[57]

ABSTRACT

An aerosol delivery article provides delivery of aerosol particles of relatively small size without the necessity of exposing the material which is aerosolized to a significant degree of heat or high temperatures. An aerosol forming material is a multi-component material comprising an active ingredient and another ingredient having a relatively low vaporization temperature, and preferably that aerosol forming material is in the form of an emulsion. The aerosol forming material is nebulized so as to provide first stage multi-component aerosol particles of fairly large size. The first stage aerosol particles then are subjected to heat so as to vaporize the other ingredient of that aerosol and cause further dispersion of that first stage aerosol. As such, a second stage aerosol composed of fine particles of active ingredient is provided. The heat used to cause the further dispersion of the first stage aerosol is less than that sufficient to cause vaporization, thermal decomposition or undesirable chemical alteration of the active ingredient.

AEROSOL DELIVERY ARTICLE

BACKGROUND OF THE INVENTION

The present invention relates to aerosol delivery articles, and in particular, to such articles which are capable of providing aerosol particles of relatively small size while subjecting the material to be aerosolized to relatively low temperatures.

a patient in vapor or aerosol form. As such, the patient inhales the medication, and that medication directly enters that patient's respiratory system. See, Science, Vol. 260, p. 912 (1993). As a result, there have been efforts towards developing various aerosol delivery 15 devices, principally for the delivery of certain pharmaceutical compositions or drugs. As used herein, the term "drug" includes articles and substances intended for use in the diagnosis, cure, mitigation, treatment or prevention of disease; and other substances and articles re- 20 ferred to in 21 U.S.C. §321(g)(1). Certain aerosol delivery articles and articles for delivering medicaments in vapor form are described in U.S. Pat. No. 1,771,366 to Wyss et al.; U.S. Pat. No. 1,968,509 to Tiffany; U.S. Pat. No. 2,030,075 to Robinson; U.S. Pat. No. 2,057,353 to 25 Whittemore, Jr.; U.S. Pat. No. 3,820,540 to Hirtz et al.; U.S. Pat. No. 4,036,224 to Choporis et al.; U.S. Pat. No. 4,214,146 to Schimanski; U.S. Pat. No. 4,303,083 to Burruss, Jr.; U.S. Pat. No. 4,735,217 to Gerth et al.; U.S. Pat. No. 4,922,901 to Brooks et al.; and U.S. Pat. No. 30 4,941,483 to Ridings et al.; as well as by Hickey in Drugs Pharm. Sci., Vol. 54, p.255 (1992). Certain other delivery articles are described in U.S. Pat. No. 3,297,029 to Brinkman et al.; U.S. Pat. No. 3,859,398 to Havstad; U.S. Pat. No. 3,864,544 to Van Amerongen; U.S. Pat. 35 No. 3,990,441 to Hoyt et al.; U.S. Pat. No. 4,190,046 to Virag and U.S. Pat. No. 4,523,589 to Krauser.

Certain of the aerosol delivery articles provide medication in aerosol form by mechanical action. In particular, the medication is provided in the form of an aerosol 40 using nebulizers and metered dose inhalers. Such aerosol delivery articles are desirable in that the pharmacological composition to be aerosolized is not subjected to exposure to heat and high temperatures. However, mechanically generated aerosols typically comprise signifi- 45 cant numbers of particles of relatively large size (i.e., greater than about 5 µm in diameter). Such large size particles do not always provide the pharmaceutical composition in a form which provides for maximum effectiveness in treating the patient. Aerosol delivery 50 aerosol in the form of a second stage dispersion of aeroarticles which employ heat to evaporate aerosol forming materials which later condense into aerosol particles of relatively small size provide aerosols which are readily inhaled. However, the pharmacological properties of certain pharmaceutical compositions which are 55 aerosolized by vaporization often are undesirably altered, because certain pharmaceutical compositions are quite sensitive to the effects of heat and temperature.

It would be desirable to provide an aerosol delivery article which is capable of producing aerosol particles 60 of relatively small size (e.g., submicron size) without the necessity of subjecting the material to be aerosolized to exposure to a significant degree of heat or high temperatures.

SUMMARY OF THE INVENTION

The present invention relates to an aerosol delivery article. The article includes an aerosol generating means

which is capable of generating an aerosol from a multicomponent aerosol forming material. Typically, the aerosol generating means includes a means for mechanically producing aerosol particles from the multi-component material (e.g., a first stage aerosol in the form of a first stage dispersion of aerosol particles). Typically, the multi-component material includes at least one active ingredient to be aerosolized, and at least one other ingredient which provides a capability for causing those It has been desirable to deliver certain medications to ¹⁰ first stage aerosol particles to undergo a second stage dispersion or transformation such that aerosol particles of significantly smaller size result. The aerosol delivery article also includes a means for causing the first stage aerosol particles to undergo a second stage dispersion. Typically, the first stage aerosol particles are subjected to heat or other conditions sufficient to destroy the integrity of a significant number of those particles, and hence cause the formation of second stage aerosol particles of relatively small size. Most preferably, the second stage aerosol particles are formed from the active ingredient. The article also includes a delivery means which provides for delivery of the resulting second stage aerosol to the user. Preferably, the aerosol is inhaled by the user into the mouth and/or nose of that user.

