity.

Measuring the return on intranet investments poses the same complexities as other information systems: calculating all of the costs involved is difficult and attributing benefits to them is even more challenging. However, such calculations are feasible, and there is reason to believe that a well-planned intranet can be profitable (Healey, 2001).

Among the obvious and easily calculated costs of an intranet are the hardware and software required for the servers, including any support contracts, and development software purchased. The costs of development may be relatively easy to measure for IS personnel involved in the system construction if they are contracted, or if the internal IS shop tracks costs on a project basis. However, much of the construction will involve the time of those outside IS, and there may be no extant tools for tracking their time, nor easy access to data on the cost of their time. Network costs for running the intranet may not be easy to track, because both utilization and marginal cost would need to be calculated. A methodological change in how such costs are calculated could make the difference in positive or negative ROI. Training costs must be included, both for the trainers' time in development and delivery and also lost productivity for trainees.

Application service providers can provide all of the infrastructure and functionality of an intranet for an organization with only an Internet connection. Infostreet.com (http://www.infostreet.com), Intranets.com (http://www.intranets.com), and others offer a broad array of cost-effective intranet services to companies of all sizes.

The decision to outsource intranet development is much like the "make or buy" decision for types of information technology. Organizations must decide what, if any, aspects of the intranet should be produced or maintained outside the organization.

While cost calculation is difficult, benefit calculation is even more difficult. Benefit calculation should include obvious direct cost reductions such as headcount, paper, and software licenses. One commonly used metric for efficiency is to credit the system for the pro-rated salary saved by using the intranet rather than the previous methods. However, this makes the assumption that all of the difference is saved. In many cases, the previous methods were not a complete loss; for instance, workers were doing other work while on the phone, or filled out forms during their commute. Not all of the recovered time will be used productively. Potentially more important than such bottom line cost reductions are top line enhancements in revenue. However, such improvements are harder to measure. Specifically, has the intranet contributed to better service, higher quality products, or improved time to market? If so, how much is that worth to the organization?

One excellent source of metrics for evaluating an intranet is the server access logs. All page accesses are automatically logged, along with the time and date of access, IP address of the user, which can be mapped to the specific intranet user, and the referring page, if any. These data may be analyzed to determine how employees are using the intranet and to identify potential enhancements. Estimates of the most and least popular pages, typical paths through the site, most used search terms, performance data, and other metrics are easily generated with simple analysis tools. This can be supplemented with direct surveys of users, online and through other channels.

WHY DO INTRANETS FAIL?

Many surveys show intranet initiative failure rates over 50%. Of course, it is important to keep this number in perspective, as surveys show similar percentages of all IS projects fail. These rates of failure may reflect unrealistic goals in some organizations, but often there are fundamental causes for failure. This section outlines common reasons for failures of intranets.

Other Channels Are Not Shut Down

Electronic systems only save paper if the paper versions are eliminated. If an employee handbook is still printed, then the intranet version is simply an added cost, and confusion arises about which version is correct.

Intranet Is Not Used

Many intranet systems languish after expensive and extensive construction. Often organizations do not bother to track intranet access, failing to identify the lack of interest earlier.

No Maintenance

Many intranets fall victim to good intentions. Intranets are often implemented, but are not made anyone's primary responsibility. There is often an initial burst of energy, but then no information is updated.

Poor Planning

Many intranets are implemented without adequate consideration of the issues described above.

Inadequate Content

In some cases, there is simply not enough reason to visit the intranet to sustain it.

Poor Performance

Intranets are likely to see lumpy access patterns, and the machines should be specified to handle these peak demands. Intranets are often implemented on disused hardware because intranets are rarely a budget priority. Poorly optimized databases can quickly bog down under volume.

Poor Interface Design

Many intranets are designed by people inside the organization with little or no design training, leading to obtuse and cumbersome systems and user frustration.

CONCLUSION

Intranets can be useful for organizations of any size to improve communication and information dissemination, and to lower costs. Powerful tools can be installed and configured quickly with relatively low investment. The technologies have standardized and are reliable and reasonably priced. Qualified, experienced personnel are readily available to build and maintain intranets. Success in intranet development and management simply requires the application of traditional business and information systems skills for establishing goals, planning, employing the proper architecture and technologies in response to business needs, and measuring outcomes.

GLOSSARY

Acceptable use policies How users may employ a system.

Content management systems Systems that use databases to store text, graphics, and other material to be displayed on a Web site, and then dynamically build pages based on previously designed templates.

Extensible markup language (XML) A language for describing the content and format of documents containing structured information.

Extranets Corporate systems containing sensitive data made accessible over the Internet to selected customers, suppliers, and business partners.

Information architecture The modeling of the structure of a Web site, including functionality and data, based on articulated goals.

Intranets Systems that use Web technologies such as HTTP, TCP/IP, FTP, and SMTP within organizations to facilitate communication and the distribution of information.

Knowledge management The process of making explicit and codifying the knowledge in an organization.

Hoteling An office configuration that allocates space temporarily on a first-come, first-served basis, similar to a hotel stay rather than assigning permanent space to workers who may not spend all of their time in the office.

Metadata The structure and content of data to facilitate future use of the data, particularly for searching.

Portals Web pages or sites that aggregate access to information and to other systems, serving as a starting point for users.

Reengineering The process of redesigning business processes to achieve radical improvements.

Scripting languages Programming tools for handling simple processing needs, two popular Web ones being Perl and JavaScript.

Self-service benefits The online management by employees of their human resource benefits administration without intervention by support staff.

Syndicated data Feeds that may be purchased to provide consistent or streaming updates such as weather, news, and stock prices.

Intrusion Detection Techniques

Peng Ning, *North Carolina State University*
Sushil Jajodia, *George Mason University*

INTRODUCTION

Intuitively, *intrusions* in an information system are the activities that violate the security policy of the system, and *intrusion detection* is the process used to identify intrusions. Intrusion detection has been studied for approximately 20 years. It is based on the beliefs that an intruder's behavior will be noticeably different from that of a legitimate user and that many unauthorized actions will be detectable.

Intrusion detection systems (IDSs) are usually deployed along with other preventive security mechanisms, such as access control and authentication, as a second line of defense that protects information systems. There are several reasons that make intrusion detection a necessary part of the entire defense system. First, many traditional systems and applications were developed without security in mind. In other cases, systems and applications were developed to work in a different environment and may become vulnerable when deployed in the current environment. (For example, a system may be perfectly secure when it is isolated but become vulnerable when it is connected to the Internet.) Intrusion detection provides a way to identify and thus allow responses to attacks against these systems. Second, due to the limitations of information security and software engineering practice, computer systems and applications may have design flaws or bugs that could be used by an intruder to attack the systems or applications. As a result, certain preventive mechanisms (e.g., firewalls) may not be as effective as expected.

Intrusion detection complements these protective mechanisms to improve the system security. Moreover, even if the preventive security mechanisms can protect information systems successfully, it is still desirable to know what intrusions have happened or are happening, so that we can understand the security threats and risks and thus be better prepared for future attacks.

In spite of their importance, IDSs are not replacements for preventive security mechanisms, such as access control and authentication. Indeed, IDSs themselves cannot provide sufficient protection for information systems. As an extreme example, if an attacker erases all the data in an information system, detecting the attacks cannot reduce the damage at all. Thus, IDSs should be deployed along with other preventive security mechanisms as a part of a comprehensive defense system.

Intrusion detection techniques are traditionally categorized into two methodologies: *anomaly detection* and *misuse detection*. Anomaly detection is based on the normal behavior of a subject (e.g., a user or a system); any action that significantly deviates from the normal behavior is considered intrusive. Misuse detection catches intrusions in terms of the characteristics of known attacks or system vulnerabilities; any action that conforms to the pattern of a known attack or vulnerability is considered intrusive.

Alternatively, IDSs may be classified into host-based IDSs, distributed IDSs, and network-based IDSs according to the sources of the audit information used by each IDS. Host-based IDSs get audit data from host audit trails and usually aim at detecting attacks against a single host; distributed IDSs gather audit data from multiple hosts and possibly the network that connects the hosts, aiming at detecting attacks involving multiple hosts. Network-based IDSs use network traffic as the audit data source, relieving the burden on the hosts that usually provide normal computing services.

This chapter starts with an overview of current intrusion detection techniques. Next, it reviews the various types of anomaly detection methods, such as statistical models and machine learning methods, followed by an overview of various types of misuse detection methods, including rule-based languages, the colored Petri-net-based method, and the abstraction-based method. The section following that discusses additional techniques for intrusion detection in distributed systems, including distributed IDSs, network-based IDSs, and interoperation between (heterogeneous) IDSs.

ANOMALY DETECTION

Statistical Models

Statistical modeling is among the earliest methods used for detecting intrusions in electronic information systems. It is assumed that an intruder's behavior is noticeably different from that of a normal user, and statistical models are used to aggregate the user's behavior and distinguish an attacker from a normal user. The techniques are applicable to other subjects, such as user groups and programs. Here, we discuss two statistical models that have been proposed for anomaly detection: NIDES/STAT and Haystack.

NIDES/STAT

The Stanford Research Institute's next-generation real-time intrusion detection expert system statistical component (NIDES/STAT) observes behaviors of subjects on a monitored computer system and adaptively learns what is normal for individual subjects, such as users and groups (Axelsson, 1999). The observed behavior of a subject is flagged as a potential intrusion if it deviates significantly from the subject's expected behavior.

The expected behavior of a subject is stored in the profile of the subject. Different measures are used to measure different aspects of a subject's behavior. When audit records are processed, the system periodically generates an overall statistic, T^2, that reflects the abnormality of the subject. This value is a function of the abnormality values of all the measures comprising the profile. Suppose that n measures $M_1, M_2, \ldots, M_n$ are used to model a subject's behavior. If $S_1, S_2, \ldots, S_n$ represent the abnormality values of M_1 through M_n, then the overall statistic T^2 is evaluated as follows, assuming that the n measures are independent of each other:

$$T^2 = {S_1}^2 + {S_2}^2 + \cdots + {S_n}^2.$$

The profile of a subject is updated to reflect the changes of the subject's behavior. To have the most recently observed behaviors influence the profile more strongly, NIDES/STAT multiplies the frequency table in each profile by an exponential decay factor before incorporating the new audit data. Thus, NIDES/STAT adaptively learns a subject's behavior patterns. This keeps human users from having to manually adjust the profiles; however, it also introduces the possibility of an attacker gradually "training" the profile to mask his/her intrusive activities as normal behavior.

Haystack

Haystack used a different statistical anomaly detection algorithm, which was adopted as the core of the host monitor in the distributed intrusion detection system (DIDS) (Axelsson, 1999). This algorithm analyzes a user's activities according to a four-step process.

First, the algorithm generates a session vector to represent the activities of the user for a particular session. The session vector $\mathbf{X} = <x_1, x_2, \ldots, x_n>$ represents the counts for various attributes used to represent a user's activities for a single session. Examples of the attributes include session duration and number of files opened for reading.

Second, the algorithm generates a Bernoulli vector to represent the attributes that are out of range for a particular session. A threshold vector $\mathbf{T} = <t_1, t_2, \ldots, t_n>$, where t_i is a tuple of the form $<t_{i,min}, t_{i,max}>$, is used to assist this step. The threshold vector is stored in a user's profile. The Bernoulli vector $\mathbf{B} = <b_1, b_2, \ldots, b_n>$ is generated so that b_i is set to 1 if x_i falls outside the range t_i, and b_i is set to 0 otherwise.

Third, the algorithm generates a weighted intrusion score, for a particular intrusion type, from the Bernoulli vector and a weighted intrusion vector. Each group and intrusion type pair has a weighted intrusion vector $\mathbf{W} = <w_1, w_2, \ldots, w_n>$ in which each w_i relates the importance of the ith attribute in the Bernoulli vector to detecting the particular intrusion type. The weight intrusion score is simply the sum of all weights, w_i, where the ith attribute falls outside the range t_i. That is,

$$\text{the weighted intrusion score} = \sum_{i=1}^{n} b_i \cdot w_i.$$

Finally, the algorithm generates a suspicion quotient to represent how suspicious this session is compared with all other sessions for a particular intrusion type. Specifically, the suspicion quotient is the probability that a random session's weighted intrusion score is less than or equal to the weighted intrusion score computed in the previous step.

Unlike NIDES/STAT, the Haystack algorithm has a step that determines resemblance to known attacks. The advantages are that more knowledge about the possible attacks can be derived from this step and better responses can follow the alarms. However, extra knowledge about possible intrusion types is required: We need to understand the impact of the intrusion types on the attributes of the session vectors and assign appropriate weights to these attributes to reflect the impact. In reality, the process of generating the weighted intrusion vectors is time consuming and error prone.

Machine Learning and Data Mining Techniques

Time-Based Inductive Machine

Teng, Chen, and Lu (1990) proposed the use of a time-based inductive machine (TIM) to capture a user's behavior pattern. As a general-purpose tool, TIM discovers temporal sequential patterns in a sequence of events. The sequential patterns represent highly repetitive activities and are expected to provide prediction. The temporal patterns, which are represented in the form of rules, are generated and modified from the input data using a logical inference called *inductive generalization*. When applied to intrusion detection, the rules describe the behavior patterns of either a user or a group of users based on past audit history. Each rule describes a sequential event pattern that predicts the next event from a given sequence of events. An example of a simplified rule produced in TIM is

$$E1 - E2 - E3 \rightarrow (E4 = 95\%; E5 = 5\%),$$

where $E1$, $E2$, $E3$, $E4$, and $E5$ are security events.

This rule says that if $E1$ is followed by $E2$, and $E2$ is followed by $E3$, then there is a 95% chance (based on the previous observation) that $E4$ will follow, and a 5% chance that $E5$ will follow. TIM can produce more generalized rules than the above. For example, it may produce a rule in the form

$$E1 - {}^{*} \rightarrow (E2 = 100\%),$$

where an asterisk matches any single event. Any number of asterisks is allowed in a rule.

The limitation of TIM is that it only considers the *immediately following* relationship between the observed events. That is, the rules only represent the event patterns in which events are adjacent to each other. However, a user may perform multiple tasks at the same time. For example, a user may check his/her e-mail during the editing of a document. The events involved in one application, which tend to have strong patterns embedded in the sequence of events, may be interleaved with events from other applications. As a result, it is very possible that the rules generated by TIM cannot precisely capture the user's behavior pattern. Nevertheless, TIM may be suitable for capturing the behavior patterns of such entities as programs that usually focus on single tasks.

Instance Based Learning

Lane and Brodley (1998) applied *instance based learning* (IBL) to learn entities' (e.g., users) normal behavior from temporal sequence data. IBL represents a concept of interest with a set of instances that exemplify the concept. The set of instances is called the instance dictionary. A new instance is classified according to its relation to stored instances. IBL requires a notion of "distance" between the instances so that the similarity of different instances can be measured and used to classify the instances.

Lane and Brodley did several things to adapt IBL to anomaly detection. First, they transformed the observed sequential data into fixed-length vectors (called *feature vectors*). Specifically, they segmented a sequence of events (e.g., a sequence of user commands) into all possible overlapping sequences of length l, where l is an empirical parameter. (Thus, each event is considered the starting point of a feature vector, and each event is replicated l times.) Second, they defined a similarity measure between the feature vectors. For a length l, the similarity between feature vectors $\mathbf{X} = (x_0, x_1, \ldots, x_{l-1})$ and $\mathbf{Y} = (y_0, y_1, \ldots, y_{l-1})$ is defined by the functions

$$w(\mathbf{X}, \mathbf{Y}, i) = \begin{cases} 0, & \text{if } i < 0 \text{ or } x_i \neq y_i \\ 1 + w(\mathbf{X}, \mathbf{Y}, i-1), & \text{if } x_i = y_i \end{cases}$$

and

$$Sim(\mathbf{X}, \mathbf{Y}) = \sum_{i=0}^{l-1} w(\mathbf{X}, \mathbf{Y}, i).$$

The converse measure, distance, is defined as $\text{Dist}(\mathbf{X}, \mathbf{Y}) = \text{Sim}_{\max} - \text{Sim}(\mathbf{X}, \mathbf{Y})$, where $\text{Sim}_{\max} = \text{Sim}(\mathbf{X}, \mathbf{X})$. Intuitively, the function $w(\mathbf{X}, \mathbf{Y}, i)$ accumulates weights from the most recently consecutively matched subsequences between $\mathbf{X}$ and $\mathbf{Y}$ at position i, whereas $\text{Sim}(\mathbf{X}, \mathbf{Y})$ is the integral of total weights.

A user profile is built to contain a collection of sequences, $\mathbf{D}$, selected from a user's observed actions (e.g., commands). The similarity between the profile and a newly observed sequence, $\mathbf{X}$, is defined as $\text{Sim}_{\text{D}}(\mathbf{X}) = \max_{\text{Y} \in \text{D}} \{\text{Sim}(\mathbf{Y}, \mathbf{X})\}$. That is, the similarity between $\mathbf{X}$ and $\mathbf{D}$ is defined as the similarity between $\mathbf{X}$ and a vector in $\mathbf{D}$ that is most similar to $\mathbf{X}$. Then a threshold r is chosen. If the similarity between an observed sequence $\mathbf{X}$ and the profile $\mathbf{D}$ is greater than r, $\mathbf{X}$ is considered normal; otherwise, $\mathbf{X}$ is abnormal.

To reduce the storage required by the profile, Lane and Brodley used the least-recently-used pruning strategy to keep the profile at a manageable size. As new instances are acquired and classification is performed, the profile instance selected as most similar is time stamped. Least-recently-used instances are removed when the profile is constrained to the desired size. In addition, they applied a clustering technique to group the instances in the profile and used a representative instance for each cluster.

This attempt shares a problem similar to that of TIM, that is, it tries to find patterns from sequences of consecutive events. As they have noted, a user may interrupt his/her normal work (e.g., programming) and do something different (e.g., answer an urgent e-mail) and thus yield a different sequence of actions from his/her profile. Their solution (Lane & Brodley, 1998) is to use a time average of the similarity signals; however, such a solution may make real anomalies unnoticeable. In addition, the least-recently-used pruning strategy gives an attacker a chance to train the profile slowly, so that intrusive activities are considered normal ones.

Neural Network

Fox, Henning, Reed, and Simmonian (1990) were the first to attempt modeling system and user behaviors using neural networks. Their choice of neural network is Kohonen's *self-organizing map* (SOM), which is a type of unsupervised learning technique that can discover underlying structures of the data without prior examples of intrusive and nonintrusive activities.

They used SOM as a real-time background monitor that alerts a more complex expert system. In their prototype system, 11 system parameters accessible from the system's statistical performance data are identified as the input to the SOM model. These parameters include (a) central processing unit (CPU) usage, (b) paging activity, (c) mailer activity, (d) disk accesses, (e) memory usage, (f) average session time, (g) number of users, (h) absentee jobs, (i) reads of "help" files, (j) failed log-ins, and (k) multiple log-ins. However, their study showed the results of only one simulated virus attack, which are not sufficient to draw serious conclusions.

In another attempt to apply neural network to anomaly detection, Ghosh, Wanken, and Charron (1998) proposed using a *back-propagation* network to monitor running programs. A back-propagation network is developed for supervised learning. That is, it needs examples of intrusive and nonintrusive activities (called *training data*) to build the intrusion detection model. Such a network consists of an input layer, at least one hidden layer (neurons that are not directly connected to the input or output nodes), and an output layer. Typically, there are no connections between neurons in the same layer or between those in one layer and those in a previous layer.

The training cycle of a back-propagation network works in two phases. In the first phase, the input is submitted to the network and propagated to the output through the network. In the second phase, the desired output is compared with the network's output. If the vectors do not agree, the network updates the weights starting at the output neurons. Then the changes in weights are calculated for the previous layer and cascade through the layers of neurons toward the input neurons.

Ghosh et al. proposed using program input and the program internal state as the input to the back-propagation network. One interesting result is that they improved the performance of detection by using randomly generated data as anomalous input. By considering randomly generated data as anomalous, the network gets more training data that is complementary to the actual training data.

Similar to statistical anomaly detection models, deciding the input parameters for neural network anomaly detectors is a difficult problem. In addition, assigning the initial weights to the neural networks is also an unresolved question. The experiments by Ghosh et al. (1998) showed that different initial weights could lead to anomaly detectors with different performance. Nevertheless, research on applying neural networks to anomaly detection is still preliminary; more work is needed to explore the capability of neural networks.

Audit Data Analysis and Mining

Audit data analysis and mining (ADAM) proposes applying data mining techniques to discover abnormal patterns in large amounts of audit data (e.g., network traffic collected by TCPdump, which is a program used to sniff and store packets transmitted in the network) (Barbara, Couto, Jajodia, & Wu, 2001; Barbara, Couto, Jajodia, & Wu, 2002). In particular, the existing research focuses on the analysis of network audit data, such as the transmission control protocol (TCP) connections. Using data mining techniques, ADAM has the potential to provide a flexible representation of the network traffic pattern, uncover some unknown patterns of attacks that cannot be detected by other techniques, and accommodate the large amount of network audit data that keeps growing in size.

ADAM uses several data-mining-related techniques to help detect abnormal network activities. The first technique ADAM uses is inspired by association rules. Given a set I of items, an association rule is a rule of the form $X \rightarrow Y$, where X and Y are subsets (called item sets) of I and $\mathrm{X} \cap \mathrm{Y} = \phi$. Association rules are usually discovered from a set T of transactions, where each transaction is a subset of I. The rule $X \rightarrow Y$ has a *support s* in the transaction set T if $s\%$ of the transactions in T contain $X \cup Y$, and it has a *confidence c* if $c\%$ of the transactions in T that contain X also contain Y.

However, ADAM doesn't use association rules directly; instead, it adopts the item sets that have large enough support (called *large item sets*) to represent the pattern of network traffic. Specifically, it assumes that each network event (e.g., a TCP connection) is described by a set of attribute values and considers each event a transaction. The large item sets discovered from the network traffic then represent the frequent events in the network traffic. The power of such a mechanism lies in the flexible representation of events.

ADAM builds a profile of normal network activities in which the frequent events (represented by large item sets) are stored. During the detection time, it adopts a sliding-window method to incrementally examine the network events. Within each window, ADAM looks for the large item sets that do not appear in the profile and considers them suspicious.

The second technique ADAM uses is called *domain-level mining*. Intuitively, it tries to generalize the event attribute values used to describe a network event. For example, an IP address that belongs to the subnet *ise.gmu.edu* can be generalized to *ise.gmu.edu*, *gmu.edu*. and *edu*. Then it discovers large item sets using the generalized attribute values. An advantage of this approach is that it provides a way to aggregate the events that share some commonality and may discover more attacks. However, the scheme used to generalize the attribute values is ad hoc; only generalization from IP addresses to subnets and from smaller subnets to larger subnets are studied.

The third technique ADAM uses is classification. ADAM is innovative in that classification is used to classify the output of the mining of large item sets. Four classification algorithms have been studied to date: C4.5 decision tree, naive Bayes, cascading classifier (which uses decision tree followed by naive Bayes and vice versa), and inductive rule learner. The results show that classification is quite effective in reducing false alarms.

Finally, ADAM uses the pseudo-Bayes estimator to accommodate unknown attacks. It is assumed that unknown attacks are the attacks that have not been observed. The training data is represented as a set of vectors, each of which corresponds to an event and is labeled as normal or as a known class of attacks. An additional class is then considered to represent the unknown attacks. Because the unknown attacks haven't been observed in the training data, the probability $P(\mathbf{x} \mid \text{class} = \text{unknown})$, where $\mathbf{x}$ is a training vector, is zero. The pseudo-Bayes estimator is used to smooth all the conditional probabilities $P(\mathbf{x} \mid \text{class})$ so that $P(\mathbf{x} \mid \text{class} = \text{unknown})$ is assigned a (small) probability. These conditional probabilities are then used to build a naive Bayes classifier.

The limitation of ADAM is that it cannot detect stealthy attacks. In other words, it can detect an attack only when it involves a relatively large number of events during a short period of time. This limitation occurs because ADAM raises an alarm only when the support of an unexpected rule (i.e., association of event attributes) exceeds a threshold. Indeed, this limitation is not unique to ADAM; most of the anomaly detection models suffer from the same problem.

Computer Immunological Approach

The computer immunological approach is based on an analogy of the immune system's capability of distinguishing self from non-self (Hofmeyr, Forrest, & Somayaji, 1998). This approach represents self as a collection of strings of length l, where l is a system-wide parameter. A string of length l is considered non-self if it does not match any string belonging to self. To generate detectors that can distinguish non-self from self, a naive approach is to randomly generate a string of length l and check whether it matches any self-string. If yes, the generated string is discarded; otherwise, it is used as a detector. However, the naive approach takes time exponential to the number of self-strings. To address this problem, Forrest et al. proposed a "r-contiguous-bits" matching rule to distinguish self from non-self: two l-bit strings match each other if they are identical in at least r contiguous positions. As a result, detectors can be generated more efficiently for this particular matching rule.

Hofmeyr et al. proposed using short sequences of system calls to distinguish self from non-self for anomaly detection. Given a program in a particular installation, the immunological approach collects a database of all unique system call sequences of a certain length made by the program over a period of normal operation. During the detection time, it monitors the system call sequences and compares them with the sequences in the aforementioned database. For an observed sequence of system calls, this approach extracts all subsequences of length l and computes the distance $d_{\min}(i)$ between each subsequence i and the normal database as $d_{\min}(i) = \min\{d(i,j)\}$ for all sequences j in the normal database}, where $d(i,j)$ is the Hamming distance between sequences i and j (i.e., the number of different bits in sequences i and j). The anomaly score of the observed sequence of system calls is then the maximum $d_{\min}(i)$ normalized by dividing the length of the sequence. This approach raises an alarm if the anomaly score is above a certain threshold.

The advantage of this approach is that it has a high probability of detecting anomalies using a small set of self-strings based on short sequences of system calls. In addition, it does not require any prior knowledge about attacks. The disadvantage is that it requires self to be well understood. That is, it requires a complete set of self-strings in order not to mistake self for non-self. This requirement may be trivial for such applications as virus detection, but it is very difficult for intrusion detection, where some of normal behaviors cannot be foreseen when the detectors are being generated.

Sekar, Bendre, Dhurjati, and Bollineni (2001) further improve the computer immunological method by using an automaton to represent a program's normal behavior. The program counter is used as the state of the automaton, and the system calls made by the program are used as the events that cause the state transitions. As a result, the automaton representation can accommodate more information about the programs' normal behavior and, thus, reduce false alert rate and improve detection rate. In addition, the automaton representation is more compact than the previous alternative. Consequently, such automata are easier to build and more efficient to use for intrusion detection.

Specification-Based Methods

Ko, Ruschitzka, & Levitt (1997) proposed a specification-based approach for intrusion detection. The idea is to use *traces*, ordered sequences of execution events, to specify the intended behaviors of concurrent programs in distributed system. A specification describes valid operation sequences of the execution of one or more programs, collectively called a (*monitored*) *subject*. A sequence of operations performed by the subject that does not conform to the specification is considered a security violation. Each specification is called a *trace policy*. A grammar called *parallel environment grammars* (PE-grammars) was developed for specifying trace policies.

The advantage of this approach is that in theory, it should be able to detect some new types of attacks that intruders will invent in the future. The drawback of this approach is that substantial work is required to specify accurately the behavior of the many privileged system programs, and these specifications will be operating-system specific. To address this issue, Ko (2000) proposed the use of *inductive logic programming* to synthesize specifications from valid traces. The automatically generated specifications may be combined with manual rules to reduce the work involved in specification of valid program behaviors.

Wagner and Dean (2001) further advanced the specification-based approach. The basic idea is to automatically generate the specification of a program by deriving an abstract model of the programs from the source or binary code. Wagner and Dean studied several alternative models, including the call-graph model and the abstract stack model. Central to these models is the control flow graph of a program; these models adopt different ways to represent the possible system call traces according to the control flow graph. Attractive features of this approach are that it has the potential to detect unknown patterns of attacks and it has no false alerts, although it may miss some attacks.

Information-Theoretic Measures

Lee and Xiang (2001) proposed the use of information-theoretic measures to help understand the characteristics of audit data and build anomaly detection models. The well-known concept *entropy* is the first information-theoretic measure. Given a set of classes C_X and a data set X, where each data item belongs to a class $x \in C_X$, the entropy of X relative to C_X is defined as

$$H(X) = \sum_{x \in C_X} P(x) \log \frac{1}{P(x)},$$

where $P(x)$ is the probability of x in X. For anomaly detection, entropy reveals the regularity of audit data with respect to some given classes.