In another aspect, the present invention relates to a method for producing an aerosol. A multi-component material capable of forming an aerosol is provided. As such, there is provided an aerosol forming material capable of undergoing a first stage dispersion to form a first aerosol, which first aerosol is capable of undergoing a second stage dispersion to form a second aerosol. The aerosol forming material includes at least one active ingredient and at least one other ingredient capable causing aerosol particles formed from the aerosol forming material to be further dispersed. The aerosol forming material is subjected to conditions sufficient to provide an aerosol from that material. Such conditions typically involve mechanically producing an aerosol from the aerosol forming material, and most preferably involve producing that aerosol under conditions which do not cause the components of that aerosol to experience significant vaporization. The aerosol in the form of a first stage dispersion then is subjected to conditions sufficient to cause a further dispersion of those aerosol particles. Typically, the first stage dispersion is subjected to heat or other conditions sufficient to destroy the integrity of a significant number of those aerosol particles of the first stage dispersion, and hence cause an sol particles of relatively small size (i.e., of reduced size relative to the first stage aerosol). In such a regard, much of the aerosol of the second stage dispersion can include vapors, gases, and the like. The aerosol so provided then is allowed to pass through a passageway so as to be delivered to the user. As such, an aerosol is delivered into the respiratory system of the user.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a partial sectional view of an aerosol delivery article of the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to FIG. 1, aerosol delivery article 10 includes an aerosol generator 13 having a reservoir 18 for an aerosol forming material 23; an enclosure member 30 for providing a passageway 35 which allows passage of

65

a first aerosol 40 produced by the aerosol generator through the aerosol delivery article towards mouthend 42 of that article; a heating unit 45, or other suitable means for providing a heating region 46 thus causing the aerosol particles to undergo further dispersion or a 5 transformation to yield a second aerosol 50; and a delivery portion 55, or other suitable means for providing delivery of the second aerosol orally and/or nasally to the user.

The aerosol generator 13 produces a first aerosol 40 10 from the aerosol forming material 23 contained in the reservoir 18 of that aerosol generator. Typically, the first aerosol 40 is mechanically produced using a nebulizer, or other suitable means for producing an aerosol. A representative nebulizer is available as Microstat ¹⁵ Ultrasonic from Mountain Medical Equipment, Inc., Littleton, Colo. Such a nebulizer 13 includes an electrically powered ultrasonic nebulizer head 60 powered by an electrical power source 62; a valve 64 for inlet of drawn atmospheric air; an inner valve 66 for allowing ²⁰ drawn air to pass near the reservoir 18 containing the aerosol forming material 23. A connection collar 65 allows the nebulizer to be assembled and disassembled in order to load that nebulizer with aerosol forming 25 material. The inner valve 66 can be adapted to provide for passage of drawn air containing nebulized aerosol forming material (i.e., the first aerosol 40) out of the aerosol generator through exit passage 70. As such, the inner valve can include a cyclone region (not shown) so 30 as to provide for a fairly lengthy aerosol passage, and a collection cone (not shown) so as to provide for deposition of overly large size aerosol particles back into the reservoir.

The first aerosol 40 exits the aerosol generator 13 and 35 enters a passageway 35. As a practical matter, the passageway also can be provided by a region of the aerosol generator. The passageway can vary in terms of its length, cross-sectional dimensions, construction and format. The length of the passage way typically is quite $_{40}$ short in order to keep the dimensions of the article small for ease of use and for ease of draw, and in order to avoid loss of aerosol by deposition so that the concentration of the drawn aerosol is not adversely affected. However, the length of the passageway typically is 45 sufficiently long in order that the first aerosol is given sufficient ability to form without being adversely affected by other components of the aerosol delivery article. For example, for the type of aerosol delivery article shown in FIG. 1, the first aerosol can pass 50 through a passageway of about 5 cm to about 10 cm from the reservoir 18 to the heating unit 45. As such, it is possible to construct the enclosure member 30 from a material (e.g., a heat resistant plastic material such as a polycarbonate or a polyimide) which is adapted so as to 55 have a smooth inner surface in order to provide for ready transfer of aerosol through the passageway. In addition, it can be desirable to construct the enclosure member 30 from a material which has a low coefficient for thermal conductivity, in order that heat generated 60 by the heating unit 45 does not adversely affect the aerosol generator 13 and the formation of the first aerosol 40. The enclosure member 30 can have a variety of shapes, such as a generally tubular shape which is shown in FIG. 1. However, the cross-sectional shape of 65 the enclosure member does not need to be consistent along its length, and can be fruscoconical or helical in shape. Although the cross-sectional area of the passage-

ΟΟΚΕ

4

way can vary, such area typically ranges from about 7 cm^2 to about 10 mm².

The enclosure member 30 then includes a heating unit 45, or other suitable means for causing the first aerosol particles to undergo a further dispersion to yield a second aerosol 50. The heating unit typically includes a region within the enclosure number 30, and such a region can be characterized as a heating region 46. That heating region can have the form of tubes, baffles, or the like. The heating unit provides for a heating region 46 where the first aerosol is heated sufficiently to form the second aerosol, and as such, heat is exchanged between the heating unit and the first aerosol. Exemplary heat exchange units and technology are described in Perry's Chemical Engineer's Handbook, Section 11, Sixth Edit. (1984). A case 71 or other means for housing other components of the heating unit 45, typically is provided outside of the enclosure member 30. The case 71 provides a convenient and aesthetic holder or chamber for components of the heating unit which are suited to be positioned outside of the enclosure member 30. Typically, the heating unit generates heat as a result of an electrical resistance heating element 72 and an electrical power source 74. The power source can be a battery power supply having one or more batteries (as shown in FIG. 1) or provided by normal household current stepped down by an appropriate transformer. The resistance heating element 72 and vary in terms of size, composition and configuration. For example, the resistance heating element can be provided by graphite yarns, graphite fabrics, Nichrome film or wire, metal screens, metal or ceramic resistance heating materials, or the like. The resistance heating element also can be in thermal contact with a conducting agent 77 (e.g., an aluminum metal sheet) which is configured so as to distribute heat over a desired region of the aerosol delivery article. As shown in FIG. 1, the resistance heating element 72 is provided by winding a resistance heating wire 72 around a coiled length of metal tubing 77 which acts as a conducting agent for electrically generated heat. It is desirable that the surface temperature of that portion of the heating unit be sufficiently high, the residence time of the aerosol be sufficiently long, and the surface configuration be such to provide a sufficiently high surface area, in order that the aerosol can be adequately heated. The heating region can have the form of a tubular passageway, a coiled passageway, an annular tube, a baffled passageway, passageways having resistance heating screens positioned thereacross, or the like. Typically, the effective length of the passageway of the heating region (i.e., the average distance travelled by the aerosol during heating) is less than about 30 cm, often less than about 25 cm and occasionally less than about 20 cm; but most often is at least about 10 cm. Insulating material 79 (e.g., glass fiber or ceramic fiber) can be positioned within enclosure member 30 so as to surround the tubular conducting agent 77, and hence ensure that heat generated by resistance heating is efficiently used to heat the aerosol.

The manner in which the heat is provided by the heating unit can vary. Typically, the heating unit includes a current regulating means 82 to control the temperature of the heating element, and representative current regulating means are described in U.S. Pat. No. 4,922,901 to Brooks et al., which is incorporated herein by reference. The current regulating means can be time-based in that a particular current can be passed through a particular resistance heating element for a controlled

Find authenticated court documents without watermarks at docketalarm.com.

period of time in order that a predetermined temperature can be reached and maintained by a time-based on/off switching mechanism which provides sufficient current over controlled intervals of time to maintain a controlled, essentially constant temperature. Current 5 regulating means which modulate current flow through the heating element can be employed in place of on/off time-based circuits. In addition, on/off and current modulating means can be connected to temperature sensors or other sensing means, rather than to a time- 10 based circuit, in order to control the passage of current through the resistance heating element. Such sensors can be temperature sensors such as infrared sensors, piezoelectric films or the like, or thermostats such as bimetallic strips. Such temperature sensors can sense 15 either the temperature of the resistance element directly or the temperature of the aerosol passing the heating element. Alternatively, the temperature sensors can sense the temperature of a second "model" resistance heating element having a heating and cooling character 20 related to that of the resistance heating element. Another type of sensor which can be employed is a dynamic resistance sensor which senses the change in electrical resistance of the heating element during the heating period.

The heating unit can include a switch (not shown) for turning that heating unit on prior to use, and for turning that heating unit off after use. However, the heating unit can be activated an deactivated by a pressure activated switch (not shown); which is actuated to allow current 30 flow and hence heat generation upon draw, and is deactuated to prevent current flow and hence heat generation when draw ceases. A representative pressure actuated switching mechanism and method for operation in a draw controlled aerosol delivery article are set forth 35 as provided by fruit or tobacco extracts). Ingredients in U.S. Pat. No. 4,922,901 to Brooks et al.