The second information-theoretic measure is *conditional entropy*. The conditional entropy of X given Y is the entropy of the probability distribution $P(x \mid y)$; that is,

$$H(X \mid Y) = \sum_{x,y \in C_X, C_Y} P(x,y) \log \frac{1}{P(x \mid y)},$$

where $P(x,y)$ is the joint probability of x and y and $P(x \mid y)$ is the conditional probability of x given y. The conditional entropy is proposed to measure the temporal or sequential characteristics of audit data. Let X be a collection of sequences where each is a sequence of n audit events and where Y is the collection of prefixes of the sequences in X that are of length k. Then $H(X \mid Y)$ indicates the uncertainty that remains for the rest of the audit events in a sequence x after we have seen the first k events of x. For anomaly detection, conditional entropy can be used as a measure of regularity of sequential dependencies.

The limitation of conditional entropy is that it only measures the sequential regularity of contiguous events. For example, a program may generate highly regular sequences of events; however, if these events are interleaved with other sequences of events, the conditional entropy will be very high, failing to reflect the regularity embedded in the interleaved sequences.

The third information-theoretic measure, *relative entropy*, measures the distance of the regularities between two data sets. The relative entropy between two probability distributions $p(x)$ and $q(x)$ that are defined over the same $x \in C_X$ is

$$\text{relEntropy}(p \mid q) = \sum_{x \in C_X} p(x) \log \frac{p(x)}{q(x)}.$$

The fourth information-theoretic measure, *relative conditional entropy*, measures the distance of the regularities with respect to the sequential dependency between two data sets. The relative entropy between two probability distributions $p(x \mid y)$ and $q(x \mid y)$ that are defined over the same $x \in C_X$ and $y \in C_Y$ is

$$\text{relCondEntropy}(p \mid q) = \sum_{x,y \in C_X,C_Y} p(x,y) \log \frac{p(x \mid y)}{q(x \mid y)}.$$

Viewing intrusion detection as a classification problem, Lee and Xiang proposed the fifth information-theoretic measure, *information gain*, to measure the performance of using some features for classification. The information gain of attribute (i.e., feature) A on data set X is

$$\text{Gain}(X, A) = H(X) - \sum_{v \in \text{Values}(A)} \frac{|X_v|}{|X|} H(X_v),$$

where Values(A) is the set of values of A and X_v is the subset of X where A has value v. This measure can help choose the right features (i.e., the features that have high information gain) to build intrusion detection models. The limitation of information gain is that it requires a relatively complete data set to help choose the right features for the classification model. Nevertheless, an intrusion detection model cannot be better than the data set from which it is built.

Limitation of Anomaly Detection

Although anomaly detection can accommodate unknown patterns of attacks, it also suffers from several drawbacks. A common problem of all anomaly detection approaches, with the exception of the specification-based approach, is that the subject's normal behavior is modeled on the basis of the (audit) data collected over a period of normal operation. If undiscovered intrusive activities occur during this period, they will be considered normal activities. In addition, because a subject's normal behavior usually changes over time (for example, a user's behavior may change when he moves from one project to another), the IDSs that use the above approaches usually allow the subject's profile to gradually change. This gives an intruder the chance to gradually train the IDS and trick it into accepting intrusive activities as normal. Also, because these approaches are all based on summarized information, they are insensitive to stealthy attacks. Finally, because of some technical reasons, the current anomaly detection approaches usually suffer from a high false-alarm rate.

Another difficult problem in building anomaly detection models is how to decide the features to be used as the input of the models (e.g., the statistical models). In the existing models, the input parameters are usually decided by domain experts (e.g., network security experts) in ad hoc ways. It is not guaranteed that all and only the features related to intrusion detection will be selected as input parameters. Although missing important intrusion-related features makes it difficult to distinguish attacks from normal activities, having non-intrusion-related features could introduce "noise" into the models and thus affect the detection performance.

MISUSE DETECTION

Misuse detection is considered complementary to anomaly detection. The rationale is that known attack patterns can be detected more effectively and efficiently by using explicit knowledge of them. Thus, misuse detection systems look for well-defined patterns of known attacks or vulnerabilities; they can catch an intrusive activity even if it is so negligible that the anomaly detection approaches tend to ignore it.

The major problem in misuse detection is how to represent known patterns of attacks. The detection algorithms usually follow directly from the representation mechanisms. In this section, we discuss the typical ways to represent attacks.

Rule-Based Languages

The rule-based expert system is the most widely used approach to misuse detection. The patterns of known attacks are specified as rule sets, and a forward-chaining expert system is usually used to look for signs of intrusions. Here we discuss two rule-based languages, rule-based sequence evaluation language (RUSSEL) (Mounji, Charlier, Zampunieris, & Habris, 1995) and production-based expert system tool set (P-BEST) (Lindqvist & Porras, 1999). Other rule-based languages exist, but they are all similar in the sense that they all specify known attack patterns as event patterns.

RUSSEL

RUSSEL is the language used in the advanced security audit trail analysis on UNIX (ASAX) project (Mounji, Charlier, Zampunieris, & Habris, 1995). It is a language specifically tailored to the problem of searching arbitrary patterns of records in sequential files. The language provides common control structures, such as conditional, repetitive, and compound actions. Primitive actions include assignment, external routine call, and rule triggering. A RUSSEL program simply consists of a set of rule declarations that are made of a rule name, a list of formal parameters and local variables, and an action part. RUSSEL also supports modules sharing global variables and exported rule declarations.

When intrusion detection is being enforced, the system analyzes the audit records one by one. For each audit record, the system executes all the active rules. The execution of an active rule may trigger (activate) new rules, raise alarms, write report messages, or alter global variables, for example. A rule can be triggered to be active for the current or the next record. In general, a rule is active for the current record because a prefix of a particular sequence of audit records has been detected. When all the rules active for the current record have been executed, the next record is read and the rules triggered for it in the previous step are executed in turn. User-defined and built-in C-routines can be called from a rule body.

RUSSEL is quite flexible in describing sequential event patterns and corresponding actions. The ability to work with user-defined C-routines gives the users the power to describe almost anything that can be specified in a programming language. The disadvantage is that it is a low-level language. Specifying an attack pattern is similar to writing a program, although it provides a general condition-trigger framework and is declarative in nature. The feature that rules can share global variables introduces the possibility of bugs along with the convenience of sharing information among different rules.

P-BEST

P-BEST was developed for the multiplexed information and computing service (Multics) intrusion detection and alerting system (MIDAS) and later employed by the intrusion detection expert system (IDES), NIDES, and the event monitoring enabling responses to anomalous live disturbances (EMERALD) (Lindqvist Y. Porras, 1999). The P-BEST toolset consists of a rule translator, a library of runtime routines, and a set of garbage collection routines. Rules and facts in P-BEST are written in production rule specification language. The rule translator is then used to translate the specification into an expert system program in C language, which can then be compiled into either a stand-alone, self-contained executable program or a set of library routines that can be linked to a larger software framework.

The P-BEST language is quite small and intuitive. In P-BEST, the user specifies the structure of a fact (e.g., an audit record) through a template definition referred to as a *pattern type*. For example, an event consisting of four fields—*event_type* (an integer), *return_code* (an integer), *username* (a string), and *hostname* (a string)—can be defined as ptype[event *event_type*: int, *return_code*: int, *username*: string, *hostname*: string].

Thus, P-BEST does not depend on the structure of the input data. One important advantage of P-BEST is that it is a language preprocessor (i.e., it generates a precompiled expert system) and can extend its ability by invoking external C functions. However, it shares a similar problem with RUSSEL: It is a low-level language. Specification of attack patterns in P-BEST is time consuming. When many related rules are included in a system, correctness of the rules is difficult to check due to the interaction of these rules.

State Transition Analysis Tool Kit

Though rule-based languages are flexible and expressive in describing attack patterns for misuse detection, in practice, they are usually difficult to use. As observed in Ilgun, Kemmerer, and Porras (1995) "in general, expert rule-bases tend to be non-intuitive, requiring the skills of experienced rule-base programmers to update them." STAT was developed to address this problem.

In STAT, state transition analysis technique was adopted to facilitate the specification of the patterns of known attacks (Ilgun, Kemmerer, & Porras, 1995). It is based on the assumption that all penetrations share two common features. First, penetrations require the attacker to possess some minimum prerequisite access to the target system. Second, all penetrations lead to the acquisition of some ability that the attacker does not have prior to the attacks. Thus, STAT views an attack as a sequence of actions performed by an attacker that leads from some initial state on a system to a target-compromised state, where a *state* is a snapshot of the system representing the values of all memory locations on the system. Accordingly, STAT models attacks as a series of state changes that lead from an initial secure state to a target-compromised state.

To represent attacks, STAT requires some critical actions, called *signature actions*, to be identified. Signature actions refer to the actions that, if omitted from the execution of an attack scenario, would prevent the attack from successful completion. With the series of state changes and the signature actions that cause the state changes, an attack scenario is then represented as a state transition diagram, where the states in the diagram are specified by assertions of certain conditions and the signature actions are events observable from, for example, audit data.

STAT has been applied for misuse detection in UNIX systems, distributed systems, and networks. USTAT is the first prototype of STAT, which is aimed at misuse detection in UNIX systems (Ilgun, Kemmerer, & Porras, 1995). It relies on Sun Microsystems' C2-Basic Security Module (BSM) to collect audit records. In addition to detecting attacks, USTAT is designed to be a real-time system that can preempt an attack before any damage can be done. USTAT was later extended to process audit data collected on multiple UNIX hosts. The resulting system is called *NSTAT*. NSTAT runs multiple daemon programs on the hosts being protected to read and forward audit data to a centralized server, which performs STAT analysis on all data.

A later application of STAT to network-based misuse detection resulted in another system, named *NetSTAT* (Vigna & Kemmerer, 1999). In this work, the network topology is further modeled as a hypergraph. Network interfaces, hosts, and links are considered the constituent elements of hypergraphs, with interfaces as the nodes, and hosts and links as hyperedges. Using the network topology model and the state transition description of network-based attacks, NetSTAT can map intrusion scenarios to specific network configurations and generate and distribute the activities to be monitored at certain places in a network.

STAT was intended to be a high-level tool to help specify attack patterns. Using STAT, the task of describing an attack scenario is much easier than using rule-based languages, although the analysis required to understand the nature of attacks remains the same. In the implementations of STAT techniques (i.e., USTAT, NSTAT, and NetSTAT), the attack scenarios are transformed into rule bases, which are enforced by a forward-chaining inference engine.

Colored Petri Automata

Kumar and Spafford (1994) and Kumar (1995) viewed misuse detection as a pattern-matching process. They proposed an abstract hierarchy for classifying intrusion signatures (i.e., attack patterns) based on the structural interrelationships among the events that compose the signature. Events in such a hierarchy are high-level events that can be defined in terms of low-level audit trail events and used to instantiate the abstract hierarchy into a concrete one. A benefit of this classification scheme is that it clarifies the complexity of detecting the signatures in each level of the hierarchy. In addition, it also identifies the requirements that patterns in all categories of the classification must meet to represent the full range of commonly occurring intrusions (i.e., the specification of context, actions, and invariants in intrusion patterns).

Kumar and Spafford adopted colored Petri nets to represent attack signatures, with guards to represent signature contexts and vertices to represent system states. User-specified actions (e.g., assignments to variables) may be associated with such patterns and then executed when patterns are matched. The adapted colored Petri nets are called *colored Petri automata* (CPA). A CPA represents the transition of system states along paths that lead to intruded states. A CPA is also associated with pre- and postconditions that must be satisfied before and after the match, as well as invariants (i.e., conditions) that must be satisfied while the pattern is being matched. CPA has been implemented in a prototype misuse detection system called Intrusion Detection In Our Time (IDIOT).

CPA is quite expressive; it provides the ability to specify partial orders, which in turn subsume sequences and regular expressions. However, if improperly used, the expressiveness may lead to potential problems: If the intrusions are described in every detail, the attacker may be able to change his/her attacking strategy and bypass the IDSs. Nevertheless, CPA is not the root the problem.

Automatically Build Misuse Detection Models

Lee and Stolfo (2000) looked at intrusion detection as a data analysis process and applied several data mining techniques to build misuse detection models. The research efforts were conducted under a project entitled JAM, the Java Agent for Meta-learning (meta-learning is a general strategy that provides the means of learning how to combine and integrate a number of separately learned classifiers or models). In particular, association rules and frequent episodes are used to automatically discover features that should be used to model a subject's behavior, and the meta classification is used to combine the results of different classifiers to get better classification results.

Lee and Stolfo extended the original association rules to take into account the "order of importance" relations among the system features (the notion of association rule was discussed above regarding ADAM). *Axis* refers to the features that are important to intrusion detection; only the association rules involving axis features are considered. For example, in the shell command records, the command is likely to reflect the intrusive activities and thus be identified as an axis feature. In some sense, axis features incorporate expert knowledge into the system and thus improve the effectiveness of association rules.

To represent frequent sequential patterns of network events, Lee et al. extended frequent episodes, which were originally proposed in Mannila, Toivonen, and Verkamo (1995), to represent the sequential interaudit record patterns. Their algorithm finds frequent sequential patterns in two phases. First, it finds the frequent associations among event attributes using the axis attributes, and then it generates the frequent sequential patterns from these associations. The algorithm also takes advantage of the "reference" relations among the system features. That is, when forming an episode, the event records covered by the constituent item sets of the episode share the same value for a given feature attribute. The mined frequent episodes are used to construct temporal statistical features, which are used to build classification models. Thus, new features can be derived from the training data set and then used for generating better intrusion detection models.

Another innovation of the JAM project is meta classification, which combines the output of several base classifiers and generates the best results out of them. Specifically, from the predictions of base classifiers and the correct classes, a meta classifier learns which base classifier can make the best prediction for each type of input. It then chooses the prediction of the best base classifier for different input and combines the powers of the base classifiers.

Lee and Stolfo (2000) advanced state-of-the-art knowledge of intrusion detection by introducing a framework that helps generate intrusion detection models automatically. The limitation is that the framework depends on the volume of the evidences. That is, intrusive activities must generate a relatively noticeable set of events so the association of event attributes or frequent episodes can reflect them. Thus, the generated models must work with some other complementary systems, such as NetSTAT.

Abstraction-Based Intrusion Detection

The implementation of many misuse detection approaches shares a common problem: Each system is written for a single environment and has proved difficult to use in other environments that may have similar policies and concerns. The primary goal of abstraction-based intrusion detection is to address this problem.