The resistance heating element 72, the electrical power source 74, the current regulating means 82, the switching mechanism, and other electronic components of the heating unit 45 are connected together using 40 known techniques by electrically conductive wires (not shown). As such, one skilled in the art of electronics can provide the circuitry capable of producing heat necessary to cause further dispersion of the first stage aerosol particles 40. 45

The heat provided by the heating unit acts to alter the character of the first aerosol 40 passing through that region of the aerosol delivery article so as to further disperse that aerosol and form second aerosol 50. The second aerosol passes through a delivery portion 55 50 which can be equipped to include a cooling region 85. The construction and dimensions of the cooling region can vary depending upon factors such as the temperature of the second aerosol upon exiting the heating region, and the desired temperature of that aerosol im- 55 phenhydramine; steroids, including cortico steroids mediately upon delivery to the user. The cooling region also can allow for condensation of vaporized aerosol forming material into aerosol particles. Typically, the length of the cooling region ranges from about 1 cm to about 5 cm. For example, the cooling region can be 60 the like. Representative pharmaceutical materials are constructed so as to provide for sufficient cooling of heated aerosol and thus provide that aerosol at a palatable temperature (i.e., at about 20° C. to about 40° C.).

In use, the user places aerosol forming material 23 into the reservoir 18 of the nebulizer 13, and provides 65 electrical current (i.e., by using an on/off switch) to power the ultrasonic nebulizer head 60. Alternatively, for other types of aerosol generators, the aerosol form-

ing material is correspondingly placed into the aerosol generator, and prepared for aerosol generation and delivery. For aerosol forming materials in the form of emulsions which can be characterized as stable, the emulsions can be used as such. However, emulsions which can be characterized as unstable may require agitation prior to use. Meanwhile, the heating unit 45 is turned on so as to generate heat in the heating region of the aerosol delivery article. When the heating unit is capable of generating a sufficient amount of heat, the aerosol delivery article is drawn upon at the extreme mouth end 42. However, the heating unit also can be draw controlled in order that current is provided to the resistance heating element immediately upon draw and during the draw period. As such, drawn air entering the aerosol generator through valve 64 is used to provide the first aerosol 40 from the aerosol forming material 18. The first aerosol 40 passes from the aerosol generator 13 through the passageway 35 and is heated in the heating region 46 to provide the second aerosol 50. The second aerosol then passes into the mouth of the user. As such, the finely dispersed particles of the second aerosol 50 can be drawn into, and hence delivered to, the respiratory system (e.g., the nose and/or mouth, throat, and 25 lungs) of the user. As such, fine particles of the active ingredient can be delivered to the respiratory system of the user.

The aerosol forming material is a multi-component material, and as such, includes at least one active ingredient and at least one other ingredient. The active ingredient can include at least one flavoring agent. The flavoring agent can provide fruit, coffee, tobacco, spice flavor or any other desired flavor, to the aerosol. The flavor can be an artificial flavor or natural flavor (e.g., such as glycerine, triethylene glycol and propylene glycol can be ingredients within the multi-component material. The active ingredient most preferably includes at least one pharmaceutical material.

Pharmaceutical materials useful herein most preferably are those which can be administered in an aerosol form directly into the respiratory system of the user. Typical of such materials are drugs or other types of medicaments which are used in the treatment of asthma, pneumonia, influenza, emphysema, bronchitis, epilepsy, depression, shock, respiratory stress in adults and premature infants, hypertension, Alzheimer's disease, Parkinson's disease, cardiac arrhythmia, sinus congestion, allergies, convulsions, anxiety, schizophrenia, hyperactivity, and the like. Examples of suitable drugs include ephedrine; nicotinic compounds such as nicotine, substituted nicotine compounds and metanicotine; metaproterenol; ritaline; resperine; terbutaline; dopamine; phenytoin; lipid molecules; propranolol; diazepam; disuch as cortisone, prednisone, triamcinolone and prednisolone; peptide and polypeptide drugs such as are described in Science, Vol. 260, p.912 (1993); synthetic pulmonary surfactants such as dipalmitoyl lecithin; and set forth in U.S. Pat. No. 5,145,861 to Ducep et al.; U.S. Pat. No. 5,109,010 to Beight et al.; U.S. Pat. No. 5,026,861 to Beight et al.; U.S. Pat. No. 4,999,431 to Cheng et al.; U.S. Pat. No. 4,990,519 to Cheng et al.; U.S. Pat. No. 4,886,811 to Cheng et al.; U.S. Pat. No. 4,861,756 to Jackson; U.S. Pat. No. 4,748,274 to Creege et al.; U.S. Pat. No. 4,650,872 to Wright; U.S. Pat. No. 4,622,422 to Creege; U.S. Pat. No. 4,435,420 to Doherty