The initial attempt of the abstraction-based approach is a misuse detection system named the adaptable real-time misuse detection system (ARMD) (Lin, Wang, & Jajodia, 1998). ARMD provides a high-level language for abstract misuse signatures, called MuSigs, and a mechanism to translate MuSigs into a monitoring program. With the notion of abstract events, the high-level language specifies a MuSig as a pattern over a sequence of abstract events, which is described as conditions that the abstract event attributes must satisfy. The gap between abstract events and audit records is bridged by an audit subsystem, which transforms the actual audit records into abstract events. In addition, on the basis of MuSigs, the available audit trail, and the strategy costs, ARMD uses a strategy generator to automatically generate monitoring strategies to govern the misuse detection process.

ARMD is a host-based misuse detection system. In addition to the features mentioned above, it also employs database query optimization techniques to speed up the processing of audit events. The experiences with ARMD show that knowing the characteristics of the audit trail helps estimate the cost of performing misuse detection and gives the security officers the opportunity to tune the misuse detection system.

A limitation of ARMD is that it requires users to have a precise understanding of the attacks and to make careful plans for the abstraction of events. This planning is not an easy job, especially when a user does not know how his/her MuSigs may be used. In particular, unforeseen attacks may invalidate previously defined abstract events and MuSigs, thus forcing the redevelopment of some/all of the MuSigs.

The work by Ning, Jajodia, and Wang (2001) further extends the result in ARMD to address the aforementioned limitation. It provides a framework for distributed attack specification and event abstraction. In this framework, abstraction is considered an ongoing process. The structures of abstract events are represented as system views, and attack signatures are represented as generic patterns on the basis of system views. This new approach allows the semantics of a system view to be modified by defining new signatures and view definitions without changing the specifications of the views or the signatures specified on the basis of the system views.

As a result, signatures in this model can potentially accommodate unknown variants of known attack patterns. Although the specification of attack signatures and the choice of right abstraction still partially depend on the users' skill, this framework provides guidance and alleviates the burden of writing and maintaining signatures.

Limitation of Misuse Detection

Current misuse detection systems usually work better than anomaly detection systems for known attacks. That is, misuse detection systems detect patterns of known attacks more accurately and generate much fewer false alarms. This better performance occurs because misuse detection systems take advantage of explicit knowledge of the attacks.

The limitation of misuse detection is that it cannot detect novel or unknown attacks. As a result, the computer systems protected solely by misuse detection systems face the risk of being comprised without detecting the attacks. In addition, due to the requirement of explicit representation of attacks, misuse detection requires the nature of the attacks to be well understood. This implies that human experts must work on the analysis and representation of attacks, which is usually time consuming and error prone. Lee and Stolfo (2000) have improved this process by automatically building the intrusion detection model; however, identification of attacks in past events is still required.

INTRUSION DETECTION IN DISTRIBUTED SYSTEMS

The rapid growth of the Internet not only provides the means for resource and information sharing, but it also brings new challenges to the intrusion detection community. Due to the complexity and the amount of audit data generated by large-scale systems, traditional IDSs, which were designed for individual hosts and small-scale networked systems, cannot be directly applied to large-scale systems.

Research on intrusion detection in distributed systems is currently focusing on two essential issues: *scalability* and *heterogeneity*. The IDSs in large distributed systems need to be scalable to accommodate the large amount of audit data in such systems. In addition, such IDSs must be able to deal with heterogeneous information from component systems of different types and that constitute large distributed systems and can cooperate with other types of IDSs.

Research on distributed intrusion detection is being conducted in three main areas. First, people are building scalable, distributed IDSs or are extending existing IDSs to make them capable of being scaled up to large systems. Second, network-based IDSs are being developed to take advantage of the standard network protocols to avoid heterogeneous audit data from different platforms. Third, standards and techniques are being developed to facilitate information sharing among different, possibly heterogeneous IDSs.

Distributed Intrusion Detection Systems

Early distributed IDSs collect audit data in a distributed manner but analyze the data in a centralized place, for example, DIDS (Snapp et al., 1991) and ASAX (Mounji, Charlier, Zampunieris, & Habra, 1995). Although audit data is usually reduced before being sent to the central analysis unit, the scalability of such systems is still limited. When the size of the distributed system grows large, not only might audit data have to travel long distances before arriving at the central place, but the central analysis component of the IDS may be overwhelmed by large amount of audit data being generated.

Recent systems, such as EMERALD (Lindqvist & Porras, 1999), GrIDS (graph-based intrusion detection systems; Axelsson, 1999), and AAFID (the autonomous agents for intrusion detection system; Spafford &

Zamboni, 2000), pay more attention to the scalability issue. To scale up to large distributed systems, these systems place IDS components in various places in a distributed system. Each of these components receives audit data or alerts from a limited number of sources (e.g., hosts or other IDS components), so the system is not overwhelmed by large amounts of audit data. Different components are often organized hierarchically in a tree structure; lower level IDS components disseminate their detection results to higher level components, so the intrusion related information from different locations can be correlated together.

Although most of the recent distributed IDSs are designed to be scalable, they only provide a partial solution to the scalability problem. The IDS components are either coordinated in an ad hoc way or are organized hierarchically. Although coordinating the IDS components in an ad hoc way is certainly not a general solution, organizing the components hierarchically does not always provide an efficient solution, especially when the suspicious activities are spread in different, unpredictable locations in a large system. In a hierarchical system, when the activities involved in a distributed attack fall beyond the scope of one IDS component, the audit data possibly related to the attack will have to be forwarded to a higher level IDS component to be correlated with data from other places. In a worst-case scenario, the audit data may have to be forwarded several times before arriving at a place where the data can finally be correlated with the related information. This process not only wastes the network's bandwidth, it also limits the scalability of the detection of distributed attacks.

The abstraction-based intrusion detection (Ning, Jajodia, & Wang, 2001) addresses this problem by generating a hierarchy of IDS components dynamically rather than statically. Intuitively, this method defines attack signatures as generic patterns (called *generic signatures*) of abstract events that may be observed in different places in a distributed system. When a particular type of attack is to be detected in a distributed system, the corresponding generic signature is mapped to the specific systems. The resulting signature is called a *specific signature*. This method then decomposes the specific signature into components called *detection tasks*, each of which corresponds to the intrusion detection activities required to process a type of event involved in the attack. A coordination mechanism is developed to arrange the messages passing between the detection tasks, so the distributed detection of attacks is equivalent to having all events processed in a central place. The abstraction-based method is more flexible and more efficient than the previous methods; however, it is limited in that it is applicable only to misuse detection.

Network-Based Intrusion Detection Systems

Network-based IDSs collect audit data from the network traffic, as opposed to host-based IDSs, which usually collect audit data from host audit trails. Examples of network-based IDSs include NSM (Network Security Monitor; Axelsson, 1999), NetSTAT (Vigna & Kemmerer, 1999), and Bro (Axelsson, 1999).

One challenge that the network-based intrusion detection is facing is the speed of high-performance networks. The great speed of the high-performance networks makes it very difficult to capture the network traffic, let alone perform intrusion detection in real time.

Several efforts have addressed enabling intrusion detection in high-speed networks. Snort, an open source IDS that specializes in network intrusion detection (Snort, 2002), was developed by Roesch (1999). It employs a fast pattern-matching algorithm to detect network misuse. However, early versions of Snort detected attacks individually, and its performance degrades when the number of attack signatures (rules) increases. Since version 1.9, Snort has incorporated new pattern-matching algorithms to address this problem.

Sekar, Guang, Verma, and Shanbhag (1999) developed a high-performance network IDS based on efficient pattern-matching algorithms. A distinguishing feature is that the performance of the system is independent of the number of misuse rules (signatures).

Kruegel, Caleur, Vigna, and Kemmerer (2002) proposed a partition approach to intrusion detection that supports misuse detection on high-speed network links. This approach is based on a slicing mechanism that divides the overall network traffic into subsets of manageable size. Thus, each subset can be processed by one or several misuse detection systems. The traffic partitioning is done such that each subset of the network traffic contains all of the evidence necessary to detect a specific attack.

Network-based IDSs offer several advantages. First, network-based IDSs can take advantage of the standard structure of network protocols, such as TCP/IP. This is a good way to avoid the confusion resulting from heterogeneity in a distributed system. Second, network-based IDSs usually run on a separate (dedicated) computer; thus, they do not consume the resources of the computers that are being protected.

Conversely, network-based IDS are not silver bullets. First, because these IDSs do not use host-based information, they may miss the opportunity to detect some attacks. For example, network-based IDSs cannot detect an attack launched from a console. Second, the standard network protocols do not solve the entire problem related to the heterogeneity of distributed systems because of the variety of application protocols and systems that use these protocols. For example, network-based IDSs must understand the UNIX shell commands if their goal is to monitor intrusive remote log-ins. As another example, network-based IDSs usually describe the suspicious network activities using the structure of the packet that standard network protocols such as TCP/IP support, which makes the specification of the suspicious activities to be detected very difficult.

Network-based IDSs have the same scalability problem as do general distributed IDSs. For example, existing network-based IDSs analyze network traffic data in a centralized place, as was done by the early distributed IDSs, although they may collect data from various places in the network. This structure limits the scale of the distributed systems that such IDSs can protect.

Sharing Information Among Intrusion Detection Systems

With the deployment of so many commercial IDSs, these IDSs must be able to share information so that they can interact and thus achieve better performance than if operating in isolation. Research and development activities are currently under way to enable different, possibly heterogeneous, IDSs to share information.

The Common Intrusion Detection Framework (CIDF) was developed to enable different intrusion detection and response (IDR) components to interoperate and share information and resources (Porras, Schnackenberg, Staniford-Chen, Stillman, & Wu, 1999). It began as a part of the Defense Advanced Research Project Agency (DARPA) Information Survivability program, with a focus on allowing DARPA projects to work together. CIDF considers IDR systems as composed of four types of components that communicate via message passing: event generators (E-boxes), event analyzers (A-boxes), event databases (D-boxes), and response units (R-boxes). A communication framework and a common intrusion specification language are provided to assist the interoperation among CIDF components.

Researchers involved in CIDF started an Intrusion Detection Working Group (IDWG) in the Internet Engineering Task Force (IETF), trying to bring the impact of CIDF to a broader community. The IDWG has been working to develop data formats and exchange procedures for sharing information among IDSs, response systems, and management systems. The extensible markup language (XML) has been chosen to provide the common format, and an intrusion detection message exchange format (IDMEF) has been defined in an Internet draft. The IDWG uses the blocks extensible exchange protocol (BEEP) as the application protocol framework for exchanging intrusion detection messages between different systems; an intrusion detection exchange protocol (IDXP) is specified as a BEEP profile, and a tunnel profile is provided to enable different systems to exchange messages through firewalls. At the time of this writing, these Internet drafts are under consideration for being adopted as IETF requests for comments (RFCs).

A negotiation protocol for CIDF components has been developed as part of the intrusion detection intercomponent adaptive negotiation (IDIAN) project (Feiertag, et al., 2000). It allows distributed IDS components to discover the intrusion detection services of other components, and to negotiate, manage, and adjust the use of those services. In particular, the notion of a filter was introduced to assist the negotiation process. A filter is essentially a pattern of CIDF messages, and the negotiation process helps determine one or several filters between two CIDF components. A CIDF component sends a CIDF message to another component only when the message matches the filters of the receiver. Similarly, a receiving CIDF component accepts an incoming CIDF message only if the message matches one of its filters. IDIAN partially addresses the information-sharing problem by enabling different IDS components to discover, negotiate, and adjust the use of services from each other.

Another effort in sharing information among different IDSs is the Hummer project (Frincke, Tobin, McConnell, Marconi, & Polla, 1998). In particular, the relationships among different IDSs (e.g., peer, friend, manager/subordinate) and policy issues (e.g., access control policy, cooperation policy) were studied, and a prototype system, HummingBird, was developed to address these issues. A limitation of the Hummer project is that it only addresses the general data-sharing issue; what information needs to be shared and how the information would be used are out of its scope. Thus, it should be used along with mechanisms such as IDIAN (Feiertag, et al., 2000) and the decentralized coordination mechanism in the abstraction-based approach (Ning, Jajodia, & Wang, 2001).

CONCLUSION

Intrusion detection continues to be an active research field. Even after 20 years of research, the intrusion detection community still faces several difficult problems. How to detect unknown patterns of attacks without generating too many false alerts remains an unresolved problem, although recently, several results have shown there is a potential resolution to this problem. The evaluating and benchmarking of IDSs is also an important problem, which, once solved, may provide useful guidance for organizational decision makers and end users. Moreover, reconstructing attack scenarios from intrusion alerts and integration of IDSs will improve both the usability and the performance of IDSs. Many researchers and practitioners are actively addressing these problems. We expect intrusion detection to become a practical and effective solution for protecting information systems.

GLOSSARY

Anomaly detection One of the two methodologies of intrusion detection. Anomaly detection is based on the normal behavior of a subject (e.g., a user or a system); any action that significantly deviates from the normal behavior is considered intrusive. The other methodology is misuse detection.

Audit trail Records a chronology of system resource usage. This includes user log-in, file access, other various activities, and whether any actual or attempted security violations occurred.

False negative An actual intrusive action that the system allows to pass as nonintrusive behavior.

False positive Classification of an action as anomalous (a possible intrusion) when it is legitimate.

IDS Intrusion detection system.

Intrusion Any activity that violates the security policy of an information system.

Intrusion detection The process of identifying intrusions by observing security logs, audit data, or other information available in computer systems and/or networks.

Misuse detection One of the two methodologies of intrusion detection. Catches intrusions in terms of the characteristics of known patterns of attacks or system vulnerabilities; any action that conforms to the pattern of a known attack or vulnerability is considered intrusive. The other methodology is anomaly detection.

Misuse signature A known pattern or attack or vulnerability, usually specified in a certain attack specification language.

Profile A set of parameters used to capture the pattern of a subject's (e.g., a user or a program) normal behavior. It is normally used to conduct anomaly detection.

Security policy A set of rules and procedures regulating the use of information, including its processing, storage, distribution, and presentation.

INTRODUCTION

Motivation: The Importance of Effective Inventory Management

According to a recent study, U.S. firms in retail managed $1.1 trillion in inventory to support $3.2 trillion in annual sales in the year 2002 (C. Lee, 2002). This inventory was spread across enterprise supply chains with $400 billion in retail, $290 billion in distribution centers, and $450 billion in manufacturing. Although the benefits associated with carrying such high levels of inventory typically include higher service levels, this is not always the case. During the same time period, approximately 8% of retail customers were unable to find their products, a supply chain stock-out glitch, which led to a 3% sales revenue opportunity loss for U.S. retailers. The crux of these problems lies in a firm's inability to manage its inventory effectively throughout the supply chain.

Furthermore, the long-term implications of poor inventory management are far reaching, ultimately having an impact on the market value of the firm. Supply chain shortfalls, stock-outs, and product delays significantly affect shareholder value by as much as 18% (Singhal & Hendricks, 2002). To illustrate, Boeing allocated $1 billion in 1997 for "production disruption" costs incurred for parts or supply shortages associated with production ramp-up for airplane production. Similarly, earnings for the candy maker Hershey's in 1999 were low because of problems created by the unsuccessful implementation of enterprise software, effectively incapacitating their order-taking and distribution systems during the crucial Halloween season. Therefore, it is clear that the market has a negative reaction of any firm that is unable to manage product supply and demand effectively within its value chain.

Inventory Measures in a Supply Chain Context

Although the importance of effective supply chain and distribution management is apparent, an appropriate set of metrics measuring a firm's performance relative to its supply chain is essential. Three important measures of supply chain success include those that assess the value of a firm's assets (including both inventory and cash), customer service and speed with which it can deliver its products (Johnson, 1998). Traditional inventory measures have included the monetary value of inventory, the time supply (e.g., 3 weeks of inventory), and inventory turnovers. The implications of effective inventory management now extend beyond the single enterprise to the entire supply chain. Moreover, the linkage between inventory management and other essential measures of supply chain success is critical for a firm's success in the marketplace.

Within the realm of supply chain metrics, customer service, a firm's ability to mediate supply with demand, is an important factor affecting business performance. A key measure of a firm's customer service level success requires the firm to ensure delivery of the right product at the right time at the right place in the right quantity while combating excessive inventory costs. The complexity of successfully delivering high customer service levels is further exacerbated by product uncertainties in demand (i.e., demand variability, short life cycles, proliferation of product variety, product volume, etc.) and supply (i.e., supplier sources, globalization, capacity constraints, process, quality, etc. [H. Lee, 2002]).

Consider the events of the eToys corporation during the 1999 holiday season (Hallowell, 2000). eToys, an online retailer of toys, experienced an unanticipated high volume of demand for their products. Although high demand in and of itself is usually a welcome phenomena amongst a firm's stockholders, eToys was also plagued with numerous supply problems that intensified its inability to meet demand. Items that were out of stock were actually listed as available on the company Web site. Orders were late or not delivered at all. Furthermore, service representatives were unable to utilize information systems effectively to answer customer questions concerning product tracking and delivery. In the short term, eToys's stock value plunged because of high costs of order fulfillment. Eventually, eToys was unable to recover from the supply debacle, and the firm went bankrupt.

One way that firms can manage such product uncertainties is through the adoption of appropriate supply chain strategies and subsequent inventory policies. In a highly competitive global environment, firms have to manage inventory within evolving distribution and supply channels at a rate commensurate with the firm's industry. To maintain competitive advantage in quick-paced industries, firms must continually evaluate how to manage inventory considering the following factors: new product introductions, sourcing, collaboration, differentiation, and lead-time compression initiatives. For example, firms manufacturing innovative products with short life cycles (typically 3 months to 1 year) require flexible and responsive supply chains that can facilitate introducing new products into the market quickly (Fisher, 1998). Utilizing inventory in the form of either parts or finished goods can be an effective buffer against uncertainty in demand and supply glitches. On the other hand, firms manufacturing functional products with longer life cycles (typically greater than 1 year) and predictable demand should focus on establishing an efficient supply chain to deliver the goods at the lowest cost. To facilitate such a strategy, firms in this environment require minimal levels of inventory and high rates of inventory turnovers.

Classical Inventory Management

Classical inventory techniques that address each of these unique environments are well established within the operations management area. For innovative products with high demand uncertainty, stochastic methods (such as reorder point variations) can be used to aid managers in inventory planning decisions. For functional products with longer life cycles and predictable demand, however, other deterministic models (such as EOQ) are appropriate. Factors typically used in these inventory decisions include the following relevant cost drivers: inventory holding, ordering and purchase, setup, stockout, and goodwill. Numerous variations of these inventory replenishment methodologies are embodied in enterprise software, including min–max, reorder point, and time-phased approaches for single and multi-echelon systems.

Technologies Enabling Effective Inventory Management

The introduction of Internet technologies has led to increases in a firm's operational efficiencies through real-time information sharing (e.g., key performance indicators, point-of-sale data) and decision sharing (e.g., vendor managed inventory) within its organization and across its dynamic supply chain. Firms today can select from among a number of Internet architected software products from supply chain management and enterprise resource planning vendors that no longer simply manage simple transactions (e.g., orders, invoices, etc.) but instead enable supply chain collaboration.

The purpose of this chapter is as follows. First, in the introduction, we provide an overview of the complexities inherent in inventory management and the implications of inventory management gone awry. Second, we present a summary of classic inventory management policies and offer guidance concerning the correct application of such policies under various circumstances. Third, we discuss more complex variations of inventory theory as it applies to planning for multiple items and multiple stocking points. Fourth, we compare and contrast traditional inventory fulfillment methods with more recently developed e-commerce models. Finally, we discuss how current Internet technologies facilitate effective inventory management. Conclusions summarizing key managerial implications for inventory management are included at the end of the chapter.

INVENTORY REPLENISHMENT METHODOLOGIES

There are two separate demand processes underlying every inventory system; it is essential to bear this in mind throughout the discussion that follows. The first demand process, that of consumer demand, may be regarded as an external one; the second demand process comprises internal requests for replenishment of stock. Clearly, the consumer demand process drives the stock replenishment process. In the real world, the consumer demand process is uncertain, to one degree or another, whereas the internal replenishment process unfolds by design. The essential task of the inventory planner is to use information about the consumer demand process to design rules governing the replenishment process.

It is relatively simple to devise optimal replenishment procedures for a single item with known demand, provided we have accurate cost estimates. At the other end of the spectrum, it is a complex task to craft an optimal inventory control system for a group of items with individual demands that are difficult to predict. The crux of the problem is to balance costs from excessive or obsolete inventories against the consequences of running out of inventory prematurely. This section offers a basic tutorial on inventory replenishment decisions for a single firm making a choice with regard to a single item with independent demand. In the following section, we generalize these policies for the multiple item, multi-echelon, and supply chain environments.

Table 1 Summary of Inventory Models

INVENTORY MODEL	DETERMINES	APPROPRIATE FOR	SIGNIFICANT FACTORS
Continuous review	Order frequency	Critical items with costly stock-outs	Information intensive
Periodic review	Order frequency	General purpose items	
Economic order quantity	Order quantity (inventory level)	Stable demand	Monthly demand Holding cost Fixed order cost Lead time
Reorder point	Order quantity (inventory level)	Uncertain demand	Average demand Standard deviation demand Customer service level
Min–max	Order quantity (inventory level)	Uncertain demand	Min stock level Max stock level
Order up-to	Order quantity (inventory level)	Uncertain demand	Max stock level

The optimal inventory replenishment decision breaks down into two interlinked choices: how often to order (i.e., frequency), and how much to order (i.e., quantity). In general, there are two approaches to determine how frequently to place orders, called the continuous and periodic review systems. Note that the decision of how much to order is directly interlinked to the frequency decision. In addition, another key factor driving the total order quantity decision concerns the stability of demand. In environments with fairly stable demand, consistent order quantities determined by the economic order quantity (EOQ) model are appropriate. In environments with unknown or unstable demand, reorder point, min-max, and order up-to policies are appropriate. Table 1 contains a summary of these inventory policies. A detailed discussion of each of these systems follows.

Periodic and Continuous Review Systems

Regardless of the underlying structural features, there are two broad classes of inventory systems determining the frequency of orders: *continuous review systems* and *periodic review systems*. A continuous review system is one in which inventory is monitored continuously. Conversely, a periodic review system is one in which inventory is checked at certain points in time separated by a fixed interval, the period. A continuous review system allows for a replenishment order to be triggered when the inventory level declines to any preset value, but this is not possible with a periodic review system. This implies that the type of inventory monitoring policy chosen determines the range of replenishment options (i.e., the order quantity decision) available.

Continuous review is clearly an information intensive policy. If a firm deals with a large number of items, it may not be feasible to review the inventory of all the items continuously. As a general rule, an item needs to be monitored continuously if a stock-out of that item is especially costly for the firm. The more critical the item, the more pressing the need to set in place a continuous review system. For example, in a wafer fabrication facility, running out of a critical part may lead to hours of costly downtime. Items of the nuts-and-bolts variety, on the other hand, may be monitored periodically; the length of the period will depend on the magnitude and variability of demand and the cost of running out of the item.

All inventory systems work by generating triggers for replenishment. The trigger is generally set off when the stock level falls below a certain level. Once the replenishment signal is triggered, the system must wait for a certain period of time before the refill arrives. This time window is the *lead time*. Lead time represents the time required to fulfill a replenishment order. It may be attributable to production time or transportation time or both.

Compared with a periodic review system, a continuous review system reduces the safety stock required to guard against unexpected surges in demand. *Safety stock* is inventory carried specifically to tide over variable demand during lead time. This is because the maximum period of time for which a continuous review system may be out of stock is simply the lead time. On the other hand, the maximum period of time for which a periodic review may be out of stock is the sum of the lead time and the period length. To illustrate this point, consider a continuous review system in which the stock level required to trigger a replenishment order is 5 or fewer units of an item. Suppose that the current stock level is 10. Now an order for 10 units of the item will trigger a replenishment signal and simultaneously plunge the stock level to zero. The time for which this system will remain out of stock is exactly the lead time. Next, consider a periodic review system for the same item in which a replenishment order is triggered at a review point whenever the stock level at the point is 5 or fewer units. Suppose that the stock level is equal to 10 units at the current review point; then no replenishment signal is triggered. But if a demand for 10 units of the item occurs immediately after the review point, it is apparent that the system will remain out of stock for a time interval equal to the sum of the period length and the lead time.

Despite the need for higher safety stock, a periodic review system may be more convenient to administer than a continuous review system. For instance, the stocks of several related items may be simultaneously checked at each review point and replenishment signals for multiple items sent out in a coordinated fashion. This is not possible with a continuous review system in which the replenishment order signals for different items are, in general, generated independently of each other.

Replenishment Rules for Known Demand: The EOQ Formula

The preceding discussion brings us to the single most famous formula in inventory management, the Economic Order Quantity (EOQ). A stable demand process permits a simple replenishment process involving a fixed, as opposed to a variable, order quantity. The EOQ formula bears out this rationale.

Consider a situation in which customer demand occurs at a steady, known rate of D units per month and a continuous review system is in place. Suppose the relevant inventory costs are an inventory holding cost of h per unit of stock per month, and a fixed cost K associated with every replenishment order. The holding cost represents the cost of physical storage, as well as the opportunity cost of capital tied up in inventory. The set up cost represents the transaction cost associated with a replenishment order. If replenishment is achieved by in-house production on a machine, K may represent the cost to set up the machine for a production run. The holding cost is in part a notional cost while the set up cost entirely reflects cash outflow and is therefore easier to quantify. Under these conditions, it may be shown using elementary calculus that the optimal policy is to order a quantity equal to

$$\sqrt{\frac{2KD}{h}}$$

units. The diagram in Figure 1 illustrates how the total costs vary with order quantity. The holding cost increases linearly while the order cost decreases nonlinearly as the order size increases. The total cost is smallest at precisely the point where order cost balances holding cost.

The trigger point for order replenishment depends on the lead time. If the lead time is practically zero, so is the trigger point; if the lead time is positive, the trigger point will also be some positive number that can be calculated by using information about the magnitude of consumer demand. In general, a replenishment is triggered when the stock on hand drops to a level equal to lead time demand.

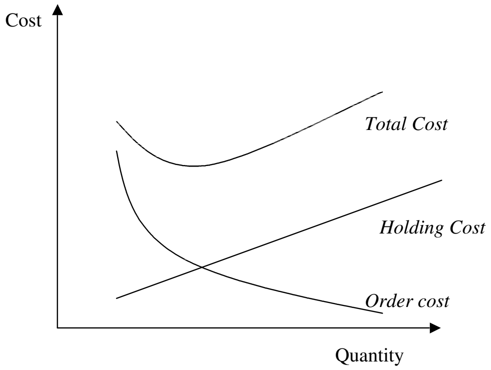

Figure 1: Total inventory costs determining economic order quantity.

Although the EOQ formula applies with complete accuracy only under idealized conditions, it is remarkably robust in the sense that the order quantity prescribed does not change appreciably even if the costs in the equation are off target. Furthermore, if the demand is variable rather than constant, a useful rule of thumb is to use the EOQ formula with average demand substituting for demand. Although the EOQ formula is not theoretically optimal when the demand process is variable, it may provide a useful benchmark. A more sophisticated procedure for handling variable demand is described in the next section. Another practical situation in which the EOQ formula does not apply directly is when the supplier offers quantity discounts. In this case, some care must be exercised in using the EOQ formula (Nahmias, 1990).

Replenishment Rules for Uncertain Demand: Reorder Point

The EOQ formula is designed to optimize an inventory system facing steady demand. If demand is expected to be variable, there are two useful statistical metrics that are used to capture the anticipated pattern of demand: *average demand* and *standard deviation of demand*. Both these metrics may be easily computed using spreadsheet functions from a database of historical demand.

Suppose we have demand for the past 12 months on file; let us denote the 12 monthly demand numbers by D_1, $D_2, \ldots, D_{12}$. Then we may use the following formulae to estimate the average and the standard deviation of demand:

$$Average = \frac{D_1 + D_2 + \cdots + D_{11} + D_{12}}{12}$$

$$Standard\ deviation = \sqrt{\frac{(D_1 - Average)^2 + (D_2 - Average)^2 + \cdots + (D_{12} - Average)^2}{12}}$$

As remarked earlier, one may substitute mean demand in the EOQ formula to obtain the order quantity for replenishment. It is advisable, on theoretical grounds, to complement information about average demand with information about demand variability, however; standard deviation is a metric that nicely captures demand variability. As we mentioned in the previous section, a simple rule of thumb for replenishment order quantity, given knowledge about both average demand and standard deviation of demand, is the EOQ with average demand substituting for demand in the formula. How does one incorporate standard deviation into the replenishment rule?

The answer lies in safety stock and the reorder point. *Safety stock* is inventory carried specifically to tide over variable demand during lead time, and the magnitude of safety stock is precisely the reorder point. The greater the anticipated variability in lead time demand, the greater the safety stock that must be carried and the greater the reorder point. A convenient rule of thumb is to set the reorder point equal to anticipated average demand during lead time *plus* a multiple (say Z) of the standard deviation of demand during lead time.

The appropriate determination of the multiplier parameter Z represents an explicit trade-off to managers between excessive inventory carrying costs and the chance of a *stock-out*. A stock-out occurs when demand is higher than current inventory levels. Another important measure of inventory performance is the *customer service level,* which is the probability that demand can be met from current inventory levels. Consider the following illustration relating the appropriate reorder point level (i.e., through choice of Z) to the overall customer service level. If demand during lead time follows a bell curve, one may use standard tables to decide on a suitable value of Z; the greater the value of Z, the greater the inventory holding cost but the smaller the risk of stock-outs. For instance, setting $Z = 0.67$ results in a 75% customer service level and a 25% chance of stock-outs, whereas setting $Z = 1.64$ results in a 95% customer service level and only a 5% chance of stock-outs. Note that the total inventory carried in the system is the sum of two distinct components: *cycle stock*, arising from the order replenishment process, and *safety stock*, carried to buffer the inventory system against demand shocks.

Replenishment Rules for Uncertain Demand: The Min–Max Replenishment Rule

One of the most popular inventory replenishment rules is the two bin or min–max policy. The rule works as follows: If the inventory level at any point is smaller than some predetermined number s, a quantity sufficient to bring the inventory level up to a level S is ordered; of course S is greater than s by design. The academic literature on inventory management generally refers to this as an (s, S) policy (Porteus, 2002). Under this rule, the specific order quantity requisitioned will vary, depending on the points in time at which successive reviews are made and on the demand conditions in the interim between two reviews.

Suppose we apply the min–max rule to an item with an inventory that is monitored continuously. If customer demand occurs in discrete units and if each order is for exactly one unit, then an order can be placed at precisely the point when the inventory level declines to s. Furthermore, the replenishment order quantity will be exactly S minus s every time a replenishment order is called for. On the other hand, under similar demand conditions, if the inventory system in place is a periodic review system, then the inventory level triggering a replenishment order will generally be smaller than s. This implies that the order quantity will be at least S minus s rather than exactly equal to it. The same observations apply to a continuous review system in which customer orders may be for multiple units of an item. It is instructive to note that the simplicity or complexity of the stock replenishment mechanism reflects the simplicity or complexity of the customer demand process. If every customer demands precisely one unit, a fixed quantity is requisitioned for replenishment under a continuous review system. If customer demand deviates from this fixed pattern, the order quantity must also vary.

Replenishment Rules for Uncertain Demand: The Order Up-To Rule

A simple rule associated with periodic review systems is to order at every review point in such a way as to bring the inventory level up to S. The order quantity resulting from this policy will, in general, vary from one review period to another; the greater the variation in demand, the greater will be the variation in order quantity. If *backorders* are allowed, the order quantity may even exceed S. Backorders occur when unsatisfied demand can be fulfilled during the following period. We introduce the notion of *inventory position* to state the "order up-to" rule in a way that covers backordered situations. The inventory position at any point in time is defined as the amount of physical stock on hand plus the amount of stock on order less the amount of backorders. So the order up-to rule is simply to restore the inventory position to S at every review point. The min–max rule, restated in a similar way, is to restore the inventory position to S provided the inventory position is smaller than s at a review point.

INVENTORY MANAGEMENT FOR MULTIPLE ITEMS AND MULTIPLE ECHELONS

We have, up to this point, discussed inventory management principles for a single item in isolation. In practice, all firms deal with several types of items, divided into groups. Inventory management rules are generally devised for groups of items stored at various places throughout the company and the supply chain. This section describes the theory and mechanics behind inventory decision making considering multiple items and multiple echelon policies. The next section offers managerial guidance concerning strategic decision making for inventory policies throughout the supply chain.

Inventory Management With Multiple Items

When managing the replenishments for several items, coordination becomes a factor. There are two conflicting dimensions to coordination in this context. When a group of items is produced on a single production line for in-house replenishment, it is desirable to trigger the replenishment orders of the items at different points in time to avoid overloading the machine. On the other hand, setup costs may be reduced, if a group of related items is produced during the same run. For instance, filling an entire truckload of items may lower transportation costs. If the items are ordered rather than produced, we may want to trigger replenishment orders for a group of items at the same time to exploit quantity discounts offered by the supplier.

When demands for different items are relatively stable over an extended period, cyclic schedules are often used to smooth the production load on a machine. This means that each item is ordered periodically, and the ordering periods of the various items are set so as to even out the production load.

Consider a situation in which a machine is used to produce four items with approximately the same demand. One feasible cyclic schedule is to produce item 1 in weeks

1, 5, 9, . . . , item 2 in weeks 2, 6, 10, . . . , item 3 in weeks 3, 7, 11, . . . , and item 4 in weeks 4, 8, 12, ...

The schedule can be implemented by using a periodic review order up-to *S* rule with a review period of 4 weeks for each of the four items. Every week, a review will occur, but in any 4 consecutive weeks, four different items will be reviewed. This inventory management policy will result in a very even production load on the machine. It may be a complicated mathematical problem to find feasible cyclic schedules for a number of items produced on a number of different production facilities; this example is a particularly simple one (Axsater, 1999).

Another important example of an inventory system in which multiple items must be managed concurrently occurs in discrete parts manufacturing, where producing one unit of a certain product may require a multiple units of different components that must be assembled to fabricate the end product. The components themselves may have to be assembled using multiple units of different subcomponents. The resulting product structure is called a *bill of material,* and the corresponding inventory planning methodology is called material requirements planning (MRP). There is one crucial distinction between the setup in MRP and that in the multiple item example discussed in the previous paragraph. An MRP system deals with a collection of items whose demands are dependent; specifically, the demands of the components are driven by the demand for the end product. On the other hand, the previous example assumed that the demands of the various items were independent of one another. In an MRP system, the stocks and replenishment policies for the components can be derived from the replenishment policy formulated for the end product, simply by staggering the replenishments of components in accordance with the lead times involved (Hopp & Spearman, 1996).

Multi-Echelon Inventory Systems

All the replenishment rules we have been discussing assume that items are produced, or procured, at a single place within a single firm. In practice, a large number of stocking points are coupled to one another and the inventory replenishment processes at the separate places must be managed in synchronism. For example, several companies use an inventory system with a central warehouse close to the production facility, and a number of dispersed stocking points serving local markets. On the production front, the site of the second of the two demand processes characterizing the inventory system, stocks of raw materials, components, and finished products are coupled to each other. To design efficient inventory control procedures for such multi-echelon systems, it is necessary to use special methods that take interdependencies between the inventories at different stocking points into account. Note that these multi-echelon inventory decisions can occur both within a single firm and throughout an entire supply chain.

One common way of controlling a multi-echelon inventory system is to apply a *reorder point, fixed quantity* replenishment rule to each facility. This rule is a variation of the min–max rule explained earlier. It operates as follows: If the inventory position at any review point is less than *R*, we place an order for *Q* units. Here *R* is the reorder point and *Q* is the order quantity. If the control system is of the continuous review type, an order for Q units is placed as soon as the inventory position declines to *R*; in a periodic review system, the inventory position will generally be smaller than *R* when a replenishment signal is sent out. Different stocking points will, in general, be governed by distinct reorder points and distinct order quantities. We call this system of multi-echelon inventory control an *installation stock reorder point policy* (Axsater, 2000).

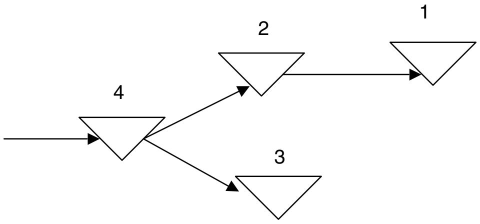

Figure 2: Echelon stock distribution example.

Another type of multi-echelon control policy is the *echelon stock reorder point policy.* Let us explain this policy with a specific example. Consider a distribution system with four installations as shown in Figure 2. The *installation stock* at each of the distribution points is simply the inventory position at that point. The *echelon stock* at each distribution point is the sum of the inventory positions of that distribution point and all the downstream points. So if the installation stocks at installations 1, 2, 3, and 4 number 5, 4, 1, and 10, respectively, then the corresponding echelon stocks work out to be 5, 9, 1, and 20. Observe that the echelon stock at each point is, by definition, greater than the installation stock at that point. An *echelon stock reorder point policy* is one that uses echelon stocks rather than installation stocks to compute reorder points.

Note that installation stocks use only local inventory information in designing the inventory control system, whereas echelon stocks process inventory information pertaining to multiple installations. An important fallout of using exclusively local information to design inventory control systems is that it tends to result in large variations in the demands on individual installations. Indeed, demand variations at the consumer level tend to get *magnified* as we traverse the supply chain from the point of external demand, downstream, all the way upstream. This effect, christened the *bullwhip effect* in the inventory literature, degrades supply chain performance (Lee, Padmanabhan, & Whang, 1997). The remedy is to formulate and employ echelon level inventory control policies that use global, rather than merely local, information.

E-COMMERCE INITIATIVES AFFECTING INVENTORY MANAGEMENT

Although the advent of the Internet has had an impact on inventory management in several ways, the traditional inventory techniques previously discussed still yield many important managerial insights. In particular, many of the parameters, variables, and costs previously discussed may be altered, but the same basic relationships still hold. In this section, we briefly discuss several of the newer e-commerce initiatives relating them directly to the traditional inventory management techniques previously discussed. In the following subsections, we describe many of these Internet-related initiatives in greater detail.

First, the availability of Internet procurement applications has altered several of the key variables traditionally used in inventory management. According to a recent report (Aberdeen Group, 1999), early adopters of Internet procurement initiatives experienced the following: (a) a 5–10% reduction in the price of materials and services, (b) a reduction in the average length of the purchase and fulfillment cycles (i.e., *lead time*) from 7.3 days to 2 days, and (c) a reduction in the administrative costs per order (i.e. *order cost K*) from $107 to $30. Consequently, these firms also decrease their overall levels of inventory, including *safety stock* and *order quantities* to suppliers.

Use of ERP and Web-based technologies has enabled more accurate prediction of demand, thereby facilitating the calculation of appropriate *reorder point* policies. Third, the advent of supply chain management techniques has emphasized the importance of analyzing the inventory position of each individual supplier in determining appropriate *echelon stock policies* throughout the supply chain. Many firms are conceding control of their inventory decisions to supply chain partners with the hopes of achieving better coordination and higher customer service levels throughout the supply chain. Moreover, functionalities offered in modern day ERP and Web services software facilitate sharing of inventory information throughout the supply chain, thereby minimizing *bullwhip effect*.

Collaborative Planning Forecasting and Replenishment

To use many of the inventory management techniques previously discussed, a firm must develop a reasonably accurate picture of demand. Companies usually rely on a variety of both subjective and objective techniques to calculate forecasts for potential product sales, depending on the types of products under consideration. For example, when planning the sales for an item with fairly stable demand, mathematical analysis of the historical sales for this product should be adequate to characterize previous demand patterns and predict future demand. For items that are completely new in the marketplace or trendy in nature (e.g., apparel and toys), subjective methods can be used such as polling experts in the industry to project the potential acceptance in the market. See Nahmias (2001) for a complete review of the topic of forecasting.

Recently, companies have recognized the value of developing a common forecast to share with supply chain partners. Collaborative planning forecasting and replenishment (CPFR) initiatives were developed to help facilitate such information sharing (see http://www.cpfr.org). Collaboration within the chain is executed through confidentiality agreements, dispute management protocols, shared performance metrics and common goal sharing. Additionally, the scope of the collaboration is qualified in terms of product (e.g., SKU, family, category, etc.), location (e.g., site, geography, etc.), and trading partner participation. The planning component implies collaborative product planning for the product level in scope as well as the target operations measures (e.g., sales volume, margins, fill rates, pricing, inventory levels, safety stocks, etc.). Collaborative planning also applies to business planning coordination of promotions, new product introductions, product phase-outs, inventory policy changes, and so forth.

The third component, forecasting or collaborative forecasting, seeks to eliminate the independent demand decisions that cause information distortion up the supply chain (i.e., the bullwhip effect). Trading partners agree to the final working forecast and jointly resolve forecast variance. Once a sales or a downstream customer forecast is reviewed, the forecast is then converted into an operations forecast using a demand planning tool commonly included with ERP systems. Finally, an appropriate inventory replenishment methodology can be adopted based on characteristics of the product, life cycle, and demand. Note that replenishment also extends into the efficient delivery of products through transportation. CPFR not only improves replenishment among trading partners but links demand and supply planning into a continuous process.

Historically, CPFR was initiated and used by retailers and consumer products companies such as Walmart, Safeway, Proctor & Gamble, Kimberly Clark, and Nabisco. More recently, however, CPFR case studies have extended beyond retail to other industries that require efficient chains such as Hewlett Packard. All of these companies have sought benefits such as greater product or category sales, greater customer service through reduced stockouts, reduced inventory held within the supply chain, compression of lead times among trading partners and increased forecast accuracy. Additionally, the adoption rate of CPFR has increased through the use of technologies such as enterprise resource planning software, EDI, Internet and Web applications, and radio frequency identification (RFID) scanning tools. However, drawbacks to CPFR exist, and include trust issues (i.e. many companies are reluctant to share the level of data necessary due to a potential loss of competitive information), technology issues (i.e., many companies don't have the technological capabilities for this type of sharing) and high implementation costs.

Virtual Inventory Management

In an effort to increase supply chain efficiencies, responsiveness and customer service, many firms engage in contracts to manage a downstream partners inventory. We term this policy virtual inventory management, and such contracts may occur between any echelon of a supply chain network. For example a Hewlett Packard (HP) network may include a contract manufacturer, an assembly manufacturer, an HP hub distributor, HP (the original equipment manufacturer [OEM]), a channel distributor, and a retail channel. A virtual inventory management scenario may occur between any direct partner within such a supply chain network. Contracts between partners may be based on target service levels, bonded products and quantities, fill rates, turns, and so forth. Additionally, the upstream supplier may own the inventory in the downstream partners warehouse (consigned inventory). In the vendor managed inventory (VMI) scenario, the supplier has the additional responsibility of monitoring and triggering the replenishment request. Many of the advances in virtual inventory management have been enabled by information technologies such as electronic data interchange, e-mail with attachments (such as the ubiquitous Excel), enterprise resource planning systems, and Web portals.

There are many benefits of such inventory collaboration within the chain. Chief among these is the leveling of purchase demand and related order quantities throughout the supply chain (i.e., eliminating or reducing the bullwhip effect). Consequently, all members of the supply chain should incur increased service levels, reduced stockouts, and lower total inventory costs. Furthermore, increased visibility of demand throughout the supply chain enables better coordination of marketing events with production planning, thereby enabling the right product at the right place in the right location in the right quantity at the right time. Nonetheless, collaboration pitfalls proliferate, challenging the best efforts of firms. Crucial managerial factors to consider are the level of trust between the trading partners and the potential for losing proprietary information. Technological pitfalls include issues with EDI (content and accuracy) and new software, response to demand spikes and information distortion, inventory over stock, information disparity (supplier system says *X* quantity whereas the downstream partner says *Y*), product obsolescence, human error (downstream partner pulled the wrong part numbers), and learning curve effects of new technologies.

Virtual Inventory Fulfillment

In addition to virtual inventory management techniques, several companies have taken the notion one step further in reducing their exposure to inventory altogether via a practice of virtual inventory fulfillment. The policy of direct (or drop) shipment is when a firm takes an order from the customer, transmits this information directly to a supplier who creates the item with the original firm's logo, and ships it directly to the customer. In effect, the firm avoids carrying any inventory whatsoever by outsourcing both the manufacture and shipment of goods to a supplier. So, in determining an appropriate way to fulfill customer demand, a firm can select either a traditional structure (i.e., brick and mortar firm that maintains inventory) or a virtual structure (i.e., drop shipments).

Randall, Netessine, and Rudi (2002) highlighted the fact that product demand patterns and product attributes influence the structure choice (see Figure 3). This dichotomy, traditional versus virtual structure, represents a trade-off between inventory costs (inventory and fulfillment) and high customer service levels. The benefits of a virtual model can be alluring. For example, companies such as Spun.com have used this strategy to reduce their investment in inventory and fulfillment infrastructure and to access wholesalers (such as Alliance Entertainment) that engage in inventory pooling strategies to leverage economies of scale. Other benefits of the virtual fulfillment strategy can include better access to a wider product selection, more predictable product availability, and lower transportation costs.

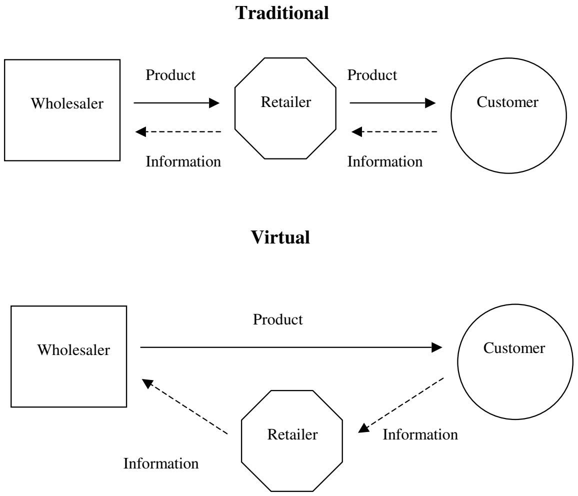

Figure 3: The two fulfillment models. Source: Randall, Netessine, and Rudi (2002). © 2003; reprinted with permission from Reed Business Information.

The pitfalls of a virtual model are numerous, however. Chief among these is the firm's loss of control over both the product quality and service levels. In addition, the strategic drawbacks are numerous because the bargaining power of the supplier is increased and the threat of forward integration is eminent because of increased knowledge of the consumer preferences. This phenomena whereby one of the members of the supply chain is essentially eliminated is widely known as the process of supply chain disintermediation. In this case, the supplier has the potential to sell directly to the customers. Interestingly enough, several prominent e-commerce firms have adopted traditional structures (i.e., similar to a brick and mortar firm that maintains inventory). To illustrate, consider Amazon.com, which has adopted a successful traditional fulfillment model with well-developed internal customer fulfillment capabilities, thereby avoiding the problems associated with a virtual structure and creating higher barriers to entry for potential competitors.

TECHNOLOGIES ENABLING INVENTORY MANAGEMENT

Enterprise Resource Planning Systems

Enterprise Software Systems, otherwise known as Enterprise Resource Planning Systems (ERPs), such as Oracle, PeopleSoft, and SAP) are a collection of application components designed to enable end-to-end business processes. Business flows enabled by ERP systems automate those business processes associated with the management of operations, customers, suppliers, partners, and employees. The technical goal of an enterprise system is to enable the disparate process flows of a firm to work within a single global database. This technical achievement provides the foundation for complete and consolidated business process information for sales, inventory, and revenue across geographically dispersed lines of business and products. A firm's inventory decision making is facilitated because of the information visibility and timeliness enabled by a common database. Additionally, enterprise systems reduce costs for firms by integrating and managing the applications for historically and organizationally disparate business processes (e.g., financials, operations, order fulfillment, etc.).

Despite the promise enterprise systems can deliver, ERP systems are not without their shortcomings. Most commonly, firms misjudge the complexity of implementing a system that models their complete enterprise. Such underestimations have led to supply chain glitches impacting the timeliness of product delivery that have torpedoed a firm's market value. For example, Hershey was unable to meet candy demand during crucial holiday seasons because of ERP implementation problems (Singhal & Hendricks, 2002).

ERP systems continue to evolve, however, and have become ubiquitous within organizations. Additionally, ERP vendors have consolidated and continue to expand their functional footprint and industry expertise. IDC (International Data Corporation) predicts that the ERP market will exceed $27 billion in 2005 (Byron, 2003).

Web Services

Cross enterprise collaboration is the greatest challenge that firms face when opting to share information between their supply chain partners. Web service solutions such as information sharing portals provide fast and low-cost alternatives for connecting partners. The costs associated with time and coordination for developing standards for information integration can be substantial. Web services technologies built on vendor neutral open standards such as TCP/IP, XML, SOAP, WSDL, and UDDI reduce or eliminate the need to develop standardized common interfaces between a partner's applications.

ERP application vendors have taken advantage of open interface standards and now provide out-of-the-box tools and application solutions that permit a firm to share information with its upstream suppliers and its downstream customers through Web portals. From the upstream side, a firm's supplier can quickly have real-time visibility into purchase orders, payment history, forecasts, performance (e.g., quality and on-time delivery), capacity management, and shipment notification (e.g., advanced ship notices, ship schedules). From the downstream side, a firm's customers can place orders, get availability dates, track shipments, review invoices and payment information, request service, return products, submit forecast, and perform myriad other customer care initiatives. Web services offer a low-cost and intuitive mechanism to share information among supply chain partners and faster integration with a firm's enterprise applications.

CONCLUSION

The advent and accessibility of Internet technologies has heightened the need for effective inventory management techniques. With the increased transparency of lead time and delivery information, customers are demanding correspondingly higher levels of service. The problems associated with poor inventory management are clear: stock-outs, product delays, loss of sales and revenues, and even a decrease in the market value of the firm experiencing the inventory related problems. Consider the case of eToys, an online retailer of toys for children. Because of the increased use of e-commerce methods as an effective way to access an increased pool of customers, eToys experienced unusually high demand during the 1999 holiday selling season. Unfortunately, eToys was unable to deliver the high volume of goods because of ineffective and costly customer fulfillment processes, and the firm eventually went bankrupt.

Existing traditional models of inventory management provide managers with a simple toolbox to plan for such situations. A detailed discussion that outlines these important decisions regarding effective inventory management is contained in the second section, Inventory Replenishment Methodologies. The first decision concerns the timing or frequency of appropriate orders to maintain an adequate supply of goods. In a continuous review system (used for costly or high-profile items), the inventory level is monitored continuously. More commonly, a period review system is used to check the inventory levels at fixed time intervals.

The second key inventory decision is the appropriate quantity of goods to order when monitoring the inventory levels. The economic order quantity (EOQ) model is one of the most commonly used inventory techniques suitable for environments with stable demand. Given estimates for demand, holding costs, and ordering costs, appropriate order quantities can be easily calculated. For environments with considerable demand uncertainty, other models take into account the cost of overstocking (i.e., having too much inventory left over after a selling season) and the cost of understocking (i.e., having too little inventory available to meet customer demand.) More specifically, the reorder point model uses information concerning both the mean and variance of demand to calculate an appropriate order quantity that ensures that customer demand can be met from current inventory levels. Although there are many variations of these two models (such as min–max and order up-to policies), the EOQ and reorder point models provide a convenient starting place for managers to think about the relative importance of several factors driving a decision concerning appropriate inventory levels.

Managers should also consider coordinating orders for multiple items to facilitate effective inventory management. For example, when ordering similar items from the same supplier, ordering them at the same time may offer the benefits of quantity discounts or lower transportation costs. Another situation warranting coordination is when the components from the bill of material (BOM) for a particular product all need to be ordered such that they arrive at the same place for assembly or fabrication at the same time. In this case, a material requirements planning system can easily determine the appropriate order quantities for individual components and stagger the replenishment according to the established lead time for the individual components.

Multi-echelon inventory systems coordinate inventory decisions across a large number of stocking points located throughout a firm or supply chain. One commonly used multi-echelon inventory system is called an installation stock reorder point policy, which essentially applies a variation of the basic reorder point model to each individual facility. Alternatively, an echelon stock reorder point policy takes into account inventory levels at all facilities downstream of a particular one to coordinate inventory levels throughout the system. A key advantage of this policy is that it minimizes the variations in orders (i.e., the bullwhip effect) that can occur between stocking points within a firm or throughout a supply chain.

More recent trends in inventory management associated with supply chain management and e-commerce initiatives are discussed in the section E-Commerce Initiatives Affecting Inventory Management. Although each of these techniques (CPFR, virtual inventory management, and drop shipping) provides certain benefits associated with minimal inventory levels, they must be carefully weighed against potential downfalls. Collaborative planning forecasting and replenishment is the technique of joint forecasting and planning for inventory management among supply chain partners. Use of CPFR techniques can yield benefits such as greater product or category sales, greater customer service through reduced stock-outs, reduced inventory held within the supply chain, compression of lead times among trading partners and increased forecast accuracy. Drawbacks to CPFR include trust issues (i.e., many companies are reluctant to share the level of data necessary due to a potential loss of competitive information), technology issues (i.e., many companies don't have the technological capabilities for this type of sharing) and high implementation costs.

Virtual Inventory Management is a common practice whereby retailers and manufacturers share their forecasted demand data with suppliers. Consequently, suppliers can monitor and maintain appropriate inventory levels for their customers. The benefits of Virtual Inventory Management include minimization of demand distortion and visibility of demand, thereby decreasing bullwhip effect and enabling better customer service. Pitfalls of such arrangements include a loss of control, access of potentially proprietary information, and technological problems. Virtual inventory fulfillment via drop shipping, another recent technique used primarily by Internet-based companies, occurs when the retailer delivers orders straight through to a wholesaler or manufacturer. In turn, the wholesaler or manufacturer ships the products directly to the customer such that the retailer holds no inventory at all. Although the retailer reaps the savings from carrying no inventory, it also has no control over the customer service and quality of goods. Moreover, the threat of the supplier sidestepping the original retailer and direct selling to the customer is a potential risk of this strategy.

Finally, several technologies are available which enable many of the inventory policies previously discussed. Enterprise resource planning systems are software that enables business process flows via a common database. Although such systems can be difficult to install, they can facilitate the planning, ordering, and monitoring of inventory levels for all of a firm's products. Whereas ERP systems are mostly used in the context of a single firm, Web service solutions such as information-sharing portals are becoming viable alternatives for connecting a firm with appropriate supply chain partners. These solutions enable real-time visibility of purchase orders, inventory levels, and supplier performance. Essentially, effective utilization of these new technologies including ERP systems and Web services can help minimize some of the ever-present risk involved with managing inventory.

GLOSSARY

Collaborative planning forecasting and replenishment (CPFR) An initiative enabling online sharing of data to establish common forecasts and production schedules among supply chain partners.

Continuous review An inventory control system whereby inventory is checked continuously.

Customer service level The probability that the inventory available during lead time will meet demand.

Direct (or drop) shipment A form of fulfillment in which a firm takes an order from the customers and then transmits this information directly to a supplier who creates the item with the original firm's logo and ships it directly to the customer.

Economic order quantity (EOQ) An inventory model appropriate for environments with stable demand that determines the optimal order size that minimizes the sum of carrying costs and ordering costs.

Enterprise resource planning systems (ERP) A collection of software application components designed to enable end-to-end business processes.

Holding (carrying) costs The costs of holding an item in inventory. These costs vary with the level of inventory.

Inventory A stock of items kept by an organization to meet internal or external customer demand.

Inventory management Decisions concerning the amount and frequency of inventory to hold and order.

Lead time The period of time between order of goods and delivery.

Min–max system A replenishment rule defined by two numbers *S* (Max) and *s* (Min). If the inventory level at a review point is *s* or less, an order is triggered for a quantity sufficient to pull the inventory level up to *S*.

Multi-echelon inventory system A supply chain with inventory stocked at multiple installations, possibly owned by distinct firms.

Order costs The costs of replenishing inventory that are independent of the order size.

Order up-to rule A replenishment rule characterized by a single number *S*; at any review point, an order sufficient to raise inventory level to *S* is triggered.

Periodic review An inventory control system whereby inventory is checked at regular intervals, not continuously.

Reorder point A predetermined inventory level below which a replenishment order is triggered.

Safety stock Inventory carried specifically to tide over variable demand during lead time; it takes into account standard deviation of demand during lead time rather than merely average demand

Underage (shortage) costs The loss of sales when demand cannot be met.

Vendor managed inventory (VMI) An agreement whereby the manufacturer is responsible for maintaining the supplier's inventory levels; the manufacturer has access to the suppliers inventory data and is responsible for generating purchase orders.

J

Java

Judith C. Simon, *The University of Memphis*
Charles J. Campbell, *The University of Memphis*

INTRODUCTION

Java is a programming language that was developed at Sun Microsystems in 1991. According to the Java Web site (http://java.sun.com), it was intended originally to be used for embedded programs in consumer devices and computers. Possibilities were expected to include various household products such as entertainment devices, appliances, and security systems. Although the expected main target, digital cable television, did not turn out to be a viable business, the Internet was becoming very popular and proved to be a feasible alternative. By May 1995, Java technology had been released for use on the Internet, and it was being incorporated into the Netscape Navigator browser. Listed below are some of the major milestones shown on the java.sun.com "time-line" Web page (http://java.sun.com):

May 1995	Official launch of Java technology
September 1996	83,000 Web pages were using Java technology
February 1997	JDK 1.1 released (JDK = Java Development Kit)
January 1998	Two-million downloads of the JDK had occurred
May 2000	Five-year anniversary; 400 Java Users Groups had been established around the world

BUSINESS USES OF JAVA

Java has become an important programming language used by businesses, especially for its features that work well for Internet applications. According to the java.sun.com site, over two-million developers have "embraced" the Java platform.

The Carnegie Mellon Software Engineering Institute's (SEI) Software Technology Review (Software Technology Review, 2001) describes Java as an object-oriented programming language that does a good job of distributing software over a network by addressing such issues as security and portability. Early Java programs were focused primarily on client-side applications, such as applets embedded in Web pages and viewed by Internet users. In contrast, Java 2 Enterprise Edition (J2EE) is a newer release with options expanded to include server-side applications, e.g., the code that a server uses to generate Web pages.

An *InformationWeek* article (Greenemeier, 2002) indicated that Java is expected to continue to be important for many information technology (IT) developers. The article reported on a study of 14,000 IT developers, which looked at the ways companies are deploying Java-based applications. Results indicated that 69% of the respondents were using Java-based applications for database management and access, and 66% were using it for Web-based data entry and retrieval.

Examples of business uses of the Java programming language continue to increase. Many are due to the features described above that make Java a good fit with many Internet Web-based activities.

The java.sun.com site contains several examples of business applications, in a range of industries. One example involves a fitness company that decided to change to Java for development of its enterprise-level Web applications, because they did not want to continue to invest in the maintenance of their proprietary software and liked the reusability of the Java technology. Another example involves the gaming industry, where it was decided to use Java to write games once that could then be deployed across many platforms, making the new games accessible worldwide very quickly.

An article in *Software Magazine* (Harding, 2002) described DaimlerChrysler's move toward Web-based applications in their deployment of client-side Java applications to a large number of users. The article reported that DaimlerChrysler had deployed six different applications so far, which are accessed by approximately 4,000 users.

A large consulting organization decided to use Java for some of its business applications and indicated the following as the primary reasons (Dennis and Rubin, 1999):

ability to support platform-independent applications,

dynamically downloaded and installed applications requiring no user assistance,

secure application download through networks such as the Internet, and

improved application quality over C and C++ development through a simpler programming language and improved error handling.

Some of the benefits identified include

use of platform independence to reduce computing platform costs by 50%,

application development productivity gains of 10 to 20%, and

approximately 75% fewer application errors in newly released production applications.

EXPECTED TRENDS RELATED TO JAVA

The continuing increase in business uses of the Internet is expected to cause a corresponding increase in the use of Java for business applications. Java technology continues to expand, which will aid in these activities. Articles at the Sun developer site (http://developer.java.sun.com) provide descriptions of the numerous options available and an idea of the trends. For example, there is now a Java Message Service for accessing enterprise messaging systems, Java APIs for various new applications, including Remote Procedure Call, messages, document processing, a wireless toolkit, a Mobile Information Device Profile, Personal Java for consumer devices with a touch sensitive screen, and Java Card Technology.

One of the interesting trends is that Java is moving into areas that were part of its initial intended market, including consumer devices such as next-generation telephones, TV set-top boxes, and smart cards that fit in your wallet. In the case of the Java Card platform, applications in the form of bytecode are loaded into the memory zone of the smart card's microprocessor, where they are run by the Java Virtual Machine (JVM). The executable code is platform independent so that any card incorporating a Java Card technology-based interpreter can run the same application (see http://java.sun.com/java2/whatis/).

It is impossible to predict what new technologies await us that might be enhanced through the use of Java technology.

OVERVIEW OF JAVA FEATURES

Included in this section are further explanations of some of the general features of the Java programming language, including its object-oriented design, its portability, its use of multithreading, and its method of handling errors. A more detailed identification of Java features and options is provided in the next section, followed by sample program code to illustrate the concepts that are discussed.

Object-Oriented Design

The object-oriented design concept involves the use of classes and objects to model the characteristics of an abstract or real object. A *class* represents a general identification of an item of interest. A class describes details common to all members of that class. An *object* is an instance of a class. A software object in an object-oriented program is a representation of a real-world object. It has some characteristics of interest to the situation. When writing an object-oriented program, the focus is on objects and their components. By way of contrast, programming languages such as C are considered "procedural" and focus on writing functions, i.e., the actions or procedures desired, rather than being based on objects.

Inheritance is an object-oriented design feature that allows a class to automatically contain the variables and methods that have been defined in its superclass. The superclass is the class from which another class (a subclass) is derived. This capability provides the desirable feature of reusability, since a subclass will automatically have the variables and methods of the superclass. Another feature about inheritance is that subclasses are not limited to what is inherited. Additional attributes and methods can be added as needed. Inherited methods can be overridden by new methods when appropriate. Multiple layers of inheritance are allowed. Therefore, a subclass can serve as a superclass to a lower-level subclass.

Encapsulation is another term associated with the concept of object-oriented design. Encapsulation refers to the feature of grouping or "bundling" knowledge about an object into a module. A program can then continue to use this object without having to be concerned about changes that might occur related to its variables and methods.

Because Java is totally object oriented, everything in a program is performed by invoking a method. (See Java programming example code for further information, as well as specific books with more extensive examples and explanations.)

Applications determined to be appropriate for object-oriented design can be written in conventional languages such as C but are normally considered easier to write in a language designed specifically for object-oriented programming. Languages such as C++ are sometimes referred to as "hybrids," because they are based on a non-object-oriented language (such as C) but have been enhanced with concepts of object-oriented design. Java is considered one of the "pure" object-oriented languages, i.e., based entirely on object-oriented design principles.

Portability

Portability refers to the capability of running a program on many different types of hardware platforms. When using many other programming languages, it is necessary for a developer to write the program for a specific destination hardware platform where the program is to be used. However, the Java platform allows an application written in Java to be used on many different kinds of computers. Java programs can run on different operating systems, allowing them to be used on a PC, a Macintosh computer, or across networks. This capability is sometimes referred to as "platform independence."

Multithreading

A "thread" in programming refers to one sequence of executable statements; i.e., all the statements are executed or performed in order, one after the other. Multithreading refers to the capability of subdividing a program so that different threads of the program code can be executed concurrently; i.e., the central processing unit (CPU) can alternate very quickly among the threads. Java is a multithreaded language. C and C++ are considered to be single-threaded languages.

The Java Virtual Machine (JVM) described in one of the following sections is an example of the use of multithreading. It contains threads that are needed for the programs to be executed properly. For example, the "garbage collector" thread automatically reclaims allocated memory no longer needed. In other programming languages, the programmer must handle memory management procedures as part of the program. Therefore, if something goes wrong with the program, memory availability could become a problem that might affect the successful completion of the program.

Error Handling

Error handling refers to ways of taking care of unexpected events during program execution. Error handling in Java is provided through "exceptions." Exceptions are events that occur during program execution that cause a disruption in the typical flow of instructions. In contrast to many other programming languages, Java's error handling methodology allows the error-handling code to be separated from the main part of the program code, making it easier to read and modify programs.

The purpose of handling exceptions is to try to catch and handle program errors or other unusual occurrences rather than just waiting to see if they occur and then trying to handle the results. In general, Java code should be (and sometimes must be) written to "throw" an exception when an error is encountered. The exception "handler" is a complementary piece of code that will "catch" the exception and handle it (assuming that it is something for which error-handling code has been written).

A MORE IN-DEPTH LOOK AT JAVA'S FEATURES

Some specific features of Java that further distinguish it from other programming languages are described briefly in this section. The use of applets is discussed, followed by descriptions of the platforms currently available. Overviews of some of the key components that make Java work are provided as well. These paragraphs are designed to be introductory in nature. The java.sun.com site (as well as numerous others) should be accessed if a more in-depth coverage of these features is needed.

Availability of Java Platforms

Most people using a computer today already have access to a Java platform. Web browsers typically include the Java platform, and most desktop computers also provide the capability of executing standalone Java code that does not require the use of a browser. Anyone who needs the Java platform can download it directly from the java.sun.com site. The entire Java Development Kit (JDK) (referred to as SDK—Software Development Kit—in newer versions) can be downloaded from Sun, typically at no expense. Some restrictions related to incorporating the Java platform into commercial products may exist. Additional software to support developers in writing Java programs is available for purchase from separate vendors.

Applet Development

An applet is a Java program that is referred to in an HTML document in the same way that an image file is specified as part of the page to be displayed. The applet is executed from within the Web browser when the HTML file is used. The popularity of applets became the first large use of Java programs. They are used often to provide executable content, such as pop-up windows that are displayed when some specified event occurs. For example, a small window with additional information might be displayed when a Web user clicks on a particular location on the page. Applets are used within Web pages, in contrast to standalone applications written in Java now widely used in businesses and executed independently of a Web browser.

The number and variety of applets available has continued to expand at a very fast pace. Many of these applets can be downloaded free to individual Web sites. Any Internet search engine can be used to locate applets. In addition, the java.sun.com site provides links to a variety of applet resources.

Specific Java Platforms

The current version of Java is generally referred to as Java 2, and several platforms are available. Each platform contains various tools for developers. The paragraphs below provide brief overviews of the platforms; extensive details are available at the java.sun.com Web site.

Java 2 Platform, Standard Edition (J2SE), is generally intended for building and deploying client-side applications in an organization. For example, it is widely used for developing corporate intranets to be used by employees of an organization, as well as for Web sites to be used by customers/clients of the organization. According to the java.sun.com Web site, J2SE provides the compiler, tools, and Application Programming Interfaces (APIs) needed for using the Java programming language for developing, deploying, and running applets and applications. J2SE also includes the facilities needed for working with XML documents. (XML is a technology expanding significantly in its use in the area of data interchange over the Internet, so the ability to use XML and Java together makes it easier and faster to create more sophisticated Web applications.)

Java 2 Platform, Enterprise Edition (J2EE), is designed to manage the infrastructure and support Web services for development of interoperable business applications. According to the java.sun.com Web site, J2EE takes advantage of many features of J2SE, such as its portability and use with XML. J2SE was used as the base from which other components were added, e.g., those related to server support.

Java 2 Platform, Micro Edition (J2ME) is intended to be used for small consumer products, such as smart cards, pagers, set-top boxes, and embedded devices. This type of use is not entirely new, as it is somewhat of a return to the original expectation of using Java for consumer devices. J2ME, however, is much more extensive and is intended as a technology solution for manufacturers of a variety of small ("micro") devices.

Java Virtual Machine (JVM)

The Java Virtual Machine (JVM) is defined as a computing device that contains a set of instructions for decoding and executing "bytecode," as well as other components needed in the background, such as areas for storing data and methods. The bytecode is a key part of this process. It is machine-independent code generated by the Java compiler when a program is developed. The program is later executed on the destination computer by the interpreter. This process provides the platform independence and portability that is a major feature of this programming language. The JVM is a part of the Java Runtime Environment.

Java Runtime Environment (JRE)

The Java Runtime Environment (JRE) refers to the subset of the JDK/ SDK that can be distributed to computer users. It contains the JVM, a bytecode verifier to check the code before execution, the bytecode interpreter for execution of the program, and Java class libraries. Class libraries are existing, previously developed classes available to programmers, described further in the section below on Java Application Programming Interface. The JRE is available from the Sun site. For example, the Java 2 Runtime Environment Standard Edition is available from Sun's J2SE homepage.

Java Application Programming Interface (API)

The Java programming language contains numerous predefined classes that have been grouped into related classes called "packages." Together, these packages are often referred to as Java Application Programming Interface (API) packages. Described briefly below are some well-known and widely used packages, many since the first release of Java. Details about these and other classes are available on many Web sites.

java.applet—Enables applets to be created and to interact with a browser.

java.awt—Refers to the Abstract Window Toolkit, which includes the classes and interfaces needed for creating graphical user interfaces (GUIs) and which has been expanded in Java 2 through the Swing component discussed below.

java.beans—Allows the development of reusable software components that can interact with both Java and non-Java components.

java.io—Provides the capability for programs to input and output data.

java.lang—Automatically imported into all programs by the compiler because it has basic classes and interfaces needed by many Java programs.

java.text—Enables a Java program to work with numbers, dates, strings, and characters.

java.util—Provides a variety of additional capabilities, such as random number processing, resizing of array-like data structures, and bit manipulation.

Java Foundation Classes (JFC) refers to API software that is available as part of the J2SE SDK. It includes the original Abstract Window Toolkit (AWT) but has extended it by adding other features, especially an extensive set of GUI class libraries. In addition to the AWT, some of the features of the JFC software are:

Swing—A GUI component kit that provides user interface elements allowing a customizable look and feel; these elements have been written entirely in Java, which has simplified the deployment of Java applications without reliance on any specific windowing system.

Pluggable Look and Feel—Gives users the capability to change the look and feel of an application without the need to restart it.

Accessibility API—Provides assistive technologies that include screen readers, screen magnifiers, and speech recognition so that applications developed using the JFC software will help developers meet federal regulations regarding accessibility.

Java 2D API—Extends the AWT graphics and imaging classes by allowing developers to incorporate two-dimensional graphics, text, and images in Java applets and applications.

JavaBeans

JavaBeans is a component architecture that is platform neutral, which means that it uses the Java capability of "Write Once, Run Anywhere" for the development of reusable components. This capability allows developers to create and then use these components in combination with an organization's existing applications, regardless of the operating system or application environment involved, whether it is within the organization or across the Internet.

Java Web Start

Java Web Start is available for download as part of the J2SE. It provides a technology for simplifying the deployment of Java applications. Applications can be launched from a Web browser by clicking on a link on the Web page. For example, a spreadsheet program could be launched without going through installation procedures. If the computer does not already have the needed application, Java Web Start will download the needed files automatically and cache them on the computer so that the application can be run again at any time. Java Web Start runs independently of a Web browser, so a computer user can continue using an application whether or not the Web page is still in use. The application itself can be relaunched from a desktop icon without returning to a browser page.
